`UpdateOTelEnrichment` replaces filters. It does not merge them. `IncludeFilters` and `ExcludeFilters` move as a pair, so whatever the request omits is cleared. The following table shows the effect of each request shape on the stored configuration.

Request	Effect on stored configuration
Both specified	Both are replaced.
Only `IncludeFilters`	`IncludeFilters` is replaced, and `ExcludeFilters` is cleared.
Only `ExcludeFilters`	`ExcludeFilters` is replaced, and `IncludeFilters` is cleared.
Neither specified	Both are cleared, and enrichment reverts to every supported namespace.

The last write wins. There is no read-modify-write helper, so to add one selector you send the full intended list. If you do not already track the current state, read it with `GetOTelEnrichment` first.

`UpdateOTelEnrichment` requires enrichment to already be running. Against a stopped account, it returns `ResourceNotFoundException` (HTTP 404), so start enrichment first.

Timestamps

`GetOTelEnrichment` returns `CreatedAt` and `UpdatedAt`.

- After `StartOTelEnrichment` starts enrichment on an account that isn't already running it, `CreatedAt` is set to the current time, and `UpdatedAt` equals `CreatedAt`. On an account that is already running enrichment, `StartOTelEnrichment` is a no-op and leaves both timestamps unchanged.
- After `UpdateOTelEnrichment`, `CreatedAt` is unchanged, and `UpdatedAt` is set to the current time.

An `UpdatedAt` value that is greater than `CreatedAt` indicates that the filters have changed at least once since enrichment started.

Reading enrichment state

`GetOTelEnrichment` returns `Status` (`Running` or `Stopped`) plus the filters and timestamps. Every member below `Status` is omitted when enrichment is stopped.

When enrichment is running, an omitted `IncludeFilters` is not unknown. It means that no include direction is stored, so every supported namespace is in scope. Likewise, an omitted `ExcludeFilters` means that nothing is excluded. Treat an absent filter as the permissive case, never as an error.

Limits

The following table lists the limits for enrichment filters.

Limit	Value	Enforced by
Selectors across `IncludeFilters` and `ExcludeFilters` combined	100	Service (the binding limit)
Selectors per individual list	100	Model length backstop
Metric names per selector	100	Model length
Namespace length	1–255 characters, must not begin with a colon	Model

Limit	Value	Enforced by
`MetricName` length	1–255 characters	Model

The combined cap is the limit that rejects requests. Two lists of 60 selectors each satisfy the per-list limit of 100, but they sum to 120 and fail with `ValidationException`.

Errors

The following table lists the errors that each operation can return.

Operation	Errors
`StartOTelEnrichment`	`ValidationException`
`UpdateOTelEnrichment`	`ValidationException` , `ResourceNotFoundException`
`GetOTelEnrichment`	None
`StopOTelEnrichment`	None

`ValidationException` covers malformed namespaces, over-long names, and exceeding the combined-selector cap. `ResourceNotFoundException` on `UpdateOTelEnrichment` means exactly one thing: enrichment is not running for this account. The framework raises throttling, internal, and access-denied errors. They are not modeled on these operations, and you handle them as you do for any other CloudWatch call.

Managing filters with the AWS CLI

To start enrichment with initial filters, run the following command.

```
aws cloudwatch start-otel-enrichment \
    --include-filters '[{"Namespace":"AWS/EC2"},{"Namespace":"AWS/RDS","MetricNames":
["CPUUtilization"]}]' \
    --exclude-filters '[{"Namespace":"AWS/EC2","MetricNames":["NetworkPacketsIn"]}]'
```

To read the current state, run the following command.

```
aws cloudwatch get-otel-enrichment
```

To replace the filters, run the following command. This command clears anything that you omit.

```
aws cloudwatch update-otel-enrichment \
    --include-filters '[{"Namespace":"AWS/EC2"},{"Namespace":"AWS/Lambda"}]' \
    --exclude-filters '[]'
```

To revert to enriching every supported namespace, run the following command.

```
aws cloudwatch update-otel-enrichment
```

To stop enrichment, run the following command.

```
aws cloudwatch stop-otel-enrichment
```

To verify that a change took effect, read it back and compare `UpdatedAt`.

```
aws cloudwatch get-otel-enrichment --query
 '{S:Status,U:UpdatedAt,I:IncludeFilters,E:ExcludeFilters}'
```

Best practices

We recommend the following practices when you filter enrichment.

- Start enrichment once, then use `UpdateOTelEnrichment` to change filters. Never restart to change filters.
- Send the complete intended filter set on every update, because omission clears.
- Copy namespace names exactly from `ListMetrics` output. Matching is case-sensitive with no wildcards.
- Budget selectors against the combined limit of 100, not 100 per list.
- Read absent filters as permissive, not as missing data.
- Confirm writes from the response rather than the request that you sent. On the `StartOTelEnrichment` no-op path they differ, and that difference is the signal.

Supported AWS resources and metrics for OpenTelemetry enrichment

When you enable OTel enrichment, CloudWatch republishes selected metrics from the following AWS services as OpenTelemetry time series. Each CloudWatch namespace maps to an OpenTelemetry instrumentation scope named `cloudwatch.aws/`*`service`* — for example, the `AWS/EC2` namespace maps to the scope `cloudwatch.aws/ec2`. All enriched instruments use Delta temporality.

Depending on the resource, enriched metrics can also carry the following resource context:

- `cloud.resource_id` — the resource ARN, added when the metric can be resolved to a specific resource.
- `tag.*` — the resource's AWS tags, added when the resource is supported for the section called "Using resource tags for telemetry".

The following tables list, per namespace, the supported resources and their enriched metrics. For each metric, the OpenTelemetry metric name matches the CloudWatch metric name unless a rewritten name is shown, and the instrument type is either `Sum` or `Histogram`. The metric's CloudWatch dimensions are emitted verbatim as OpenTelemetry data point attributes (the attribute key is the dimension name); the *Data point attributes* column lists the dimension sets each metric is published with.

TimeToFirstToken	TimeToFirstToken	Histogram	ModelId

AWS/BedrockMantle

The `AWS/BedrockMantle` namespace is published under the OpenTelemetry instrumentation scope `cloudwatch.aws/bedrock-mantle`. All enriched instruments use Delta temporality.

- AWS::BedrockMantle::Project

AWS::BedrockMantle::Project

- `cloud.resource_id` enrichment: Supported
- `tag.*` enrichment: Not supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
`Inference ClientErrors`	`Inference ClientErrors`	Sum	`Model`, `Project`
`Inferences`	`Inferences`	Sum	`Model`, `Project`
`InputTokens`	`InputTokens`	Histogram	`Model`, `Project`
`OutputTokens`	`OutputTokens`	Histogram	`Model`, `Project`
`TotalInpu tTokens`	`TotalInpu tTokens`	Sum	`Project`
`TotalOutp utTokens`	`TotalOutp utTokens`	Sum	`Project`

AWS/ClientVPN

The `AWS/ClientVPN` namespace is published under the OpenTelemetry instrumentation scope `cloudwatch.aws/ec2`. All enriched instruments use Delta temporality.

- AWS::EC2::ClientVpnEndpoint

AWS::EC2::ClientVpnEndpoint

- `cloud.resource_id` enrichment: Supported
- `tag.*` enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
`ActiveConnectionsCount`	`ActiveConnectionsCount`	Histogram	`Endpoint`
`AuthenticationFailures`	`AuthenticationFailures`	Sum	`Endpoint`
`ClientConnectHandlerDeniedConnections`	`ClientConnectHandlerDeniedConnections`	Sum	`Endpoint`
`ClientConnectHandlerFailedServiceErrors`	`ClientConnectHandlerFailedServiceErrors`	Sum	`Endpoint`
`ClientConnectHandlerInvalidResponses`	`ClientConnectHandlerInvalidResponses`	Sum	`Endpoint`
`ClientConnectHandlerOtherExecutionErrors`	`ClientConnectHandlerOtherExecutionErrors`	Sum	`Endpoint`
`ClientConnectHandl`	`ClientConnectHandl`	Sum	`Endpoint`

Metric	OpenTelemetry metric	Instrument type	Data point attributes
erThrottl ingErrors	erThrottl ingErrors		
ClientCon nectHandl erTimeouts	ClientCon nectHandl erTimeouts	Sum	Endpoint
CrlDaysToExpiry	CrlDaysToExpiry	Histogram	Endpoint
EgressBytes	EgressBytes	Sum	Endpoint
EgressPackets	EgressPackets	Sum	Endpoint
IngressBytes	IngressBytes	Sum	Endpoint
IngressPackets	IngressPackets	Sum	Endpoint
SelfServi cePortalC lientConf iguration Downloads	SelfServi cePortalC lientConf iguration Downloads	Sum	Endpoint
ZeroHealt hItemsCount	ZeroHealt hItemsCount	Histogram	Endpoint

AWS/CloudFront

The `AWS/CloudFront` namespace is published under the OpenTelemetry instrumentation scope `cloudwatch.aws/cloudfront`. All enriched instruments use Delta temporality.

- AWS::CloudFront::Distribution
- AWS::CloudFront::Function

AWS::CloudFront::Distribution

- `cloud.resource_id` enrichment: Supported
- `tag.*` enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
`401ErrorRate`	`401ErrorRate`	Histogram	`DistributionId` , `Region`
`403ErrorRate`	`403ErrorRate`	Histogram	`DistributionId` , `Region`
`404ErrorRate`	`404ErrorRate`	Histogram	`DistributionId` , `Region`
`4xxErrorRate`	`4xxErrorRate`	Histogram	`DistributionId` , `Region`
`5xxErrorRate`	`5xxErrorRate`	Histogram	`DistributionId` , `Region`
`BytesDownloaded`	`BytesDownloaded`	Sum	`DistributionId` , `Region`
`BytesUploaded`	`BytesUploaded`	Sum	`DistributionId` , `Region`
`CacheHitRate`	`CacheHitRate`	Histogram	`DistributionId` , `Region`
`OriginLatency`	`OriginLatency`	Histogram	`DistributionId` , `Region`
`Requests`	`Requests`	Sum	`DistributionId` , `Region`

Metric	OpenTelemetry metric	Instrument type	Data point attributes
TotalErrorRate	TotalErrorRate	Histogram	DistributionId , Region

AWS::CloudFront::Function

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
FunctionComputeUtilization	FunctionComputeUtilization	Histogram	DistributionId , FunctionName , Region
FunctionExecutionErrors	FunctionExecutionErrors	Sum	DistributionId , FunctionName , Region
FunctionInvocations	FunctionInvocations	Sum	DistributionId , FunctionName , Region
FunctionThrottles	FunctionThrottles	Sum	DistributionId , FunctionName , Region
FunctionValidationErrors	FunctionValidationErrors	Sum	DistributionId , FunctionName , Region

Metric	OpenTelemetry metric	Instrument type	Data point attributes
KvsReadErrors	KvsReadErrors	Sum	DistributionId , FunctionName , Region
KvsReadRequests	KvsReadRequests	Sum	DistributionId , FunctionName , Region

AWS/CloudWatch/MetricStreams

The AWS/CloudWatch/MetricStreams namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/cloudwatch. All enriched instruments use Delta temporality.

- AWS::CloudWatch::MetricStream

AWS::CloudWatch::MetricStream

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
MetricUpdate	MetricUpdate	Sum	MetricStreamName
PublishErrorRate	PublishErrorRate	Histogram	MetricStreamName
TotalMetricUpdate	TotalMetricUpdate	Sum	MetricStreamName

AWS/CodeGuruProfiler

The `AWS/CodeGuruProfiler` namespace is published under the OpenTelemetry instrumentation scope `cloudwatch.aws/codeguru-profiler`. All enriched instruments use Delta temporality.

- AWS::CodeGuruProfiler::ProfilingGroup

AWS::CodeGuruProfiler::ProfilingGroup

- `cloud.resource_id` enrichment: Supported
- `tag.*` enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
`Recommendations`	`Recommendations`	Histogram	`ProfilingGroupName`

AWS/Cognito

The `AWS/Cognito` namespace is published under the OpenTelemetry instrumentation scope `cloudwatch.aws/cognito-idp`. All enriched instruments use Delta temporality.

- AWS::Cognito::UserPool

AWS::Cognito::UserPool

- `cloud.resource_id` enrichment: Supported
- `tag.*` enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
AccountTakeoverRisk	AccountTakeoverRisk	Sum	Operation , RiskLevel , UserPoolId
CompromisedCredentialRisk	CompromisedCredentialRisk	Sum	Operation , RiskLevel , UserPoolId
FederationSuccesses	FederationSuccesses	Sum	IdentityProvider , UserPool, UserPoolClient
FederationThrottles	FederationThrottles	Sum	IdentityProvider , UserPool, UserPoolClient
NoRisk	NoRisk	Sum	Operation , UserPoolId
Risk	Risk	Sum	Operation , UserPoolId
SignInSuccesses	SignInSuccesses	Sum	UserPool, UserPoolClient
SignInThrottles	SignInThrottles	Sum	UserPool, UserPoolClient
SignUpSuccesses	SignUpSuccesses	Sum	UserPool, UserPoolClient
SignUpThrottles	SignUpThrottles	Sum	UserPool, UserPoolClient

Metric	OpenTelemetry metric	Instrument type	Data point attributes
TokenRefreshSuccesses	TokenRefreshSuccesses	Sum	UserPool, UserPoolClient
TokenRefreshThrottles	TokenRefreshThrottles	Sum	UserPool, UserPoolClient

AWS/Connect

The AWS/Connect namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/connect. All enriched instruments use Delta temporality.

- AWS::Connect::Instance
- contact

AWS::Connect::Instance

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
CallRecordingUploadError	CallRecordingUploadError	Sum	InstanceId , MetricGroup
CallsBreachingConcurrencyQuota	CallsBreachingConcurrencyQuota	Sum	InstanceId , MetricGroup
CallsPerInterval	CallsPerInterval	Sum	InstanceId , MetricGroup

Metric	OpenTelemetry metric	Instrument type	Data point attributes
ChatsBreachingActiveChatQuota	ChatsBreachingActiveChatQuota	Sum	InstanceId , MetricGroup
ConcurrentActiveChats	ConcurrentActiveChats	Histogram	InstanceId , MetricGroup
ConcurrentActiveChatsPercentage	ConcurrentActiveChatsPercentage	Histogram	InstanceId , MetricGroup
ConcurrentCalls	ConcurrentCalls	Histogram	InstanceId , MetricGroup
ConcurrentCallsPercentage	ConcurrentCallsPercentage	Histogram	InstanceId , MetricGroup
ConcurrentTasks	ConcurrentTasks	Histogram	InstanceId , MetricGroup
ConcurrentTasksPercentage	ConcurrentTasksPercentage	Histogram	InstanceId , MetricGroup
ContactFlowErrors	ContactFlowErrors	Sum	ContactFlowName , InstanceId , MetricGroup
LongestQueueWaitTime	LongestQueueWaitTime	Histogram	InstanceId , MetricGroup , QueueName
MisconfiguredPhoneNumbers	MisconfiguredPhoneNumbers	Sum	InstanceId , MetricGroup

Metric	OpenTelemetry metric	Instrument type	Data point attributes
MissedCalls	MissedCalls	Sum	InstanceId , MetricGroup
PublicSigningKeyUsage	PublicSigningKeyUsage	Sum	InstanceId , SigningKeyId
QueueCapacityExceededError	QueueCapacityExceededError	Sum	InstanceId , MetricGroup , QueueName
QueueSize	QueueSize	Histogram	InstanceId , MetricGroup , QueueName
SuccessfulChatsPerInterval	SuccessfulChatsPerInterval	Sum	InstanceId , MetricGroup
TasksBreachingConcurrencyQuota	TasksBreachingConcurrencyQuota	Sum	InstanceId , MetricGroup
ToInstancePacketLossRate	ToInstancePacketLossRate	Histogram	InstanceId , Participant , Stream Type, Type of Connection

contact

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Not supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
TasksExpired	TasksExpired	Sum	ContactId , InstanceId , MetricGroup
TasksExpiryWarningReached	TasksExpiryWarningReached	Sum	ContactId , InstanceId , MetricGroup

AWS/DAX

The AWS/DAX namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/dax. All enriched instruments use Delta temporality.

- AWS::DAX::Cluster

AWS::DAX::Cluster

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
BaselineNetworkBytesInUtilization	BaselineNetworkBytesInUtilization	Histogram	ClusterId , NodeId
BaselineNetworkBytesOutUtilization	BaselineNetworkBytesOutUtilization	Histogram	ClusterId , NodeId

Metric	OpenTelemetry metric	Instrument type	Data point attributes
BatchGetItemRequestCount	BatchGetItemRequestCount	Sum	ClusterId , NodeId

TCP_ELB_Reset_Count	TCP_ELB_Reset_Count	Sum	AvailabilityZone, LoadBalancer
TCP_Target_Reset_Count	TCP_Target_Reset_Count	Sum	AvailabilityZone, LoadBalancer
UnHealthyHostCount	UnHealthyHostCount	Histogram	AvailabilityZone, LoadBalancer, TargetGroup

AWS/NetworkFirewall

The AWS/NetworkFirewall namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/network-firewall. All enriched instruments use Delta temporality.

- AWS::NetworkFirewall::Firewall

AWS::NetworkFirewall::Firewall

- cloud.resource_id enrichment: Supported

- `tag.*` enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
DroppedPackets	DroppedPackets	Sum	AvailabilityZone, Engine, FirewallName
InvalidDroppedPackets	InvalidDroppedPackets	Sum	AvailabilityZone, Engine, FirewallName
OtherDroppedPackets	OtherDroppedPackets	Sum	AvailabilityZone, Engine, FirewallName
Packets	Packets	Sum	AvailabilityZone, CustomAction, Engine, FirewallName
PassedPackets	PassedPackets	Sum	AvailabilityZone, Engine, FirewallName
ReceivedPackets	ReceivedPackets	Sum	AvailabilityZone, Engine, FirewallName
RejectedPackets	RejectedPackets	Sum	AvailabilityZone, Engine, FirewallName

Metric	OpenTelemetry metric	Instrument type	Data point attributes
StreamExceptionPolicyPackets	StreamExceptionPolicyPackets	Sum	AvailabilityZone ,Engine, FirewallName
TLSDroppedPackets	TLSDroppedPackets	Sum	AvailabilityZone ,Engine, FirewallName
TLSErrors	TLSErrors	Sum	AvailabilityZone ,Engine, FirewallName
TLSPassedPackets	TLSPassedPackets	Sum	AvailabilityZone ,Engine, FirewallName
TLSReceivedPackets	TLSReceivedPackets	Sum	AvailabilityZone ,Engine, FirewallName
TLSRejectedPackets	TLSRejectedPackets	Sum	AvailabilityZone ,Engine, FirewallName
TLSRevocationStatusOKConnections	TLSRevocationStatusOKConnections	Sum	AvailabilityZone ,Engine, FirewallName
TLSRevocationStatusRevokedConnections	TLSRevocationStatusRevokedConnections	Sum	AvailabilityZone ,Engine, FirewallName

Metric	OpenTelemetry metric	Instrument type	Data point attributes
TLSRevocationStatusUnknownConnections	TLSRevocationStatusUnknownConnections	Sum	AvailabilityZone ,Engine, FirewallName
TLSTimedOutConnections	TLSTimedOutConnections	Sum	AvailabilityZone ,Engine, FirewallName

AWS/Pinpoint

The AWS/Pinpoint namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/mobiletargeting. All enriched instruments use Delta temporality.

- AWS::Pinpoint::App

AWS::Pinpoint::App

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Not supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
CampaignSendMessageLatency	CampaignSendMessageLatency	Histogram	ApplicationId , Channel
CampaignSendMessagePermanentFailure	CampaignSendMessagePermanentFailure	Sum	ApplicationId , Channel

Metric	OpenTelemetry metric	Instrument type	Data point attributes
CampaignSendMessageSuccess	CampaignSendMessageSuccess	Sum	ApplicationId , Channel
CampaignSendMessageTemporaryFailure	CampaignSendMessageTemporaryFailure	Sum	ApplicationId , Channel
CampaignSendMessageThrottled	CampaignSendMessageThrottled	Sum	ApplicationId , Channel
DLRFailure	DLRFailure	Sum	ApplicationId , IsoCountryCode
DLRSuccess	DLRSuccess	Sum	ApplicationId , IsoCountryCode
DestinationChannelCount	DestinationChannelCount	Histogram	ApplicationId , Channel
DirectSendMessageLatency	DirectSendMessageLatency	Histogram	ApplicationId , Channel
DirectSendMessagePermanentFailure	DirectSendMessagePermanentFailure	Sum	ApplicationId , Channel
DirectSendMessageSuccess	DirectSendMessageSuccess	Sum	ApplicationId , Channel

Metric	OpenTelemetry metric	Instrument type	Data point attributes
DirectSendMessageTemporaryFailure	DirectSendMessageTemporaryFailure	Sum	ApplicationId , Channel
DirectSendMessageThrottled	DirectSendMessageThrottled	Sum	ApplicationId , Channel
EndpointRegistrationFailure	EndpointRegistrationFailure	Sum	ApplicationId
ExportEventErrors	ExportEventErrors	Sum	ApplicationId , ErrorCode
ExportedEvents	ExportedEvents	Sum	ApplicationId
ImportJobDuration	ImportJobDuration	Histogram	ApplicationId
ImportJobFailure	ImportJobFailure	Sum	ApplicationId
ImportedEndpointFailure	ImportedEndpointFailure	Sum	ApplicationId
JourneySendMessageLatency	JourneySendMessageLatency	Histogram	ApplicationId , Channel
JourneySendMessagePermanentFailure	JourneySendMessagePermanentFailure	Sum	ApplicationId , Channel

Metric	OpenTelemetry metric	Instrument type	Data point attributes
JourneySendMessageSuccess	JourneySendMessageSuccess	Sum	ApplicationId , Channel
OTPSendMessageLatency	OTPSendMessageLatency	Histogram	ApplicationId , Channel
OTPSendMessageSuccess	OTPSendMessageSuccess	Sum	ApplicationId , Channel
OTPVerificationAttempt	OTPVerificationAttempt	Sum	ApplicationId , Channel
OTPVerificationFailure	OTPVerificationFailure	Sum	ApplicationId , Channel
OTPVerificationFailureFinalAttempt	OTPVerificationFailureFinalAttempt	Sum	ApplicationId
OTPVerificationSuccess	OTPVerificationSuccess	Sum	ApplicationId , Channel
TotalEvents	TotalEvents	Sum	ApplicationId

AWS/Prometheus

The AWS/Prometheus namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/aps. All enriched instruments use Delta temporality.

- AWS::APS::AnomalyDetector
- AWS::APS::RuleGroupsNamespace
- AWS::APS::Workspace

AWS::APS::AnomalyDetector

- `cloud.resource_id` enrichment: Supported
- `tag.*` enrichment: Not supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
`AnomalyDetectorEvaluationFailures`	`AnomalyDetectorEvaluationFailures`	Sum	`AnomalyDetectorId`, `Workspace`
`AnomalyDetectorEvaluations`	`AnomalyDetectorEvaluations`	Sum	`AnomalyDetectorId`, `Workspace`
`AnomalyDetectorLastEvaluationDuration`	`AnomalyDetectorLastEvaluationDuration`	Histogram	`AnomalyDetectorId`, `Workspace`

AWS::APS::RuleGroupsNamespace

- `cloud.resource_id` enrichment: Supported
- `tag.*` enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
`RuleEvaluationFailures`	`RuleEvaluationFailures`	Sum	`RuleGroup`, `Workspace`
`RuleEvaluations`	`RuleEvaluations`	Sum	`RuleGroup`, `Workspace`

Metric	OpenTelemetry metric	Instrument type	Data point attributes
RuleGroupIterationsMissed	RuleGroupIterationsMissed	Sum	RuleGroup, Workspace
RuleGroupLastEvaluationDuration	RuleGroupLastEvaluationDuration	Histogram	RuleGroup, Workspace

AWS::APS::Workspace

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
ActiveSeriesLimitPerLabelSet	ActiveSeriesLimitPerLabelSet	Histogram	LabelSet, Workspace
ActiveSeriesPerLabelSet	ActiveSeriesPerLabelSet	Histogram	LabelSet, Workspace
AlertManagerAlertsReceived	AlertManagerAlertsReceived	Sum	Workspace
AlertManagerNotificationsFailed	AlertManagerNotificationsFailed	Sum	Workspace
AlertManagerNotifi	AlertManagerNotifi	Sum	Workspace

Metric	OpenTelemetry metric	Instrument type	Data point attributes
cationsFailedByIntegration	cationsFailedByIntegration		
AlertManagerNotificationsThrottled	AlertManagerNotificationsThrottled	Sum	Workspace
AlertManagerNotificationsThrottledByIntegration	AlertManagerNotificationsThrottledByIntegration	Sum	Workspace
DiscardedSamples	DiscardedSamples	Sum	Reason, Workspace
DiscardedSamplesPerLabelSet	DiscardedSamplesPerLabelSet	Sum	LabelSet, Reason, Workspace
DiscardedSeries	DiscardedSeries	Sum	Reason, Workspace
DiscardedSeriesPerLabelSet	DiscardedSeriesPerLabelSet	Sum	LabelSet, Reason, Workspace
IngestionRatePerLabelSet	IngestionRatePerLabelSet	Histogram	LabelSet, Workspace
QuerySamplesProcessed	QuerySamplesProcessed	Sum	Workspace

Metric	OpenTelemetry metric	Instrument type	Data point attributes
SecretFetchFailure	SecretFetchFailure	Sum	Workspace

AWS/RDS

The AWS/RDS namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/rds. All enriched instruments use Delta temporality.

- AWS::RDS::DBCluster
- AWS::RDS::DBInstance

AWS::RDS::DBCluster

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
AbortedClients	AbortedClients	Sum	DBClusterIdentifier, Role
ActiveTransactions	ActiveTransactions	Histogram	DBClusterIdentifier, Role
AuroraBinlogReplicaLag	AuroraBinlogReplicaLag	Histogram	DBClusterIdentifier, Role

WLMQueueWaitTime	WLMQueueWaitTime	Histogram	ClusterIdentifier ,wlmid
WLMRunningQueries	WLMRunningQueries	Histogram	ClusterIdentifier , QueueName
WriteIOPS	WriteIOPS	Histogram	ClusterIdentifier ,NodeID
WriteLatency	WriteLatency	Histogram	ClusterIdentifier ,NodeID
WriteThroughput	WriteThroughput	Histogram	ClusterIdentifier ,NodeID

AWS/Redshift-Serverless

The AWS/Redshift-Serverless namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/redshift-serverless. All enriched instruments use Delta temporality.

- AWS::RedshiftServerless::Namespace
- AWS::RedshiftServerless::Workgroup

AWS::RedshiftServerless::Namespace

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Not supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
DataStorage	DataStorage	Histogram	Namespace
TotalTableCount	TotalTableCount	Histogram	DatabaseName , Namespace

AWS::RedshiftServerless::Workgroup

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Not supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
ComputeCapacity	ComputeCapacity	Histogram	Workgroup
ComputeSeconds	ComputeSeconds	Sum	Workgroup
DatabaseConnections	DatabaseConnections	Histogram	DatabaseName , Workgroup
QueriesCompletedPerSecond	QueriesCompletedPerSecond	Histogram	DatabaseName , LatencyRange , Workgroup
QueriesFailed	QueriesFailed	Sum	DatabaseName , QueryType , Workgroup
QueriesQueued	QueriesQueued	Histogram	DatabaseName , QueryType , Workgroup

Metric	OpenTelemetry metric	Instrument type	Data point attributes
QueriesRunning	QueriesRunning	Histogram	DatabaseName , QueryType , Workgroup
QueriesSucceeded	QueriesSucceeded	Sum	DatabaseName , QueryType , Workgroup
QueryDuration	QueryDuration	Histogram	DatabaseName , LatencyRange , Workgroup
QueryRuntimeBreakdown	QueryRuntimeBreakdown	Sum	DatabaseName , Workgroup ,stage
UsageLimitAvailable	UsageLimitAvailable	Histogram	UsageLimitId , UsageType , Workgroup
UsageLimitConsumed	UsageLimitConsumed	Histogram	UsageLimitId , UsageType , Workgroup

AWS/Route53

The AWS/Route53 namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/route53. All enriched instruments use Delta temporality.

- AWS::Route53::HealthCheck

AWS::Route53::HealthCheck

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
ChildHealthCheckHealthyCount	ChildHealthCheckHealthyCount	Histogram	HealthCheckId
ConnectionTime	ConnectionTime	Histogram	HealthCheckId , Region
HealthCheckPercentageHealthy	HealthCheckPercentageHealthy	Histogram	HealthCheckId
HealthCheckStatus	HealthCheckStatus	Histogram	HealthCheckId
SSLHandshakeTime	SSLHandshakeTime	Histogram	HealthCheckId , Region
TimeToFirstByte	TimeToFirstByte	Histogram	HealthCheckId , Region

AWS/Route53Resolver

The AWS/Route53Resolver namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/route53resolver. All enriched instruments use Delta temporality.

- AWS::Route53Resolver::FirewallRuleGroup
- AWS::Route53Resolver::ResolverEndpoint

AWS::Route53Resolver::FirewallRuleGroup

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
FirewallRuleGroupQueryVolume	FirewallRuleGroupQueryVolume	Sum	FirewallRuleGroupId
FirewallRuleGroupVpcQueryVolume	FirewallRuleGroupVpcQueryVolume	Sum	FirewallRuleGroupId , VpcId

AWS::Route53Resolver::ResolverEndpoint

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
AverageResponseTime	AverageResponseTime	Histogram	EndpointId , RniId
CapacityUsage_BETA	CapacityUsage_BETA	Histogram	EndpointId , RniId
ConntrackUtilization	ConntrackUtilization	Histogram	EndpointId , RniId
EndpointHealthyENICount	EndpointHealthyENICount	Histogram	EndpointId
EndpointUnhealthyENICount	EndpointUnhealthyENICount	Histogram	EndpointId

Metric	OpenTelemetry metric	Instrument type	Data point attributes
FormErrCount	FormErrCount	Sum	EndpointId , RniId
FormError Queries	FormError Queries	Sum	EndpointId , RniId
InboundQu eryVolume	InboundQu eryVolume	Sum	EndpointId
NXDomainCount	NXDomainCount	Sum	EndpointId , RniId
NoErrorCount	NoErrorCount	Sum	EndpointId , RniId
NxDomainQueries	NxDomainQueries	Sum	EndpointId , RniId
OutboundQ ueryAggre gateVolume	OutboundQ ueryAggre gateVolume	Sum	EndpointId
OutboundQ ueryVolume	OutboundQ ueryVolume	Sum	EndpointId
P90ResponseTime	P90ResponseTime	Histogram	• EndpointI D ,TargetNam eServerIP • EndpointId , RniId
RefusedCount	RefusedCount	Sum	EndpointId , RniId
RefusedQueries	RefusedQueries	Sum	EndpointId , RniId

Metric	OpenTelemetry metric	Instrument type	Data point attributes
ReplyCount	ReplyCount	Sum	EndpointId , RniId
RequestQueries	RequestQueries	Sum	EndpointID ,TargetNameServerIP
ResolverEndpointCapacityStatus	ResolverEndpointCapacityStatus	Histogram	EndpointId
ServFailQueries	ServFailQueries	Sum	EndpointId , RniId
ServfailCount	ServfailCount	Sum	EndpointId , RniId
TimeoutCount	TimeoutCount	Sum	EndpointId , RniId
TimeoutQueries	TimeoutQueries	Sum	• EndpointID ,TargetNameServerIP • EndpointId , RniId
tcpRequestCount	tcpRequestCount	Sum	EndpointId , RniId
udpRequestCount	udpRequestCount	Sum	EndpointId , RniId

AWS/S3

The `AWS/S3` namespace is published under the OpenTelemetry instrumentation scope `cloudwatch.aws/s3`. All enriched instruments use Delta temporality.

- AWS::S3::Bucket

AWS::S3::Bucket

- `cloud.resource_id` enrichment: Supported
- `tag.*` enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
`4xxErrors`	`4xxErrors`	Sum	`BucketName` , `FilterId`
`5xxErrors`	`5xxErrors`	Sum	`BucketName` , `FilterId`
`AllRequests`	`AllRequests`	Sum	`BucketName` , `FilterId`
`BucketSizeBytes`	`BucketSizeBytes`	Histogram	`BucketName` , `StorageType`
`BytesDownloaded`	`BytesDownloaded`	Sum	`BucketName` , `FilterId`
`BytesPendingReplication`	`BytesPendingReplication`	Histogram	`DestinationBucket` , `RuleId`, `SourceBucket`
`BytesUploaded`	`BytesUploaded`	Sum	`BucketName` , `FilterId`

Metric	OpenTelemetry metric	Instrument type	Data point attributes
DeleteRequests	DeleteRequests	Sum	BucketName , FilterId
FirstByte Latency	FirstByte Latency	Histogram	BucketName , FilterId
GetRequests	GetRequests	Sum	BucketName , FilterId
HeadRequests	HeadRequests	Sum	BucketName , FilterId
ListRequests	ListRequests	Sum	BucketName , FilterId
NumberOfObjects	NumberOfObjects	Histogram	BucketName , StorageType
Operation sFailedRe plication	Operation sFailedRe plication	Sum	Destinati onBucket , RuleId, SourceBucket
Operation sPendingR eplication	Operation sPendingR eplication	Histogram	Destinati onBucket , RuleId, SourceBucket
PostRequests	PostRequests	Sum	BucketName , FilterId
PutRequests	PutRequests	Sum	BucketName , FilterId
Replicati onLatency	Replicati onLatency	Histogram	Destinati onBucket , RuleId, SourceBucket

Metric	OpenTelemetry metric	Instrument type	Data point attributes
TotalRequestLatency	TotalRequestLatency	Histogram	BucketName , FilterId

AWS/SNS

The AWS/SNS namespace is published under the OpenTelemetry instrumentation scope cloudwatch.aws/sns. All enriched instruments use Delta temporality.

- AWS::SNS::Topic

AWS::SNS::Topic

- cloud.resource_id enrichment: Supported
- tag.* enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
NumberOfMessagesPublished	NumberOfMessagesPublished	Sum	TopicName
NumberOfNotificationsDelivered	NumberOfNotificationsDelivered	Sum	TopicName
NumberOfNotificationsFailed	NumberOfNotificationsFailed	Sum	TopicName
PublishSize	PublishSize	Histogram	TopicName

AWS/SQS

The AWS/SQS namespace is published under the OpenTelemetry instrumentation scope `cloudwatch.aws/sqs`. All enriched instruments use Delta temporality.

- AWS::SQS::Queue

AWS::SQS::Queue

- `cloud.resource_id` enrichment: Supported
- `tag.*` enrichment: Supported

Metric	OpenTelemetry metric	Instrument type	Data point attributes
ApproximateAgeOfOldestMessage	ApproximateAgeOfOldestMessage	Histogram	QueueName
ApproximateAgeOfOldestMessageInQuietGroups	ApproximateAgeOfOldestMessageInQuietGroups	Histogram	QueueName
ApproximateNumberOfGroupsWithInflightMessages	ApproximateNumberOfGroupsWithInflightMessages	Histogram	QueueName
ApproximateNumberOfMessagesDelayed	ApproximateNumberOfMessagesDelayed	Histogram	QueueName

Metric	OpenTelemetry metric	Instrument type	Data point attributes

DesiredUserSessionCapacity	DesiredUserSessionCapacity	Histogram	WorkSpaces pool ID

Metric	OpenTelemetry metric	Instrument type	Data point attributes
InsufficientCapacityError	InsufficientCapacityError	Sum	WorkSpaces pool ID
PendingUserSessionCapacity	PendingUserSessionCapacity	Histogram	WorkSpaces pool ID
UserSessionsCapacityUtilization	UserSessionsCapacityUtilization	Histogram	WorkSpaces pool ID

Resource tags for telemetry

Use Amazon CloudWatch to enrich your AWS infrastructure metrics and CloudWatch Logs with AWS resource tags. You can set up comprehensive monitoring with CloudWatch metrics and alarms using tags. This helps monitor cloud infrastructure at scale by adapting alarms and metrics analysis as resources change.

To begin discovering and visualizing your telemetry by tags, you must first enable the resource tags for telemetry feature for your AWS account. When you enable this feature, Resource Explorer creates an AWS index and managed view that indexes and discovers resources and tags in your account. For more information, see Index in the Resource Explorer API reference guide and AWS managed views in the Resource Explorer user guide. CloudWatch uses this information to enrich your AWS infrastructure metrics and log events with related AWS resource tags. You can enable **resource tags for telemetry** at no additional cost.

Topics

- Enable resource tags on telemetry
- Using resource tags for telemetry
- Disable resource tags on telemetry
- Troubleshooting

Enable resource tags on telemetry

To add tag information to your telemetry data, enable resource tags for telemetry from the CloudWatch console, AWS SDK, CLI, or CloudFormation. The feature remains active until you turn it off. For more information, see Disable resource tags on telemetry.

Make sure you have permissions to enable resource tags for telemetry.

> **Note**
>
> To enable resource tags on telemetry, you must be signed in to an IAM principal that has the `observabilityadmin:StartTelemetryEnrichment`, `iam:CreateServiceLinkedRole`, `resource-explorer-2:CreateIndex`, `resource-explorer-2:CreateManagedView` and `resource-explorer-2:CreateStreamingAccessForService` permissions.

To enable resource tags for telemetry (CloudWatch Console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **CloudWatch**, then choose **Settings**.
3. In the **Enable resource tags for telemetry** pane, toggle the feature On.

> **Note**
>
> In the CloudWatch console, you must be signed in to an IAM principal that has the `observabilityadmin:GetTelemetryEnrichmentStatus` permission.

To enable resource tags for telemetry (AWS CLI)

Use the `start-telemetry-enrichment` command to enable resource tags for telemetry.

```
aws observabilityadmin start-telemetry-enrichment
```

After you complete these steps, CloudWatch begins enriching telemetry with tags.

To enable resource tags for telemetry (AWS CloudFormation)

You can enable resource tags for telemetry by adding an AWS::ObservabilityAdmin::TelemetryEnrichment resource to your CloudFormation template. Set the `Scope` property to `ACCOUNT` to enable the feature for your account.

Using resource tags for telemetry

Once you have enabled resource tags for telemetry, you can use this enriched data to create powerful monitoring solutions that scale with your infrastructure. Use tag-based queries to group and filter metrics across multiple resources, create dynamic alarms that automatically adapt to resource changes, and gain insights into your AWS environment organized by meaningful business or operational categories. This approach enables you to monitor resources by team, environment, application, or any other tagging strategy you use in your organization.

- **Creating tag-based Metrics Insights queries** – After you enable resource tags for telemetry in your account, you can create tag-based Metrics Insights queries to discover and visualize your AWS infrastructure metrics by tag. Example queries using tags can be seen in the CloudWatch Metrics Insights query builder documentation. *Monitoring accounts* can also make tag-based queries for metrics in *source accounts* which have enabled resource tags on their telemetry.
- **Creating tag-based CloudWatch alarms** – After you enable resource tags for telemetry in your account, you can create CloudWatch alarms on tag-based Metrics Insights queries to alert on your AWS infrastructure metrics by tag. Example alarms using tag-based queries can be seen in the CloudWatch Metric Insights alarms documentation.
- **Querying AWS metrics with PromQL using resource tags** – After you enable resource tags for telemetry in your account, you can enable OTel enrichment to query your AWS infrastructure metrics using PromQL with resource tags as labels. This lets you filter, aggregate, and alert on metrics by any tag you've applied to your AWS resources. For more information, see Enabling vended metrics in PromQL. For example queries using tags, see Querying vended AWS metrics with PromQL.
- **Creating tag-based CloudWatch Logs Insights queries** – After you enable resource tags for telemetry in your account, log events from supported resources are enriched with the associated resource tags. You can create tag-based Logs Insights queries to discover your log events by tag using facets such as `@aws.tag.env` or `@aws.tag.team`. For example: `filter @aws.tag.env = 'production'`. For more information, see the CloudWatch Logs Insights query syntax documentation.

Supported AWS resources

The following table lists the AWS resources that support resource tags for telemetry enrichment. When you enable resource tags for telemetry, CloudWatch can enrich metrics and log events from these resources with their associated resource tags.

For the specific metrics that CloudWatch enriches for each resource type, see Supported metrics for resource tags for telemetry.

Resource type	Metrics	Logs
AWS::APS::RuleGroupsNamespace	Yes	No
AWS::APS::Workspace	Yes	Yes
AWS::ApiGatewayV2::Api	Yes	No
AWS::AppFlow::Flow	Yes	No
AWS::AppSync::GraphQLApi	Yes	Yes
AWS::Athena::WorkGroup	Yes	No

Supported AWS Regions for resource tags for telemetry

The following table lists the AWS Regions where the resource tags for telemetry feature is available.

Region name	Region
Africa (Cape Town)	af-south-1
Asia Pacific (Hong Kong)	ap-east-1
Asia Pacific (Taipei)	ap-east-2
Asia Pacific (Tokyo)	ap-northeast-1
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Osaka)	ap-northeast-3
Asia Pacific (Mumbai)	ap-south-1
Asia Pacific (Hyderabad)	ap-south-2

Region name	Region
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Asia Pacific (Jakarta)	ap-southeast-3
Asia Pacific (Melbourne)	ap-southeast-4
Asia Pacific (Malaysia)	ap-southeast-5
Asia Pacific (New Zealand)	ap-southeast-6
Asia Pacific (Thailand)	ap-southeast-7
Canada (Central)	ca-central-1
Canada West (Calgary)	ca-west-1
Europe (Frankfurt)	eu-central-1
Europe (Zurich)	eu-central-2
Europe (Stockholm)	eu-north-1
Europe (Milan)	eu-south-1
Europe (Spain)	eu-south-2
Europe (Ireland)	eu-west-1
Europe (London)	eu-west-2
Europe (Paris)	eu-west-3
Mexico (Central)	mx-central-1
South America (São Paulo)	sa-east-1
US East (N. Virginia)	us-east-1

Region name	Region
US East (Ohio)	us-east-2
US West (N. California)	us-west-1
US West (Oregon)	us-west-2

Supported metrics for resource tags for telemetry

The following sections list the metrics that CloudWatch enriches with AWS resource tags, grouped by namespace. For each namespace, the supported resource types are listed, with a table of metrics and the dimensions you can use with each.

CloudWatch treats each unique combination of dimensions as a separate metric. In the following tables, each bullet in the Dimensions column is a combination of dimensions that are published together.

AWS/AOSS

The AWS/AOSS namespace includes enriched metrics for the following resource types.

- AWS::OpenSearchServerless::Collection

AWS::OpenSearchServerless::Collection

Metric	Dimensions
2xx	• ClientId, CollectionId , CollectionName
3xx	• ClientId, CollectionId , CollectionName
4xx	• ClientId, CollectionId , CollectionName
5xx	• ClientId, CollectionId , CollectionName

Metric	Dimensions
ActiveCollection	• ClientId, CollectionId , CollectionName
ActiveCollection-Shadow	• ClientId, CollectionId , CollectionName
AutoOptimizeJob	• ClientId, CollectionId , CollectionName
IngestionDataRate-Shadow	• ClientId, CollectionId , CollectionName
IngestionDocumentErrors-Shadow	• ClientId, CollectionId , CollectionName
IngestionDocumentRate-Shadow	• ClientId, CollectionId , CollectionName
IngestionRequestErrors	• ClientId, CollectionId , CollectionName
IngestionRequestErrors-Shadow	• ClientId, CollectionId , CollectionName
IngestionRequestLatency	• ClientId, CollectionId , CollectionName
IngestionRequestRate	• ClientId, CollectionId , CollectionName
IngestionRequestRate-Shadow	• ClientId, CollectionId , CollectionName
IngestionRequestSuccess	• ClientId, CollectionId , CollectionName

Metric	Dimensions
IngestionRequestSuccess-Shadow	• ClientId, CollectionId , CollectionName
KNNRemoteIndexBuildFailureCount	• ClientId, CollectionId , CollectionName
KNNRemoteIndexBuildSuccessCount	• ClientId, CollectionId , CollectionName
KNNRemoteIndexBuildTime	• ClientId, CollectionId , CollectionName
SearchRequestErrors-Shadow	• ClientId, CollectionId , CollectionName
SearchRequestLatency	• ClientId, CollectionId , CollectionName
SearchRequestRate	• ClientId, CollectionId , CollectionName
SearchRequestRate-Shadow	• ClientId, CollectionId , CollectionName
SemanticSearchOCU	• AwsAccountId , CollectionId • ClientId, CollectionId , CollectionName

AWS/ApiGateway

The AWS/ApiGateway namespace includes enriched metrics for the following resource types.

- AWS::ApiGatewayV2::Api

AWS::ApiGatewayV2::Api

Metric	Dimensions
4xx	• ApiId • ApiId, Method, Resource, Stage
5xx	• ApiId • ApiId, Method, Resource, Stage
ClientError	• ApiId • ApiId, Route, Stage
ConnectCount	• ApiId • ApiId, Route, Stage
Count	• ApiId • ApiId, Method, Resource, Stage
DataProcessed	• ApiId • ApiId, Method, Resource, Stage
ExecutionError	• ApiId • ApiId, Route, Stage
IntegrationError	• ApiId • ApiId, Route, Stage
IntegrationLatency	• ApiId • ApiId, Method, Resource, Stage • ApiId, Route, Stage
Latency	• ApiId • ApiId, Method, Resource, Stage
MessageCount	• ApiId • ApiId, Route, Stage

AWS/AppFlow

The AWS/AppFlow namespace includes enriched metrics for the following resource types.

- AWS::AppFlow::Flow

AWS::AppFlow::Flow

Metric	Dimensions
FlowExecutionRecordsProcessed	• FlowName
FlowExecutionTime	• FlowName
FlowExecutionsFailed	• FlowName
FlowExecutionsStarted	• FlowName
FlowExecutionsSucceeded	• FlowName

AWS/AppSync

The AWS/AppSync namespace includes enriched metrics for the following resource types.

- AWS::AppSync::GraphQLApi

AWS::AppSync::GraphQLApi

Metric	Dimensions
4XXError	• GraphQLAPIId
5XXError	• GraphQLAPIId
ActiveConnections	• GraphQLAPIId
ActiveSubscriptions	• GraphQLAPIId

UnHealthyHostCount	• AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer ,TargetGroup
UnhealthyRoutingRequestCount	• AvailabilityZone ,LoadBalancer • AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer • LoadBalancer ,TargetGroup
UnhealthyStateDNS	• AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer ,TargetGroup
UnhealthyStateRouting	• AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer ,TargetGroup

AWS::ElasticLoadBalancingV2::TargetGroup

Metric	Dimensions
GrpcRequestCount	• AvailabilityZone ,TargetGroup • TargetGroup
LambdaInternalError	• TargetGroup

Metric	Dimensions
LambdaUserError	• TargetGroup
RequestCountPerTarget	• AvailabilityZone ,TargetGroup • TargetGroup

AWS/Athena

The AWS/Athena namespace includes enriched metrics for the following resource types.

- AWS::Athena::WorkGroup

AWS::Athena::WorkGroup

Metric	Dimensions
DPUConsumed	• WorkGroup
DPUCount	• QueryState ,QueryType ,WorkGroup
EngineExecutionTime	• QueryState ,QueryType ,WorkGroup
ProcessedBytes	• QueryState ,QueryType ,WorkGroup • WorkGroup
QueryPlanningTime	• QueryState ,QueryType ,WorkGroup
QueryQueueTime	• QueryState ,QueryType ,WorkGroup
ServicePreProcessingTime	• QueryState ,QueryType ,WorkGroup
ServiceProcessingTime	• QueryState ,QueryType ,WorkGroup
TotalExecutionTime	• QueryState ,QueryType ,WorkGroup

AWS/Backup

The AWS/Backup namespace includes enriched metrics for the following resource types.

- AWS::Backup::BackupVault

AWS::Backup::BackupVault

Metric	Dimensions
NumberOfBackupJobsCompleted	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfBackupJobsCreated	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfBackupJobsExpired	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfBackupJobsFailed	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfBackupJobsPartial	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfBackupJobsPending	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfBackupJobsRunning	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfCopyJobsCompleted	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfCopyJobsCreated	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfCopyJobsFailed	• BackupVaultName

Metric	Dimensions
	• BackupVaultName ,ResourceType
NumberOfCopyJobsRunning	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRecoveryPointsCold	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRecoveryPointsCompleted	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRecoveryPointsCreating	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRecoveryPointsDeleting	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRecoveryPointsExpired	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRecoveryPointsPartial	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRestoreJobsCompleted	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRestoreJobsFailed	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRestoreJobsPending	• BackupVaultName • BackupVaultName ,ResourceType
NumberOfRestoreJobsRunning	• BackupVaultName • BackupVaultName ,ResourceType

AWS/ClientVPN

The AWS/ClientVPN namespace includes enriched metrics for the following resource types.

- AWS::EC2::ClientVpnEndpoint

AWS::EC2::ClientVpnEndpoint

Metric	Dimensions
ActiveConnectionsCount	• Endpoint
AuthenticationFailures	• Endpoint
ClientConnectHandlerDeniedConnections	• Endpoint
ClientConnectHandlerFailedServiceErrors	• Endpoint
ClientConnectHandlerInvalidResponses	• Endpoint
ClientConnectHandlerOtherExecutionErrors	• Endpoint
ClientConnectHandlerThrottlingErrors	• Endpoint
ClientConnectHandlerTimeouts	• Endpoint
CrlDaysToExpiry	• Endpoint
EgressBytes	• Endpoint
EgressPackets	• Endpoint
IngressBytes	• Endpoint
IngressPackets	• Endpoint

Metric	Dimensions
SelfServicePortalClientConfigurationDownloads	• Endpoint
ZeroHealthItemsCount	• Endpoint

AWS/CloudFront

The AWS/CloudFront namespace includes enriched metrics for the following resource types.

- AWS::CloudFront::Distribution
- AWS::CloudFront::Function

AWS::CloudFront::Distribution

Metric	Dimensions
401ErrorRate	• DistributionId ,Region
403ErrorRate	• DistributionId ,Region
404ErrorRate	• DistributionId ,Region
4xxErrorRate	• DistributionId ,Region
5xxErrorRate	• DistributionId ,Region
BytesDownloaded	• DistributionId ,Region
BytesUploaded	• DistributionId ,Region
CacheHitRate	• DistributionId ,Region
OriginLatency	• DistributionId ,Region
Requests	• DistributionId ,Region
TotalErrorRate	• DistributionId ,Region

AWS::CloudFront::Function

Metric	Dimensions
FunctionComputeUtilization	• DistributionId ,FunctionName , Region
FunctionExecutionErrors	• DistributionId ,FunctionName , Region
FunctionInvocations	• DistributionId ,FunctionName , Region
FunctionThrottles	• DistributionId ,FunctionName , Region
FunctionValidationErrors	• DistributionId ,FunctionName , Region
KvsReadErrors	• DistributionId ,FunctionName , Region
KvsReadRequests	• DistributionId ,FunctionName , Region

AWS/CloudWatch/MetricStreams

The AWS/CloudWatch/MetricStreams namespace includes enriched metrics for the following resource types.

- AWS::CloudWatch::MetricStream

AWS::CloudWatch::MetricStream

Metric	Dimensions
MetricUpdate	• MetricStreamName

Metric	Dimensions
PublishErrorRate	• MetricStreamName
TotalMetricUpdate	• MetricStreamName

AWS/CodeGuruProfiler

The AWS/CodeGuruProfiler namespace includes enriched metrics for the following resource types.

- AWS::CodeGuruProfiler::ProfilingGroup

AWS::CodeGuruProfiler::ProfilingGroup

Metric	Dimensions
Recommendations	• ProfilingGroupName

AWS/Cognito

The AWS/Cognito namespace includes enriched metrics for the following resource types.

- AWS::Cognito::UserPool

AWS::Cognito::UserPool

Metric	Dimensions
AccountTakeoverRisk	• Operation ,RiskLevel ,UserPoolId
CompromisedCredentialRisk	• Operation ,RiskLevel ,UserPoolId
FederationSuccesses	• IdentityProvider ,UserPool, UserPoolClient

Metric	Dimensions
FederationThrottles	• IdentityProvider ,UserPool, UserPoolClient
NoRisk	• Operation ,UserPoolId
Risk	• Operation ,UserPoolId
SignInSuccesses	• UserPool, UserPoolClient
SignInThrottles	• UserPool, UserPoolClient
SignUpSuccesses	• UserPool, UserPoolClient
SignUpThrottles	• UserPool, UserPoolClient
TokenRefreshSuccesses	• UserPool, UserPoolClient
TokenRefreshThrottles	• UserPool, UserPoolClient

AWS/Connect

The AWS/Connect namespace includes enriched metrics for the following resource types.

- AWS::Connect::Instance

AWS::Connect::Instance

Metric	Dimensions
CallRecordingUploadError	• InstanceId ,MetricGroup
CallsBreachingConcurrencyQuota	• InstanceId ,MetricGroup
CallsPerInterval	• InstanceId ,MetricGroup
ChatsBreachingActiveChatQuota	• InstanceId ,MetricGroup

Metric	Dimensions
ConcurrentActiveChats	• InstanceId ,MetricGroup
ConcurrentActiveChatsPercentage	• InstanceId ,MetricGroup
ConcurrentCalls	• InstanceId ,MetricGroup
ConcurrentCallsPercentage	• InstanceId ,MetricGroup
ConcurrentTasks	• InstanceId ,MetricGroup
ConcurrentTasksPercentage	• InstanceId ,MetricGroup
ContactFlowErrors	• ContactFlowName ,InstanceId , MetricGroup
LongestQueueWaitTime	• InstanceId ,MetricGroup , QueueName
MisconfiguredPhoneNumbers	• InstanceId ,MetricGroup
MissedCalls	• InstanceId ,MetricGroup
PublicSigningKeyUsage	• InstanceId ,SigningKeyId
QueueCapacityExceededError	• InstanceId ,MetricGroup , QueueName
QueueSize	• InstanceId ,MetricGroup , QueueName
SuccessfulChatsPerInterval	• InstanceId ,MetricGroup
TasksBreachingConcurrencyQuota	• InstanceId ,MetricGroup
ToInstancePacketLossRate	• InstanceId ,Participant ,Stream Type, Type of Connection

AWS/DAX

The AWS/DAX namespace includes enriched metrics for the following resource types.

- AWS::DAX::Cluster

AWS::DAX::Cluster

Metric	Dimensions
BaselineNetworkBytesInUtilization	• ClusterId • ClusterId ,NodeId
BaselineNetworkBytesOutUtilization	• ClusterId • ClusterId ,NodeId
BatchGetItemRequestCount	• ClusterId • ClusterId ,NodeId
BatchWriteItemRequestCount	• ClusterId • ClusterId ,NodeId
CPUCreditBalance	• ClusterId ,NodeId
CPUCreditUsage	• ClusterId • ClusterId ,NodeId
CPUSurplusCreditBalance	• ClusterId • ClusterId ,NodeId
CPUSurplusCreditsCharged	• ClusterId • ClusterId ,NodeId
CPUUtilization	• ClusterId • ClusterId ,NodeId
CacheMemoryUtilization	• ClusterId

Metric	Dimensions
	• ClusterId ,NodeId
ClientConnections	• ClusterId • ClusterId ,NodeId
DeleteItemRequestCount	• ClusterId • ClusterId ,NodeId
ErrorRequestCount	• ClusterId • ClusterId ,NodeId
EstimatedDbSize	• ClusterId • ClusterId ,NodeId
EvictedSize	• ClusterId • ClusterId ,NodeId
FailedRequestCount	• ClusterId • ClusterId ,NodeId
FaultRequestCount	• ClusterId • ClusterId ,NodeId
GetItemRequestCount	• ClusterId • ClusterId ,NodeId
ItemCacheHits	• ClusterId • ClusterId ,NodeId
ItemCacheMisses	• ClusterId • ClusterId ,NodeId
NetworkBytesIn	• ClusterId • ClusterId ,NodeId

Metric	Dimensions
NetworkBytesOut	• ClusterId • ClusterId ,NodeId
NetworkMaxBytesIn	• ClusterId • ClusterId ,NodeId
NetworkMaxBytesOut	• ClusterId • ClusterId ,NodeId
NetworkMaxPacketsIn	• ClusterId • ClusterId ,NodeId
NetworkMaxPacketsOut	• ClusterId • ClusterId ,NodeId
NetworkPacketsIn	• ClusterId • ClusterId ,NodeId
NetworkPacketsOut	• ClusterId • ClusterId ,NodeId
PutItemRequestCount	• ClusterId • ClusterId ,NodeId
QueryCacheHits	• ClusterId • ClusterId ,NodeId
QueryCacheMisses	• ClusterId • ClusterId ,NodeId
QueryRequestCount	• ClusterId • ClusterId ,NodeId
ScanCacheHits	• ClusterId • ClusterId ,NodeId

Metric	Dimensions
ScanCacheMisses	• ClusterId • ClusterId ,NodeId
ScanRequestCount	• ClusterId • ClusterId ,NodeId
ThrottledRequestCount	• ClusterId • ClusterId ,NodeId
TotalRequestCount	• ClusterId • ClusterId ,NodeId
TransactGetItemsCount	• ClusterId • ClusterId ,NodeId
TransactWriteItemsCount	• ClusterId • ClusterId ,NodeId
UpdateItemRequestCount	• ClusterId • ClusterId ,NodeId

AWS/DataSync

The AWS/DataSync namespace includes enriched metrics for the following resource types.

- AWS::DataSync::Task

AWS::DataSync::Task

Metric	Dimensions
BytesCompressed	• TaskId
BytesPreparedDestination	• TaskId

Metric	Dimensions
BytesPreparedSource	• TaskId
BytesTransferred	• TaskId
BytesVerifiedDestination	• TaskId
BytesVerifiedSource	• TaskId
BytesWritten	• TaskId
FilesDeleted	• TaskId
FilesListedSource	• TaskId
FilesPrepared	• TaskId
FilesPreparedDestination	• TaskId
FilesPreparedSource	• TaskId
FilesSkipped	• TaskId
FilesTransferred	• TaskId
FilesVerified	• TaskId
FilesVerifiedDestination	• TaskId
FilesVerifiedSource	• TaskId

AWS/DynamoDB

The AWS/DynamoDB namespace includes enriched metrics for the following resource types.

- AWS::DynamoDB::Table

AWS::DynamoDB::Table

Metric	Dimensions
AgeOfOldestUnreplicatedRecord	• DelegatedOperation ,TableName
ConditionalCheckFailedRequests	• TableName
ConsumedChangeDataCaptureUnits	• DelegatedOperation ,TableName
ConsumedReadCapacityUnits	• TableName
ConsumedWriteCapacityUnits	• GlobalSecondaryIndexName ,Source, TableName • Source, TableName • TableName
ProvisionedReadCapacityUnits	• TableName
ProvisionedWriteCapacityUnits	• TableName
ReadThrottleEvents	• TableName
ReturnedItemCount	• Operation ,TableName • Operation ,TableName ,Verb
SuccessfulRequestLatency	• Operation ,OperationType , TableName • Operation ,TableName • Operation ,TableName ,Verb
SystemErrors	• Operation ,TableName
ThrottledPutRecordCount	• DelegatedOperation ,TableName
ThrottledRequests	• Operation ,TableName • Operation ,TableName ,Verb
TimeToLiveDeletedItemCount	• TableName

Metric	Dimensions
TransactionConflict	• TableName
WriteThrottleEvents	• TableName

AWS/EBS

The AWS/EBS namespace includes enriched metrics for the following resource types.

- AWS::EC2::Volume

AWS::EC2::Volume

Metric	Dimensions
BurstBalance	• VolumeId
VolumeAvgIOPS	• InstanceId , VolumeId
VolumeAvgReadLatency	• InstanceId , VolumeId
VolumeAvgThroughput	• InstanceId , VolumeId
VolumeAvgWriteLatency	• InstanceId , VolumeId
VolumeConsumedReadWriteOps	• VolumeId
VolumeIOPSExceededCheck	• InstanceId , VolumeId
VolumeIdleTime	• VolumeId
VolumeQueueLength	• VolumeId
VolumeReadBytes	• VolumeId
VolumeReadOps	• VolumeId
VolumeStalledIOCheck	• InstanceId , VolumeId

Metric	Dimensions
VolumeThroughputExceededCheck	• InstanceId , VolumeId
VolumeThroughputPercentage	• VolumeId
VolumeTotalReadTime	• VolumeId
VolumeTotalWriteTime	• VolumeId
VolumeWriteBytes	• VolumeId
VolumeWriteOps	• VolumeId

AWS/EC2

The AWS/EC2 namespace includes enriched metrics for the following resource types.

- AWS::EC2::Host
- AWS::EC2::Instance
- AWS::EC2::VPC

AWS::EC2::Host

Metric	Dimensions
DedicatedHostCPUUtilization	• HostId

AWS::EC2::Instance

Metric	Dimensions
CPUCreditBalance	• InstanceId
CPUCreditUsage	• InstanceId
CPUSurplusCreditBalance	• InstanceId

Metric	Dimensions
CPUSurplusCreditsCharged	• InstanceId
CPUUtilization	• InstanceId
DiskReadBytes	• InstanceId
DiskReadOps	• InstanceId
DiskWriteBytes	• InstanceId
DiskWriteOps	• InstanceId
EBSByteBalance%	• InstanceId
EBSIOBalance%	• InstanceId
EBSReadBytes	• InstanceId
EBSReadOps	• InstanceId
EBSWriteBytes	• InstanceId
EBSWriteOps	• InstanceId
GPUPowerUtilization	• InstanceId
InstanceEBSIOPSExceededCheck	• InstanceId
InstanceEBSThroughputExceeded Check	• InstanceId
MetadataNoToken	• InstanceId
MetadataNoTokenRejected	• InstanceId
NetworkIn	• InstanceId
NetworkMirrorIn	• InstanceId
NetworkMirrorOut	• InstanceId

Metric	Dimensions
NetworkOut	• InstanceId
NetworkPacketsIn	• InstanceId
NetworkPacketsMirrorIn	• InstanceId
NetworkPacketsMirrorOut	• InstanceId
NetworkPacketsOut	• InstanceId
NetworkPacketsSkipMirrorIn	• InstanceId
NetworkPacketsSkipMirrorOut	• InstanceId
NetworkSkipMirrorIn	• InstanceId
NetworkSkipMirrorOut	• InstanceId
StatusCheckFailed	• InstanceId
StatusCheckFailed_Application	• InstanceId
StatusCheckFailed_AttachedEBS	• InstanceId
StatusCheckFailed_Instance	• InstanceId
StatusCheckFailed_System	• InstanceId

AWS::EC2::VPC

Metric	Dimensions
NetworkAddressUsage	• Per-VPC Metrics
NetworkAddressUsagePeered	• Per-VPC Metrics

AWS/EC2CapacityReservations

The AWS/EC2CapacityReservations namespace includes enriched metrics for the following resource types.

- AWS::EC2::CapacityReservation

AWS::EC2::CapacityReservation

Metric	Dimensions
AvailableInstanceCount	• CapacityReservationId
InstanceUtilization	• CapacityReservationId
TotalInstanceCount	• CapacityReservationId
UsedInstanceCount	• CapacityReservationId

AWS/ECS

The AWS/ECS namespace includes enriched metrics for the following resource types.

- AWS::ECS::Cluster
- AWS::ECS::Service

AWS::ECS::Cluster

Metric	Dimensions
CPUReservation	• ClusterName
CPUUtilization	• ClusterName
GPUReservation	• ClusterName
MemoryReservation	• ClusterName

Metric	Dimensions
MemoryUtilization	• ClusterName

AWS::ECS::Service

Metric	Dimensions
CPUUtilization	• ClusterName , ServiceName
MemoryUtilization	• ClusterName , ServiceName

AWS/EFS

The AWS/EFS namespace includes enriched metrics for the following resource types.

- AWS::EFS::FileSystem

AWS::EFS::FileSystem

Metric	Dimensions
BurstCreditBalance	• FileSystemId
ClientConnections	• FileSystemId
DataReadIOBytes	• FileSystemId
DataWriteIOBytes	• FileSystemId
MetadataIOBytes	• FileSystemId
MeteredIOBytes	• FileSystemId
PercentIOLimit	• FileSystemId
PermittedThroughput	• FileSystemId

Metric	Dimensions
StorageBytes	• FileSystemId , StorageClass
TimeSinceLastSync	• DestinationFileSystemId , FileSystemId
TotalIOBytes	• FileSystemId

AWS/EKS

The AWS/EKS namespace includes enriched metrics for the following resource types.

- AWS::EKS::Cluster

AWS::EKS::Cluster

Metric	Dimensions
apiserver_admission_webhook_rejection_count_ADMIT	• ClusterName
apiserver_admission_webhook_rejection_count_VALIDATING	• ClusterName
apiserver_admission_webhook_request_total	• ClusterName
apiserver_admission_webhook_request_total_ADMIT	• ClusterName
apiserver_admission_webhook_request_total_VALIDATING	• ClusterName
apiserver_current_inflight_requests_MUTATING	• ClusterName

Metric	Dimensions
apiserver_current_inflight_requests_READONLY	• ClusterName
apiserver_flowcontrol_current_executing_seats	• ClusterName
apiserver_request_duration_seconds_DELETE_P99	• ClusterName
apiserver_request_duration_seconds_GET_P99	• ClusterName
apiserver_request_duration_seconds_LIST_P99	• ClusterName
apiserver_request_duration_seconds_PATCH_P99	• ClusterName
apiserver_request_duration_seconds_POST_P99	• ClusterName
apiserver_request_duration_seconds_PUT_P99	• ClusterName
apiserver_request_total	• ClusterName
apiserver_request_total_429	• ClusterName
apiserver_request_total_4XX	• ClusterName
apiserver_request_total_5XX	• ClusterName
apiserver_request_total_LIST_PODS	• ClusterName
apiserver_storage_size_bytes	• ClusterName

Metric	Dimensions
etcd_mvcc_db_total_size_in_use_in_bytes	• ClusterName
scheduler_pending_pods	• ClusterName
scheduler_pending_pods_ACTIVEQ	• ClusterName
scheduler_pending_pods_BACKOFF	• ClusterName
scheduler_pending_pods_GATED	• ClusterName
scheduler_pending_pods_UNSCHEDULABLE	• ClusterName
scheduler_schedule_attempts_ERROR	• ClusterName
scheduler_schedule_attempts_SCHEDULED	• ClusterName
scheduler_schedule_attempts_UNSCHEDULABLE	• ClusterName
scheduler_schedule_attempts_total	• ClusterName

AWS/ELB

The AWS/ELB namespace includes enriched metrics for the following resource types.

- AWS::ElasticLoadBalancing::LoadBalancer

AWS::ElasticLoadBalancing::LoadBalancer

Metric	Dimensions
BackendConnectionErrors	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
DesyncMitigationMode_NonCompliant_Request_Count	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
EstimatedALBActiveConnectionCount	• LoadBalancerName
EstimatedALBNewConnectionCount	• LoadBalancerName
EstimatedProcessedBytes	• LoadBalancerName
HTTPCode_Backend_2XX	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
HTTPCode_Backend_3XX	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
HTTPCode_Backend_4XX	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
HTTPCode_Backend_5XX	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
HTTPCode_ELB_4XX	• AvailabilityZone ,LoadBalancerName

Metric	Dimensions
	• LoadBalancerName
HTTPCode_ELB_5XX	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
HealthyHostCount	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
Latency	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
RequestCount	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
SpilloverCount	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
SurgeQueueLength	• AvailabilityZone ,LoadBalancerName • LoadBalancerName
UnHealthyHostCount	• AvailabilityZone ,LoadBalancerName • LoadBalancerName

AWS/EMRServerless

The AWS/EMRServerless namespace includes enriched metrics for the following resource types.

- AWS::EMRServerless::Application

AWS::EMRServerless::Application

Metric	Dimensions
CPUAllocated	• ApplicationId • ApplicationId ,ApplicationName • ApplicationId ,ApplicationName , CapacityAllocationType , WorkerType • ApplicationId ,CapacityA llocationType ,WorkerType
CancelledJobs	• ApplicationId • ApplicationId ,ApplicationName
CancellingJobs	• ApplicationId • ApplicationId ,ApplicationName
FailedJobs	• ApplicationId • ApplicationId ,ApplicationName
IdleWorkerCount	• ApplicationId • ApplicationId ,ApplicationName • ApplicationId ,ApplicationName , CapacityAllocationType , WorkerType • ApplicationId ,CapacityA llocationType ,WorkerType
MaxCPUAllowed	• ApplicationId • ApplicationId ,ApplicationName
MaxMemoryAllowed	• ApplicationId • ApplicationId ,ApplicationName
MaxStorageAllowed	• ApplicationId

Metric	Dimensions
	• ApplicationId ,ApplicationName
MemoryAllocated	• ApplicationId • ApplicationId ,ApplicationName • ApplicationId ,ApplicationName , CapacityAllocationType , WorkerType • ApplicationId ,CapacityA llocationType ,WorkerType
PendingCreationWorkerCount	• ApplicationId • ApplicationId ,ApplicationName • ApplicationId ,ApplicationName , CapacityAllocationType , WorkerType • ApplicationId ,CapacityA llocationType ,WorkerType
PendingJobs	• ApplicationId • ApplicationId ,ApplicationName
RunningJobs	• ApplicationId • ApplicationId ,ApplicationName
RunningWorkerCount	• ApplicationId • ApplicationId ,ApplicationName • ApplicationId ,ApplicationName , CapacityAllocationType , WorkerType • ApplicationId ,CapacityA llocationType ,WorkerType
ScheduledJobs	• ApplicationId • ApplicationId ,ApplicationName

Metric	Dimensions
StorageAllocated	• ApplicationId • ApplicationId ,ApplicationName • ApplicationId ,ApplicationName , CapacityAllocationType , WorkerType • ApplicationId ,CapacityA llocationType ,WorkerType
SubmittedJobs	• ApplicationId • ApplicationId ,ApplicationName
SuccessJobs	• ApplicationId • ApplicationId ,ApplicationName
TotalWorkerCount	• ApplicationId • ApplicationId ,ApplicationName • ApplicationId ,ApplicationName , CapacityAllocationType , WorkerType • ApplicationId ,CapacityA llocationType ,WorkerType
WorkerCpuAllocated	• ApplicationId ,ApplicationName , CapacityAllocationType ,JobId, JobName, WorkerType • ApplicationId ,CapacityA llocationType ,JobId, WorkerType
WorkerCpuUsed	• ApplicationId ,ApplicationName , CapacityAllocationType ,JobId, JobName, WorkerType • ApplicationId ,CapacityA llocationType ,JobId, WorkerType

Metric	Dimensions
WorkerEphemeralStorageAllocated	• ApplicationId , ApplicationName , CapacityAllocationType , JobId, JobName, WorkerType • ApplicationId , CapacityA llocationType , JobId, WorkerType
WorkerEphemeralStorageUsed	• ApplicationId , ApplicationName , CapacityAllocationType , JobId, JobName, WorkerType • ApplicationId , CapacityA llocationType , JobId, WorkerType
WorkerMemoryAllocated	• ApplicationId , ApplicationName , CapacityAllocationType , JobId, JobName, WorkerType • ApplicationId , CapacityA llocationType , JobId, WorkerType
WorkerMemoryUsed	• ApplicationId , ApplicationName , CapacityAllocationType , JobId, JobName, WorkerType • ApplicationId , CapacityA llocationType , JobId, WorkerType
WorkerStorageReadBytes	• ApplicationId , ApplicationName , CapacityAllocationType , JobId, JobName, WorkerType • ApplicationId , CapacityA llocationType , JobId, WorkerType

Metric	Dimensions
WorkerStorageWriteBytes	• ApplicationId , ApplicationName , CapacityAllocationType , JobId, JobName, WorkerType • ApplicationId , CapacityAllocationType , JobId, WorkerType

AWS/ES

The AWS/ES namespace includes enriched metrics for the following resource types.

- AWS::OpenSearchService::Domain

AWS::OpenSearchService::Domain

Metric	Dimensions
2xx	• ClientId, DomainName
3xx	• ClientId, DomainName
4xx	• ClientId, DomainName
5xx	• ClientId, DomainName
ADAnomalyDetectorsIndexStatus.red	• ClientId, DomainName
ADAnomalyDetectorsIndexStatusIndexExists	• ClientId, DomainName
ADAnomalyResultsIndexStatus.red	• ClientId, DomainName
ADAnomalyResultsIndexStatusIndexExists	• ClientId, DomainName
ADExecuteFailureCount	• ClientId, DomainName

Metric	Dimensions
	• ClientId, DomainName , NodeId
ADExecuteRequestCount	• ClientId, DomainName • ClientId, DomainName , NodeId
ADHCExecuteFailureCount	• ClientId, DomainName • ClientId, DomainName , NodeId
ADHCExecuteRequestCount	• ClientId, DomainName • ClientId, DomainName , NodeId
ADModelsCheckpointIndexStatus.red	• ClientId, DomainName
ADModelsCheckpointIndexStatusIndexExists	• ClientId, DomainName
ADPluginUnhealthy	• ClientId, DomainName
ActiveDataNode	• ClientId, DomainName , NodeId
AlertingDegraded	• ClientId, DomainName
AlertingIndexExists	• ClientId, DomainName
AlertingIndexStatus.green	• ClientId, DomainName
AlertingIndexStatus.red	• ClientId, DomainName
AlertingIndexStatus.yellow	• ClientId, DomainName
AlertingNodesNotOnSchedule	• ClientId, DomainName
AlertingNodesOnSchedule	• ClientId, DomainName
AlertingScheduledJobEnabled	• ClientId, DomainName

Metric	Dimensions
AsyncQueryCancelApiFailedRequestCusErrCount	• ClientId, DomainName
AsyncQueryCancelApiFailedRequestSysErrCount	• ClientId, DomainName
AsyncQueryCancelApiRequestCount	• ClientId, DomainName
AsyncQueryCreateApiFailedRequestCusErrCount	• ClientId, DomainName
AsyncQueryCreateApiFailedRequestSysErrCount	• ClientId, DomainName
AsyncQueryCreateApiRequestCount	• ClientId, DomainName
AsyncQueryGetApiFailedRequestCusErrCount	• ClientId, DomainName
AsyncQueryGetApiFailedRequestSysErrCount	• ClientId, DomainName

TotalNodesRequested	• JobFlowId
TotalNodesRunning	• JobFlowId
TotalNotebookKernels	• JobFlowId
TotalUnitsRequested	• JobFlowId
TotalUnitsRunning	• JobFlowId
TotalVCPURequested	• JobFlowId
TotalVCPURunning	• JobFlowId

AWS/EventBridge/Pipes

The AWS/EventBridge/Pipes namespace includes enriched metrics for the following resource types.

- AWS::Pipes::Pipe

AWS::Pipes::Pipe

Metric	Dimensions
Duration	• PipeName
EnrichmentStageDuration	• PipeName
EnrichmentStageFailed	• PipeName
EventCount	• PipeName
EventSize	• PipeName
ExecutionFailed	• PipeName
ExecutionPartiallyFailed	• PipeName
ExecutionTimeout	• PipeName
TargetStageDuration	• PipeName
TargetStageFailed	• PipeName
TargetStagePartiallyFailed	• PipeName
TargetStageSkipped	• PipeName

AWS/Events

The AWS/Events namespace includes enriched metrics for the following resource types.

- AWS::Events::Rule

AWS::Events::Rule

Metric	Dimensions
DeadLetterInvocations	• EventBusName ,RuleName • RuleName
FailedInvocations	• EventBusName ,RuleName • RuleName
IngestiontoInvocationCompleteLatency	• EventBusName ,RuleName
IngestiontoInvocationStartLatency	• EventBusName ,RuleName
Invocations	• EventBusName ,RuleName • RuleName
InvocationsFailedToBeSentToDlq	• EventBusName ,RuleName • RuleName
InvocationsSentToDlq	• EventBusName ,RuleName • RuleName
ThrottledRules	• EventBusName ,RuleName • RuleName
TriggeredRules	• EventBusName ,RuleName • RuleName

AWS/FSx

The AWS/FSx namespace includes enriched metrics for the following resource types.

- AWS::FSx::FileSystem

AWS::FSx::FileSystem

Metric	Dimensions
AgeOfOldestQueuedMessage	• FileSystemId , Publisher
CPUUtilization	• FileServer , FileSystemId • FileSystemId
CapacityPoolReadBytes	• FileSystemId , VolumeId
CapacityPoolReadOperations	• FileSystemId , VolumeId
CapacityPoolWriteBytes	• FileSystemId , VolumeId
CapacityPoolWriteOperations	• FileSystemId , VolumeId
ClientConnections	• FileSystemId
CompressionRatio	• FileSystemId , VolumeId
DataReadBytes	• FileSystemId • FileSystemId , VolumeId
DataReadOperationTime	• FileSystemId , VolumeId
DataReadOperations	• FileSystemId • FileSystemId , VolumeId
DataWriteBytes	• FileSystemId • FileSystemId , VolumeId
DataWriteLatency	• FileSystemId , StorageTargetId
DataWriteOperationTime	• FileSystemId , VolumeId
DataWriteOperations	• FileSystemId • FileSystemId , VolumeId

Metric	Dimensions
DirectoryCreateOperations	• FileSystemId , JobId, StorageTargetId • FileSystemId , StorageTargetId
DirectoryDeleteOperations	• FileSystemId , JobId, StorageTargetId • FileSystemId , StorageTargetId
DiskIopsExceededCheck	• FileSystemId , StorageTargetId
DiskIopsUtilization	• Aggregate , FileSystemId • FileSystemId , StorageTargetId
DiskReadBytes	• Aggregate , FileSystemId • FileSystemId , StorageTargetId
DiskReadOperations	• Aggregate , FileSystemId • FileSystemId , StorageTargetId
DiskThroughputBalance	• FileSystemId
DiskThroughputExceededCheck	• FileSystemId , StorageTargetId
DiskThroughputUtilization	• FileSystemId
DiskWriteBytes	• Aggregate , FileSystemId • FileSystemId , StorageTargetId
DiskWriteOperations	• Aggregate , FileSystemId • FileSystemId , StorageTargetId
FileCreateOperations	• FileSystemId , JobId, StorageTargetId • FileSystemId , StorageTargetId

Metric	Dimensions
FileDeleteOperations	• FileSystemId , JobId, StorageTargetId • FileSystemId , StorageTargetId
FileOpenOperations	• FileSystemId , JobId, StorageTargetId • FileSystemId , StorageTargetId
FileServerCacheHitRatio	• CacheType , FileSystemId • FileServer , FileSystemId
FileServerDiskIopsBalance	• FileServer , FileSystemId • FileSystemId
FileServerDiskIopsUtilization	• FileServer , FileSystemId • FileSystemId
FileServerDiskThroughputBalance	• FileServer , FileSystemId
FileServerDiskThroughputUtilization	• FileServer , FileSystemId • FileSystemId
FilesCapacity	• FileSystemId , VolumeId
FilesUsed	• FileSystemId , VolumeId
FreeDataStorageCapacity	• FileSystemId • FileSystemId , StorageTargetId
FreeStorageCapacity	• FileSystemId
MemoryUtilization	• FileSystemId
MetadataOperationTime	• FileSystemId , VolumeId

Metric	Dimensions
MetadataOperations	• FileSystemId • FileSystemId , VolumeId
NetworkReceivedBytes	• FileServer , FileSystemId
NetworkSentBytes	• FileServer , FileSystemId
NetworkThroughputUtilization	• FileServer , FileSystemId • FileSystemId
RenameOperations	• FileSystemId , JobId, StorageTargetId
RepositoryRenameOperations	• FileSystemId , Publisher
StatOperations	• FileSystemId , JobId, StorageTargetId
StorageCapacity	• Aggregate , DataType, FileSystemId , StorageTier • DataType, FileSystemId , StorageTier • FileSystemId , VolumeId
StorageCapacityUtilization	• Aggregate , DataType, FileSystemId , StorageTier • DataType, FileSystemId , StorageTier • DataType, FileSystemId , StorageTier , VolumeId • FileSystemId , StorageTargetId • FileSystemId , VolumeId

Metric	Dimensions
StorageUsed	• Aggregate , DataType, FileSystemId , StorageTier • DataType, FileSystemId , StorageTier • DataType, FileSystemId , StorageTier , VolumeId • FileSystemId , VolumeId
UsedStorageCapacity	• DataType, FileSystemId , StorageTier • DataType, FileSystemId , StorageTier , VolumeId • FileSystemId , VolumeId

AWS/Firehose

The AWS/Firehose namespace includes enriched metrics for the following resource types.

- AWS::KinesisFirehose::DeliveryStream

AWS::KinesisFirehose::DeliveryStream

Metric	Dimensions
BackupToS3.Bytes	• DeliveryStreamName
BackupToS3.DataFreshness	• DeliveryStreamName
BackupToS3.Records	• DeliveryStreamName
BackupToS3.Success	• DeliveryStreamName
BytesPerSecondLimit	• DeliveryStreamName

Metric	Dimensions
	• DeliveryStreamName ,SourcePartitionId
DataReadFromKinesisStream.Bytes	• DeliveryStreamName
DataReadFromKinesisStream.Records	• DeliveryStreamName
DataReadFromSource.Backpressured	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
DataReadFromSource.Bytes	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
DataReadFromSource.Records	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
DeliveryToAmazonOpenSearchServerless.AuthFailure	• DeliveryStreamName
DeliveryToAmazonOpenSearchServerless.Bytes	• DeliveryStreamName
DeliveryToAmazonOpenSearchServerless.DataFreshness	• DeliveryStreamName
DeliveryToAmazonOpenSearchServerless.DeliveryRejected	• DeliveryStreamName
DeliveryToAmazonOpenSearchServerless.Records	• DeliveryStreamName
DeliveryToAmazonOpenSearchServerless.Success	• DeliveryStreamName

Metric	Dimensions
DeliveryToAmazonOpenSearchService.AuthFailure	• DeliveryStreamName
DeliveryToAmazonOpenSearchService.Bytes	• DeliveryStreamName
DeliveryToAmazonOpenSearchService.DataFreshness	• DeliveryStreamName
DeliveryToAmazonOpenSearchService.DeliveryRejected	• DeliveryStreamName
DeliveryToAmazonOpenSearchService.Records	• DeliveryStreamName
DeliveryToAmazonOpenSearchService.Success	• DeliveryStreamName
DeliveryToHttpEndpoint.Bytes	• DeliveryStreamName
DeliveryToHttpEndpoint.DataFreshness	• DeliveryStreamName
DeliveryToHttpEndpoint.ProcessedBytes	• DeliveryStreamName
DeliveryToHttpEndpoint.ProcessedRecords	• DeliveryStreamName
DeliveryToHttpEndpoint.Records	• DeliveryStreamName
DeliveryToHttpEndpoint.Success	• DeliveryStreamName
DeliveryToIceberg.Bytes	• DeliveryStreamName ,IcebergTableName
DeliveryToIceberg.DataFreshness	• DeliveryStreamName ,IcebergTableName

Metric	Dimensions
DeliveryToIceberg.Success	• DeliveryStreamName ,IcebergTableName
DeliveryToIceberg.SuccessfulRowCount	• DeliveryStreamName ,IcebergTableName
DeliveryToRedshift.Bytes	• DeliveryStreamName
DeliveryToRedshift.Records	• DeliveryStreamName
DeliveryToRedshift.Success	• DeliveryStreamName
DeliveryToS3.Bytes	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
DeliveryToS3.DataFreshness	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
DeliveryToS3.Records	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
DeliveryToS3.Success	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
DeliveryToSnowflake.Bytes	• DeliveryStreamName
DeliveryToSnowflake.DataCommitLatency	• DeliveryStreamName
DeliveryToSnowflake.DataFreshness	• DeliveryStreamName
DeliveryToSnowflake.Records	• DeliveryStreamName

Metric	Dimensions
DeliveryToSnowflake.Success	• DeliveryStreamName
DeliveryToSplunk.Bytes	• DeliveryStreamName
DeliveryToSplunk.DataAckLatency	• DeliveryStreamName
DeliveryToSplunk.DataFreshness	• DeliveryStreamName
DeliveryToSplunk.Records	• DeliveryStreamName
DeliveryToSplunk.Success	• DeliveryStreamName
DescribeDeliveryStream.Latency	• DeliveryStreamName
DescribeDeliveryStream.Requests	• DeliveryStreamName
ExecuteProcessing.Duration	• DeliveryStreamName
ExecuteProcessing.Success	• DeliveryStreamName
FailedConversion.Bytes	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
FailedConversion.Records	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
FailedValidation.Bytes	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
FailedValidation.Records	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
IncomingBytes	• DeliveryStreamName

Metric	Dimensions
IncomingPutRequests	• DeliveryStreamName
IncomingRecords	• DeliveryStreamName
KMSKeyAccessDenied	• DeliveryStreamName
KMSKeyDisabled	• DeliveryStreamName
KMSKeyInvalidState	• DeliveryStreamName
KMSKeyNotFound	• DeliveryStreamName
KafkaOffsetLag	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
KinesisMillisBehindLatest	• DeliveryStreamName
ListDeliveryStreams.Latency	• DeliveryStreamName
ListDeliveryStreams.Requests	• DeliveryStreamName
OutputDecompressedBytes.Failed	• DeliveryStreamName
OutputDecompressedBytes.Success	• DeliveryStreamName
OutputDecompressedRecords.Failed	• DeliveryStreamName
OutputDecompressedRecords.Success	• DeliveryStreamName
PutRecord.Bytes	• DeliveryStreamName
PutRecord.Latency	• DeliveryStreamName
PutRecord.Requests	• DeliveryStreamName
PutRecordBatch.Bytes	• DeliveryStreamName

Metric	Dimensions
PutRecordBatch.Latency	• DeliveryStreamName
PutRecordBatch.Records	• DeliveryStreamName
PutRecordBatch.Requests	• DeliveryStreamName
PutRequestsPerSecondLimit	• DeliveryStreamName
RecordsPerSecondLimit	• DeliveryStreamName
SourceThrottled.Delay	• DeliveryStreamName
SourceToDelivery.DataFreshness	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
SucceedConversion.Bytes	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
SucceedConversion.Records	• DeliveryStreamName • DeliveryStreamName ,SourcePartitionId
SucceedProcessing.Bytes	• DeliveryStreamName
SucceedProcessing.Records	• DeliveryStreamName
ThrottledDescribeStream	• DeliveryStreamName
ThrottledGetRecords	• DeliveryStreamName
ThrottledGetShardIterator	• DeliveryStreamName
ThrottledRecords	• DeliveryStreamName
UpdateDeliveryStream.Latency	• DeliveryStreamName

Metric	Dimensions
UpdateDeliveryStream.Requests	• DeliveryStreamName

AWS/FraudDetector

The AWS/FraudDetector namespace includes enriched metrics for the following resource types.

- AWS::FraudDetector::Detector

AWS::FraudDetector::Detector

Metric	Dimensions
GetEventPrediction	• DetectorID
GetEventPrediction4xxError	• DetectorID
GetEventPrediction5xxError	• DetectorID
GetEventPredictionLatency	• DetectorID
ModelInvocation	• DetectorID ,DetectorVersionID , ModelEndpoint • DetectorID ,DetectorVersionID , ModelID, ModelType ,ModelVersionNumber
ModelInvocationError	• DetectorID ,DetectorVersionID , ModelEndpoint • DetectorID ,DetectorVersionID , ModelID, ModelType ,ModelVersionNumber
ModelInvocationLatency	• DetectorID ,DetectorVersionID , ModelEndpoint

Metric	Dimensions
	• DetectorID ,DetectorVersionID , ModelID, ModelType ,ModelVersionNumber
OutcomeReturned	• DetectorID ,DetectorVersionID , OutcomeName • DetectorID ,OutcomeName
Prediction	• DetectorID ,DetectorVersionID
PredictionError	• DetectorID ,DetectorVersionID
PredictionLatency	• DetectorID ,DetectorVersionID
RuleEvaluateFalse	• DetectorID ,DetectorVersionID , RuleID
RuleEvaluateTrue	• DetectorID ,DetectorVersionID , RuleID
RuleNotEvaluated	• DetectorID ,DetectorVersionID , RuleID
VariableUsed	• DetectorID ,DetectorVersionID , VariableName

AWS/GameLift

The AWS/GameLift namespace includes enriched metrics for the following resource types.

- AWS::GameLift::GameSessionQueue
- AWS::GameLift::MatchmakingConfiguration

AWS::GameLift::GameSessionQueue

Metric	Dimensions
AverageWaitTime	• Location, QueueName • QueueName
FirstChoiceNotViable	• QueueName
FirstChoiceOutOfCapacity	• QueueName
GameSessionPlaced	• LocationName , QueueName
LowestLatencyPlacement	• QueueName
LowestPricePlacement	• QueueName
PlacementApNortheast1	• QueueName
PlacementApNortheast2	• QueueName
PlacementApSouth1	• QueueName
PlacementApSoutheast2	• QueueName
PlacementEuCentral1	• QueueName
PlacementEuNorth1	• QueueName
PlacementEuWest1	• QueueName
PlacementEuWest2	• QueueName
PlacementMeSouth1	• QueueName
PlacementSaEast1	• QueueName
PlacementUsEast1	• QueueName
PlacementUsEast2	• QueueName

Metric	Dimensions
PlacementUsWest1	• QueueName
PlacementUsWest2	• QueueName
PlacementsCanceled	• QueueName
PlacementsStarted	• QueueName
PlacementsSucceeded	• QueueName
PlacementsTimedOut	• QueueName
QueueDepth	• Location, QueueName • QueueName

AWS::GameLift::MatchmakingConfiguration

Metric	Dimensions
CurrentTickets	• ConfigurationName
MatchesAccepted	• ConfigurationName
MatchesCreated	• ConfigurationName
MatchesPlaced	• ConfigurationName
MatchesRejected	• ConfigurationName
MatchmakingSearchTime	• ConfigurationName
PlayersStarted	• ConfigurationName
TicketsStarted	• ConfigurationName
TicketsTimedOut	• ConfigurationName
TimeToMatch	• ConfigurationName

Metric	Dimensions
TimeToTicketCancel	• ConfigurationName
TimeToTicketSuccess	• ConfigurationName

AWS/GatewayELB

The AWS/GatewayELB namespace includes enriched metrics for the following resource types.

- AWS::ElasticLoadBalancingV2::LoadBalancer

AWS::ElasticLoadBalancingV2::LoadBalancer

Metric	Dimensions
ActiveFlowCount	• AvailabilityZone ,LoadBalancer • LoadBalancer
ConsumedLCUs	• LoadBalancer
HealthyHostCount	• AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer ,TargetGroup
NewFlowCount	• AvailabilityZone ,LoadBalancer • LoadBalancer
ProcessedBytes	• AvailabilityZone ,LoadBalancer • LoadBalancer
UnHealthyHostCount	• AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer ,TargetGroup

AWS/IVSChat

The AWS/IVSChat namespace includes enriched metrics for the following resource types.

- AWS::IVSChat::LoggingConfiguration

AWS::IVSChat::LoggingConfiguration

Metric	Dimensions
LogDestinationAccessDeniedError	• LoggingConfiguration
LogDestinationErrors	• LoggingConfiguration
LogDestinationResourceNotFoundErrors	• LoggingConfiguration

AWS/IoT

The AWS/IoT namespace includes enriched metrics for the following resource types.

- AWS::IoT::CACertificate
- AWS::IoT::ScheduledAudit
- AWS::IoT::SecurityProfile
- AWS::IoT::TopicRule

AWS::IoT::CACertificate

Metric	Dimensions
ProvisionThing.ClientError	• CaCertificateId
ProvisionThing.ServerError	• CaCertificateId
ProvisionThing.Success	• CaCertificateId

AWS::IoT::ScheduledAudit

Metric	Dimensions
MisconfiguredDeviceDefender Notification	• CheckName , ScheduledAuditName
NonCompliantResources	• CheckName , ScheduledAuditName
ResourcesEvaluated	• CheckName , ScheduledAuditName

AWS::IoT::SecurityProfile

Metric	Dimensions
BehaviorEvaluationCompleted	• BehaviorName , SecurityProfileNam e
BehaviorEvaluationSkipped	• BehaviorName , SecurityProfileNam e
MisconfiguredDeviceDefender Notification	• BehaviorName , SecurityProfileNam e
NumOfMetricsExceedingSizeLimit	• BehaviorName , SecurityProfileNam e
NumOfMetricsExported	• BehaviorName , SecurityProfileNam e
NumOfMetricsSkipped	• BehaviorName , SecurityProfileNam e
Violations	• BehaviorName , SecurityProfileNam e • SecurityProfileName

Metric	Dimensions
ViolationsCleared	• BehaviorName ,SecurityProfileName • SecurityProfileName
ViolationsInvalidated	• BehaviorName ,SecurityProfileName • SecurityProfileName

AWS::IoT::TopicRule

Metric	Dimensions
ErrorActionFailure	• ActionType ,RuleName
ErrorActionHttpDestinationNotEnabled	• ActionType ,RuleName
ErrorActionSuccess	• ActionType ,RuleName
Failure	• ActionType ,RuleName
HttpCode_4XX	• ActionType ,RuleName
HttpCode_5XX	• ActionType ,RuleName
HttpCode_Other	• ActionType ,RuleName
HttpInvalidUrl	• ActionType ,RuleName
HttpRequestTimeout	• ActionType ,RuleName
HttpUnknownHost	• ActionType ,RuleName
ParseError	• RuleName
RequestTimeout	• ActionType ,RuleName

Metric	Dimensions
RuleMessageThrottled	• RuleName
RuleNotFound	• RuleName
RulesExecuted	• RuleName
SaslAuthFailed	• ActionType ,RuleName
Success	• ActionType ,RuleName
TopicMatch	• RuleName

AWS/KMS

The AWS/KMS namespace includes enriched metrics for the following resource types.

- AWS::KMS::Key

AWS::KMS::Key

Metric	Dimensions
SecondsUntilKeyMaterialExpiration	• KeyId

AWS/Kendra

The AWS/Kendra namespace includes enriched metrics for the following resource types.

- AWS::Kendra::DataSource
- AWS::Kendra::Index

AWS::Kendra::DataSource

Metric	Dimensions
DataSourceDocumentCount	• DataSourceId ,IndexId
DataSourceSyncRuntime	• DataSourceId ,IndexId
DocumentsCrawled	• AwsAccountId ,DataSourceId , DataSourceType ,IndexId • DataSourceId ,IndexId
DocumentsFailedToIndex	• DataSourceId ,IndexId
DocumentsIndexed	• DataSourceId ,IndexId
DocumentsSkippedInvalidMetadata	• DataSourceId ,IndexId
DocumentsSkippedNoChange	• DataSourceId ,IndexId
DocumentsSubmittedForDeletion	• AwsAccountId ,DataSourceId , DataSourceType ,IndexId • DataSourceId ,IndexId

AWS/Kinesis

The AWS/Kinesis namespace includes enriched metrics for the following resource types.

- AWS::Kinesis::Stream

AWS::Kinesis::Stream

Metric	Dimensions
GetRecords.Bytes	• StreamName
GetRecords.IteratorAgeMilliseconds	• StreamName
GetRecords.Latency	• StreamName
GetRecords.Records	• StreamName
GetRecords.Success	• StreamName
IncomingBytes	• ShardId, StreamName • StreamName
IncomingRecords	• ShardId, StreamName • StreamName
IteratorAgeMilliseconds	• ShardId, StreamName
OutgoingBytes	• ShardId, StreamName
OutgoingRecords	• ShardId, StreamName
PutRecord.Success	• StreamName
PutRecords.Bytes	• StreamName
PutRecords.Success	• StreamName

Metric	Dimensions
ReadProvisionedThroughputExceeded	• ShardId, StreamName • StreamName
SubscribeToShard.RateExceeded	• ConsumerName , StreamName
SubscribeToShard.Success	• ConsumerName , StreamName
SubscribeToShardEvent.Bytes	• ConsumerName , StreamName
SubscribeToShardEvent.MillisBehindLatest	• ConsumerName , StreamName
SubscribeToShardEvent.Records	• ConsumerName , StreamName
SubscribeToShardEvent.Success	• ConsumerName , StreamName
WriteProvisionedThroughputExceeded	• ShardId, StreamName • StreamName

AWS/KinesisAnalytics

The AWS/KinesisAnalytics namespace includes enriched metrics for the following resource types.

- AWS::KinesisAnalyticsV2::Application

AWS::KinesisAnalyticsV2::Application

Metric	Dimensions
KPUs	• Application
KPUs-Interactive	• Application
backPressuredTimeMsPerSecond	• Application • Application , Task

Metric	Dimensions
	• Application , Task, TaskParal lelismIndex
busyTimeMsPerSecond	• Application • Application , Task • Application , Task, TaskParal lelismIndex
bytesRequestedPerFetch	• Application , Flow, Id • Application , Flow, Id, ShardId

AWS/Lambda

The AWS/Lambda namespace includes enriched metrics for the following resource types.

- AWS::Lambda::EventSourceMapping
- AWS::Lambda::Function

AWS::Lambda::EventSourceMapping

Metric	Dimensions
CommittedEventCount	• EventSourceMappingUUID
DeletedEventCount	• EventSourceMappingUUID
DroppedEventCount	• EventSourceMappingUUID
EventPollerThroughputInBytes	• EventSourceMappingUUID
EventPollerUnit	• EventSourceMappingUUID
FailedInvokeEventCount	• EventSourceMappingUUID
FilteredOutEventCount	• EventSourceMappingUUID
InvokedEventCount	• EventSourceMappingUUID
IteratorAge	• EventSourceMappingUUID
MaxOffsetLag	• EventSourceMappingUUID
OnFailureDestinationDeliveredEventCount	• EventSourceMappingUUID
PolledEventCount	• EventSourceMappingUUID
ProvisionedPollers	• EventSourceMappingUUID
SumOffsetLag	• EventSourceMappingUUID

AWS::Lambda::Function

Metric	Dimensions
AsyncEventAge	• FunctionName • FunctionName ,Resource
AsyncEventsDropped	• FunctionName • FunctionName ,Resource
AsyncEventsReceived	• FunctionName • FunctionName ,Resource
CPUThrottles	• FunctionName • FunctionName ,Resource
ConcurrencyThrottles	• FunctionName • FunctionName ,Resource
ConcurrentExecutions	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
DeadLetterErrors	• FunctionName • FunctionName ,Resource
DestinationDeliveryFailures	• FunctionName • FunctionName ,Resource
DiskThrottles	• FunctionName • FunctionName ,Resource
DurableExecutionDuration	• ExecutedVersion ,FunctionName , Resource • FunctionName

Metric	Dimensions
	• FunctionName ,Resource
DurableExecutionFailed	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
DurableExecutionOperations	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
DurableExecutionStarted	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
DurableExecutionStopped	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
DurableExecutionStorageWrit tenBytes	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
DurableExecutionSucceeded	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource

Metric	Dimensions
DurableExecutionTimedOut	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
Duration	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
Errors	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
Invocations	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
IteratorAge	• FunctionName • FunctionName ,Resource
MemoryThrottles	• FunctionName • FunctionName ,Resource
OffsetLag	• FunctionName • FunctionName ,Resource
PostRuntimeExtensionsDuration	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource

Metric	Dimensions
ProvisionedConcurrencyInvocations	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
ProvisionedConcurrencySpilloverInvocations	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
ProvisionedConcurrencyUtilization	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
ProvisionedConcurrentExecutions	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
RecursiveInvocationsDropped	• FunctionName • FunctionName ,Resource
SignatureValidationErrors	• FunctionName • FunctionName ,Resource
StreamedOutboundBytes	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource

Metric	Dimensions
StreamedOutboundThroughput	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
Throttles	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
TimeToFirstByteLatency	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
TimeToLastByteLatency	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
Url4xxCount	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource
Url5xxCount	• ExecutedVersion ,FunctionName , Resource • FunctionName • FunctionName ,Resource

Metric	Dimensions
UrlRequestCount	• ExecutedVersion , FunctionName , Resource • FunctionName • FunctionName , Resource
UrlRequestLatency	• ExecutedVersion , FunctionName , Resource • FunctionName • FunctionName , Resource

AWS/MWAA

The AWS/MWAA namespace includes enriched metrics for the following resource types.

- AWS::MWAA::Environment

AWS::MWAA::Environment

Metric	Dimensions
ActiveConnectionCount	• Environment
ApproximateAgeOfOldestTask	• Environment
CPUUtilization	• Cluster, Environment • DatabaseRole , Environment
DatabaseConnections	• DatabaseRole , Environment
DiskQueueDepth	• DatabaseRole , Environment
EphemeralStorageReserved	• Cluster, Environment
EphemeralStorageUtilized	• Cluster, Environment

Metric	Dimensions
FreeableMemory	• DatabaseRole , Environment
MemoryUtilization	• Cluster, Environment
NetworkReceiveThroughput	• DatabaseRole , Environment
NetworkRxBytes	• Cluster, Environment
NetworkTransmitThroughput	• DatabaseRole , Environment
NetworkTxBytes	• Cluster, Environment
QueuedTasks	• Environment
ReadIOPS	• DatabaseRole , Environment
ReadLatency	• DatabaseRole , Environment
ReadThroughput	• DatabaseRole , Environment
RunningTasks	• Environment
WriteIOPS	• DatabaseRole , Environment
WriteLatency	• DatabaseRole , Environment
WriteThroughput	• DatabaseRole , Environment

AWS/MediaTailor

The AWS/MediaTailor namespace includes enriched metrics for the following resource types.

- AWS::MediaTailor::Channel

AWS::MediaTailor::Channel

Metric	Dimensions
4xxErrorCount	• Channel • Channel, Output
5xxErrorCount	• Channel • Channel, Output
RequestCount	• Channel • Channel, Output
TotalTime	• Channel • Channel, Output

AWS/MemoryDB

The AWS/MemoryDB namespace includes enriched metrics for the following resource types.

- AWS::MemoryDB::Cluster

AWS::MemoryDB::Cluster

Metric	Dimensions
ActiveDefragHits	• ClusterName • ClusterName , NodeName
AuthenticationFailures	• ClusterName • ClusterName , NodeName
BytesReadFromDisk	• ClusterName , NodeName
BytesUsedForMemoryDB	• ClusterName • ClusterName , NodeName

Metric	Dimensions
BytesWrittenToDisk	• ClusterName ,NodeName
CPUUtilization	• ClusterName • ClusterName ,NodeName
ChannelAuthorizationFailures	• ClusterName • ClusterName ,NodeName
CommandAuthorizationFailures	• ClusterName • ClusterName ,NodeName
CurrConnections	• ClusterName • ClusterName ,NodeName
CurrItems	• ClusterName • ClusterName ,NodeName
DB0AverageTTL	• ClusterName • ClusterName ,NodeName
DatabaseCapacityUsagePercentage	• ClusterName • ClusterName ,NodeName
DatabaseMemoryUsagePercentage	• ClusterName • ClusterName ,NodeName
EngineCPUUtilization	• ClusterName • ClusterName ,NodeName
ErrorCount	• ClusterName • ClusterName ,NodeName
EvalBasedCmds	• ClusterName • ClusterName ,NodeName

Metric	Dimensions
Evictions	• ClusterName • ClusterName ,NodeName
FreeableMemory	• ClusterName • ClusterName ,NodeName
GetTypeCmds	• ClusterName • ClusterName ,NodeName
HashBasedCmds	• ClusterName • ClusterName ,NodeName
IamAuthenticationExpirations	• ClusterName • ClusterName ,NodeName
IamAuthenticationThrottling	• ClusterName • ClusterName ,NodeName
IsPrimary	• ClusterName • ClusterName ,NodeName
JsonBasedCmds	• ClusterName • ClusterName ,NodeName
JsonBasedGetCmds	• ClusterName • ClusterName ,NodeName
JsonBasedSetCmds	• ClusterName • ClusterName ,NodeName
KeyAuthorizationFailures	• ClusterName • ClusterName ,NodeName
KeyBasedCmds	• ClusterName • ClusterName ,NodeName

Metric	Dimensions
KeysTracked	• ClusterName • ClusterName ,NodeName
KeyspaceHits	• ClusterName • ClusterName ,NodeName
KeyspaceMisses	• ClusterName • ClusterName ,NodeName
ListBasedCmds	• ClusterName • ClusterName ,NodeName
MaxReplicationThroughput	• ClusterName • ClusterName ,NodeName
MemoryFragmentationRatio	• ClusterName • ClusterName ,NodeName
NetworkBandwidthInAllowance Exceeded	• ClusterName • ClusterName ,NodeName
NetworkBandwidthOutAllowanc eExceeded	• ClusterName • ClusterName ,NodeName
NetworkBytesIn	• ClusterName • ClusterName ,NodeName
NetworkBytesOut	• ClusterName • ClusterName ,NodeName
NetworkConntrackAllowanceEx ceeded	• ClusterName • ClusterName ,NodeName
NetworkMaxBytesIn	• ClusterName • ClusterName ,NodeName

Metric	Dimensions
NetworkMaxBytesOut	• ClusterName • ClusterName ,NodeName
NetworkMaxPacketsIn	• ClusterName • ClusterName ,NodeName
NetworkMaxPacketsOut	• ClusterName • ClusterName ,NodeName
NetworkPacketsIn	• ClusterName • ClusterName ,NodeName
NetworkPacketsOut	• ClusterName • ClusterName ,NodeName
NetworkPacketsPerSecondAllowanceExceeded	• ClusterName • ClusterName ,NodeName
NewConnections	• ClusterName • ClusterName ,NodeName
NonKeyTypeCmds	• ClusterName • ClusterName ,NodeName
NumItemsReadFromDisk	• ClusterName • ClusterName ,NodeName
NumItemsWrittenToDisk	• ClusterName • ClusterName ,NodeName
PrimaryLinkHealthStatus	• ClusterName • ClusterName ,NodeName
PubSubBasedCmds	• ClusterName • ClusterName ,NodeName

Metric	Dimensions
Reclaimed	• ClusterName • ClusterName ,NodeName
ReplicationBytes	• ClusterName • ClusterName ,NodeName
ReplicationDelayedWriteCommands	• ClusterName • ClusterName ,NodeName
ReplicationLag	• ClusterName • ClusterName ,NodeName
SearchBasedCmds	• ClusterName • ClusterName ,NodeName
SearchBasedGetCmds	• ClusterName • ClusterName ,NodeName
SearchBasedSetCmds	• ClusterName • ClusterName ,NodeName
SearchNumberOfIndexedKeys	• ClusterName • ClusterName ,NodeName
SearchNumberOfIndexes	• ClusterName • ClusterName ,NodeName
SearchTotalIndexSize	• ClusterName • ClusterName ,NodeName
SetBasedCmds	• ClusterName • ClusterName ,NodeName
SetTypeCmds	• ClusterName • ClusterName ,NodeName

Metric	Dimensions
SortedSetBasedCmds	• ClusterName • ClusterName ,NodeName
StreamBasedCmds	• ClusterName • ClusterName ,NodeName
StringBasedCmds	• ClusterName • ClusterName ,NodeName
SuccessfulReadRequestLatency	• ClusterName • ClusterName ,NodeName
SuccessfulWriteRequestLatency	• ClusterName • ClusterName ,NodeName
SwapUsage	• ClusterName • ClusterName ,NodeName

AWS/NATGateway

The AWS/NATGateway namespace includes enriched metrics for the following resource types.

- AWS::EC2::NatGateway

AWS::EC2::NatGateway

Metric	Dimensions
ActiveConnectionCount	• AvailabilityZone ,NatGatewayId • NatGatewayId
BytesInFromDestination	• AvailabilityZone ,NatGatewayId • NatGatewayId
BytesInFromSource	• AvailabilityZone ,NatGatewayId

Metric	Dimensions
	• NatGatewayId
BytesOutToDestination	• AvailabilityZone ,NatGatewayId • NatGatewayId
BytesOutToSource	• AvailabilityZone ,NatGatewayId • NatGatewayId
ConnectionAttemptCount	• AvailabilityZone ,NatGatewayId • NatGatewayId
ConnectionEstablishedCount	• AvailabilityZone ,NatGatewayId • NatGatewayId
ErrorPortAllocation	• AvailabilityZone ,NatGatewayId • NatGatewayId
IdleTimeoutCount	• AvailabilityZone ,NatGatewayId • NatGatewayId
PacketsDropCount	• AvailabilityZone ,NatGatewayId • NatGatewayId
PacketsInFromDestination	• AvailabilityZone ,NatGatewayId • NatGatewayId
PacketsInFromSource	• AvailabilityZone ,NatGatewayId • NatGatewayId
PacketsOutToDestination	• AvailabilityZone ,NatGatewayId • NatGatewayId
PacketsOutToSource	• AvailabilityZone ,NatGatewayId • NatGatewayId

Metric	Dimensions
PeakBytesPerSecond	• AvailabilityZone ,NatGatewayId • NatGatewayId
PeakPacketsPerSecond	• AvailabilityZone ,NatGatewayId • NatGatewayId

AWS/NetworkELB

The AWS/NetworkELB namespace includes enriched metrics for the following resource types.

- AWS::ElasticLoadBalancingV2::LoadBalancer

AWS::ElasticLoadBalancingV2::LoadBalancer

Metric	Dimensions
ActiveFlowCount	• AvailabilityZone ,LoadBalancer • AvailabilityZone ,LoadBalancer ,TargetGroup • LoadBalancer • LoadBalancer ,TargetGroup
ActiveFlowCount_TCP	• AvailabilityZone ,LoadBalancer • AvailabilityZone ,LoadBalancer ,TargetGroup • LoadBalancer • LoadBalancer ,TargetGroup
ActiveFlowCount_TLS	• AvailabilityZone ,LoadBalancer • AvailabilityZone ,LoadBalancer ,TargetGroup • LoadBalancer

Metric	Dimensions
ActiveFlowCount_UDP	• AvailabilityZone ,LoadBalancer • AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer • LoadBalancer ,TargetGroup
ActiveZonalShiftHostCount	• AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer ,TargetGroup
ClientTLSNegotiationErrorCount	• LoadBalancer
ConsumedLCUs	• LoadBalancer
ConsumedLCUs_TCP	• LoadBalancer
ConsumedLCUs_TLS	• LoadBalancer
ConsumedLCUs_UDP	• LoadBalancer
HealthyHostCount	• AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer ,TargetGroup
NewFlowCount	• AvailabilityZone ,LoadBalancer • AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer • LoadBalancer ,TargetGroup

Metric	Dimensions
NewFlowCount_TCP	• AvailabilityZone ,LoadBalancer • AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer • LoadBalancer ,TargetGroup
NewFlowCount_TLS	• AvailabilityZone ,LoadBalancer • AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer
NewFlowCount_UDP	• AvailabilityZone ,LoadBalancer • AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer • LoadBalancer ,TargetGroup
PeakPacketsPerSecond	• AvailabilityZone ,LoadBalancer • LoadBalancer
PortAllocationErrorCount	• AvailabilityZone ,LoadBalancer • LoadBalancer
ProcessedBytes	• AvailabilityZone ,LoadBalancer • LoadBalancer
ProcessedBytes_TCP	• AvailabilityZone ,LoadBalancer • LoadBalancer
ProcessedBytes_TLS	• AvailabilityZone ,LoadBalancer • LoadBalancer

Metric	Dimensions
ProcessedBytes_UDP	• AvailabilityZone ,LoadBalancer • LoadBalancer
ProcessedPackets	• AvailabilityZone ,LoadBalancer • LoadBalancer
TCP_Client_Reset_Count	• AvailabilityZone ,LoadBalancer • LoadBalancer
TCP_ELB_Reset_Count	• AvailabilityZone ,LoadBalancer • LoadBalancer
TCP_Target_Reset_Count	• AvailabilityZone ,LoadBalancer • LoadBalancer
TargetTLSNegotiationErrorCount	• LoadBalancer
UnHealthyHostCount	• AvailabilityZone ,LoadBalancer , TargetGroup • LoadBalancer ,TargetGroup

AWS/NetworkFirewall

The AWS/NetworkFirewall namespace includes enriched metrics for the following resource types.

- AWS::NetworkFirewall::Firewall

AWS::NetworkFirewall::Firewall

Metric	Dimensions
DroppedPackets	• AvailabilityZone ,Engine, FirewallName

Metric	Dimensions
InvalidDroppedPackets	• AvailabilityZone , Engine, FirewallName
OtherDroppedPackets	• AvailabilityZone , Engine, FirewallName
Packets	• AvailabilityZone , CustomAction , Engine, FirewallName
PassedPackets	• AvailabilityZone , Engine, FirewallName
ReceivedPackets	• AvailabilityZone , Engine, FirewallName
RejectedPackets	• AvailabilityZone , Engine, FirewallName
StreamExceptionPolicyPackets	• AvailabilityZone , Engine, FirewallName
TLSDroppedPackets	• AvailabilityZone , Engine, FirewallName
TLSErrors	• AvailabilityZone , Engine, FirewallName
TLSPassedPackets	• AvailabilityZone , Engine, FirewallName
TLSReceivedPackets	• AvailabilityZone , Engine, FirewallName
TLSRejectedPackets	• AvailabilityZone , Engine, FirewallName

Metric	Dimensions
TLSRevocationStatusOKConnections	• AvailabilityZone ,Engine, FirewallName
TLSRevocationStatusRevokedConnections	• AvailabilityZone ,Engine, FirewallName
TLSRevocationStatusUnknownConnections	• AvailabilityZone ,Engine, FirewallName
TLSTimedOutConnections	• AvailabilityZone ,Engine, FirewallName

AWS/Prometheus

The AWS/Prometheus namespace includes enriched metrics for the following resource types.

- AWS::APS::RuleGroupsNamespace
- AWS::APS::Workspace

AWS::APS::RuleGroupsNamespace

Metric	Dimensions
RuleEvaluationFailures	• RuleGroup ,Workspace
RuleEvaluations	• RuleGroup ,Workspace
RuleGroupIterationsMissed	• RuleGroup ,Workspace
RuleGroupLastEvaluationDuration	• RuleGroup ,Workspace

AWS::APS::Workspace

Metric	Dimensions
ActiveSeriesLimitPerLabelSet	• LabelSet, Workspace
ActiveSeriesPerLabelSet	• LabelSet, Workspace
AlertManagerAlertsReceived	• Workspace
AlertManagerNotificationsFailed	• Workspace
AlertManagerNotificationsFailedByIntegration	• Workspace
AlertManagerNotificationsThrottled	• Workspace
AlertManagerNotificationsThrottledByIntegration	• Workspace
DiscardedSamples	• Reason, Workspace
DiscardedSamplesPerLabelSet	• LabelSet, Reason, Workspace
DiscardedSeries	• Reason, Workspace
DiscardedSeriesPerLabelSet	• LabelSet, Reason, Workspace
IngestionRatePerLabelSet	• LabelSet, Workspace
QuerySamplesProcessed	• Workspace
SecretFetchFailure	• Workspace

AWS/RDS

The AWS/RDS namespace includes enriched metrics for the following resource types.

- AWS::RDS::DBCluster

- AWS::RDS::DBInstance

AWS::RDS::DBCluster

Metric	Dimensions
AbortedClients	• DBClusterIdentifier ,Role
ActiveTransactions	• DBClusterIdentifier ,Role
AuroraBinlogReplicaLag	• DBClusterIdentifier ,Role
AuroraDMLRejectedMasterFull	• DBClusterIdentifier ,Role
AuroraReplicaLagMaximum	• DBClusterIdentifier ,Role

ReadLatency	• DBInstanceIdentifier

Metric	Dimensions
ReadThroughput	• DBInstanceIdentifier
ReplicaLag	• DBInstanceIdentifier
TransactionLogsDiskUsage	• DBInstanceIdentifier
TransactionLogsGeneration	• DBInstanceIdentifier
WriteIOPS	• DBInstanceIdentifier
WriteLatency	• DBInstanceIdentifier
WriteThroughput	• DBInstanceIdentifier

AWS/RUM

The AWS/RUM namespace includes enriched metrics for the following resource types.

- AWS::RUM::AppMonitor

AWS::RUM::AppMonitor

Metric	Dimensions
Http4xxCount	• application_name
Http5xxCount	• application_name
HttpStatusCodeCount	• application_name ,event_details.response.status ,event_type
JsErrorCount	• application_name
NavigationFrustratedTransaction	• application_name
NavigationSatisfiedTransaction	• application_name

Metric	Dimensions
NavigationToleratedTransaction	• application_name
PageViewCount	• application_name
PerformanceNavigationDuration	• application_name
PerformanceResourceDuration	• application_name ,event_details.file.type ,event_type
RumEventPayloadSize	• application_name
SessionCount	• application_name
WebVitalsCumulativeLayoutShift	• application_name
WebVitalsFirstInputDelay	• application_name
WebVitalsLargestContentfulPaint	• application_name

AWS/Redshift

The AWS/Redshift namespace includes enriched metrics for the following resource types.

- AWS::Redshift::Cluster

AWS::Redshift::Cluster

Metric	Dimensions
CPUUtilization	• ClusterIdentifier • ClusterIdentifier ,NodeID
CommitQueueLength	• ClusterIdentifier • ClusterIdentifier ,NodeID
ConcurrencyScalingActiveClusters	• ClusterIdentifier

Metric	Dimensions
ConcurrencyScalingSeconds	• ClusterIdentifier
DatabaseConnections	• ClusterIdentifier • ClusterIdentifier ,NodeID
HealthStatus	• ClusterIdentifier • ClusterIdentifier ,NodeID
MaintenanceMode	• ClusterIdentifier • ClusterIdentifier ,NodeID
MaxConfiguredConcurrencyScalingClusters	• ClusterIdentifier
NetworkReceiveThroughput	• ClusterIdentifier • ClusterIdentifier ,NodeID
NetworkTransmitThroughput	• ClusterIdentifier • ClusterIdentifier ,NodeID
NumExceededSchemaQuotas	• ClusterIdentifier
PercentageDiskSpaceUsed	• ClusterIdentifier • ClusterIdentifier ,NodeID
QueriesCompletedPerSecond	• ClusterIdentifier ,NodeID, latency • ClusterIdentifier ,latency
QueryDuration	• ClusterIdentifier ,NodeID, latency • ClusterIdentifier ,latency
QueryRuntimeBreakdown	• ClusterIdentifier ,NodeID, stage • ClusterIdentifier ,stage

Metric	Dimensions
ReadIOPS	• ClusterIdentifier • ClusterIdentifier ,NodeID
ReadLatency	• ClusterIdentifier • ClusterIdentifier ,NodeID
ReadThroughput	• ClusterIdentifier • ClusterIdentifier ,NodeID
RedshiftManagedStorageTotal Capacity	• ClusterIdentifier
TotalTableCount	• ClusterIdentifier • ClusterIdentifier ,NodeID
WLMQueriesCompletedPerSecond	• ClusterIdentifier ,NodeID, wlmid • ClusterIdentifier ,QueueName • ClusterIdentifier ,wlmid
WLMQueryDuration	• ClusterIdentifier ,NodeID, wlmid • ClusterIdentifier ,QueueName • ClusterIdentifier ,wlmid
WLMQueueLength	• ClusterIdentifier • ClusterIdentifier ,NodeID • ClusterIdentifier ,NodeID, QueueName • ClusterIdentifier ,NodeID, service class • ClusterIdentifier ,QueueName • ClusterIdentifier ,service class

Metric	Dimensions
WLMQueueWaitTime	• ClusterIdentifier ,QueryPriority • ClusterIdentifier ,QueueName • ClusterIdentifier ,wlmid
WLMRunningQueries	• ClusterIdentifier • ClusterIdentifier ,QueueName • ClusterIdentifier ,wlmid
WriteIOPS	• ClusterIdentifier • ClusterIdentifier ,NodeID
WriteLatency	• ClusterIdentifier • ClusterIdentifier ,NodeID
WriteThroughput	• ClusterIdentifier • ClusterIdentifier ,NodeID

AWS/Route53

The AWS/Route53 namespace includes enriched metrics for the following resource types.

- AWS::Route53::HealthCheck

AWS::Route53::HealthCheck

Metric	Dimensions
ChildHealthCheckHealthyCount	• HealthCheckId
ConnectionTime	• HealthCheckId • HealthCheckId ,Region
HealthCheckPercentageHealthy	• HealthCheckId

Metric	Dimensions
HealthCheckStatus	• HealthCheckId
SSLHandshakeTime	• HealthCheckId • HealthCheckId ,Region
TimeToFirstByte	• HealthCheckId • HealthCheckId ,Region

AWS/Route53Resolver

The AWS/Route53Resolver namespace includes enriched metrics for the following resource types.

- AWS::Route53Resolver::FirewallRuleGroup
- AWS::Route53Resolver::ResolverEndpoint

AWS::Route53Resolver::FirewallRuleGroup

Metric	Dimensions
FirewallRuleGroupQueryVolume	• FirewallRuleGroupId
FirewallRuleGroupVpcQueryVolume	• FirewallRuleGroupId ,VpcId

AWS::Route53Resolver::ResolverEndpoint

Metric	Dimensions
AverageResponseTime	• EndpointId ,RniId
CapacityUsage_BETA	• EndpointId ,RniId
ConntrackUtilization	• EndpointId ,RniId
EndpointHealthyENICount	• EndpointId

Metric	Dimensions
EndpointUnhealthyENICount	• EndpointId
FormErrCount	• EndpointId ,RniId
FormErrorQueries	• EndpointId ,RniId
InboundQueryVolume	• EndpointId
NXDomainCount	• EndpointId ,RniId
NoErrorCount	• EndpointId ,RniId
NxDomainQueries	• EndpointId ,RniId
OutboundQueryAggregateVolume	• EndpointId
OutboundQueryVolume	• EndpointId
P90ResponseTime	• EndpointID ,TargetNameServerIP • EndpointId ,RniId
RefusedCount	• EndpointId ,RniId
RefusedQueries	• EndpointId ,RniId
ReplyCount	• EndpointId ,RniId
RequestQueries	• EndpointID ,TargetNameServerIP
ResolverEndpointCapacityStatus	• EndpointId
ServFailQueries	• EndpointId ,RniId
ServfailCount	• EndpointId ,RniId
TimeoutCount	• EndpointId ,RniId
TimeoutQueries	• EndpointID ,TargetNameServerIP • EndpointId ,RniId

Metric	Dimensions
tcpRequestCount	• EndpointId , RniId
udpRequestCount	• EndpointId , RniId

AWS/S3

The AWS/S3 namespace includes enriched metrics for the following resource types.

- AWS::S3::Bucket

AWS::S3::Bucket

Metric	Dimensions
4xxErrors	• BucketName , FilterId
5xxErrors	• BucketName , FilterId
AllRequests	• BucketName , FilterId
BucketSizeBytes	• BucketName , StorageType
BytesDownloaded	• BucketName , FilterId
BytesPendingReplication	• DestinationBucket , RuleId, SourceBucket
BytesUploaded	• BucketName , FilterId
DeleteRequests	• BucketName , FilterId
FirstByteLatency	• BucketName , FilterId
GetRequests	• BucketName , FilterId
HeadRequests	• BucketName , FilterId

Metric	Dimensions
ListRequests	• BucketName , FilterId
NumberOfObjects	• BucketName , StorageType
OperationsFailedReplication	• DestinationBucket , RuleId, SourceBucket
OperationsPendingReplication	• DestinationBucket , RuleId, SourceBucket
PostRequests	• BucketName , FilterId
PutRequests	• BucketName , FilterId
ReplicationLatency	• DestinationBucket , RuleId, SourceBucket
TotalRequestLatency	• BucketName , FilterId

AWS/SNS

The AWS/SNS namespace includes enriched metrics for the following resource types.

- AWS::SNS::Topic

AWS::SNS::Topic

Metric	Dimensions
NumberOfMessagesPublished	• TopicName
NumberOfNotificationsDelivered	• TopicName
NumberOfNotificationsFailed	• TopicName
PublishSize	• TopicName

AWS/SQS

The AWS/SQS namespace includes enriched metrics for the following resource types.

- AWS::SQS::Queue

AWS::SQS::Queue

Metric	Dimensions
ApproximateAgeOfOldestMessage	• QueueName
ApproximateAgeOfOldestMessageInQuietGroups	• QueueName
ApproximateNumberOfGroupsWithInflightMessages	• QueueName
ApproximateNumberOfMessagesDelayed	• QueueName
ApproximateNumberOfMessagesDelayedInQuietGroups	• QueueName
ApproximateNumberOfMessagesNotVisible	• QueueName
ApproximateNumberOfMessagesNotVisibleInQuietGroups	• QueueName
ApproximateNumberOfMessagesVisible	• QueueName
ApproximateNumberOfMessagesVisibleInQuietGroups	• QueueName
ApproximateNumberOfNoisyGroups	• QueueName
NumberOfDeduplicatedSentMessages	• QueueName

Metric	Dimensions
NumberOfEmptyReceives	• QueueName
NumberOfMessagesDeleted	• QueueName
NumberOfMessagesReceived	• QueueName
NumberOfMessagesSent	• QueueName
SentMessageSize	• QueueName

AWS/SageMaker

The AWS/SageMaker namespace includes enriched metrics for the following resource types.

- AWS::SageMaker::Endpoint
- AWS::SageMaker::InferenceComponent

AWS::SageMaker::Endpoint

Metric	Dimensions
ConcurrentRequestsPerCopy	• EndpointName , VariantName
ConcurrentRequestsPerModel	• AvailabilityZone , EndpointName , InstanceType , Region, VariantName • EndpointName , VariantName
FirstChunkLatency	• AvailabilityZone , EndpointName , InstanceType , Region, VariantName • EndpointName , VariantName
FirstChunkModelLatency	• AvailabilityZone , EndpointName , InstanceType , Region, VariantName • EndpointName , VariantName

Metric	Dimensions
FirstChunkOverheadLatency	• AvailabilityZone , EndpointName , InstanceType , Region, VariantName • EndpointName , VariantName
Invocation4XXErrors	• AvailabilityZone , EndpointName , InstanceType , Region, VariantName • ContainerId , EndpointName , InferenceComponentName , InstanceId , VariantName • EndpointName , InstanceId , VariantName • EndpointName , VariantName
Invocation5XXErrors	• AvailabilityZone , EndpointName , InstanceType , Region, VariantName • ContainerId , EndpointName , InferenceComponentName , InstanceId , VariantName • EndpointName , InstanceId , VariantName • EndpointName , VariantName
InvocationModelErrors	• AvailabilityZone , EndpointName , InstanceType , Region, VariantName • ContainerId , EndpointName , InferenceComponentName , InstanceId , VariantName • EndpointName , InstanceId , VariantName • EndpointName , VariantName

Metric	Dimensions
Invocations	• AvailabilityZone , EndpointName , InstanceType , Region, VariantName • ContainerId , EndpointName , InferenceComponentName , InstanceId , VariantName • EndpointName , InstanceId , VariantName • EndpointName , VariantName
InvocationsPerCopy	• EndpointName , VariantName
InvocationsPerInstance	• AvailabilityZone , EndpointName , InstanceType , Region, VariantName • EndpointName , InstanceId , VariantName • EndpointName , VariantName
MidStreamErrors	• EndpointName , VariantName

AWS/Scheduler

The AWS/Scheduler namespace includes enriched metrics for the following resource types.

- AWS::Scheduler::ScheduleGroup

AWS::Scheduler::ScheduleGroup

Metric	Dimensions
InvocationAttemptCount	• ScheduleGroup
InvocationDroppedCount	• ScheduleGroup
InvocationThrottleCount	• ScheduleGroup
InvocationsFailedToBeSentToDeadLetterCount	• ScheduleGroup
InvocationsFailedToBeSentToDeadLetterCount_AWS.SimpleQueueService.NonExistentQueue	• ScheduleGroup
InvocationsFailedToBeSentToDeadLetterCount_AccessDenied	• ScheduleGroup
InvocationsFailedToBeSentToDeadLetterCount_KMS.AccessDeniedException	• ScheduleGroup
InvocationsSentToDeadLetterCount	• ScheduleGroup
TargetErrorCount	• ScheduleGroup
TargetErrorThrottledCount	• ScheduleGroup

AWS/Transfer

The AWS/Transfer namespace includes enriched metrics for the following resource types.

- AWS::Transfer::Connector
- AWS::Transfer::Server

AWS::Transfer::Connector

Metric	Dimensions
OutboundFailedMessage	• ConnectorId
OutboundMessage	• ConnectorId

AWS::Transfer::Server

Metric	Dimensions
BytesIn	• ServerId
BytesOut	• ServerId
ConcurrentSessions	• ServerId
FilesIn	• ServerId
FilesOut	• ServerId
InboundFailedMessage	• ServerId
InboundMessage	• ServerId
OnUploadExecutionsFailed	• ServerId
OnUploadExecutionsStarted	• ServerId
OnUploadExecutionsSuccess	• ServerId
OutboundFailedMessage	• ServerId

AWS/TransitGateway

The AWS/TransitGateway namespace includes enriched metrics for the following resource types.

- AWS::EC2::TransitGateway

AWS::EC2::TransitGateway

Metric	Dimensions
BytesDropCountBlackhole	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
BytesDropCountInternalError	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
BytesDropCountNoPolicy	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
BytesDropCountNoRoute	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
BytesIn	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment

Metric	Dimensions
	• TransitGateway • TransitGateway ,TransitGa tewayAttachment
BytesOut	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
PacketDropCountBlackhole	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
PacketDropCountInternalError	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
PacketDropCountNoPolicy	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment

Metric	Dimensions
PacketDropCountNoRoute	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
PacketDropCountTTLExpired	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
PacketsIn	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment
PacketsOut	• AvailabilityZone ,TransitGateway • AvailabilityZone ,TransitGateway , TransitGatewayAttachment • TransitGateway • TransitGateway ,TransitGa tewayAttachment

AWS/VPN

The AWS/VPN namespace includes enriched metrics for the following resource types.

- AWS::EC2::VPNConnection

AWS::EC2::VPNConnection

Metric	Dimensions
TunnelDataIn	• VpnId
TunnelDataOut	• VpnId
TunnelState	• VpnId

AWS/VpcLattice

The AWS/VpcLattice namespace includes enriched metrics for the following resource types.

- AWS::VpcLattice::Service

AWS::VpcLattice::Service

Metric	Dimensions
HTTPCode_2XX_Count	• AvailabilityZone ,Service
HTTPCode_3XX_Count	• AvailabilityZone ,Service
HTTPCode_4XX_Count	• AvailabilityZone ,Service
HTTPCode_5XX_Count	• AvailabilityZone ,Service
RequestTime	• AvailabilityZone ,Service
RequestTimeoutCount	• AvailabilityZone ,Service
TotalRequestCount	• AvailabilityZone ,Service

AWS/WorkSpaces

The AWS/WorkSpaces namespace includes enriched metrics for the following resource types.

- AWS::WorkSpaces::Workspace

AWS::WorkSpaces::Workspace

Metric	Dimensions
Available	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
CPUUsage	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
ConnectionAttempt	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
ConnectionFailure	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId

Metric	Dimensions
	• WorkspaceId
ConnectionSuccess	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
InSessionLatency	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
Maintenance	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
MemoryUsage	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId

Metric	Dimensions
Restoring	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
RootVolumeDiskUsage	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
SessionDisconnect	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
SessionLaunchTime	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId

Metric	Dimensions
Stopped	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
UDPPacketLossRate	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
Unhealthy	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
UpTime	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId

Metric	Dimensions
UserConnected	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId
UserVolumeDiskUsage	• AwsAccountId , BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • AwsAccountId , WorkspaceId • BundleId, ComputeType , Protocol, RunningMode , WorkspaceId • WorkspaceId

CloudWatchSynthetics

The CloudWatchSynthetics namespace includes enriched metrics for the following resource types.

- AWS::Synthetics::Canary

AWS::Synthetics::Canary

Metric	Dimensions
2xx	• CanaryName
4xx	• CanaryName
5xx	• CanaryName
Duration	• CanaryName

Metric	Dimensions
Error	• CanaryName
Failed	• CanaryName
Failed requests	• CanaryName
SuccessPercent	• CanaryName
VisualMonitoringSuccessPercent	• CanaryName
VisualMonitoringTotalComparisons	• CanaryName

ContainerInsights

The ContainerInsights namespace includes enriched metrics for the following resource types.

- AWS::EKS::Cluster

AWS::EKS::Cluster

Metric	Dimensions
cluster_failed_node_count	• ClusterName
cluster_node_count	• ClusterName
node_cpu_limit	• ClusterName
node_cpu_usage_total	• ClusterName
node_filesystem_utilization	• ClusterName
node_memory_limit	• ClusterName
node_memory_working_set	• ClusterName
node_network_total_bytes	• ClusterName

Metric	Dimensions
pod_cpu_utilization	• ClusterName
pod_network_rx_bytes	• ClusterName
pod_network_tx_bytes	• ClusterName

ECS/ContainerInsights

The ECS/ContainerInsights namespace includes enriched metrics for the following resource types.

- AWS::ECS::Cluster
- AWS::ECS::Service

AWS::ECS::Cluster

Metric	Dimensions
ContainerInstanceCount	• ClusterName
CpuReserved	• ClusterName • ClusterName ,TaskDefinitionFamily
CpuUtilized	• ClusterName • ClusterName ,TaskDefinitionFamily
EphemeralStorageReserved	• ClusterName • ClusterName ,TaskDefinitionFamily
EphemeralStorageUtilized	• ClusterName • ClusterName ,TaskDefinitionFamily

Metric	Dimensions
MemoryReserved	• ClusterName • ClusterName ,TaskDefinitionFamily
MemoryUtilized	• ClusterName • ClusterName ,TaskDefinitionFamily
NetworkRxBytes	• ClusterName • ClusterName ,TaskDefinitionFamily
NetworkTxBytes	• ClusterName • ClusterName ,TaskDefinitionFamily
ServiceCount	• ClusterName
StorageReadBytes	• ClusterName ,TaskDefinitionFamily
StorageWriteBytes	• ClusterName ,TaskDefinitionFamily
TaskCount	• ClusterName

AWS::ECS::Service

Metric	Dimensions
CpuReserved	• ClusterName ,ServiceName
CpuUtilized	• ClusterName ,ServiceName
DeploymentCount	• ClusterName ,ServiceName

Metric	Dimensions
DesiredTaskCount	• ClusterName , ServiceName
EphemeralStorageReserved	• ClusterName , ServiceName
EphemeralStorageUtilized	• ClusterName , ServiceName
MemoryReserved	• ClusterName , ServiceName
MemoryUtilized	• ClusterName , ServiceName
NetworkRxBytes	• ClusterName , ServiceName
NetworkTxBytes	• ClusterName , ServiceName
PendingTaskCount	• ClusterName , ServiceName
RunningTaskCount	• ClusterName , ServiceName
TaskSetCount	• ClusterName , ServiceName

Glue

The Glue namespace includes enriched metrics for the following resource types.

- AWS::Glue::Job

AWS::Glue::Job

Metric	Dimensions
glue.ALL.jvm.heap.usage	• JobName, JobRunId, Type
glue.ALL.jvm.heap.used	• JobName, JobRunId, Type
glue.ALL.s3.filesystem.read_bytes	• JobName, JobRunId, Type

Metric	Dimensions
glue.ALL.s3.filesystem.write_bytes	• JobName, JobRunId, Type
glue.ALL.system.cpuSystemLoad	• JobName, JobRunId, Type
glue.driver.BlockManager.disk.diskSpaceUsed_MB	• JobName, JobRunId, Type
glue.driver.ExecutorAllocationManager.executors.numberAllExecutors	• JobName, JobRunId, Type
glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors	• JobName, JobRunId, Type
glue.driver.aggregate.bytesRead	• JobName, JobRunId, Type
glue.driver.aggregate.elapsedTime	• JobName, JobRunId, Type
glue.driver.aggregate.numCompletedStages	• JobName, JobRunId, Type
glue.driver.aggregate.numCompletedTasks	• JobName, JobRunId, Type
glue.driver.aggregate.numFailedTasks	• JobName, JobRunId, Type
glue.driver.aggregate.numKilledTasks	• JobName, JobRunId, Type
glue.driver.aggregate.recordsRead	• JobName, JobRunId, Type

Metric	Dimensions
glue.driver.aggregate.shuffleBytesWritten	• JobName, JobRunId, Type
glue.driver.aggregate.shuffleLocalBytesRead	• JobName, JobRunId, Type
glue.driver.jvm.heap.usage	• JobName, JobRunId, Type
glue.driver.jvm.heap.used	• JobName, JobRunId, Type
glue.driver.s3.filesystem.read_bytes	• JobName, JobRunId, Type
glue.driver.s3.filesystem.write_bytes	• JobName, JobRunId, Type
glue.driver.streaming.batchProcessingTimeInMs	• JobName, JobRunId, Type
glue.driver.streaming.numRecords	• JobName, JobRunId, Type
glue.driver.system.cpuSystemLoad	• JobName, JobRunId, Type

LambdaInsights

The LambdaInsights namespace includes enriched metrics for the following resource types.

- AWS::Lambda::Function

AWS::Lambda::Function

Metric	Dimensions
cpu_total_time	• function_name
init_duration	• function_name

Metric	Dimensions
memory_utilization	• function_name
rx_bytes	• function_name
total_memory	• function_name
total_network	• function_name
tx_bytes	• function_name
used_memory_max	• function_name

Disable resource tags on telemetry

If you don't need resource tags for telemetry, disable the feature. When disabled, CloudWatch stops enriching telemetry with tags. You can enable it again at any time. For more information, see Enable resource tags on telemetry.

Verify you have permissions to disable resource tags for telemetry.

> **Note**
>
> To disable resource tags on telemetry, you must be signed in to an IAM principal that has the `observabilityadmin:StopTelemetryEnrichment` and `resource-explorer-2:DeleteStreamingAccessForService` permissions.

To disable resource tags for telemetry (CloudWatch Console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **CloudWatch**, then choose **Settings**.
3. In the **Enable resource tags for telemetry** pane, choose **off**.
4. In the confirm modal, read through the consequences of disabling resource tags for telemetry, then type **`confirm`** and choose **Disable resource tags**.

> **Note**
>
> In the CloudWatch console, you must be signed in to an IAM principal that has the `observabilityadmin:GetTelemetryEnrichmentStatus` permission.

To disable resource tags for telemetry (AWS CLI)

Use the `stop-telemetry-enrichment` command to disable resource tags for telemetry.

```
aws observabilityadmin stop-telemetry-enrichment
```

After you complete these steps, CloudWatch stops enriching telemetry with tags. Metrics previously enriched with resource tags can still be discovered for up to 14 days. Logs previously enriched with resource tags can still be queried until the log group's retention period expires.

To disable resource tags for telemetry (AWS CloudFormation)

If you enabled resource tags for telemetry by using an AWS::ObservabilityAdmin::TelemetryEnrichment resource, disable the feature by removing that resource from your CloudFormation template and updating the stack.

Troubleshooting

CloudWatch cannot enable or disable resource tags for telemetry

If you receive an error when trying to enable or disable resource tags for telemetry, verify that the required roles and permissions are correctly configured.

To enable resource tags on telemetry, you must be signed in to an IAM principal that has the `observabilityadmin:StartTelemetryEnrichment`, `iam:CreateServiceLinkedRole`, `resource-explorer-2:CreateIndex`, `resource-explorer-2:CreateManagedView` and `resource-explorer-2:CreateStreamingAccessForService` permissions.

To disable resource tags on telemetry, you must be signed in to an IAM principal that has the `observabilityadmin:StopTelemetryEnrichment` and `resource-explorer-2:DeleteStreamingAccessForService` permissions.

> **Note**
>
> In the CloudWatch console, you must be signed in to an IAM principal that has the `observabilityadmin:GetTelemetryEnrichmentStatus` permission.

Telemetry enrichment status is `Impaired`

When the status shows as Impaired, the enable/disable request failed to complete. Retry your request to achieve the desired Running or Stopped status.

Missing tags after enabling telemetry enrichment

After you enable the feature, CloudWatch begins enriching telemetry with tags. CloudWatch can take up to 3 hours to discover all your tags for enrichment.

I turned off resource tags for telemetry, I can still see tags enriching my telemetry

After you disable the feature:

- Metrics previously enriched with resource tags can still be discovered for up to 14 days.
- Logs previously enriched with resource tags can still be queried until the log group's retention period expires.

CloudWatch Metrics (Classic)

CloudWatch Metrics (Classic) uses the `PutMetricData` API and embedded metric format (EMF) for ingestion, and provides CloudWatch Metrics Insights (SQL-based queries) for analysis. Classic metrics support up to 30 dimensions per metric with per-metric-per-month pricing.

Use Classic metrics when you have existing integrations with the CloudWatch API, need compatibility with AWS service metrics that are not yet available in OpenTelemetry format, or prefer SQL-based querying with CloudWatch Metrics Insights.

Topics

- Metrics concepts
- Basic monitoring and detailed monitoring in CloudWatch
- Publish custom metrics (PutMetricData / EMF)

- Query your CloudWatch metrics with CloudWatch Metrics Insights
- View available metrics
- Retrieve metric data (GetMetricData)
- Get statistics for a metric (GetMetricStatistics)
- Use metrics explorer to monitor resources by their tags and properties
- Use search expressions in graphs
- Use metric streams
- Math expressions with metrics
- Using CloudWatch anomaly detection
- Query metrics from other data sources
- Grafana integration
- AWS services that publish CloudWatch metrics

Metrics concepts

The following terminology and concepts are central to your understanding and use of Amazon CloudWatch:

- Namespaces
- Metrics
- Dimensions
- Resolution
- Statistics
- Percentiles
- Alarms

For information about the service quotas for CloudWatch metrics, alarms, API requests, and alarm email notifications, see CloudWatch service quotas.

Namespaces

A *namespace* is a container for CloudWatch metrics. Metrics in different namespaces are isolated from each other, so that metrics from different applications are not mistakenly aggregated into the same statistics.

There is no default namespace. You must specify a namespace for each data point you publish to CloudWatch. You can specify a namespace name when you create a metric. These names must contain valid ASCII characters, and be 255 or fewer characters. Possible characters are: alphanumeric characters (0-9A-Za-z), period (.), hyphen (-), underscore (_), forward slash (/), hash (#), colon (:), and the space character. A namespace must contain at least one non-whitespace character.

The AWS namespaces typically use the following naming convention: `AWS/service`. For example, Amazon EC2 uses the `AWS/EC2` namespace. For the list of AWS namespaces, see AWS services that publish CloudWatch metrics.

Metrics

Metrics are the fundamental concept in CloudWatch. A metric represents a time-ordered set of data points that are published to CloudWatch. Think of a metric as a variable to monitor, and the data points as representing the values of that variable over time. For example, the CPU usage of a particular EC2 instance is one metric provided by Amazon EC2. The data points themselves can come from any application or business activity from which you collect data.

By default, many AWS services provide metrics at no charge for resources (such as Amazon EC2 instances, Amazon EBS volumes, and Amazon RDS DB instances). For a charge, you can also enable detailed monitoring for some resources, such as your Amazon EC2 instances, or publish your own application metrics. For custom metrics, you can add the data points in any order, and at any rate you choose. You can retrieve statistics about those data points as an ordered set of time-series data.

Metrics exist only in the Region in which they are created. Metrics cannot be deleted, but they automatically expire after 15 months if no new data is published to them. Data points older than 15 months expire on a rolling basis; as new data points come in, data older than 15 months is dropped.

Metrics are uniquely defined by a name, a namespace, and zero or more dimensions. Each data point in a metric has a time stamp, and (optionally) a unit of measure. You can retrieve statistics from CloudWatch for any metric.

For more information, see View available metrics and Publish custom metrics (PutMetricData / EMF).

Time stamps

Each metric data point must be associated with a time stamp. The time stamp can be up to two weeks in the past and up to two hours into the future. If you do not provide a time stamp, CloudWatch creates a time stamp for you based on the time the data point was received.

Time stamps are `dateTime` objects, with the complete date plus hours, minutes, and seconds (for example, 2016-10-31T23:59:59Z). For more information, see dateTime. Although it is not required, we recommend that you use UTC. When you retrieve statistics from CloudWatch, all times are in UTC.

CloudWatch alarms check metrics based on the current time in UTC. Custom metrics sent to CloudWatch with time stamps other than the current UTC time can cause alarms to display the **Insufficient Data** state or result in delayed alarms.

Metrics retention

CloudWatch retains metric data as follows:

- Data points with a period of less than 60 seconds are available for 3 hours. These data points are high-resolution custom metrics.
- Data points with a period of 60 seconds (1 minute) are available for 15 days
- Data points with a period of 300 seconds (5 minutes) are available for 63 days
- Data points with a period of 3600 seconds (1 hour) are available for 455 days (15 months)

Data points that are initially published with a shorter period are aggregated together for long-term storage. For example, if you collect data using a period of 1 minute, the data remains available for 15 days with 1-minute resolution. After 15 days this data is still available, but is aggregated and is retrievable only with a resolution of 5 minutes. After 63 days, the data is further aggregated and is available with a resolution of 1 hour.

> **Note**
>
> Metrics that have not had any new data points in the past two weeks do not appear in the console. They also do not appear when you type their metric name or dimension names in the search box in the **Browse** tab in the console. They are not returned in the results of a list-metrics command. The best way to retrieve these metrics is with the get-metric-data or get-metric-statistics commands in the AWS CLI.

Dimensions

A *dimension* is a name/value pair that is part of the identity of a metric. You can assign up to 30 dimensions to a metric.

Every metric has specific characteristics that describe it, and you can think of dimensions as categories for those characteristics. Dimensions help you design a structure for your statistics plan. Because dimensions are part of the unique identifier for a metric, whenever you add a unique name/value pair to one of your metrics, you are creating a new variation of that metric.

AWS services that send data to CloudWatch attach dimensions to each metric. You can use dimensions to filter the results that CloudWatch returns. For example, you can get statistics for a specific EC2 instance by specifying the `InstanceId` dimension when you search for metrics.

For metrics produced by certain AWS services, such as Amazon EC2, CloudWatch can aggregate data across dimensions. For example, if you search for metrics in the `AWS/EC2` namespace but do not specify any dimensions, CloudWatch aggregates all data for the specified metric to create the statistic that you requested. CloudWatch does not aggregate across dimensions for your custom metrics.

Dimension combinations

CloudWatch treats each unique combination of dimensions as a separate metric, even if the metrics have the same metric name. You can only retrieve statistics using combinations of dimensions that you specifically published. When you retrieve statistics, specify the same values for the namespace, metric name, and dimension parameters that were used when the metrics were created. You can also specify the start and end times for CloudWatch to use for aggregation.

For example, suppose that you publish four distinct metrics named ServerStats in the DataCenterMetric namespace with the following properties:

```
Dimensions: Server=Prod, Domain=Frankfurt, Unit: Count, Timestamp:
 2016-10-31T12:30:00Z, Value: 105
Dimensions: Server=Beta, Domain=Frankfurt, Unit: Count, Timestamp:
 2016-10-31T12:31:00Z, Value: 115
Dimensions: Server=Prod, Domain=Rio,       Unit: Count, Timestamp:
 2016-10-31T12:32:00Z, Value: 95
Dimensions: Server=Beta, Domain=Rio,       Unit: Count, Timestamp:
 2016-10-31T12:33:00Z, Value: 97
```

If you publish only those four metrics, you can retrieve statistics for these combinations of dimensions:

- `Server=Prod,Domain=Frankfurt`
- `Server=Prod,Domain=Rio`
- `Server=Beta,Domain=Frankfurt`
- `Server=Beta,Domain=Rio`

You can't retrieve statistics for the following dimensions or if you specify no dimensions. (The exception is by using the metric math **SEARCH** function, which can retrieve statistics for multiple metrics. For more information, see Use search expressions in graphs.)

- `Server=Prod`
- `Server=Beta`
- `Domain=Frankfurt`
- `Domain=Rio`

> **Note**
>
> OpenTelemetry metrics use labels instead of dimensions. Labels serve a similar purpose but follow OpenTelemetry semantic conventions and support up to 150 labels per metric. For more information, see OpenTelemetry Metrics (Recommended).

Resolution

Each metric is one of the following:

- Standard resolution, with data having a one-minute granularity
- High resolution, with data at a granularity of one second

Metrics produced by AWS services are standard resolution by default. When you publish a custom metric, you can define it as either standard resolution or high resolution. When you publish a high-resolution metric, CloudWatch stores it with a resolution of 1 second, and you can read and retrieve it with a period of 1 second, 5 seconds, 10 seconds, 30 seconds, or any multiple of 60 seconds.

High-resolution metrics can give you more immediate insight into your application's sub-minute activity. Keep in mind that every `PutMetricData` call for a custom metric is charged, so calling `PutMetricData` more often on a high-resolution metric can lead to higher charges. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms with a period of 10 or 30 seconds.

> **Note**
>
> OpenTelemetry metrics are ingested at the resolution they are sent, with no minimum granularity restriction. Resolution and rollup behavior for OpenTelemetry metrics differs from traditional CloudWatch metrics.

Statistics

Statistics are metric data aggregations over specified periods of time. CloudWatch provides statistics based on the metric data points provided by your custom data or provided by other AWS services to CloudWatch. Aggregations are made using the namespace, metric name, dimensions, and the data point unit of measure, within the time period you specify.

For detailed definitions of the statistics supported by CloudWatch, see CloudWatch statistics definitions.

Units

Each statistic has a unit of measure. Example units include `Bytes`, `Seconds`, `Count`, and `Percent`. For the complete list of the units that CloudWatch supports, see the MetricDatum data type in the *Amazon CloudWatch API Reference*.

You can specify a unit when you create a custom metric. If you do not specify a unit, CloudWatch uses None as the unit. Units help provide conceptual meaning to your data. Though CloudWatch attaches no significance to a unit internally, other applications can derive semantic information based on the unit.

Metric data points that specify a unit of measure are aggregated separately. When you get statistics without specifying a unit, CloudWatch aggregates all data points of the same unit

together. If you have two otherwise identical metrics with different units, two separate data streams are returned, one for each unit.

Periods

A *period* is the length of time associated with a specific Amazon CloudWatch statistic. Each statistic represents an aggregation of the metrics data collected for a specified period of time. Periods are defined in numbers of seconds, and valid values for period are 1, 5, 10, 30, or any multiple of 60. For example, to specify a period of six minutes, use 360 as the period value. You can adjust how the data is aggregated by varying the length of the period. The default value of a period is 60 seconds. A period can be as short as one second, and must be a multiple of 60 if it is greater than the default value of 60 seconds.

Only custom metrics that you define with a storage resolution of 1 second support sub-minute periods. Even though the option to set a period below 60 is always available in the console, you should select a period that aligns to how the metric is stored. For more information about metrics that support sub-minute periods, see High-resolution metrics.

When you retrieve statistics, you can specify a period, start time, and end time. These parameters determine the overall length of time associated with the statistics. The default values for the start time and end time get you the last hour's worth of statistics. The values that you specify for the start time and end time determine how many periods CloudWatch returns. For example, retrieving statistics using the default values for the period, start time, and end time returns an aggregated set of statistics for each minute of the previous hour. If you prefer statistics aggregated in ten-minute blocks, specify a period of 600. For statistics aggregated over the entire hour, specify a period of 3600.

When statistics are aggregated over a period of time, they are stamped with the time corresponding to the beginning of the period. For example, data aggregated from 7:00pm to 8:00pm is stamped as 7:00pm. Additionally, data aggregated between 7:00pm and 8:00pm begins to be visible at 7:00pm, then the values of that aggregated data may change as CloudWatch collects more samples during the period.

Periods are also important for CloudWatch alarms. When you create an alarm to monitor a specific metric, you are asking CloudWatch to compare that metric to the threshold value that you specified. You have extensive control over how CloudWatch makes that comparison. Not only can you specify the period over which the comparison is made, but you can also specify how many evaluation periods are used to arrive at a conclusion. For example, if you specify three evaluation

periods, CloudWatch compares a window of three data points. CloudWatch only notifies you if the oldest data point is breaching and the others are breaching or missing.

Aggregation

Amazon CloudWatch aggregates statistics according to the period length that you specify when retrieving statistics. You can publish as many data points as you want with the same or similar time stamps. CloudWatch aggregates them according to the specified period length. CloudWatch does not automatically aggregate data across Regions, but you can use metric math to aggregate metrics from different Regions.

You can publish data points for a metric that share not only the same time stamp, but also the same namespace and dimensions. CloudWatch returns aggregated statistics for those data points. You can also publish multiple data points for the same or different metrics, with any time stamp.

For large datasets, you can insert a pre-aggregated dataset called a *statistic set*. With statistic sets, you give CloudWatch the Min, Max, Sum, and SampleCount for a number of data points. This is commonly used when you need to collect data many times in a minute. For example, suppose you have a metric for the request latency of a web page. It doesn't make sense to publish data with every web page hit. Consider collecting the latency of all hits to that web page, aggregate them once a minute, and send that statistic set to CloudWatch.

Amazon CloudWatch doesn't differentiate the source of a metric. If you publish a metric with the same namespace and dimensions from different sources, CloudWatch treats this as a single metric. This can be useful for service metrics in a distributed, scaled system. For example, all the hosts in a web server application could publish identical metrics representing the latency of requests they are processing. CloudWatch treats these as a single metric, allowing you to get the statistics for minimum, maximum, average, and sum of all requests across your application.

Percentiles

A *percentile* indicates the relative standing of a value in a dataset. For example, the 95th percentile means that 95 percent of the data is lower than this value and 5 percent of the data is higher than this value. Percentiles help you get a better understanding of the distribution of your metric data.

Percentiles are often used to isolate anomalies. In a normal distribution, 95 percent of the data is within two standard deviations from the mean and 99.7 percent of the data is within three standard deviations from the mean. Any data that falls outside three standard deviations is often considered to be an anomaly because it differs so greatly from the average value. For example,

suppose that you are monitoring the CPU utilization of your EC2 instances to make sure that your customers have a good experience. If you monitor the average, this can hide anomalies. If you monitor the maximum, a single anomaly can skew the results. Using percentiles, you can monitor the 95th percentile of CPU utilization to check for instances with an unusually heavy load.

Some CloudWatch metrics support percentiles as a statistic. For these metrics, you can monitor your system and applications using percentiles as you would when using the other CloudWatch statistics (Average, Minimum, Maximum, and Sum). For example, when you create an alarm, you can use percentiles as the statistical function. You can specify the percentile with up to ten decimal places (for example, p95.0123456789).

Percentile statistics are available for custom metrics as long as you publish the raw, unsummarized data points for your custom metric. Percentile statistics are not available for metrics when any of the metric values are negative numbers.

CloudWatch needs raw data points to calculate percentiles. If you publish data using a statistic set instead, you can only retrieve percentile statistics for this data if one of the following conditions is true:

- The SampleCount value of the statistic set is 1 and Min, Max, and Sum are all equal.
- The Min and Max are equal, and Sum is equal to Min multiplied by SampleCount.

The following AWS services include metrics that support percentile statistics.

- API Gateway
- Application Load Balancer
- Amazon EC2
- Elastic Load Balancing
- Kinesis
- Lambda
- Amazon RDS

CloudWatch also supports trimmed mean and other performance statistics, which can have a similar use as percentiles. For more information, see CloudWatch statistics definitions.

Alarms

You can use an *alarm* to automatically initiate actions on your behalf. An alarm watches a single metric over a specified time period, and performs one or more specified actions, based on the value of the metric relative to a threshold over time. The action is a notification sent to an Amazon SNS topic or an Auto Scaling policy. You can also add alarms to dashboards.

Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods.

When creating an alarm, select an alarm monitoring period that is greater than or equal to the metrics resolution. For example, basic monitoring for Amazon EC2 provides metrics for your instances every 5 minutes. When setting an alarm on a basic monitoring metric, select a period of at least 300 seconds (5 minutes). Detailed monitoring for Amazon EC2 provides metrics for your instances with a resolution of 1 minute. When setting an alarm on a detailed monitoring metric, select a period of at least 60 seconds (1 minute).

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms. For more information about high-resolution metrics, see Publish custom metrics (PutMetricData / EMF).

For more information, see Using Amazon CloudWatch alarms and Create an alarm from a metric on a graph.

For OpenTelemetry metrics, you can create PromQL-based CloudWatch Alarms. These alarms use PromQL queries to define alarm conditions, using the same query language available in CloudWatch Query Studio.

Basic monitoring and detailed monitoring in CloudWatch

CloudWatch provides two categories of monitoring: *basic monitoring* and *detailed monitoring*.

Many AWS services offer basic monitoring by publishing a default set of metrics to CloudWatch with no charge to customers. By default, when you start using one of these AWS services, basic monitoring is automatically enabled. For a list of services that offer basic monitoring, see AWS services that publish CloudWatch metrics.

Detailed monitoring is offered by only some services. It also incurs charges. To use it for an AWS service, you must choose to activate it. For more information about pricing, see Amazon CloudWatch pricing.

Detailed monitoring options differ based on the services that offer it. For example, Amazon EC2 detailed monitoring provides more frequent metrics, published at one-minute intervals, instead of the five-minute intervals used in Amazon EC2 basic monitoring. Detailed monitoring for Amazon S3 and Amazon Managed Streaming for Apache Kafka means more fine-grained metrics.

In different AWS services, detailed monitoring also has different names. For example, in Amazon EC2 it is called detailed monitoring, in AWS Elastic Beanstalk it is called enhanced monitoring, and in Amazon S3 it is called request metrics.

Using detailed monitoring for Amazon EC2 helps you better manage your Amazon EC2 resources, so that you can find trends and take action faster. For Amazon S3 request metrics are available at one-minute intervals to help you quickly identify and act on operational issues. On Amazon MSK, when you enable the `PER_BROKER`, `PER_TOPIC_PER_BROKER`, or `PER_TOPIC_PER_PARTITION` level monitoring, you get additional metrics that provide more visibility.

The following table lists the services that offer detailed monitoring. It also includes links to the documentation for those services that explain more about the detailed monitoring and provide instructions for how to activate it.

Service	Documentation
Amazon API Gateway	Dimensions for API Gateway metrics
AWS AppSync	CloudWatch metrics
Amazon CloudFront	Viewing additional CloudFront distribution metrics
Amazon EC2	Manage detailed monitoring for your EC2 instances
Elastic Beanstalk	Enhanced health reporting and monitoring
Amazon Kinesis Data Streams	Enhanced Shard-level Metrics
AWS Lambda	Event source mapping metrics

Service	Documentation
Amazon MSK	Amazon MSK Metrics for Monitoring with CloudWatch
Amazon S3	Amazon S3 request metrics in CloudWatch
Amazon SES	Collect CloudWatch detailed monitoring metrics using Amazon SES event publishing.

Additionally, CloudWatch offers out-of-the-box monitoring solutions with more detailed metrics and pre-created dashboards for some AWS services, as shown in the following table.

Service	Feature documentation
Lambda	Lambda Insights
Amazon ECS	Container Insights for Amazon ECS
Amazon EKS	Container Insights for Amazon EKS and Kubernetes
Amazon RDS	CloudWatch Database Insights
Amazon Aurora	CloudWatch Database Insights

Publish custom metrics (PutMetricData / EMF)

You can publish your own custom metrics to CloudWatch using the `PutMetricData` API or the AWS CLI. This approach uses CloudWatch namespaces, metric names, and dimensions.

> **Note**
>
> For new implementations, we recommend using OpenTelemetry to publish custom metrics. For more information, see Publish custom metrics with OpenTelemetry.

Topics

- High-resolution metrics
- Use dimensions
- Publish single data points
- Publish statistic sets
- Publish the value zero
- Stop publishing metrics

High-resolution metrics

Each metric is one of the following:

- Standard resolution, with data having a one-minute granularity
- High resolution, with data at a granularity of one second

Metrics produced by AWS services are standard resolution by default. When you publish a custom metric, you can define it as either standard resolution or high resolution. When you publish a high-resolution metric, CloudWatch stores it with a resolution of 1 second, and you can read and retrieve it with a period of 1 second, 5 seconds, 10 seconds, 30 seconds, or any multiple of 60 seconds.

High-resolution metrics can give you more immediate insight into your application's sub-minute activity. Keep in mind that every `PutMetricData` call for a custom metric is charged, so calling `PutMetricData` more often on a high-resolution metric can lead to higher charges. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms with a period of 10 or 30 seconds.

Use dimensions

In custom metrics, the `--dimensions` parameter is common. A dimension further clarifies what the metric is and what data it stores. You can have up to 30 dimensions assigned to one metric, and each dimension is defined by a name and value pair.

How you specify a dimension is different when you use different commands. With put-metric-data, you specify each dimension as *MyName*=*MyValue*, and with get-metric-statistics or put-metric-

alarm you use the format Name=*MyName*, Value=*MyValue*. For example, the following command publishes a Buffers metric with 2 dimensions named InstanceId and InstanceType.

```
aws cloudwatch put-metric-data --metric-name Buffers --namespace MyNameSpace --unit
 Bytes --value 231434333 --dimensions InstanceId=1-23456789,InstanceType=m1.small
```

This command retrieves statistics for that same metric. Separate the Name and Value parts of a single dimension with commas, but if you have multiple dimensions, use a space between one dimension and the next.

```
aws cloudwatch get-metric-statistics --metric-name Buffers --namespace MyNameSpace --
dimensions Name=InstanceId,Value=1-23456789 Name=InstanceType,Value=m1.small --start-
time 2016-10-15T04:00:00Z --end-time 2016-10-19T07:00:00Z --statistics Average --period
 60
```

If a single metric includes multiple dimensions, you must specify a value for every defined dimension when you use get-metric-statistics. For example, the Amazon S3 metric BucketSizeBytes includes the dimensions BucketName and StorageType, so you must specify both dimensions with get-metric-statistics.

```
aws cloudwatch get-metric-statistics --metric-name BucketSizeBytes --start-time
 2017-01-23T14:23:00Z --end-time 2017-01-26T19:30:00Z --period 3600 --namespace
 AWS/S3 --statistics Maximum --dimensions Name=BucketName,Value=amzn-s3-demo-bucket
 Name=StorageType,Value=StandardStorage --output table
```

To see what dimensions are defined for a metric, use the list-metrics command.

Publish single data points

To publish a single data point for a new or existing metric, use the put-metric-data command with one value and time stamp. For example, the following actions each publish one data point.

```
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService --
value 2 --timestamp 2016-10-20T12:00:00.000Z
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService --
value 4 --timestamp 2016-10-20T12:00:01.000Z
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService --
value 5 --timestamp 2016-10-20T12:00:02.000Z
```

If you call this command with a new metric name, CloudWatch creates a metric for you. Otherwise, CloudWatch associates your data with the existing metric that you specified.

> **Note**
>
> When you create a metric, it can take up to 2 minutes before you can retrieve statistics for the new metric using the get-metric-statistics command. However, it can take up to 15 minutes before the new metric appears in the list of metrics retrieved using the list-metrics command.

Although you can publish data points with time stamps as granular as one-thousandth of a second, CloudWatch aggregates the data to a minimum granularity of 1 second. CloudWatch records the average (sum of all items divided by number of items) of the values received for each period, as well as the number of samples, maximum value, and minimum value for the same time period. For example, the `PageViewCount` metric from the previous examples contains 3 data points with time stamps just seconds apart. If you have your period set to 1 minute, CloudWatch aggregates the 3 data points because they all have time stamps within a 1-minute period.

You can use the **get-metric-statistics** command to retrieve statistics based on the data points that you published.

```
aws cloudwatch get-metric-statistics --namespace MyService --metric-name PageViewCount
 \
--statistics "Sum" "Maximum" "Minimum" "Average" "SampleCount" \
--start-time 2016-10-20T12:00:00.000Z --end-time 2016-10-20T12:05:00.000Z --period 60
```

The following is example output.

```
{
    "Datapoints": [
        {
            "SampleCount": 3.0,
            "Timestamp": "2016-10-20T12:00:00Z",
            "Average": 3.6666666666666665,
            "Maximum": 5.0,
            "Minimum": 2.0,
            "Sum": 11.0,
            "Unit": "None"
        }
```

```
    ],
    "Label": "PageViewCount"
}
```

Publish statistic sets

You can aggregate your data before you publish to CloudWatch. When you have multiple data points per minute, aggregating data minimizes the number of calls to **put-metric-data**. For example, instead of calling **put-metric-data** multiple times for 3 data points that are within 3 seconds of each other, you can aggregate the data into a statistic set that you publish with one call, using the `--statistic-values` parameter.

```
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService
 --statistic-values Sum=11,Minimum=2,Maximum=5,SampleCount=3 --
timestamp 2016-10-14T12:00:00.000Z
```

CloudWatch needs raw data points to calculate percentiles. If you publish data using a statistic set instead, you can't retrieve percentile statistics for this data unless one of the following conditions is true:

- The `SampleCount` of the statistic set is 1
- The `Minimum` and the `Maximum` of the statistic set are equal

Publish the value zero

When your data is more sporadic and you have periods that have no associated data, you can choose to publish the value zero (`0`) for that period or no value at all. If you use periodic calls to `PutMetricData` to monitor the health of your application, you might want to publish zero instead of no value. For example, you can set a CloudWatch alarm to notify you if your application fails to publish metrics every five minutes. You want such an application to publish zeros for periods with no associated data.

You might also publish zeros if you want to track the total number of data points or if you want statistics such as minimum and average to include data points with the value 0.

Stop publishing metrics

To stop publishing custom metrics to CloudWatch, change your application's or service's code to stop using **PutMetricData**. CloudWatch doesn't pull metrics from applications, it only receives what is pushed to it, so to stop publishing your metrics you must stop them at the source.

Query your CloudWatch metrics with CloudWatch Metrics Insights

CloudWatch Metrics Insights is a powerful high-performance SQL query engine that you can use to query your metrics at scale. You can identify trends and patterns within all of your CloudWatch metrics in real time, with access to up to two weeks of historical data for comprehensive trend analysis.

You can also set alarms on any Metrics Insights queries that return a single time series. This can be especially useful to create alarms that watch aggregated metrics across a fleet of your infrastructure or applications. Create the alarm once, and it dynamically adjusts as resources are added to or removed from the fleet.

You can perform a CloudWatch Metrics Insights query in the console with the CloudWatch Metrics Insights query editor. You can also perform a CloudWatch Metrics Insights query with the AWS CLI or an AWS SDK by running `GetMetricData` or `PutDashboard`. There's no charge for queries that you run with the CloudWatch Metrics Insights query editor. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

With the CloudWatch Metrics Insights query editor, you can choose from a variety of prebuilt sample queries and also create your own queries. As you create your queries, you can use a builder view to browse your existing metrics and dimensions. Alternatively, use an editor view to manually write queries.

With Metrics Insights, you can run queries at scale. With the **GROUP BY** clause, you can group your metrics in real time into separate time series per specific dimension value. Because Metrics Insights queries include an **ORDER BY** ability, you can use Metrics Insights to make "Top N" type queries. For example, "Top N" type queries can scan millions of metrics in your account and return the 10 instances that consume the most CPU. This can help you pinpoint and remedy latency issues in your applications. To use tags with alarms, opt in through CloudWatch Settings. After tags is enabled, you can also filter and group metrics using AWS resource tags, enabling you to query metrics aligned with your organizational structure, such as by application, environment, or team.

Topics

- Building your queries in CloudWatch Metrics Insights
- Query components and syntax in CloudWatch Metrics Insights
- Alarms on CloudWatch Metrics Insights queries in CloudWatch

- Troubleshooting Metrics Insights

Building your queries in CloudWatch Metrics Insights

You can run a CloudWatch Metrics Insights query using the CloudWatch console, the AWS CLI, or the AWS SDKs. Queries run in the console are free of charge. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

With CloudWatch Metrics Insights, you can analyze metric data across extended time periods of up to two weeks, allowing for more comprehensive historical analysis and trend identification compared to shorter retention periods. For optimal performance when querying longer time ranges, consider using larger periods (such as 5 minutes or 1 hour) to reduce the number of data points returned. When analyzing trends over the full two-week period, use aggregate functions like AVG() or MAX() in your ORDER BY clauses to efficiently identify patterns.

For more information about using the AWS SDKs to perform a Metrics Insights query, see GetMetricData.

To run a query using the CloudWatch console, follow these steps:

To query your metrics using Metrics Insights

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. (Optional) To run a pre-built sample query, choose **Add query** and select the query to run. If you are satisfied with this query, you can skip the rest of this procedure. Or, you can choose **Editor** to edit the sample query and then choose **Run** to run the modified query.

4. To create your own query, choose **Multi source query**. You can then use the **Builder** view (default) to get a guided experience, or the **Editor** view if you prefer to see the query syntax. You can switch between the two views anytime and see your work in progress in both views.

   In the **Builder** view, click on the namespace, metric name, filter, group, order, and limit fields to browse and select possible values. You can start typing any part of the value you are looking for to filter the list presented by the builder. You can reference resource tags in the filter and group inputs.

   In the **Editor** view, you can write the query using the subset of SQL supported by Metrics Insights. The editor offers auto-complete options based on the characters you have typed so far, including name of resource tags for metrics that support them.

   CloudWatch Metrics Insights supports querying metrics by AWS resource tags. You can use tags to filter and group your metric data for more targeted monitoring and analysis.

   The following examples shows how you can use queries with tags.

   To see the CPU utilization for Amazon EC2 instances within your production environment:

   ```
   SELECT MAX(CPUUtilization) FROM SCHEMA("AWS/EC2") WHERE tag.env='prod'
   ```

   To group the metrics by environment using the GROUP BY clause:

   ```
   SELECT MAX(CPUUtilization) FROM SCHEMA("AWS/EC2") GROUP BY tag.env
   ```

   To use the GROUP BY clause where you specify the tag name:

   ```
   SELECT AVG(CPUUtilization) FROM "AWS/EC2" GROUP BY tag."aws:cloudformation:stack-
   name"
   ```

   To combine tag queries with existing metric dimensions:

   ```
   SELECT MAX(CPUUtilization) FROM SCHEMA("AWS/EC2") WHERE tag.env='prod' AND
    InstanceId='i-1234567890abcdef0'
   ```

5. When you are satisfied with your query, choose **Run**.

6. (Optional) Another way to edit a query that you have graphed is to choose the **Graphed metrics** tab and choose the edit icon next to the query formula in the **Details** column.

7. (Optional) To remove a query from the graph, choose **Graphed metrics** and choose the **X** icon at the right side of the row that displays your query.

Query components and syntax in CloudWatch Metrics Insights

CloudWatch Metrics Insights syntax is as follows.

```
SELECT FUNCTION(metricName)
FROM namespace | SCHEMA(...)
[ WHERE labelKey OPERATOR labelValue [AND ... ] ]
[ GROUP BY labelKey [ , ... ] ]
[ ORDER BY FUNCTION() [ DESC | ASC ] ]
[ LIMIT number ]
```

The possible clauses in a Metrics Insights query are as follows. None of the keywords are case sensitive, but the identifiers such as the names of metrics, namespaces, and dimensions are case sensitive.

SELECT

Required. Specifies the function to use to aggregate observations in each time bucket (determined by the provided period). Also specifies the name of the metric to query.

The valid values for **FUNCTION** are `AVG`, `COUNT`, `MAX`, `MIN`, and `SUM`.

- `AVG` calculates the average of the observations matched by the query.
- `COUNT` returns the count of the observations matched by the query.
- `MAX` returns the maximum value of the observations matched by the query.
- `MIN` returns the minimum value of the observations matched by the query.
- `SUM` calculates the sum of the observations matched by the query.

FROM

Required. Specifies the source of the metric. You can specify either the metric namespace that contains the metric that is to be queried, or a **SCHEMA** table function. Examples of metric namespaces include `"AWS/EC2"`, `"AWS/Lambda"`, and metric namespaces that you have created for your custom metrics.

Metric namespaces that include **/** or any other character that is not a letter, number, or underscore must be surrounded by double quotation marks. For more information, see What needs quotation marks or escape characters?.

SCHEMA

An optional table function that can be used within a **FROM** clause. Use **SCHEMA** to scope down the query results to only the metrics that exactly match a list of dimensions, or to metrics that have no dimensions.

If you use a **SCHEMA** clause, it must contain at least one argument, and this first argument must be the metric namespace being queried. If you specify **SCHEMA** with only this namespace argument, the results are scoped down to only metrics that do not have any dimensions.

If you specify **SCHEMA** with additional arguments, the additional arguments after the namespace argument must be *label* keys. Label keys must be dimension names. If you specify one or more of these label keys, the results are scoped down to only those metrics that have that exact set of dimensions. The order of these label keys does not matter.

For example:

- **SELECT AVG(CPUUtilization) FROM "AWS/EC2"** matches all `CPUUtilization` metrics in the `AWS/EC2` namespace, no matter their dimensions, and returns a single aggregated time series.
- **SELECT AVG(CPUUtilization) FROM SCHEMA("AWS/EC2")** matches only the `CPUUtilization` metrics in the `AWS/EC2` namespace that do not have any dimensions defined.
- **SELECT AVG(CPUUtilization) FROM SCHEMA("AWS/EC2", InstanceId)** matches only the `CPUUtilization` metrics that were reported to CloudWatch with exactly one dimension, `InstanceId`.
- **SELECT SUM(RequestCount) FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)** matches only the `RequestCount` metrics that were reported to CloudWatch from `AWS/ApplicationELB` with exactly two dimensions, `LoadBalancer` and `AvailabilityZone`.

WHERE

Optional. Filters the results to only those metrics that match your specified expression using specific label values for one or more label keys. For example, **WHERE InstanceType =**

'c3.4xlarge' filters the results to only `c3.4xlarge` instance types, and **WHERE InstanceType != 'c3.4xlarge'** filters the results to all instance types except `c3.4xlarge`.

When you run a query in a monitoring account, you can use `WHERE AWS.AccountId` to limit results to only the account that you specify. For example, `WHERE AWS.AccountId=444455556666` queries metrics from only account `444455556666`. To limit your query to only metrics in the monitoring account itself, use `WHERE AWS.AccountId=CURRENT_ACCOUNT_ID()`.

Label values must always be enclosed with single quotation marks.

Using tags in WHERE clauses

You can filter results by AWS resource tags using the syntax `tag.keyName`. Tag filters follow the same operator rules as dimension filters. For example:

- WHERE `tag.env = 'prod'` filters to metrics from resources tagged with *env=prod*
- WHERE `tag.department != 'test'` excludes metrics from resources tagged with *department=test*

Tag filters can be combined with dimension filters:

```
WHERE tag.env = 'prod' AND InstanceType = 'm5.large'
```

Supported operators

The **WHERE** clause supports the following operators:

- **=** Label value must match the specified string.
- **!=** Label value must not match the specified string.
- **AND** Both conditions that are specified must be true to match. You can use multiple **AND** keywords to specify two or more conditions.

GROUP BY

Optional. Groups the query results into multiple time series, each one corresponding to a different value for the specified label key or keys. For example, using `GROUP BY InstanceId` returns a different time series for each value of `InstanceId`. Using `GROUP BY ServiceName, Operation` creates a different time series for each possible combination of the values of `ServiceName` and `Operation`.

With a **GROUP BY** clause, by default the results are ordered in alphabetical ascending order, using the sequence of labels specified in the **GROUP BY** clause. To change the order of the results, add an **ORDER BY** clause to your query.

When you run a query in a monitoring account, you can use `GROUP BY AWS.AccountId` to group the results based on the accounts they are from.

Using tags in GROUP BY clauses

You can group results by AWS resource tag values using the syntax `tag.keyName`. For example:

- *GROUP BY tag.environment* creates separate time series for each environment tag value
- *GROUP BY tag.team, InstanceType* groups by both tag and dimension values
- *GROUP BY tag.team, AWS.AccountId* groups by both tag and linked source AccountIDs

> **Note**
>
> If some of the matching metrics don't include a specific label key specified in the **GROUP BY** clause, a null group named `Other` is returned. For example, if you specify `GROUP BY ServiceName, Operation` and some of the returned metrics don't include `ServiceName` as a dimension, then those metrics are displayed as having `Other` as the value for `ServiceName`.

ORDER BY

Optional. Specifies the order to use for the returned time series, if the query returns more than one time series. The order is based on the values found by the **FUNCTION** that you specify in the **ORDER BY** clause. The **FUNCTION** is used to calculate a single scalar value from each returned time series, and that value is used to determine the order.

You also specify whether to use ascending **ASC** or descending **DESC** order. If you omit this, the default is ascending **ASC**.

For example, adding an `ORDER BY MAX() DESC` clause orders the results by the maximum data point observed within the time range, in descending order: meaning that the time series that has the highest maximum data point is returned first.

The valid functions to use within an **ORDER BY** clause are `AVG()`, `COUNT()`, `MAX()`, `MIN()`, and `SUM()`.

If you use an **ORDER BY** clause with a **LIMIT** clause, the resulting query is a "Top N" query. **ORDER BY** is also useful for queries that might return a large number of metrics, because each query can return no more than 500 time series. If a query matches more than 500 time series, and you use an **ORDER BY** clause, the time series are sorted and then the 500 time series that come first in the sort order are the ones that are returned.

LIMIT

Optional. Limits the number of time series returned by the query to the value that you specify. The maximum value that you can specify is 500, and a query that does not specify a **LIMIT** can also return no more than 500 time series.

Using a **LIMIT** clause with an **ORDER BY** clause gives you a "Top N" query.

What needs quotation marks or escape characters?

In a query, label values must always be surrounded with single quotation marks. For example, **SELECT MAX(CPUUtilization) FROM "AWS/EC2" WHERE AutoScalingGroupName = 'my-production-fleet'**.

Metric namespaces, metric names, and label keys that contain characters other than letters, numbers, and underscore (_) must be surrounded by double quote marks. For example, **SELECT MAX("My.Metric")**.

If one of these contains a double quotation mark or single quotation mark itself (such as `Bytes"Input"`), you must escape each quotation mark with a backslash, as in **SELECT AVG("Bytes \"Input\"")**.

If a metric namespace, metric name, or label key, contains a word that is a reserved keyword in Metrics Insights, these must also be enclosed in double quotation marks. For example, if you have a metric named `LIMIT`, you would use `SELECT AVG("LIMIT")`. It is also valid to enclose any namespace, metric name, or label in double quotation marks even if it does not include a reserved keyword.

For a complete list of reserved keywords, see Reserved keywords.

Build a rich query step by step

This section illustrates building a full example that uses all possible clauses, step by step.

You can start with the following query, which aggregates all of the Application Load Balancer `RequestCount` metrics that are collected with both the dimensions `LoadBalancer` and `AvailabilityZone`.

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
```

To see metrics only from a specific load balancer, you can add a **WHERE** clause to limit the metrics returned to only those metrics where the value of the `LoadBalancer` dimension is `app/load-balancer-1`.

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
WHERE LoadBalancer = 'app/load-balancer-1'
```

The preceding query aggregates the `RequestCount` metrics from all Availability Zones for this load balancer into one time series. If you want to see different time series for each Availability Zone, we can add a **GROUP BY** clause.

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
WHERE LoadBalancer = 'app/load-balancer-1'
GROUP BY AvailabilityZone
```

Next, you can order the results to see the highest values first. The following **ORDER BY** clause orders the time series in descending order, by the maximum value reported by each time series during the query time range:

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
WHERE LoadBalancer = 'app/load-balancer-1'
GROUP BY AvailabilityZone
ORDER BY MAX() DESC
```

You can also use tags to further filter the results. For example, if you want to see results only for load balancers tagged with a specific environment, you can add tag filtering to the WHERE clause:

```
SELECT SUM(RequestCount) FROM SCHEMA("AWS/ApplicationELB", LoadBalancer,
 AvailabilityZone) WHERE LoadBalancer = 'app/load-balancer-1' AND tag.Environment =
 'prod' GROUP BY AvailabilityZone ORDER BY MAX() DESC
```

You can also group the results by tag values instead of (or in addition to) dimensions. For example, grouping by the Application tag:

```
SELECT SUM(RequestCount) FROM SCHEMA("AWS/ApplicationELB", LoadBalancer,
 AvailabilityZone) WHERE tag.Environment = 'prod' GROUP BY tag.Application ORDER BY
 MAX() DESC
```

Finally, if we are primarily interested in a "Top N" type of query, we can use a **LIMIT** clause. This final example limits the results to only the time series with the five highest `MAX` values.

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
WHERE LoadBalancer = 'app/load-balancer-1'
GROUP BY AvailabilityZone
ORDER BY MAX() DESC
LIMIT 5
```

Cross-account query examples

These examples are valid when run in an account set up as a monitoring account in CloudWatch cross-account observability.

The following example searches all Amazon EC2 instances in the source account 123456789012 and returns the average.

```
SELECT AVG(CpuUtilization)
FROM "AWS/EC2"
WHERE AWS.AccountId ='123456789012'
```

The following example queries the `CPUUtilization` metric in `AWS/EC2` in all the linked source accounts, and groups the results by account ID and instance type.

```
SELECT AVG(CpuUtilization)
FROM "AWS/EC2"
GROUP BY AWS.AccountId, InstanceType
```

The following example queries the `CPUUtilization` in the monitoring account itself.

```
SELECT AVG(CpuUtilization)
FROM "AWS/EC2"
WHERE AWS.AccountId = CURRENT_ACCOUNT_ID()
```

Reserved keywords

The following are reserved keywords in CloudWatch Metrics Insights. If any of these words are in a namespace, metric name, or label key in a query, you must enclose them in double quote marks. Reserved keywords are not case sensitive.

```
"ABORT" "ABORTSESSION" "ABS" "ABSOLUTE" "ACCESS" "ACCESSIBLE" "ACCESS_LOCK" "ACCOUNT"

Alarms on CloudWatch Metrics Insights queries in CloudWatch

You can create alarms on Metrics Insights queries. This helps you have alarms that track multiple resources without needing to be updated later. The query catches new resources and resources that change. For example, you can create an alarm that watches the CPU utilization of your fleet, and the alarm automatically evaluates new instances that you launch after creating the alarm.

In a monitoring account that is set up for CloudWatch cross-account observability, your Metrics Insights alarms can watch resources in source accounts and in the monitoring account itself. For more information about how to limit your alarm queries to a specific account or to group the results by account ID, see the `WHERE` and `GROUP BY` sections in Query components and syntax in CloudWatch Metrics Insights.

Using tags in alarm queries

You can create alarms on Metrics Insights queries that use AWS resource tags to filter and group metrics. To use tags with alarms, on the CloudWatch console, choose **Settings**. On the **CloudWatch Settings** page, under **Enable resource tags on telemetry**, choose **Enable**. Context-aware alarms monitor specific applications, environments, or teams automatically as resources change.

For example, you can create an alarm that monitors CPU utilization for all Amazon EC2 instances tagged with a specific application.

```
SELECT MAX(CPUUtilization) FROM "AWS/EC2" WHERE tag.Application = 'Orders' AND
 tag.Environment = 'Prod'
```

Tag-based alarms automatically adapt as you add or remove resources with matching tags, providing dynamic monitoring aligned with your operational structure.

Contents

- Creating a Metrics Insights CloudWatch alarm

Creating a Metrics Insights CloudWatch alarm

To create an alarm on a Metrics Insights query using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **Classic metrics**.
3. (Optional) To run a pre-built sample query, choose **Add query** and select the query to run. Or, you can choose **Editor** to edit the sample query and then choose **Run** to run the modified query.
4. To create your own query, choose **Multi source query**. You can then use the **Builder** view, the **Editor** view, and also use a combination of both. You can switch between the two views anytime and see your work in progress in both views.

   In the **Builder** view, you can browse and select the metric namespace, metric name, filter, group, and order options. For each of these options, the query builder offers you a list of possible selections from your environment to choose from.

   In the **Editor** view, you can start writing your query. As you type, the editor offers suggestions based on the characters that you have typed so far.

   For example, when creating your Metrics Insights query for the alarm, you can use tags to filter and group metrics for more targeted monitoring.

   - Filter by tags – Use `WHERE tag.keyName = 'value'` to monitor resources with specific tags

     ```
     SELECT MAX(CPUUtilization) FROM "AWS/EC2" WHERE tag.Environment = 'Prod'
     ```

   - Combine tags with dimensions – Mix tag filters with existing metric dimensions

     ```
     SELECT AVG(Duration) FROM "AWS/Lambda" WHERE tag.Application = 'OrderService' AND
      FunctionName = 'process%'
     ```

   > **Note**
   >
   > When using tags, alarms will match the metrics only if the specified tags existed on the associated resources during the evaluated time period.

5. When you are satisfied with your query, choose **Run**.
6. Choose **Create alarm**.
7. Under **Conditions**, specify the following:

   a. For **Whenever *metric* is**, specify whether the metric must be greater than, less than, or equal to the threshold. Under **than...**, specify the threshold value.

   b. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the ALARM state to trigger the alarm. If the two values here match, you create an alarm that goes to ALARM state if that many consecutive periods are breaching.

      To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Alarm evaluation.

   c. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.
8. Choose **Next**.
9. Under **Notification**, select an SNS topic to notify when the alarm is in ALARM state, OK state, or INSUFFICIENT_DATA state.

   To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

   To have the alarm not send notifications, choose **Remove**.
10. To have the alarm perform Auto Scaling, EC2, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

    > **Note**
    >
    > To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for AWS Systems Manager Incident Manager.

11. When finished, choose **Next**.

12. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.
13. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

To create an alarm on a Metrics Insights query using the AWS CLI

Use the `put-metric-alarm` command and specify a Metrics Insights query in the `metrics` parameter. For example, the following command sets an alarm that goes into ALARM state if any of your instances go above 80% in CPU utilization.

```
aws cloudwatch put-metric-alarm --alarm-name Prod-App-CPU-Alarm --evaluation-periods 1
 --comparison-operator GreaterThanThreshold --metrics '[{"Id":"m1","Expression":"SELECT
 MAX(CPUUtilization) FROM \"AWS/EC2\" WHERE tag.Environment = '\''Prod'\'' AND
 tag.Application = '\''OrderService'\''", "Period":60}]' --threshold 80
```

Use Metrics Insights queries with metric math

You can use a Metrics Insights query as an input to a metric math function. For more information about metric math, see Math expressions with metrics.

A Metrics Insights query that does not include a **GROUP BY** clause returns a single time series. Therefore, its returned results can be used with any metric math function that takes a single time series as input.

A Metrics Insights query that includes a **GROUP BY** clause returns multiple time series. Therefore, its returned results can be used with any metric math function that takes an array of time series as input.

For example, the following query returns the total number of bytes downloaded for each bucket in the Region, as an array of time series:

```
SELECT SUM(BytesDownloaded)
FROM SCHEMA("AWS/S3", BucketName, FilterId)
WHERE FilterId = 'EntireBucket'
GROUP BY BucketName
```

On a graph in the console or in a GetMetricData operation, the results of this query are q1. This query returns the result in bytes, so if you want to see the result as MB instead, you can use the following math function:

```
q1/1024/1024
```

Use natural language to generate and update CloudWatch Metrics Insights queries

CloudWatch supports a natural language query capability to help you generate and update queries for CloudWatch Metrics Insights and CloudWatch Logs Insights.

With this capability, you can ask questions about or describe the CloudWatch data you're looking for in plain English. The natural language capability generates a query based on a prompt that you enter and provides a line-by-line explanation of how the query works. You can also update your query to further investigate your data.

Depending on your environment, you can enter prompts like "Which Amazon Elastic Compute Cloud instance has the highest network out?" and "Show me the top 10 Amazon DynamoDB Tables by consumed reads."

Note

The natural-language query feature is generally available in 10 Regions. For some Regions, the feature makes cross-Region calls to Regions in the United States to process the query prompts. The following table lists the supported Regions, and shows where each Region processes its prompts.

Supported Region	Region where prompt is processed
US East (N. Virginia)	US East (N. Virginia)
US East (Ohio)	US East (N. Virginia)
US West (Oregon)	US West (Oregon)
Asia Pacific (Hong Kong)	US West (Oregon)
Asia Pacific (Singapore)	US West (Oregon)
Asia Pacific (Sydney)	US West (Oregon)

Europe (Stockholm)	US East (N. Virginia)

To generate a CloudWatch Metrics Insights query with this capability, open the CloudWatch Metrics Insights query editor in the *builder* or *editor* view and choose **Generate query**.

Important

To use the natural language query capability, you must use the CloudWatchFullAccess, CloudWatchReadOnlyAccess, CloudWatchFullAccessV2, AdministratorAccess, or ReadOnlyAccess policy.
You can also include the `cloudwatch:GenerateQuery` action in a new or existing customer managed or inline policy.

Example queries

The examples in this section describe how to generate and update queries using the natural language capability.

Note

For more information on the CloudWatch Metrics Insights query editor and syntax, see CloudWatch Metrics Insights query components and syntax.

Example: Generate a natural language query

To generate a query using natural language, enter a prompt and choose **Generate new query**. This example shows a query that performs a basic search.

Prompt

The following is an example of a prompt that directs the capability to search for the top 10 DynamoDB Tables that consume the most read capacity.

```
Show top 10 DynamoDB Tables by consumed reads
```

Query

The following is an example of a query that the natural language capability generates based on the prompt. Notice how the prompt appears in a comment before the query. After the query, you can read an explanation that describes how the query works.

```
# Show top 10 DynamoDB Tables by consumed reads
SELECT SUM("ConsumedReadCapacityUnits")
FROM "AWS/DynamoDB"
GROUP BY TableName
ORDER BY SUM() DESC
LIMIT 10
# This query selects the sum of consumed read capacity units for each DynamoDB table,
 groups the results by table name, orders the results from highest to lowest read
 capacity consumption, and limits the results to the top 10 tables.
```

> **Note**
>
> To turn off the appearance of your prompt and the explanation of how the query works, use the gear icon in your editor.

Example: Update a natural language query

You can update a query by editing the initial prompt and then choosing **Update query**.

Updated prompt

The following example shows an updated version of the previous prompt. Instead of a prompt that searches for the top 10 DynamoDB Tables that consume the most read capacity, this prompt now directs the capability to sort the results by the number of bytes returned.

```
Sort by bytes returned instead
```

Updated query

The following is an example of the updated query. Notice how the updated prompt appears in a comment before the updated query. After the query, you can read an explanation that describes how the original query has been updated.

```
# Sort by bytes returned instead
SELECT SUM("ReturnedBytes")
FROM "AWS/DynamoDB"
GROUP BY TableName
ORDER BY SUM() DESC
LIMIT 10
# This query modifies the original query to select the sum of returned bytes instead
 of consumed read capacity units, and orders the results from highest to lowest sum of
 returned bytes, limiting the results to the top 10 tables.
```

Opting out of using your data for service improvement

The natural language prompt data you provide to train the AI model and generate relevant queries is used solely to provide and maintain your service. This data might be used to improve the quality of CloudWatch Metrics Insights. Your trust and privacy, as well as the security of your content, is our highest priority. For more information, see AWS Service Terms and AWS responsible AI policy.

You can opt out of having your content used to develop or improve the quality of natural language queries by creating an AI service opt-out policy. To opt-out of data collection for all CloudWatch AI features, including the query generation capability, you must create an opt-out policy for CloudWatch. For more information, see AI services opt-out policies in the *AWS Organizations User Guide*.

SQL inference

CloudWatch Metrics Insights uses several mechanisms to infer the intention of a given SQL query.

Topics

- Time bucketing
- Fields projection
- ORDER BY global aggregation

Time bucketing

Time series data points resulting from a query are rolled up into time buckets based on the requested period. To aggregate values in standard SQL, an explicit GROUP BY clause must be

defined to collect all the observations of a given period together. Because this is the standard way to query time series data, CloudWatch Metrics Insights infers time bucketing without the need to express an explicit **GROUP BY** clause.

For example, when a query is performed with a period of one minute, all the observations belonging to that minute until the next (excluded) are rolled up to the start time of the time bucket. This makes Metrics Insights SQL statements more concise and less verbose.

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
```

The previous query returns a single time series (timestamp-value pairs), representing the average CPU utilization of all Amazon EC2 instances. Assuming the requested period is one minute, each data point returned represents the average of all observations measured within a specific one-minute interval (start time inclusive, end time exclusive). The timestamp related to the specific data point is the start time of the bucket

Fields projection

Metrics Insights queries always return the timestamp projection. You don't need to specify a timestamp column in the **SELECT** clause to get the timestamp of each corresponding data point value. For details about how timestamp is calculated, see Time bucketing.

When using **GROUP BY**, each group name is also inferred and projected in the result, so that you can group the returned time series.

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
GROUP BY InstanceId
```

The previous query returns a time series for each Amazon EC2 instance. Each time series is labeled after the value of the instance ID.

ORDER BY global aggregation

When using **ORDER BY**, **FUNCTION()** infers which aggregate function that you want to order by (the data point values of the queried metrics). The aggregate operation is performed across all the matched data points of each individual time series across the queried time window.

```
SELECT AVG(CPUUtilization)
```

```
FROM SCHEMA("AWS/EC2", InstanceId)
GROUP BY InstanceId
ORDER BY MAX()
LIMIT 10
```

The previous query returns the CPU utilization for each Amazon EC2 instance, limiting the result set to 10 entries. The results are ordered based on the maximum value of the individual time series within the requested time window. The **ORDER BY** clause is applied before **LIMIT**, so that the ordering is calculated against more than 10 time series.

Metrics Insights quotas

CloudWatch Metrics Insights currently has the following quotas:

- Query up to two weeks of data for visualization in your metrics, widgets, and alarm graphs. You can query the most recent three hours of data for alarm condition evaluations.
- A single query can process no more than 10,000 metrics. This means that if the **SELECT**, **FROM**, and **WHERE** clauses match more than 10,000 metrics, the query only processes the first 10,000 of these metrics that it finds.
- A single query can return no more than 500 time series. This means that if the query would return more than 500 metrics, not all metrics will be returned in the query results. If you use an **ORDER BY** clause, then all the metrics being processed are sorted, and the 500 that have the highest or lowest values according to your **ORDER BY** clause are returned.

  If you do not include an **ORDER BY** clause, you can't control which 500 matching metrics are returned.
- You can have as many as 200 Metrics Insights alarms per Region.
- Metrics Insights does not support high-resolution data, which is metric data reported with a granularity of less than one minute. If you request high-resolution data, the request does not fail, but the output is aggregated at one-minute granularity.
- Each GetMetricData operation can have only one query, but you can have multiple widgets in a dashboard that each include a query.
- If a query using tag(s) with a **GROUP BY** or **WHERE** matches a metric that has more than 10 tag updates, only the most recent 10 tagged versions of the metric will be included in the query results.

Metrics Insights sample queries

This section contains examples of useful CloudWatch Metrics Insights queries that you can copy and use directly or copy and modify in query editor. Some of these examples are already available in the console, and you can access them by choosing **Add query** in the **Metrics** view.

Application Load Balancer examples

Total requests across all load balancers

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer)
```

Top 10 most active load balancers

```
SELECT MAX(ActiveConnectionCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer)
GROUP BY LoadBalancer
ORDER BY SUM() DESC
LIMIT 10
```

AWS API usage examples

Top 20 AWS APIs by the number of calls in your account

```
SELECT COUNT(CallCount)
FROM SCHEMA("AWS/Usage", Class, Resource, Service, Type)
WHERE Type = 'API'
GROUP BY Service, Resource
ORDER BY COUNT() DESC
LIMIT 20
```

CloudWatch APIs sorted by calls

```
SELECT COUNT(CallCount)
FROM SCHEMA("AWS/Usage", Class, Resource, Service, Type)
WHERE Type = 'API' AND Service = 'CloudWatch'
GROUP BY Resource
ORDER BY COUNT() DESC
```

DynamoDB examples

Top 10 tables by consumed reads

```
SELECT SUM(ProvisionedWriteCapacityUnits)
FROM SCHEMA("AWS/DynamoDB", TableName)
GROUP BY TableName
ORDER BY MAX() DESC LIMIT 10
```

Top 10 tables by returned bytes

```
SELECT SUM(ReturnedBytes)
FROM SCHEMA("AWS/DynamoDB", TableName)
GROUP BY TableName
ORDER BY MAX() DESC LIMIT 10
```

Top 10 tables by user errors

```
SELECT SUM(UserErrors)
FROM SCHEMA("AWS/DynamoDB", TableName)
GROUP BY TableName
ORDER BY MAX() DESC LIMIT 10
```

Amazon Elastic Block Store examples

Top 10 Amazon EBS volumes by bytes written

```
SELECT SUM(VolumeWriteBytes)
FROM SCHEMA("AWS/EBS", VolumeId)
GROUP BY VolumeId
ORDER BY SUM() DESC
LIMIT 10
```

Average Amazon EBS volume write time

```
SELECT AVG(VolumeTotalWriteTime)
FROM SCHEMA("AWS/EBS", VolumeId)
```

Amazon EC2 examples

CPU utilization of EC2 instances sorted by highest

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
GROUP BY InstanceId
ORDER BY AVG() DESC
```

Average CPU utilization across the entire fleet

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
```

Top 10 instances by highest CPU utilization

```
SELECT MAX(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
GROUP BY InstanceId
ORDER BY MAX() DESC
LIMIT 10
```

In this case, the CloudWatch agent is collecting a `CPUUtilization` metric per application. This query filters the average of this metric for a specific application name.

```
SELECT AVG(CPUUtilization)
FROM "AWS/CWAgent"
WHERE ApplicationName = 'eCommerce'
```

Amazon Elastic Container Service examples

Average CPU utilization across all ECS clusters

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/ECS", ClusterName)
```

Top 10 clusters by memory utilization

```
SELECT AVG(MemoryUtilization)
FROM SCHEMA("AWS/ECS", ClusterName)
GROUP BY ClusterName
ORDER BY AVG() DESC
LIMIT 10
```

Top 10 services by CPU utilization

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/ECS", ClusterName, ServiceName)
GROUP BY ClusterName, ServiceName
ORDER BY AVG() DESC
LIMIT 10
```

Top 10 services by running tasks (Container Insights)

```
SELECT AVG(RunningTaskCount)
FROM SCHEMA("ECS/ContainerInsights", ClusterName, ServiceName)
GROUP BY ClusterName, ServiceName
ORDER BY AVG() DESC
LIMIT 10
```

Amazon Elastic Kubernetes Service Container Insights examples

Average CPU utilization across all EKS clusters

```
SELECT AVG(pod_cpu_utilization)
FROM SCHEMA("ContainerInsights", ClusterName)
```

Top 10 clusters by node CPU utilization

```
SELECT AVG(node_cpu_utilization)
FROM SCHEMA("ContainerInsights", ClusterName)
GROUP BY ClusterName
ORDER BY AVG() DESC LIMIT 10
```

Top 10 clusters by pod memory utilization

```
SELECT AVG(pod_memory_utilization)
FROM SCHEMA("ContainerInsights", ClusterName)
GROUP BY ClusterName
ORDER BY AVG() DESC LIMIT 10
```

Top 10 nodes by CPU utilization

```
SELECT AVG(node_cpu_utilization)
```

```
FROM SCHEMA("ContainerInsights", ClusterName, NodeName)
GROUP BY ClusterName, NodeName
ORDER BY AVG() DESC LIMIT 10
```

Top 10 pods by memory utilization

```
SELECT AVG(pod_memory_utilization)
FROM SCHEMA("ContainerInsights", ClusterName, PodName)
GROUP BY ClusterName, PodName
ORDER BY AVG() DESC LIMIT 10
```

EventBridge examples

Top 10 rules by invocations

```
SELECT SUM(Invocations)
FROM SCHEMA("AWS/Events", RuleName)
GROUP BY RuleName
ORDER BY MAX() DESC LIMIT 10
```

Top 10 rules by failed invocations

```
SELECT SUM(FailedInvocations)
FROM SCHEMA("AWS/Events", RuleName)
GROUP BY RuleName
ORDER BY MAX() DESC LIMIT 10
```

Top 10 rules by matched rules

```
SELECT SUM(MatchedEvents)
FROM SCHEMA("AWS/Events", RuleName)
GROUP BY RuleName
ORDER BY MAX() DESC LIMIT 10
```

Kinesis examples

Top 10 streams by bytes written

```
SELECT SUM("PutRecords.Bytes")
FROM SCHEMA("AWS/Kinesis", StreamName)
GROUP BY StreamName
```

```
ORDER BY SUM() DESC LIMIT 10
```

Top 10 streams by earliest items in the stream

```
SELECT MAX("GetRecords.IteratorAgeMilliseconds")
FROM SCHEMA("AWS/Kinesis", StreamName)
GROUP BY StreamName
ORDER BY MAX() DESC LIMIT 10
```

Lambda examples

Lambda functions ordered by number of invocations

```
SELECT SUM(Invocations)
FROM SCHEMA("AWS/Lambda", FunctionName)
GROUP BY FunctionName
ORDER BY SUM() DESC
```

Top 10 Lambda functions by longest runtime

```
SELECT AVG(Duration)
FROM SCHEMA("AWS/Lambda", FunctionName)
GROUP BY FunctionName
ORDER BY MAX() DESC
LIMIT 10
```

Top 10 Lambda functions by error count

```
SELECT SUM(Errors)
FROM SCHEMA("AWS/Lambda", FunctionName)
GROUP BY FunctionName
ORDER BY SUM() DESC
LIMIT 10
```

CloudWatch Logs examples

Top 10 log groups by incoming events

```
SELECT SUM(IncomingLogEvents)
FROM SCHEMA("AWS/Logs", LogGroupName)
GROUP BY LogGroupName
```

```
ORDER BY SUM() DESC LIMIT 10
```

Top 10 log groups by written bytes

```
SELECT SUM(IncomingBytes)
FROM SCHEMA("AWS/Logs", LogGroupName)
GROUP BY LogGroupName
ORDER BY SUM() DESC LIMIT 10
```

Amazon RDS examples

Top 10 Amazon RDS instances by highest CPU utilization

```
SELECT MAX(CPUUtilization)
FROM SCHEMA("AWS/RDS", DBInstanceIdentifier)
GROUP BY DBInstanceIdentifier
ORDER BY MAX() DESC
LIMIT 10
```

Top 10 Amazon RDS clusters by writes

```
SELECT SUM(WriteIOPS)
FROM SCHEMA("AWS/RDS", DBClusterIdentifier)
GROUP BY DBClusterIdentifier
ORDER BY MAX() DESC
LIMIT 10
```

Amazon Simple Storage Service examples

Average latency by bucket

```
SELECT AVG(TotalRequestLatency)
FROM SCHEMA("AWS/S3", BucketName, FilterId)
WHERE FilterId = 'EntireBucket'
GROUP BY BucketName
ORDER BY AVG() DESC
```

Top 10 buckets by bytes downloaded

```
SELECT SUM(BytesDownloaded)
FROM SCHEMA("AWS/S3", BucketName, FilterId)
```

```
WHERE FilterId = 'EntireBucket'
GROUP BY BucketName
ORDER BY SUM() DESC
LIMIT 10
```

Amazon Simple Notification Service examples

Total messages published by SNS topics

```
SELECT SUM(NumberOfMessagesPublished)
FROM SCHEMA("AWS/SNS", TopicName)
```

Top 10 topics by messages published

```
SELECT SUM(NumberOfMessagesPublished)
FROM SCHEMA("AWS/SNS", TopicName)
GROUP BY TopicName
ORDER BY SUM() DESC
LIMIT 10
```

Top 10 topics by message delivery failures

```
SELECT SUM(NumberOfNotificationsFailed)
FROM SCHEMA("AWS/SNS", TopicName)
GROUP BY TopicName
ORDER BY SUM() DESC
LIMIT 10
```

Amazon SQS examples

Top 10 queues by number of visible messages

```
SELECT AVG(ApproximateNumberOfMessagesVisible)
FROM SCHEMA("AWS/SQS", QueueName)
GROUP BY QueueName
ORDER BY AVG() DESC
LIMIT 10
```

Top 10 most active queues

```
SELECT SUM(NumberOfMessagesSent)
```

```
FROM SCHEMA("AWS/SQS", QueueName)
GROUP BY QueueName
ORDER BY SUM() DESC
LIMIT 10
```

Top 10 queues by age of earliest message

```
SELECT AVG(ApproximateAgeOfOldestMessage)
FROM SCHEMA("AWS/SQS", QueueName)
GROUP BY QueueName
ORDER BY AVG() DESC
LIMIT 10
```

Metrics Insights glossary

label

In Metrics Insights, a label is a key-value pair that is used to scope a query to return a particular set of data, or to define criteria by which query results are to be separated into separate time series. A label key is similar to a column name in SQL. Labels must be CloudWatch metric dimensions.

observation

An observation is a value recorded for a given metric at a given time.

Troubleshooting Metrics Insights

The results include "Other," but I don't have this as a dimension

This means that the query includes a **GROUP BY** clause that specifies a label key that is not used in some of the metrics that are returned by the query. In this case, a null group named `Other` is returned. The metrics that do not include that label key are probably aggregated metrics that return values aggregated across all values of that label key.

For example, suppose you have the following query:

```
SELECT AVG(Faults)
FROM MyCustomNamespace
GROUP BY Operation, ServiceName
```

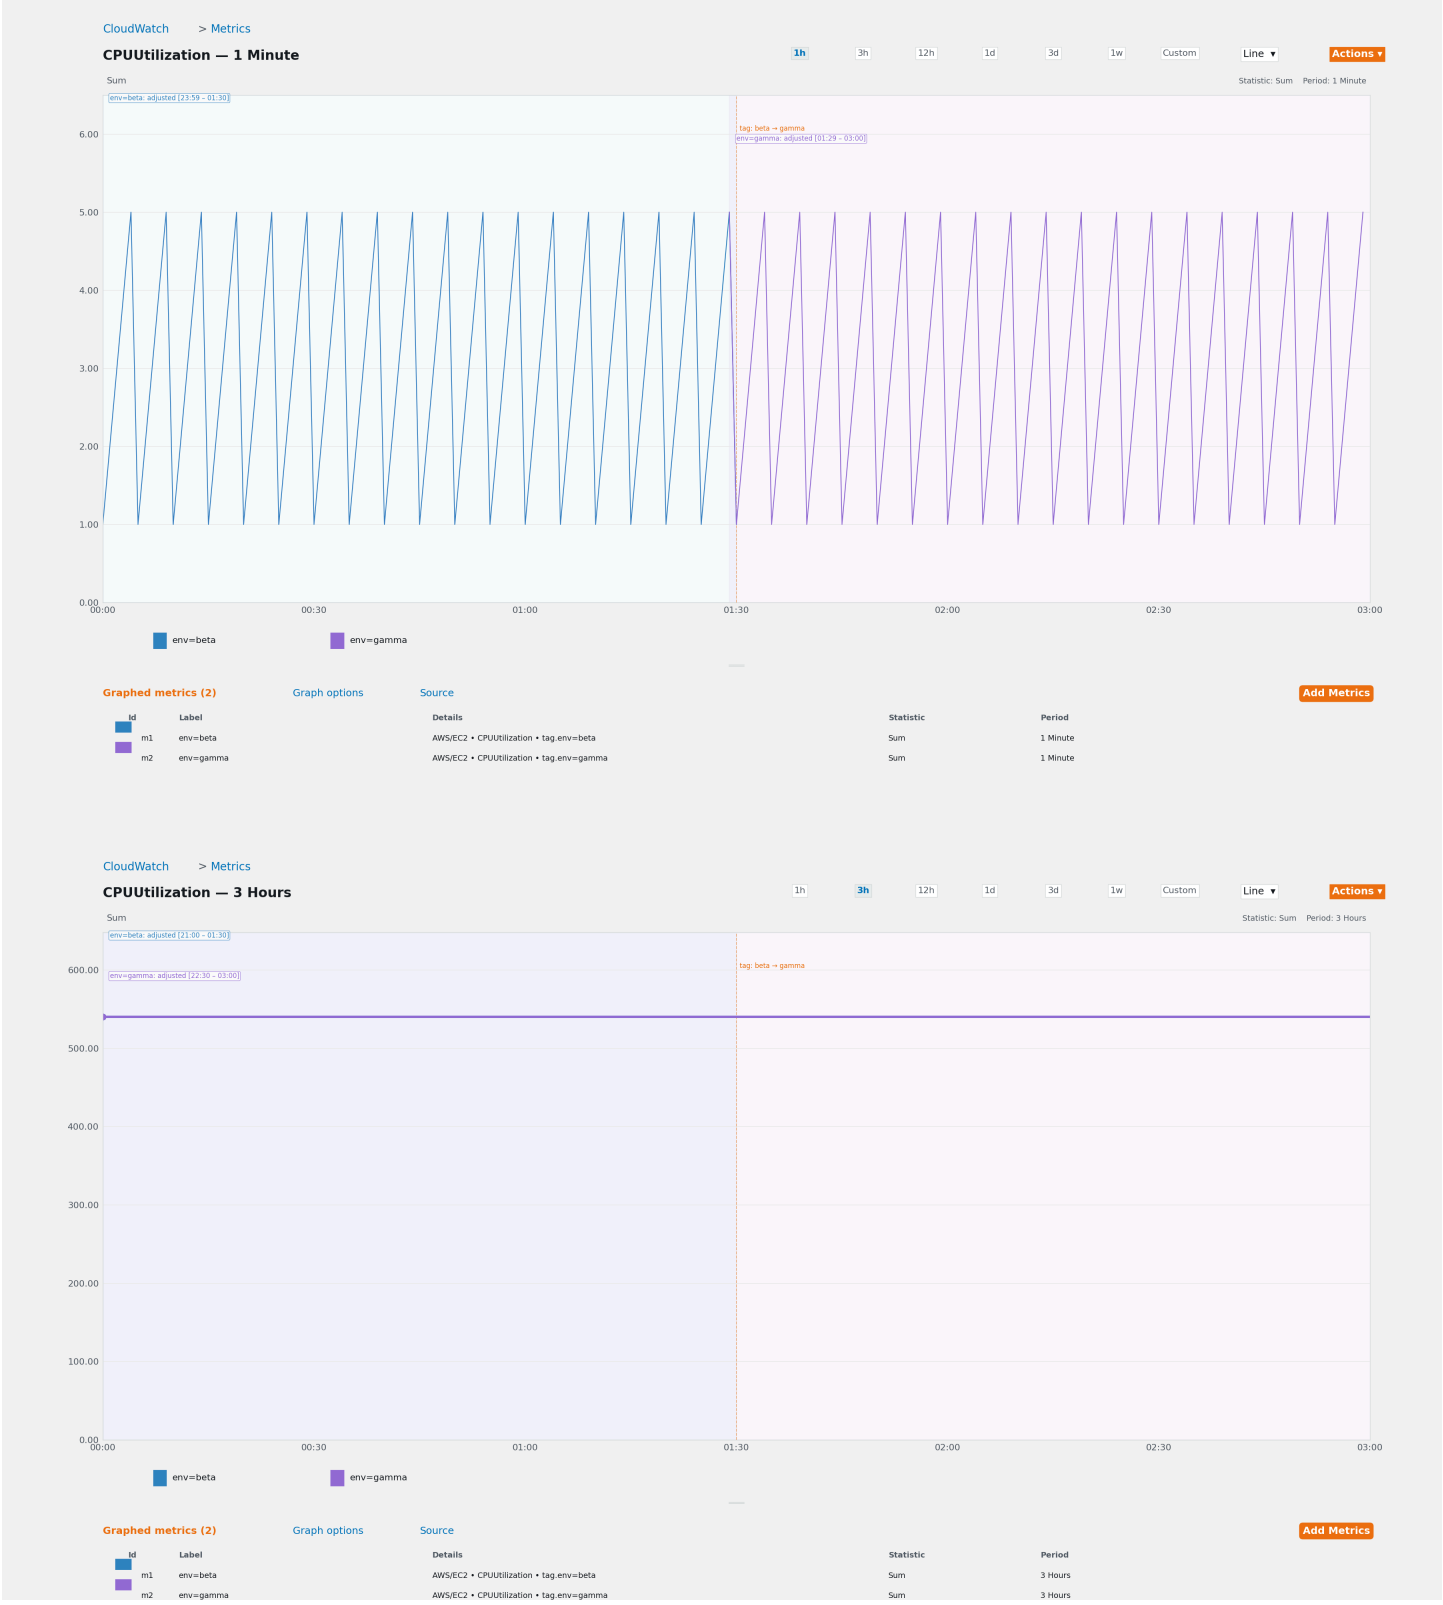
If some of the returned metrics don't include `ServiceName` as a dimension, then those metrics are displayed as having `Other` as the value for `ServiceName`.

To prevent seeing "Other" in your results, use **SCHEMA** in your **FROM** clause, as in the following example:

```
SELECT AVG(Faults)
FROM SCHEMA(MyCustomNamespace, Operation)
GROUP BY Operation, ServiceName
```

This limits the returned results to only the metrics that have both the `Operation` and `ServiceName` dimensions.

The oldest timestamp in my graph has a lower metric value than the others



CloudWatch Metrics Insights supports up to two weeks of historical data. When you graph with a period larger than one minute, there could be cases where the oldest data point differs from the expected value. This is because the CloudWatch Metrics Insights queries return only data within the two-week retention period. In this case, the oldest data point in the query returns only the observations that have been measured within the two-week boundary, instead of returning all the observations within the period of that data point.

Inconsistent metric values across different time periods when using tag-based queries

When you use `WHERE` or `GROUP BY` clauses with tags in CloudWatch Metrics Insights queries, you might see different metric values depending on the selected time period. For example, a 6-hour period might show a peak value of 20, while a 1-hour period shows only 2 for the same time window.

This occurs because tag timestamps are stored with second-level resolution, while metric data points are aligned to period boundaries (for example, the start of each minute or hour). To determine which data points match a tag time range, CloudWatch adjusts the start of the range by subtracting one period. With larger periods, this adjustment creates a wider gap between the tag timestamp and the earliest included data point, which can cause data points near the start of the range to be excluded.

The following example shows how this affects query results. A metric has two tag values: `env=beta` (from 00:00 to 01:30) and `env=gamma` (from 01:30 to 03:00). Each tag covers 90 minutes of data with a SUM of 270.

Source
Add Metrics
Id Label Details Statistic Period
m1 env=beta AWS/EC2 • CPUUtilization • tag.env=beta Sum 3 Hours
m2 env=gamma AWS/EC2 • CPUUtilization • tag.env=gamma Sum 3 Hours

env=beta with 1-minute period			
Statistic	**Expected**	**Returned**	**Difference**
SUM	270	271	+1
AVG	3.0	3.0	0
MIN	1	1	0
MAX	5	5	0
SAMPLE_COUNT	90	91	+1

env=gamma with 1-minute period			
Statistic	**Expected**	**Returned**	**Difference**
SUM	270	275	+5
AVG	3.0	3.0	0
MIN	1	1	0
MAX	5	5	0
SAMPLE_COUNT	90	91	+1

With a 1-minute period, the alignment adjustment is small (1 minute), so only 1 extra data point is included per tag. With a 3-hour period, the adjustment spans the entire query range:

env=beta with 3-hour period			
Statistic	**Expected**	**Returned**	**Difference**
SUM	270	540	+270
AVG	3.0	3.0	0

env=beta with 3-hour period			
Statistic	**Expected**	**Returned**	**Difference**
MIN	1	1	0
MAX	5	5	0
SAMPLE_COUNT	90	180	+90

env=gamma with 3-hour period			
Statistic	**Expected**	**Returned**	**Difference**
SUM	270	540	+270
AVG	3.0	3.0	0
MIN	1	1	0
MAX	5	5	0
SAMPLE_COUNT	90	180	+90

With the 3-hour period, both tags return the entire dataset (SUM=540, SAMPLE_COUNT=180) because the single aggregated data point's timestamp falls within both adjusted ranges. The tag boundary is effectively erased.

To reduce the impact of this behaviour, try the following approaches:

- **Use smaller aggregation periods.** Smaller periods (such as 1 minute or 5 minutes) more closely match the second-level resolution of tag timestamps, which minimizes the alignment gap and makes it more likely that all relevant data points are included.
- **Use dimension-based filtering instead of tags.** If your use case allows it, filter by dimensions rather than tags. Dimension-based queries are not affected by this behaviour. For example, use `WHERE InstanceId = 'i-1234567890abcdef0'` instead of `WHERE tag."my-tag" = 'my-value'`.

- **Query at a consistent granularity.** When comparing metric data across different time windows, use the same period to avoid unexpected differences caused by the alignment adjustment.

View available metrics

Metrics are grouped first by namespace, and then by the various dimension combinations within each namespace. For example, you can view all EC2 metrics, EC2 metrics grouped by instance, or EC2 metrics grouped by Auto Scaling group.

Only the AWS services that you're using send metrics to Amazon CloudWatch.

For a list of AWS services that send metrics to CloudWatch, see AWS services that publish CloudWatch metrics. From this page, you can also see the metrics and dimensions that are published by each of those services.

> **Note**
>
> Metrics that have not had any new data points in the past two weeks do not appear in the console. They also do not appear when you type their metric name or dimension names in the search box in the **Browse** tab in the console. They are not returned in the results of a list-metrics command. The best way to retrieve these metrics is with the get-metric-data or get-metric-statistics commands in the AWS CLI.
> If the old metric you want to view has a current metric with similar dimensions, you can view that current similar metric and then choose the **Source** tab, and change the metric name and dimension fields to the ones that you want, and also change the time range to a time when the metric was being reported.

The following steps help you browse through the metric namespaces to find and view metrics. You can also search for metrics using targeted search terms. For more information, see Search for available metrics.

If you are browsing in an account set up as a monitoring account in CloudWatch cross-account observability, you can view metrics from the source accounts linked to this monitoring account. When metrics from source accounts are displayed, the ID or label of the account that they are from is also displayed. For more information, see CloudWatch cross-account observability.

> **Note**
>
> After the source account stops sharing the metrics with the *Monitoring* account, the *Source* account metrics data is not accessible to the monitoring account. Source metric names can be visible to the monitoring account for upto 14 days.

To view available metrics by namespace and dimension using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Select a metric namespace (for example, **EC2** or **Lambda**).
4. Select a metric dimension (for example, **Per-Instance Metrics** or **By Function Name**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. By each metric name is an information button you can choose to see a pop-up with the metric definition.

   If this is a monitoring account in CloudWatch cross-account observability, you also see the metrics from the source accounts linked to this monitoring account. The **Account label** and **Account id** columns in the table display which account each metric is from.

   You can do the following:

   a. To sort the table, use the column heading.
   b. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.
   c. To filter by account, choose the account label or account ID and then choose **Add to search**.
   d. To filter by resource, choose the resource ID and then choose **Add to search**.
   e. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

To view available metrics by account namespace, dimension, or metric using the AWS CLI

Use the list-metrics command to list CloudWatch metrics. For a list of the namespaces, metrics, and dimensions for all services that publish metrics, see AWS services that publish CloudWatch metrics.

The following example command lists all the metrics for Amazon EC2.

```
aws cloudwatch list-metrics --namespace AWS/EC2
```

The following is example output.

```
{
"Metrics" : [
  ...
  {
      "Namespace": "AWS/EC2",
      "Dimensions": [
          {
              "Name": "InstanceId",
              "Value": "i-1234567890abcdef0"
          }
      ],
      "MetricName": "NetworkOut"
  },
  {
      "Namespace": "AWS/EC2",
      "Dimensions": [
          {
              "Name": "InstanceId",
              "Value": "i-1234567890abcdef0"
          }
      ],
      "MetricName": "CPUUtilization"
  },
  {
      "Namespace": "AWS/EC2",
      "Dimensions": [
          {
              "Name": "InstanceId",
              "Value": "i-1234567890abcdef0"
          }
      ],
      "MetricName": "NetworkIn"
  },
  ...
]
}
```

To list all the available metrics for a specified resource

The following example specifies the AWS/EC2 namespace and the InstanceId dimension to view the results for the specified instance only.

```
aws cloudwatch list-metrics --namespace AWS/EC2 --dimensions
 Name=InstanceId,Value=i-1234567890abcdef0
```

To list a metric for all resources

The following example specifies the AWS/EC2 namespace and a metric name to view the results for the specified metric only.

```
aws cloudwatch list-metrics --namespace AWS/EC2 --metric-name CPUUtilization
```

To retrieve metrics from linked source accounts in CloudWatch cross-account observability

The following example is run in a monitoring account to retrieve metrics from both the monitoring account and all linked source accounts. If you do not add --include-linked-accounts, the command returns only the monitoring account's metrics.

```
aws cloudwatch list-metrics --include-linked-accounts
```

To retrieve metrics from a source account in CloudWatch cross-account observability

The following example is run in a monitoring account to retrieve metrics from the source account with the ID 111122223333.

```
aws cloudwatch list-metrics --include-linked-accounts --owning-account "111122223333"
```

Search for available metrics

You can search within all of the metrics in your account using targeted search terms. Metrics are returned that have matching results within their namespace, metric name, or dimensions.

If this is a monitoring account in CloudWatch cross-account observability, you also search for metrics from the source accounts linked to this monitoring account.

> **Note**
>
> Metrics that have not had any new data points in the past two weeks do not appear in the console. They also do not appear when you type their metric name or dimension names in

the search box in the **Browse** tab in the console. They are not returned in the results of a list-metrics command. The best way to retrieve these metrics is with the get-metric-data or get-metric-statistics commands in the AWS CLI.

To search for available metrics in CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. In the search field, enter a search term, such as a metric name, namespace, account ID, account label, dimension name or value, or resource name. This shows you all of the namespaces with metrics with this search term.

   For example, if you search for **`volume`**, this shows the namespaces that contain metrics with this term in their name.

   For more information on search, see Use search expressions in graphs
4. To graph all the search results, choose **Graph search**

   or

   Select a namespace to view the metrics from that namespace. You can then do the following:

   a. To graph one or more metrics, select the check box next to each metric. To select all metrics, select the check box in the heading row of the table.

   b. To refine your search, hover over a metric name and choose **Add to search** or **Search for this only**.

   c. To view one of the resources on its console, choose the resource ID and then choose **Jump to resource**.

   d. To view help for a metric, select the metric name and choose **What is this?**.

   The selected metrics appear on the graph.

5. (Optional) Select one of the buttons in the search bar to edit that part of the search term.

Retrieve metric data (GetMetricData)

`GetMetricData` is the primary API for retrieving Classic metric data points programmatically. It supports batch queries, math expressions, and queries in a single call.

Basic usage

Retrieve a single metric:

```
aws cloudwatch get-metric-data \
  --metric-data-queries '[
    {
      "Id": "cpu",
      "MetricStat": {
        "Metric": {
          "Namespace": "AWS/EC2",
          "MetricName": "CPUUtilization",
          "Dimensions": [{"Name": "InstanceId", "Value": "i-1234567890abcdef0"}]
        },
        "Period": 300,
        "Stat": "Average"
      }
    }
  ]' \
  --start-time $(date -u -d '1 hour ago' +%Y-%m-%dT%H:%M:%S) \
```

```
  --end-time $(date -u +%Y-%m-%dT%H:%M:%S) \
  --output json
```

Batch queries

Retrieve multiple metrics in a single call (up to 500 queries):

```
aws cloudwatch get-metric-data \
  --metric-data-queries '[
    {"Id": "cpu", "MetricStat": {"Metric": {"Namespace": "AWS/EC2", "MetricName":
 "CPUUtilization", "Dimensions": [{"Name": "InstanceId", "Value": "i-abc"}]}, "Period":
 300, "Stat": "Average"}},
    {"Id": "mem", "MetricStat": {"Metric": {"Namespace": "CWAgent", "MetricName":
 "mem_used_percent", "Dimensions": [{"Name": "InstanceId", "Value": "i-abc"}]},
 "Period": 300, "Stat": "Average"}}
  ]' \
  --start-time 2024-01-01T00:00:00 \
  --end-time 2024-01-01T01:00:00
```

Math expressions

Combine metrics using arithmetic:

```
[
  {"Id": "rx", "MetricStat": {"Metric": {"Namespace": "AWS/EC2", "MetricName":
 "NetworkIn", "Dimensions": [{"Name": "InstanceId", "Value": "i-abc"}]}, "Period": 300,
 "Stat": "Sum"}},
  {"Id": "tx", "MetricStat": {"Metric": {"Namespace": "AWS/EC2", "MetricName":
 "NetworkOut", "Dimensions": [{"Name": "InstanceId", "Value": "i-abc"}]}, "Period":
 300, "Stat": "Sum"}},
  {"Id": "total", "Expression": "rx + tx", "Label": "TotalNetwork"}
]
```

GetMetricData vs GetMetricStatistics

	GetMetricData	GetMetricStatistics
Batch support	Up to 500 queries per call	Single metric per call
Math expressions	Yes	No

	GetMetricData	GetMetricStatistics
queries	Yes	No
Pagination	Yes (NextToken)	No
Recommended	Yes — primary API	Legacy — use GetMetricData instead

Pricing

$0.01 per 1,000 metrics requested through `GetMetricData`.

> **Note**
>
> For OTel metrics, use the Prometheus-compatible query API or CloudWatch Query Studio with PromQL. `GetMetricData` does not query OTel metrics.

Get statistics for a metric (GetMetricStatistics)

`GetMetricStatistics` is the legacy single-metric API. For new code, use Retrieve metric data (GetMetricData) instead — it supports batch queries and math expressions.

Usage

```
aws cloudwatch get-metric-statistics \
  --namespace "AWS/EC2" \
  --metric-name "CPUUtilization" \
  --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
  --start-time $(date -u -d '1 hour ago' +%Y-%m-%dT%H:%M:%S) \
  --end-time $(date -u +%Y-%m-%dT%H:%M:%S) \
  --period 300 \
  --statistics Average Maximum
```

CloudWatch statistics definitions

Statistics are metric data aggregations over specified periods of time. When you graph or retrieve the statistics for a metric, you specify the *Period* of time, such as five minutes, to use to calculate

each statistical value. For example, if the **Period** is five minutes, the **Sum** is the sum of all sample values collected during the five-minute period, while the **Minimum** is the lowest value collected during the five-minute period.

CloudWatch supports the following statistics for metrics.

- **SampleCount** is the number of data points during the period.
- **Sum** is the sum of the values of all the data points collected during the period.
- **Average** is the value of `Sum/SampleCount` during the specified period.
- **Minimum** is the lowest value observed during the specified period.
- **Maximum** is the highest value observed during the specified period.
- **Percentile (p)** indicates the relative standing of a value in a dataset. For example, **p95** is the 95th percentile and means that 95 percent of the data within the period is lower than this value and 5 percent of the data is higher than this value. Percentiles help you get a better understanding of the distribution of your metric data.
- **Trimmed mean (TM)** is the mean of all values that are between two specified boundaries. Values outside of the boundaries are ignored when the mean is calculated. You define the boundaries as one or two numbers between 0 and 100, up to 10 decimal places. The numbers can be absolute values or percentages. For example, **tm90** calculates the average after removing the 10% of data points with the highest values. **TM(2%:98%)** calculates the average after removing the 2% lowest data points and the 2% highest data points. **TM(150:1000)** calculates the average after removing all data points that are lower than or equal to 150, or higher than 1000.
- **Interquartile mean (IQM)** is the trimmed mean of the *interquartile range*, or the middle 50% of values. It is equivalent to **TM(25%:75%)**.
- **Winsorized mean (WM)** is similar to trimmed mean. However, with winsorized mean, the values that are outside the boundary are not ignored, but instead are considered to be equal to the value at the edge of the appropriate boundary. After this normalization, the average is calculated. You define the boundaries as one or two numbers between 0 and 100, up to 10 decimal places. For example, **wm98** calculates the average while treating the 2% of the highest values to be equal to the value at the 98th percentile. **WM(10%:90%)** calculates the average while treating the highest 10% of data points to be the value of the 90% boundary, and treating the lowest 10% of data points to be the value of the 10% boundary.
- **Percentile rank (PR)** is the percentage of values that meet a fixed threshold. For example, **PR(:300)** returns the percentage of data points that have a value of 300 or less. **PR(100:2000)** returns the percentage of data points that have a value between 100 and 2000.

Percentile rank is exclusive on the lower bound and inclusive on the upper bound.

- **Trimmed count (TC)** is the number of data points in the chosen range for a trimmed mean statistic. For example, **tc90** returns the number of data points not including any data points that fall in the highest 10% of the values. **TC(0.005:0.030)** returns the number of data points with values between 0.005 (exclusive) and 0.030 (inclusive).

  Trimmed count can return a decimal value instead of an integer. This is because it is an interpolated, approximate value and can give fractional results.
- **Trimmed sum (TS)** is the sum of the values of data points in a chosen range for a trimmed mean statistic. It is equivalent to (Trimmed Mean) * (Trimmed count). For example, **ts90** returns the sum of the data points not including any data points that fall in the highest 10% of the values. **TS(80%:)** returns the sum of the data point values, not including any data points with values in the lowest 80% of the range of values.

> **Note**
>
> For Trimmed Mean, Trimmed Count, Trimmed Sum, and Winsorized Mean, if you define two boundaries as fixed values instead of percentages, the calculation includes values equal to the higher boundary, but does not include values equal to the lower boundary.

Syntax

For Trimmed Mean, Trimmed Count, Trimmed Sum, and Winsorized Mean, the following syntax rules apply:

- Using parentheses with one or two numbers with percent signs defines the boundaries to use as the values in the data set that fall in between the two percentiles that you specify. For example, **TM(10%:90%)** uses only the values between the 10th and 90th percentiles. **TM(:95%)** uses the values from the lowest end of the data set up to the 95th percentile, ignoring the 5% of data points with the highest values.
- Using parenthesis with one or two numbers without percent signs defines the boundaries to use as the values in the data set that fall in between the explicit values that you specify. For example, **TC(80:500)** uses only the values that are between 80 (exclusive) and 500 (inclusive). **TC(:0.5)** uses only the values that equal 0.5 or are lower.

- Using one number without parentheses calculates using percentages, ignoring data points that are higher than the specified percentile. For example, **tm99** calculates the mean while ignoring the 1% of the data points with the highest value. It is the same as **TM(:99%)**.
- Trimmed mean, Trimmed Count, Trimmed Sum, and Winsorized Mean can all be abbreviated using uppercase letters when specifying a range, such as **TM(5%:95%)**, **TM(100:200)**, or **TM(:95%)**. They can only be abbreviated using lowercase letters when you specifying only one number, such as **tm99**.

Statistics use cases

- **Trimmed mean** is most useful for metrics with a large sample size, such as webpage latency. For example, **tm99** disregards extreme high outliers that could result from network problems or human errors, to give a more accurate number for the average latency of typical requests. Similarly, **TM(10%:)** disregards the lowest 10% of latency values, such as those resulting from cache hits. And **TM(10%:99%)** excludes both of these types of outliers. We recommend that you use trimmed mean for monitoring latency.
- It is a good idea to keep watch on trimmed count whenever you are using trimmed mean, to make sure that the number of values being used in your trimmed mean calculations are enough to be statistically significant.
- Percentile rank enables you to put values into "bins" of ranges, and you can use this to manually create a histogram. To do this, break your values down into various bins, such as **PR(:1)**, **PR(1:5)**, **PR(5:10)**, and **PR(10:)**. Put each of these bins into a visualization as bar charts, and you have a histogram.

  Percentile rank is exclusive on the lower bound and inclusive on the upper bound.

Percentiles versus trimmed mean

A percentile such as **p99** and a trimmed mean such as **tm99** measure similar, but not identical values. Both **p99** and **tm99** ignore the 1% of the data points with the highest values, which are considered outliers. After that, **p99** is the maximum value of the remaining 99%, while **tm99** is the *average* of the remaining 99%. If you are looking at the latency of web requests, **p99** tells you the worst customer experience, ignoring outliers, while **tm99** tells you the average customer experience, ignoring outliers.

Trimmed mean is a good latency statistic to watch if you are looking to optimize your customer experience.

Requirements to use percentiles, trimmed mean, and some other statistics

CloudWatch needs raw data points to calculate the following statistics:

- Percentiles
- Trimmed mean
- Interquartile mean
- Winsorized mean
- Trimmed sum
- Trimmed count
- Percentile rank

If you publish data for a custom statistics using a statistic set instead of raw data, you can retrieve these types of statistics for this data only if one of the following conditions is true:

- The SampleCount value of the statistic set is 1 and Min, Max, and Sum are all equal.
- The Min and Max are equal, and Sum is equal to Min multiplied by SampleCount.

The following AWS services include metrics that support these types of statistics.

- API Gateway
- Application Load Balancer
- Amazon EC2
- Elastic Load Balancing
- Kinesis
- Amazon RDS

Additionally, these type of statistics are not available for metrics when any of the metric values are negative numbers.

When to use this API

- Legacy applications that already depend on it
- Simple single-metric retrievals where batch isn't needed

For everything else, use Retrieve metric data (GetMetricData).

Use metrics explorer to monitor resources by their tags and properties

Metrics explorer is a tag-based tool that enables you to filter, aggregate, and visualize your metrics by tags and resource properties, to enhance observability for your services. This gives you a flexible and dynamic troubleshooting experience, so that you can create multiple graphs at a time and use these graphs to build your application health dashboards.

Metrics explorer visualizations are dynamic, so if a matching resource is created after you create a metrics explorer widget and add it to a CloudWatch dashboard, the new resource automatically appears in the explorer widget.

For example, if all of your EC2 production instances have the **`production`** tag, you can use metrics explorer to filter and aggregate metrics from all of these instances to understand their health and performance. If a new instance with a matching tag is later created, it's automatically added to the metrics explorer widget.

> **Note**
>
> Metrics explorer provides a point-in-time experience. Resources that have been terminated, or no longer exist with the property or tag that you specified are not displayed in the visualisation. However, you can still find the metrics for these resources in CloudWatch metrics views.

With metrics explorer, you can choose how to aggregate metrics from the resources that match the criteria, and whether to show them all in a single graph or on different graphs within one metrics explorer widget.

Metrics explorer includes templates that you can use to see useful visualization graphs with a single selection, and you can also extend these templates to create completely customized metrics explorer widgets.

You can use metrics explorer across accounts if you are using the Cross-account cross-Region CloudWatch console. However, metrics explorer is not supported for cross-account use from a monitoring account in CloudWatch cross-account observability.

Metrics explorer supports metrics emitted by AWS and EC2 metrics that are published by the CloudWatch agent, including memory, disk, and CPU metrics. To use metrics explorer to see the

metrics that are published by the CloudWatch agent, you might have to update your CloudWatch agent configuration file. For more information, see CloudWatch agent configuration for metrics explorer

To create a visualization with metrics explorer and optionally add it to a dashboard, follow these steps.

To create a visualization with metrics explorer

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Explorer**.
3. Do one of the following:
   - To use a template, select it in the box that currently shows **Empty Explorer**.

     Depending on the template, the explorer might immediately display graphs of metrics. If it doesn't, choose one or more tags or properties in the **From** box and then data should appear. If it doesn't, use the options at the top of the page to display a longer time range in the graphs.
   - To create a custom visualization, under **Metrics**, choose a single metric or all the available metrics from a service.

     After you choose a metric, you can optionally repeat this step to add more metrics.
4. For each metric selected, CloudWatch displays the statistic that it will use immediately after the metric name. To change this, choose the statistic name, and then choose the statistic that you want.
5. Under **From**, choose a tag or a resource property to filter your results.

   After you do this, you can optionally repeat this step to choose more tags or resource properties.

   If you choose multiple values of the same property, such as two EC2 instance types, the explorer displays all the resources that match either chosen property. It's treated as an OR operation.

   If you choose different properties or tags, such as the **`Production`** tag and the M5 instance type, only the resources that match all of these selections are displayed. It's treated as an AND operation.

6. (Optional) For **Aggregate by**, choose a statistic to use to aggregate the metrics. Then, next to **for**, choose how to aggregate the metric from the list. You can aggregate together all the resources that are currently displayed, or aggregate by a single tag or resource property.

   Depending on how you choose to aggregate, the result may be a single time series or multiple time series.
7. Under **Split by**, you can choose to split a single graph with multiple time series into multiple graphs. The split can be made by a variety of criteria, which you choose under **Split by**.
8. Under **Graph options**, you can refine the graph by changing the period, the type of graph, the legend placement, and the layout.
9. To add this visualization as a widget to a CloudWatch dashboard, choose **Add to dashboard**.

CloudWatch agent configuration for metrics explorer

To enable metrics explorer to discover EC2 metrics published by the CloudWatch agent, make sure that the CloudWatch agent configuration file contains the following values:

- In the `metrics` section, make sure that the `aggregation_dimensions` parameter includes `["InstanceId"]`. It can also contain other dimensions.
- In the `metrics` section, make sure that the `append_dimensions` parameter includes a `{"InstanceId":"${aws:InstanceId}"}` line. It can also contain other lines.
- In the `metrics` section, inside the `metrics_collected` section, check the sections for each resource type that you want metrics explorer to discover, such as the `cpu`, `disk`, and `memory` sections. Make sure that each of these sections has a `"resources": [ "*"] line.`.
- In the `cpu` section of the `metrics_collected` section, make sure there is a `"totalcpu": true` line.
- You must use the default `CWAgent` namespace for the metrics collected by the CloudWatch agent, instead of a custom namespace.

The settings in the previous list cause the CloudWatch agent to publish aggregate metrics for disks, CPUs, and other resources that can be plotted in metrics explorer for all the instances that use it.

These settings will republish the metrics that you had previously set up to be published with multiple dimensions, adding to your metric costs.

For more information about editing the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

Use search expressions in graphs

Search expressions are a type of math expression that you can add to CloudWatch graphs. Search expressions enable you to quickly add multiple related metrics to a graph. They also enable you to create dynamic graphs that automatically add appropriate metrics to their display, even if those metrics don't exist when you first create the graph.

For example, you can create a search expression that displays the `AWS/EC2 CPUUtilization` metric for all instances in the Region. If you later launch a new instance, the `CPUUtilization` of the new instance is automatically added to the graph.

When you use a search expression in a graph, the search finds the search expression in metric names, namespaces, dimension names, and dimension values. You can use Boolean operators for more complex and powerful searches. A search expression can find only metrics that have reported data within the past two weeks.

You can't create an alarm based on the **SEARCH** expression. This is because search expressions return multiple time series, and an alarm based on a math expression can watch only one time series.

If you are using a monitoring account in CloudWatch cross-account observability, your search expressions can find metrics in the source accounts linked to that monitoring account.

Topics

- CloudWatch search expression syntax
- CloudWatch search expression examples
- Create a CloudWatch graph with a search expression

CloudWatch search expression syntax

A valid search expression has the following format.

```
SEARCH(' {Namespace, DimensionName1, DimensionName2, ...} SearchTerm', 'Statistic')
```

For example:

```
SEARCH('{AWS/EC2,InstanceId} MetricName="CPUUtilization"', 'Average')
```

- The first part of the query after the word SEARCH, enclosed in curly braces, is the *metric schema* to be searched. The metric schema contains a metric namespace and one or more dimension names. Including a metric schema in a search query is optional. If specified, the metric schema must contain a namespace and can optionally contain one or more dimension names that are valid in that namespace.

  You don't need to use quote marks inside the metric schema unless a namespace or dimension name includes spaces or non-alphanumeric characters. In that case, you must enclose the name that contains those characters with double quotes.

- The `SearchTerm` is also optional, but a valid search must contain either the metric schema, the `SearchTerm`, or both. The `SearchTerm` usually contains one or more account IDs, metric names or dimension values. The `SearchTerm` can include multiple terms to search for, by both partial match and exact match. It can also contain Boolean operators.

  Using an account ID in a `SearchTerm` works only in accounts that are set up as monitoring accounts for CloudWatch cross-account observability. The syntax for an account ID in `SearchTerm` is `:aws.AccountId = 444455556666`. You can also use `'LOCAL'` to specify the monitoring account itself: `:aws.AccountId = 'LOCAL'`

  For more information, see CloudWatch cross-account observability.

  The `SearchTerm` can include one or more designators, such as `MetricName=` as in this example, but using designators isn't required.

  The metric schema and `SearchTerm` must be enclosed together in a pair of single quote marks.

- The `Statistic` is the name of any valid CloudWatch statistic. It must be enclosed by single quotes. For more information, see Statistics.

The preceding example searches the `AWS/EC2` namespace for any metrics that have `InstanceId` as a dimension name. It returns all `CPUUtilization` metrics that it finds, with the graph showing the `Average` statistic.

A search expression can find only metrics that have reported data within the past two weeks.

Search expression limits

The maximum search expression query size is 1024 characters. You can have as many as 100 search expressions on one graph. A graph can display as many as 500 time series.

CloudWatch search expressions: Tokenization

When you specify a `SearchTerm`, the search function searches for *tokens*, which are substrings that CloudWatch automatically generates from full metric names, dimension names, dimension values, and namespaces. CloudWatch generates tokens distinguished by the camel-case capitalization in the original string. Numeric characters also serve as the start of new tokens, and non-alphanumeric characters serve as delimiters, creating tokens before and after the non-alphanumeric characters.

A continuous string of the same type of token delimiter character results in one token.

All generated tokens are in lowercase. The following table shows some examples of tokens generated.

Original string	Tokens generated
CustomCount1	`customcount1` , `custom`, `count`, `1`
SDBFailure	`sdbfailure` , `sdb`, `failure`
Project2-trial333	`project2trial333` , `project`, `2`, `trial`, `333`

CloudWatch search expressions: Partial matches

When you specify a `SearchTerm`, the search term is also tokenized. CloudWatch finds metrics based on partial matches, which are matches of a single token generated from the search term to a single token generated from a metric name, namespace, dimension name, or dimension value.

Partial match searches to match a single token are case insensitive. For example, using any of the following search terms can return the `CustomCount1` metric:

- `count`
- `Count`
- `COUNT`

However, using `couNT` as a search term doesn't find `CustomCount1` because the capitalization in the search term `couNT` is tokenized into `cou` and `NT`.

Searches can also match composite tokens, which are multiple tokens that appear consecutively in the original name. To match a composite token, the search is case sensitive. For example, if the original term is `CustomCount1`, searches for `CustomCount` or `Count1` are successful, but searches for `customcount` or `count1` aren't.

CloudWatch search expressions: Exact matches

You can define a search to find only exact matches of your search term by using double quotes around the part of the search term that requires an exact match. These double-quotes are enclosed in the single-quotes used around the entire search term. For example, **`SEARCH(' {MyNamespace}, "CustomCount1" ', 'Maximum')`** finds the exact string `CustomCount1` if it exists as a metric name, dimension name, or dimension value in the namespace named `MyNamespace`. However, the searches **`SEARCH(' {MyNamespace}, "customcount1" ', 'Maximum')`** or **`SEARCH(' {MyNamespace}, "Custom" ', 'Maximum')`** do not find this string.

You can combine partial match terms and exact match terms in a single search expression. For example, **`SEARCH(' {AWS/NetworkELB, LoadBalancer} "ConsumedLCUs" OR flow ', 'Maximum')`** returns the Elastic Load Balancing metric named `ConsumedLCUs` as well as all Elastic Load Balancing metrics or dimensions that contain the token `flow`.

Using exact match is also a good way to find names with special characters, such as non-alphanumeric characters or spaces, as in the following example.

```
SEARCH(' {"My Namespace", "Dimension@Name"}, "Custom:Name[Special_Characters" ',
 'Maximum')
```

CloudWatch search expressions: Excluding a metric schema

All examples shown so far include a metric schema, in curly braces. Searches that omit a metric schema are also valid.

For example, **`SEARCH(' "CPUUtilization" ', 'Average')`** returns all metric names, dimension names, dimension values, and namespaces that are an exact match for the string `CPUUtilization`. In the AWS metric namespaces, this can include metrics from several services including Amazon EC2, Amazon ECS, SageMaker AI, and others.

To narrow this search to only one AWS service, the best practice is to specify the namespace and any necessary dimensions in the metric schema, as in the following example. Although this narrows the search to the AWS/EC2 namespace, it would still return results of other metrics if you have defined CPUUtilization as a dimension value for those metrics.

```
SEARCH(' {AWS/EC2, InstanceType} "CPUUtilization" ', 'Average')
```

Alternatively you could add the namespace in the SearchTerm as in the following example. But in this example, the search would match any AWS/EC2 string, even if it was a custom dimension name or value.

```
SEARCH(' "AWS/EC2" MetricName="CPUUtilization" ', 'Average')
```

CloudWatch search expressions: Specifying property names in the search

The following exact match search for "CustomCount1" returns all metrics with exactly that name.

```
SEARCH(' "CustomCount1" ', 'Maximum')
```

But it also returns metrics with dimension names, dimension values, or namespaces of CustomCount1. To structure your search further, you can specify the property name of the type of object that you want to find in your searches. The following example searches all namespaces and returns metrics named CustomCount1.

```
SEARCH(' MetricName="CustomCount1" ', 'Maximum')
```

You can also use namespaces and dimension name/value pairs as property names, as in the following examples. The first of these examples also illustrates that you can use property names with partial match searches as well.

```
SEARCH(' InstanceType=micro ', 'Average')
```

```
SEARCH(' InstanceType="t2.micro" Namespace="AWS/EC2" ', 'Average')
```

CloudWatch search expressions: Non-alphanumeric characters

Non-alphanumeric characters serve as delimiters, and mark where the names of metrics, dimensions, namespaces, and search terms are to be separated into tokens. When terms are

tokenized, non-alphanumeric characters are stripped out and don't appear in the tokens. For example, `Network-Errors_2` generates the tokens `network`, `errors`, and `2`.

Your search term can include any non-alphanumeric characters. If these characters appear in your search term, they can specify composite tokens in a partial match. For example, all of the following searches would find metrics named either `Network-Errors-2` or `NetworkErrors2`.

```
network/errors
network+errors
network-errors
Network_Errors
```

When you're doing an exact value search, any non-alphanumeric characters used in the exact search must be the correct characters that appear in the string being searched for. For example, if you want to find `Network-Errors-2`, searching for `"Network-Errors-2"` is successful, but a search for `"Network_Errors_2"` isn't.

When you perform an exact match search, the following characters must be escaped with a backslash.

```
" \ ( )
```

For example, to find the metric name `Europe\France Traffic(Network)` by exact match, use the search term **`"Europe\\France Traffic\(Network\)"`**

CloudWatch search expressions: Boolean operators

Search supports the use of the Boolean operators `AND`, `OR`, and `NOT` within the `SearchTerm`. Boolean operators are enclosed in the single quote marks that you use to enclose the entire search term. Boolean operators are case sensitive, so `and`, `or`, and `not` aren't valid as Boolean operators.

You can use `AND` explicitly in your search, such as **`SEARCH('{AWS/EC2,InstanceId} network AND packets', 'Average')`**. Not using any Boolean operator between search terms implicitly searches them as if there were an `AND` operator, so **`SEARCH(' {AWS/EC2,InstanceId} network packets ', 'Average')`** yields the same search results.

Use `NOT` to exclude subsets of data from the results. For example, **`SEARCH(' {AWS/EC2,InstanceId} MetricName="CPUUtilization" NOT i-1234567890123456 ', 'Average')`** returns the `CPUUtilization` for all your instances, except for the instance

i-1234567890123456. You can also use a NOT clause as the only search term. For example, **SEARCH('NOT Namespace=AWS ', 'Maximum')** yields all your custom metrics (metrics with namespaces that don't include AWS).

You can use multiple NOT phrases in a query. For example, **SEARCH(' {AWS/EC2,InstanceId} MetricName="CPUUtilization" NOT "ProjectA" NOT "ProjectB" ', 'Average')** returns the CPUUtilization of all instances in the Region, except for those with dimension values of ProjectA or ProjectB.

You can combine Boolean operators for more powerful and detailed searches, as in the following examples. Use parentheses to group the operators.

Both of the next two examples return all metric names containing ReadOps from both the EC2 and EBS namespaces.

```
SEARCH(' (EC2 OR EBS) AND MetricName=ReadOps ', 'Maximum')
```

```
SEARCH(' (EC2 OR EBS) MetricName=ReadOps ', 'Maximum')
```

The following example narrows the previous search to only results that include ProjectA, which could be the value of a dimension.

```
SEARCH(' (EC2 OR EBS) AND ReadOps AND ProjectA ', 'Maximum')
```

The following example uses nested grouping. It returns Lambda metrics for Errors from all functions, and Invocations of functions with names that include the strings ProjectA or ProjectB.

```
SEARCH(' {AWS/Lambda,FunctionName} MetricName="Errors" OR (MetricName="Invocations" AND
 (ProjectA OR ProjectB)) ', 'Average')
```

CloudWatch search expressions: Using math expressions

You can use a search expression within a math expressions in a graph.

For example, **SUM(SEARCH(' {AWS/Lambda, FunctionName} MetricName="Errors" ', 'Sum'))** returns the sum of the Errors metric of all your Lambda functions.

Using separate lines for your search expression and math expression might yield more useful results. For example, suppose that you use the following two expressions in a graph. The first line displays separate `Errors` lines for each of your Lambda functions. The ID of this expression is `e1`. The second line adds another line showing the sum of the errors from all of the functions.

```
SEARCH(' {AWS/Lambda, FunctionName}, MetricName="Errors" ', 'Sum')
SUM(e1)
```

CloudWatch search expression examples

The following examples illustrate more search expression uses and syntax. Let's start with a search for `CPUUtilization` across all instances in the Region and then look at variations.

This example displays one line for each instance in the Region, showing the `CPUUtilization` metric from the `AWS/EC2` namespace.

```
SEARCH(' {AWS/EC2,InstanceId} MetricName="CPUUtilization" ', 'Average')
```

Changing `InstanceId` to `InstanceType` changes the graph to show one line for each instance type used in the Region. Data from all instances of each type is aggregated into one line for that instance type.

```
SEARCH(' {AWS/EC2,InstanceType} MetricName="CPUUtilization" ', 'Average')
```

The following example aggregates the `CPUUtilization` by instance type and displays one line for each instance type that includes the string `micro`.

```
SEARCH('{AWS/EC2,InstanceType} InstanceType=micro MetricName="CPUUtilization" ',
 'Average')
```

This example narrows the previous example, changing the `InstanceType` to an exact search for t2.micro instances.

```
SEARCH('{AWS/EC2,InstanceType} InstanceType="t2.micro" MetricName="CPUUtilization" ',
 'Average')
```

The following search removes the `{metric schema}` part of the query, so the `CPUUtilization` metric from all namespaces appears in the graph. This can return quite a few results because the

graph includes multiple lines for the CPUUtilization metric from each AWS service, aggregated along different dimensions.

```
SEARCH('MetricName="CPUUtilization" ', 'Average')
```

To narrow these results a bit, you can specify two specific metric namespaces.

```
SEARCH('MetricName="CPUUtilization" AND ("AWS/ECS" OR "AWS/ES") ', 'Average')
```

The preceding example is the only way to do a search of specific multiple namespaces with one search query, as you can specify only one metric schema in each query. However, to add more structure, you could use two queries in the graph, as in the following example. This example also adds more structure by specifying a dimension to use to aggregate the data for Amazon ECS.

```
SEARCH('{AWS/ECS ClusterName}, MetricName="CPUUtilization" ', 'Average')
SEARCH(' {AWS/EBS} MetricName="CPUUtilization" ', 'Average')
```

The following example returns the Elastic Load Balancing metric named ConsumedLCUs as well as all Elastic Load Balancing metrics or dimensions that contain the token flow.

```
SEARCH('{AWS/NetworkELB, LoadBalancer} "ConsumedLCUs" OR flow ', 'Maximum')
```

The following example uses nested grouping. It returns Lambda metrics for Errors from all functions and Invocations of functions with names that include the strings ProjectA or ProjectB.

```
SEARCH('{AWS/Lambda,FunctionName} MetricName="Errors" OR (MetricName="Invocations" AND
 (ProjectA OR ProjectB)) ', 'Average')
```

The following example displays all of your custom metrics, excluding metrics generated by AWS services.

```
SEARCH('NOT Namespace=AWS ', 'Average')
```

The following example displays metrics with metric names, namespaces, dimension names, and dimension values that contain the string Errors as part of their name.

```
SEARCH('Errors', 'Average')
```

The following example narrows that search to exact matches. For example, this search finds the metric name `Errors` but not metrics named `ConnectionErrors` or `errors`.

```
SEARCH(' "Errors" ', 'Average')
```

The following example shows how to specify names that contain spaces or special characters in the metric schema part of the search term.

```
SEARCH('{"Custom-Namespace", "Dimension Name With Spaces"}, ErrorCount ', 'Maximum')
```

CloudWatch cross-account observability search expression examples

CloudWatch cross-account observability examples

If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can use the **SEARCH** function to return metrics from specified source accounts. For more information, see CloudWatch cross-account observability.

The following example retrieves all Lambda metrics from the account with the account ID 111122223333.

```
SEARCH(' AWS/Lambda :aws.AccountId = 111122223333 ', 'Average')
```

The following example retrieves all `AWS/EC2` metrics from two accounts: 111122223333 and 777788889999.

```
SEARCH(' AWS/EC2 :aws.AccountId = (111122223333 OR 777788889999) ', 'Average')
```

The following example retrieves all `AWS/EC2` metrics from the source account 111122223333 and from the monitoring account itself.

```
SEARCH(' AWS/EC2 :aws.AccountId = (111122223333 OR 'LOCAL') ', 'Average')
```

The following example retrieves the `SUM` of the `MetaDataToken` metric from the account `444455556666` with the `InstanceId` dimension.

```
SEARCH('{AWS/EC2,InstanceId} :aws.AccountId=444455556666 MetricName=\"MetadataNoToken
\"','Sum')
```

Create a CloudWatch graph with a search expression

On the CloudWatch console, you can access search capability when you add a graph to a dashboard, or by using the **Metrics** view.

You can't create an alarm based on a **SEARCH** expression. This is because search expressions return multiple time series, and an alarm based on a math expression can watch only one time series.

To add a graph with a search expression to an existing dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards** and select a dashboard.
3. Choose **Add widget**.
4. Choose either **Line** or **Stacked area** and choose **Configure**.
5. On the **Graphed metrics** tab, choose **Add a math expression**.
6. For **Details**, enter the search expression that you want. For example, **`SEARCH('{AWS/EC2,InstanceId} MetricName="CPUUtilization"', 'Average')`**
7. (Optional) To add another search expression or math expression to the graph, choose **Add a math expression**
8. (Optional) After you add a search expression, you can specify a dynamic label to appear on the graph legend for each metric. Dynamic labels display a statistic about the metric and automatically update when the dashboard or graph is refreshed. To add a dynamic label, choose **Graphed metrics** and then **Dynamic labels**.

   By default, the dynamic values you add to the label appear at the beginning of the label. You can then choose the **Label** value for the metric to edit the label. For more information, see Use dynamic labels.
9. (Optional) To add a single metric to the graph, choose the **All metrics** tab and drill down to the metric you want.
10. (Optional) To change the time range shown on the graph, choose either **custom** at the top of the graph or one of the time periods to the left of **custom**.
11. (Optional) Horizontal annotations help dashboard users quickly see when a metric has spiked to a certain level or whether the metric is within a predefined range. To add a horizontal annotation, choose **Graph options** and then **Add horizontal annotation**:

    a. For **Label**, enter a label for the annotation.

b. For **Value**, enter the metric value where the horizontal annotation appears.

c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose `Above` or `Below` for the corresponding area to be filled. If you specify `Between`, another `Value` field appears, and the area of the graph between the two values is filled.

d. For **Axis**, specify whether the numbers in `Value` refer to the metric associated with the left y-axis or the right y-axis if the graph includes multiple metrics.

You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

Repeat these steps to add multiple horizontal annotations to the same graph.

To hide an annotation, clear the check box in the left column for that annotation.

To delete an annotation, choose **x** in the **Actions** column.

12. (Optional) Vertical annotations help you mark milestones in a graph, such as operational events or the beginning and end of a deployment. To add a vertical annotation, choose **Graph options** and then **Add vertical annotation**:

a. For **Label**, enter a label for the annotation. To show only the date and time on the annotation, keep the **Label** field blank.

b. For **Date**, specify the date and time where the vertical annotation appears.

c. For **Fill**, specify whether to use fill shading before or after a vertical annotation or between two vertical annotations. For example, choose `Before` or `After` for the corresponding area to be filled. If you specify `Between`, another `Date` field appears, and the area of the graph between the two values is filled.

Repeat these steps to add multiple vertical annotations to the same graph.

To hide an annotation, clear the check box in the left column for that annotation.

To delete an annotation, choose **x** in the **Actions** column.

13. Choose **Create widget**.

14. Choose **Save dashboard**.

To use the Metrics view to graph searched metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. In the search field, enter the tokens to search for: for example, **`cpuutilization t2.small`**.

   Results that match your search appear.
4. To graph all of the metrics that match your search, choose **Graph search**.

   or

   To refine your search, choose one of the namespaces that appeared in your search results.
5. If you selected a namespace to narrow your results, you can do the following:

   a. To graph one or more metrics, select the check box next to each metric. To select all metrics, select the check box in the heading row of the table.
   b. To refine your search, hover over a metric name and choose **Add to search** or **Search for this only**.
   c. To view help for a metric, select the metric name and choose **What is this?**.

   The selected metrics appear on the graph.
6. (Optional) Select one of the buttons in the search bar to edit that part of the search term.
7. (Optional) To add the graph to a dashboard, choose **Actions** and then **Add to dashboard**.

Use metric streams

You can use *metric streams* to continually stream CloudWatch metrics to a destination of your choice, with near-real-time delivery and low latency. Supported destinations include AWS destinations such as Amazon Simple Storage Service and several third-party service provider destinations.

There are three main usage scenarios for CloudWatch metric streams:

- **Custom setup with Firehose**— Create a metric stream and direct it to an Amazon Data Firehose delivery stream that delivers your CloudWatch metrics to where you want them to go. You can stream them to a data lake such as Amazon S3, or to any destination or endpoint supported by Firehose including third-party providers. JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0

formats are supported natively, or you can configure transformations in your Firehose delivery stream to convert the data to a different format such as Parquet. With a metric stream, you can continually update monitoring data, or combine this CloudWatch metric data with billing and performance data to create rich datasets. You can then use tools such as Amazon Athena to get insight into cost optimization, resource performance, and resource utilization.

- **Quick S3 setup**— Stream to Amazon Simple Storage Service with a quick setup process. By default, CloudWatch creates the resources needed for the stream. JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0 formats are supported.
- **Quick AWS partner setup**— CloudWatch provides a quick setup experience for some third-party partners. You can use third-party service providers to monitor, troubleshoot, and analyze your applications using the streamed CloudWatch data. When you use the quick partner setup workflow, you need to provide only a destination URL and API key for your destination, and CloudWatch handles the rest of the setup. Quick partner setup is available for the following third-party providers:

  - Datadog
  - Dynatrace
  - Elastic
  - New Relic
  - Splunk Observability Cloud
  - SumoLogic

You can stream all of your CloudWatch metrics, or use filters to stream only specified metrics. Each metric stream can include up to 1000 filters that either include or exclude metric namespaces or specific metrics. A single metric stream can have only include or exclude filters, but not both.

After a metric stream is created, if new metrics are created that match the filters in place, the new metrics are automatically included in the stream.

There is no limit on the number of metric streams per account or per Region, and no limit on the number of metric updates being streamed.

Each stream can use either JSON format, OpenTelemetry 1.0.0, or OpenTelemetry 0.7.0 format. You can edit the output format of a metric stream at any time, such as for upgrading from OpenTelemetry 0.7.0 to OpenTelemetry 1.0.0. For more information about output formats, see CloudWatch metric stream output in JSON format, CloudWatch metric stream output in

OpenTelemetry 1.0.0 format, and CloudWatch metric stream output in OpenTelemetry 0.7.0 format.

For metric streams in monitoring accounts, you can choose whether to include metrics from the source accounts linked to that monitoring account. For more information, see CloudWatch cross-account observability.

Metric streams always include the `Minimum`, `Maximum`, `SampleCount`, and `Sum` statistics. You can also choose to include additional statistics at an additional charge. For more information, see Statistics that can be streamed.

Metric streams pricing is based on the number of metric updates. You also incur charges from Firehose for the delivery stream used for the metric stream. For more information, see Amazon CloudWatch Pricing.

Topics

- Set up a metric stream
- Statistics that can be streamed
- Metric stream operation and maintenance
- Monitoring your metric streams with CloudWatch metrics
- Trust between CloudWatch and Firehose
- CloudWatch metric stream output in JSON format
- CloudWatch metric stream output in OpenTelemetry 1.0.0 format
- CloudWatch metric stream output in OpenTelemetry 0.7.0 format
- Troubleshooting metric streams in CloudWatch

Set up a metric stream

Use the steps in the following sections to set up a CloudWatch metric stream.

After a metric stream is created, the time it takes for metric data to appear at the destination depends on the configured buffering settings on the Firehose delivery stream. The buffering is expressed in maximum payload size or maximum wait time, whichever is reached first. If these are set to the minimum values (60 seconds, 1MB) the expected latency is within 3 minutes if the selected CloudWatch namespaces have active metric updates.

In a CloudWatch metric stream, data is sent every minute. Data might arrive at the final destination out of order. All specified metrics in the specified namespaces are sent in the metric stream, except metrics with a timestamp that is more than two days old.

For each combination of metric name and namespace that you stream, all dimension combinations of that metric name and namespace are streamed.

For metric streams in monitoring accounts, you can choose whether to include metrics from the source accounts linked to that monitoring account. For more information, see CloudWatch cross-account observability.

To create and manage metric streams, you must be logged on to an account that has the **CloudWatchFullAccess** policy and the `iam:PassRole` permission, or an account that has the following list of permissions:

- `iam:PassRole`
- `cloudwatch:PutMetricStream`
- `cloudwatch:DeleteMetricStream`
- `cloudwatch:GetMetricStream`
- `cloudwatch:ListMetricStreams`
- `cloudwatch:StartMetricStreams`
- `cloudwatch:StopMetricStreams`

If you're going to have CloudWatch set up the IAM role needed for metric streams, you must also have the `iam:CreateRole` and `iam:PutRolePolicy` permissions.

> **Important**
>
> A user with the `cloudwatch:PutMetricStream` has access to the CloudWatch metric data that is being streamed, even if they don't have the `cloudwatch:GetMetricData` permission.

Topics

- Custom setup with Firehose
- Use Quick Amazon S3 setup
- Quick partner setup

Custom setup with Firehose

Use this method to create a metric stream and direct it to an Amazon Data Firehose delivery stream that delivers your CloudWatch metrics to where you want them to go. You can stream them to a data lake such as Amazon S3, or to any destination or endpoint supported by Firehose including third-party providers.

JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0 formats are supported natively, or you can configure transformations in your Firehose delivery stream to convert the data to a different format such as Parquet. With a metric stream, you can continually update monitoring data, or combine this CloudWatch metric data with billing and performance data to create rich datasets. You can then use tools such as Amazon Athena to get insight into cost optimization, resource performance, and resource utilization.

You can use the CloudWatch console, the AWS CLI, AWS CloudFormation, or the AWS Cloud Development Kit (AWS CDK) to set up a metric stream.

The Firehose delivery stream that you use for your metric stream must be in the same account and the same Region where you set up the metric stream. To achieve cross-Region functionality, you can configure the Firehose delivery stream to stream to a final destination that is in a different account or a different Region.

CloudWatch console

This section describes how to use the CloudWatch console to set up a metric stream using Firehose.

To set up a custom metric stream using Firehose

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **Streams**. Then choose **Create metric stream**.
3. (Optional) If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can choose whether to include metrics from linked source accounts in this metric stream. To include metrics from source accounts, choose **Include source account metrics**.
4. Choose **Custom setup with Firehose**.
5. For **Select your Kinesis Data Firehose stream**, select the Firehose delivery stream to use. It must be in the same account. The default format for this option is OpenTelemetry 0.7.0, but you can change the format later in this procedure.

Then select the Firehose delivery stream to use under **Select your Firehose delivery stream**.

6. (Optional)You can choose **Select existing service role** to use an existing IAM role instead of having CloudWatch create a new one for you.

   > **Note**
   >
   > If role manager is enabled in your account, CloudWatch attaches the role for you, and the role options described here (for example the **Create new role** button) are replaced by a **Customize** option. To use a different role, choose **Customize**. For more information, see IAM role creation in the *IAM User Guide*.

7. (Optional) To change the output format from the default format for your scenario, choose **Change output format**. The supported formats are JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0.

8. For **Metrics to be streamed**, choose either **All metrics** or **Select metrics**.

   If you choose **All metrics**, all metrics from this account will be included in the stream.

   Consider carefully whether to stream all metrics, because the more metrics that you stream the higher your metric stream charges will be.

   If you choose **Select metrics**, do one of the following:

   - To stream most metric namespaces, choose **Exclude** and select the namespaces or metrics to exclude. When you specify a namespace in **Exclude**, you can optionally select some specific metrics from that namespace to exclude. If you choose to exclude a namespace but don't then select metrics in that namespace, all metrics from that namespace are excluded.
   - To include only a few metric namespaces or metrics in the metric stream, choose **Include** and then select the namespaces or metrics to include. If you choose to include a namespace but don't then select metrics in that namespace, all metrics from that namespace are included.

9. (Optional) To stream additional statistics for some of these metrics beyond Minimum, Maximum, SampleCount, and Sum, choose **Add additional statistics**. Either choose **Add recommended metrics** to add some commonly used statistics, or manually select the namespace and metric name to stream additional statistics for. Next, select the additional statistics to stream.

To then choose another group of metrics to stream a different set of additional statistics for, choose **Add additional statistics**. Each metric can include as many as 20 additional statistics, and as many as 100 metrics within a metric stream can include additional statistics.

Streaming additional statistics incurs more charges. For more information, see Statistics that can be streamed.

For definitions of the additional statistics, see CloudWatch statistics definitions.

10. (Optional) Customize the name of the new metric stream under **Metric stream name**.
11. Choose **Create metric stream**.

AWS CLI or AWS API

Use the following steps to create a CloudWatch metric stream.

To use the AWS CLI or AWS API to create a metric stream

1. If you're streaming to Amazon S3, first create the bucket. For more information, see Creating a bucket.
2. Create the Firehose delivery stream. For more information, see Creating a Firehose stream.
3. Create an IAM role that enables CloudWatch to write to the Firehose delivery stream. For more information about the contents of this role, see Trust between CloudWatch and Firehose.
4. Use the `aws cloudwatch put-metric-stream` CLI command or the `PutMetricStream` API to create the CloudWatch metric stream.

AWS CloudFormation

You can use CloudFormation to set up a metric stream. For more information, see AWS::CloudWatch::MetricStream.

To use CloudFormation to create a metric stream

1. If you're streaming to Amazon S3, first create the bucket. For more information, see Creating a bucket.
2. Create the Firehose delivery stream. For more information, see Creating a Firehose stream.
3. Create an IAM role that enables CloudWatch to write to the Firehose delivery stream. For more information about the contents of this role, see Trust between CloudWatch and Firehose.

4. Create the stream in CloudFormation. For more information, see AWS::CloudWatch::MetricStream.

AWS Cloud Development Kit (AWS CDK)

You can use AWS Cloud Development Kit (AWS CDK) to set up a metric stream.

To use the AWS CDK to create a metric stream

1. If you're streaming to Amazon S3, first create the bucket. For more information, see Creating a bucket.
2. Create the Firehose delivery stream. For more information, see Creating an Amazon Data Firehose Delivery Stream.
3. Create an IAM role that enables CloudWatch to write to the Firehose delivery stream. For more information about the contents of this role, see Trust between CloudWatch and Firehose.
4. Create the metric stream. The metric stream resource is available in AWS CDK as a Level 1 (L1) Construct named `CfnMetricStream`. For more information, see Using L1 constructs.

Use Quick Amazon S3 setup

The **Quick S3 Setup** method works well if you want to quickly set up a stream to Amazon S3 and you don't need any formatting transformation beyond the supported JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0 formats. CloudWatch will create all necessary resources including the Firehose delivery stream and the necessary IAM roles. The default format for this option is JSON, but you can change the format while you set up the stream.

Alternatively, if you want the final format to be Parquet format or Optimized Row Columnar (ORC), you should instead follow the steps in Custom setup with Firehose.

CloudWatch console

This section describes how to use the CloudWatch console to set up a metric stream Amazon S3 using Quick S3 setup.

To set up a metric stream using Quick S3 setup

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **Streams**. Then choose **Create metric stream**.

3. (Optional) If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can choose whether to include metrics from linked source accounts in this metric stream. To include metrics from source accounts, choose **Include source account metrics**.
4. Choose **Quick S3 setup**. CloudWatch will create all necessary resources including the Firehose delivery stream and the necessary IAM roles. The default format for this option is JSON, but you can change the format later in this procedure.
5. (Optional) Choose **Select existing resources** to use an existing S3 bucket or existing IAM roles instead of having CloudWatch create new ones for you.

   > **Note**
   >
   > If role manager is enabled in your account, CloudWatch attaches the role for you, and the role options described here (for example the **Create new role** button) are replaced by a **Customize** option. To use a different role, choose **Customize**. For more information, see IAM role creation in the *IAM User Guide*.

6. (Optional) To change the output format from the default format for your scenario, choose **Change output format**. The supported formats are JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0.
7. For **Metrics to be streamed**, choose either **All metrics** or **Select metrics**.

   If you choose **All metrics**, all metrics from this account will be included in the stream.

   Consider carefully whether to stream all metrics, because the more metrics that you stream the higher your metric stream charges will be.

   If you choose **Select metrics**, do one of the following:

   - To stream most metric namespaces, choose **Exclude** and select the namespaces or metrics to exclude. When you specify a namespace in **Exclude**, you can optionally select some specific metrics from that namespace to exclude. If you choose to exclude a namespace but don't then select metrics in that namespace, all metrics from that namespace are excluded.
   - To include only a few metric namespaces or metrics in the metric stream, choose **Include** and then select the namespaces or metrics to include. If you choose to include a namespace but don't then select metrics in that namespace, all metrics from that namespace are included.

8. (Optional) To stream additional statistics for some of these metrics beyond Minimum, Maximum, SampleCount, and Sum, choose **Add additional statistics**. Either choose **Add recommended metrics** to add some commonly used statistics, or manually select the namespace and metric name to stream additional statistics for. Next, select the additional statistics to stream.

   To then choose another group of metrics to stream a different set of additional statistics for, choose **Add additional statistics**. Each metric can include as many as 20 additional statistics, and as many as 100 metrics within a metric stream can include additional statistics.

   Streaming additional statistics incurs more charges. For more information, see Statistics that can be streamed.

   For definitions of the additional statistics, see CloudWatch statistics definitions.
9. (Optional) Customize the name of the new metric stream under **Metric stream name**.
10. Choose **Create metric stream**.

Quick partner setup

CloudWatch provides a quick setup experience for the following third-party partners. To use this workflow, you need to provide only a destination URL and API key for your destination. CloudWatch handles the rest of setup including creating the Firehose delivery stream and the necessary IAM roles.

> **Important**
>
> Before you use quick partner setup to create a metric stream, we strongly recommend that you read that partner's documentation, linked in the following list.

- Datadog
- Dynatrace
- Elastic
- New Relic
- Splunk Observability Cloud
- SumoLogic

When you set up a metric stream to one of these partners, the stream is created with some default settings, as listed in the following sections.

Topics

- Set up a metric stream using quick partner setup
- Datadog stream defaults
- Dynatrace stream defaults
- Elastic stream defaults
- New Relic stream defaults
- Splunk Observability Cloud stream defaults
- Sumo Logic stream defaults

Set up a metric stream using quick partner setup

CloudWatch provides a quick setup option for some third-party partners. Before you start the steps in this section, you must have certain information for the partner. This information might include a destination URL and/or an API key for your partner destination. You should also read the documentation at the partner's website linked in the previous section, and the defaults for that partner listed in the following sections.

To stream to a third-party destination not supported by quick setup, you can follow the instructions in Follow the instructions in Custom setup with Firehose to set up a stream using Firehose, and then send those metrics from Firehose to the final destination.

To use quick partner setup to create a metric stream to third-party provider

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **Streams**. Then choose **Create metric stream**.
3. (Optional) If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can choose whether to include metrics from linked source accounts in this metric stream. To include metrics from source accounts, choose **Include source account metrics**.
4. Choose **Quick Amazon Web Services partner setup**
5. Select the name of the partner that you want to stream metrics to.
6. For **Endpoint URL**, enter the destination URL.

7. For **Access Key** or **API Key**, enter the access key for the partner. Not all partners require an access key.
8. For **Metrics to be streamed**, choose either **All metrics** or **Select metrics**.

   If you choose **All metrics**, all metrics from this account will be included in the stream.

   Consider carefully whether to stream all metrics, because the more metrics that you stream the higher your metric stream charges will be.

   If you choose **Select metrics**, do one of the following:

   - To stream most metric namespaces, choose **Exclude** and select the namespaces or metrics to exclude. When you specify a namespace in **Exclude**, you can optionally select some specific metrics from that namespace to exclude. If you choose to exclude a namespace but don't then select metrics in that namespace, all metrics from that namespace are excluded.
   - To include only a few metric namespaces or metrics in the metric stream, choose **Include** and then select the namespaces or metrics to include. If you choose to include a namespace but don't then select metrics in that namespace, all metrics from that namespace are included.
9. (Optional) To stream additional statistics for some of these metrics beyond Minimum, Maximum, SampleCount, and Sum, choose **Add additional statistics**. Either choose **Add recommended metrics** to add some commonly used statistics, or manually select the namespace and metric name to stream additional statistics for. Next, select the additional statistics to stream.

   To then choose another group of metrics to stream a different set of additional statistics for, choose **Add additional statistics**. Each metric can include as many as 20 additional statistics, and as many as 100 metrics within a metric stream can include additional statistics.

   Streaming additional statistics incurs more charges. For more information, see Statistics that can be streamed.

   For definitions of the additional statistics, see CloudWatch statistics definitions.
10. (Optional) Customize the name of the new metric stream under **Metric stream name**.
11. Choose **Create metric stream**.

Datadog stream defaults

Quick partner setup streams to Datadog use the following defaults:

- **Output format:** OpenTelemetry 0.7.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 4 MBs
- **Firehose stream retry option** Duration of 60 seconds

When you use quick partner setup to create a metric stream to Datadog and you stream certain metrics, by default those metrics include some additional statistics. Streaming additional statistics can incur additional charges. For more information about statistics and their charges, see Statistics that can be streamed.

The following list shows the metrics that have additional statistics streamed by default, if you choose to stream those metrics. You can choose to de-select these additional statistics before you start the stream.

- **`Duration` in `AWS/Lambda`:** p50, p80, p95, p99, p99.9
- **`PostRuntimeExtensionDuration` in `AWS/Lambda`:** p50, p99
- **`FirstByteLatency` and `TotalRequestLatency`in `AWS/S3`:** p50, p90, p95, p99, p99.9
- **`ResponseLatency` in `AWS/Polly` and `TargetResponseTime` in `AWS/ApplicationELB`:** p50, p90, p95, p99
- **`Latency` and `IntegrationLatency` in `AWS/ApiGateway`:** p90, p95, p99
- **`Latency` and `TargetResponseTime` in `AWS/ELB`:** p95, p99
- **`RequestLatency` in `AWS/AppRunner`:** p50, p95, p99
- **`ActivityTime`, `ExecutionTime`, `LambdaFunctionRunTime`, `LambdaFunctionScheduleTime`, `LambdaFunctionTime`, `ActivityRunTime`, and `ActivityScheduleTime` in `AWS/States`:** p95, p99
- **`EncoderBitRate`, `ConfiguredBitRate`, and `ConfiguredBitRateAvailable` in `AWS/MediaLive`:** p90
- **`Latency` in `AWS/AppSync`:** p90

Dynatrace stream defaults

Quick partner setup streams to Dynatrace use the following defaults:

- **Output format:** OpenTelemetry 0.7.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 5 MBs
- **Firehose stream retry option** Duration of 600 seconds

Elastic stream defaults

Quick partner setup streams to Elastic use the following defaults:

- **Output format:** OpenTelemetry 1.0.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 1 MB
- **Firehose stream retry option** Duration of 60 seconds

New Relic stream defaults

Quick partner setup streams to New Relic use the following defaults:

- **Output format:** OpenTelemetry 0.7.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 1 MB
- **Firehose stream retry option** Duration of 60 seconds

Splunk Observability Cloud stream defaults

Quick partner setup streams to Splunk Observability Cloud use the following defaults:

- **Output format:** OpenTelemetry 1.0.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 1 MB
- **Firehose stream retry option** Duration of 300 seconds

Sumo Logic stream defaults

Quick partner setup streams to Sumo Logic use the following defaults:

- **Output format:** OpenTelemetry 0.7.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 1 MB
- **Firehose stream retry option** Duration of 60 seconds

Statistics that can be streamed

Metric streams always include the following statistics: `Minimum`, `Maximum`, `SampleCount`, and `Sum`. You can also choose to include the following additional statistics in a metric stream. This choice is on a per-metric basis. For more information about these statistics, see CloudWatch statistics definitions.

- Percentile values such as p95 or p99 (For streams with either JSON or OpenTelemetry format)
- Trimmed mean (Only for streams with the JSON format)
- Winsorized mean (Only for streams with the JSON format)
- Trimmed count (Only for streams with the JSON format)
- Trimmed sum (Only for streams with the JSON format)
- Percentile rank (Only for streams with the JSON format)
- Interquartile mean (Only for streams with the JSON format)

Streaming additional statistics incurs additional charges. Streaming between one and five of these additional statistics for a particular metric is billed as an additional metric update. Thereafter, each additional set of up to five of these statistics is billed as another metric update.

For example, suppose that for one metric you are streaming the following six additional statistics: p95, p99, p99.9, Trimmed mean, Winsorized mean, and Trimmed sum. Each update of this metric is billed as three metric updates: one for the metric update which includes the default statistics, one for the first five additional statistics, and one for the sixth additional statistic. Adding up to four more additional statistics for a total of ten would not increase the billing, but an eleventh additional statistic would do so.

When you specify a metric name and namespace combination to stream additional statistics, all dimension combinations of that metric name and namespace are streamed with the additional statistics.

CloudWatch metric streams publishes a new metric, `TotalMetricUpdate`, which reflects the base number of metric updates plus extra metric updates incurred by streaming additional statistics. For more information, see Monitoring your metric streams with CloudWatch metrics.

For more information, see Amazon CloudWatch Pricing.

> **Note**
>
> Some metrics do not support percentiles. Percentile statistics for these metrics are excluded from the stream and do not incur metric stream charges. An example of these statistics that do not support percentiles are some metrics in the `AWS/ECS` namespace.

The additional statistics that you configure are streamed only if they match the filters for the stream. For example, if you create a stream that has only `EC2` and `RDS` in the include filters, and then your statistics configuration lists `EC2` and `Lambda`, then the stream includes `EC2` metrics with additional statistics, `RDS` metrics with only the default statistics, and doesn't include `Lambda` statistics at all.

Metric stream operation and maintenance

Metric streams are always in one of two states, **Running** or **Stopped**.

- **Running**— The metric stream is running correctly. There might not be any metric data streamed to the destination because of the filters on the stream.
- **Stopped**— The metric stream has been explicitly stopped by someone, and not because of an error. It might be useful to stop your stream to temporarily pause the streaming of data without deleting the stream.

If you stop and restart a metric stream, the metric data that was published to CloudWatch while the metric stream was stopped is not backfilled to the metric stream.

If you change the output format of a metric stream, in certain cases you might see a small amount of metric data written to the destination in both the old format and the new format. To avoid

this situation, you can create a new Firehose delivery stream with the same configuration as your current one, then change to the new Firehose delivery stream and change the output format at the same time. This way, the Kinesis records with different output format are stored on Amazon S3 in separate objects. Later, you can direct the traffic back to the original Firehose delivery stream and delete the second delivery stream.

To view, edit, stop, and start your metric streams

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **Streams**.

   The list of streams appears, and the **Status** column displays whether each stream is running or stopped.
3. To stop or start a metric stream, select the stream and choose **Stop** or **Start**.
4. To see the details about a metric stream, select the stream and choose **View details**.
5. To change the stream's output format, filters, destination Firehose stream, or roles, choose **Edit** and make the changes that you want.

   If you change the filters, there might be some gaps in the metric data during the transition.

Monitoring your metric streams with CloudWatch metrics

Metric streams emit CloudWatch metrics about their health and operation in the `AWS/CloudWatch/MetricStreams` namespace. The following metrics are emitted. These metrics are emitted with a `MetricStreamName` dimension and with no dimension. You can use the metrics with no dimensions to see aggregated metrics for all of your metric streams. You can use the metrics with the `MetricStreamName` dimension to see the metrics about only that metric stream.

For all of these metrics, values are emitted only for metric streams that are in the **Running** state.

Metric	Description
`MetricUpdate`	The number of metric updates sent to the metric stream. If no metric updates are streamed during a time period, this metric is not emitted during that time period. If you stop the metric stream, this metric stops being emitted until the metric stream is started again.

Metric	Description
	Valid Statistic: Sum Units: None
TotalMetricUpdate	This is calculated as **MetricUpdate + a number based on additional statistics that are being streamed**. For each unique namespace and metric name combination, streaming 1-5 additional statistics adds 1 to the TotalMetricUpdate , streaming 6-10 additional statistics adds 2 to TotalMetricUpdate , and so on. Valid Statistic: Sum Units: None
PublishErrorRate	The number of unrecoverable errors that occur when putting data into the Firehose delivery stream. If no errors occur during a time period, this metric is not emitted during that time period. If you stop the metric stream, this metric stops being emitted until the metric stream is started again. Valid Statistic: Average to see the rate of metric updates unable to be written. This value will be between 0.0 and 1.0. Units: None

Trust between CloudWatch and Firehose

The Firehose delivery stream must trust CloudWatch through an IAM role that has write permissions to Firehose. These permissions can be limited to the single Firehose delivery stream that the CloudWatch metric stream uses. The IAM role must trust the streams.metrics.cloudwatch.amazonaws.com service principal.

If you use the CloudWatch console to create a metric stream, you can have CloudWatch create the role with the correct permissions. If you use another method to create a metric stream, or you want to create the IAM role itself, it must contain the following permissions policy and trust policy.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "firehose:PutRecord",
                "firehose:PutRecordBatch"
            ],
            "Effect": "Allow",
            "Resource": "arn:aws:firehose:us-east-1:123456789012:deliverystream/
*"
        }
    ]
}
```

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "streams.metrics.cloudwatch.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Metric data is streamed by CloudWatch to the destination Firehose delivery stream on behalf of the source that owns the metric stream resource.

CloudWatch metric stream output in JSON format

In a CloudWatch metric stream that uses the JSON format, each Firehose record contains multiple JSON objects separated by a newline character (\n). Each object includes a single data point of a single metric.

The JSON format that is used is fully compatible with AWS Glue and with Amazon Athena. If you have a Firehose delivery stream and an AWS Glue table formatted correctly, the format can be automatically transformed into Parquet format or Optimized Row Columnar (ORC) format before being stored in S3. For more information about transforming the format, see Converting Your Input Record Format in Firehose. For more information about the correct format for AWS Glue, see Which AWS Glue schema should I use for JSON output format?.

In the JSON format, the valid values for `unit` are the same as for the value of `unit` in the `MetricDatum` API structure. For more information, see MetricDatum. The value for the `timestamp` field is in epoch milliseconds, such as `1616004674229`.

The following is an example of the format. In this example, the JSON is formatted for easy reading, but in practice the whole format is on a single line.

```
{
    "metric_stream_name": "MyMetricStream",
    "account_id": "1234567890",
    "region": "us-east-1",
    "namespace": "AWS/EC2",
    "metric_name": "DiskWriteOps",
    "dimensions": {
        "InstanceId": "i-123456789012"
    },
    "timestamp": 1611929698000,
    "value": {
        "count": 3.0,
        "sum": 20.0,
        "max": 18.0,
        "min": 0.0,
        "p99": 17.56,
        "p99.9": 17.8764,
        "TM(25%:75%)": 16.43
    },
    "unit": "Seconds"
}
```

Which AWS Glue schema should I use for JSON output format?

The following is an example of a JSON representation of the `StorageDescriptor` for an AWS Glue table, which would then be used by Firehose. For more information about `StorageDescriptor`, see StorageDescriptor.

```
{
  "Columns": [
    {
      "Name": "metric_stream_name",
      "Type": "string"
    },
    {
      "Name": "account_id",
      "Type": "string"
    },
    {
      "Name": "region",
      "Type": "string"
    },
    {
      "Name": "namespace",
      "Type": "string"
    },
    {
      "Name": "metric_name",
      "Type": "string"
    },
    {
      "Name": "timestamp",
      "Type": "timestamp"
    },
    {
      "Name": "dimensions",
      "Type": "map<string,string>"
    },
    {
      "Name": "value",
      "Type":
 "struct<min:double,max:double,count:double,sum:double,p99:double,p99.9:double>"
    },
    {
      "Name": "unit",
```

```
      "Type": "string"
    }
  ],
  "Location": "s3://amzn-s3-demo-bucket/",
  "InputFormat": "org.apache.hadoop.mapred.TextInputFormat",
  "OutputFormat": "org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat",
  "SerdeInfo": {
    "SerializationLibrary": "org.apache.hive.hcatalog.data.JsonSerDe"
  },
  "Parameters": {
    "classification": "json"
  }
}
```

The preceding example is for data written on Amazon S3 in JSON format. Replace the values in the following fields with the indicated values to store the data in Parquet format or Optimized Row Columnar (ORC) format.

- **Parquet:**
  - inputFormat: org.apache.hadoop.hive.ql.io.parquet.MapredParquetInputFormat
  - outputFormat: org.apache.hadoop.hive.ql.io.parquet.MapredParquetOutputFormat
  - SerDeInfo.serializationLib: org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe
  - parameters.classification: parquet
- **ORC:**
  - inputFormat: org.apache.hadoop.hive.ql.io.orc.OrcInputFormat
  - outputFormat: org.apache.hadoop.hive.ql.io.orc.OrcOutputFormat
  - SerDeInfo.serializationLib: org.apache.hadoop.hive.ql.io.orc.OrcSerde
  - parameters.classification: orc

CloudWatch metric stream output in OpenTelemetry 1.0.0 format

Note

With the OpenTelemetry 1.0.0 format, metric attributes are encoded as a list of `KeyValue` objects instead of the `StringKeyValue` type used in the 0.7.0 format. As a consumer, this is the only major change between the 0.7.0 and 1.0.0 formats. A parser generated from the 0.7.0 proto files won't parse metric attributes encoded in the 1.0.0 format. The same is

true in reverse, a parser generated from the 1.0.0 proto files will not parse metric attributes encoded in the 0.7.0 format.

OpenTelemetry is a collection of tools, APIs, and SDKs. You can use it to instrument, generate, collect, and export telemetry data (metrics, logs, and traces) for analysis. OpenTelemetry is part of the Cloud Native Computing Foundation. For more information, see OpenTelemetry.

For information about the full OpenTelemetry 1.0.0 specification, see Release version 1.0.0.

A Kinesis record can contain one or more `ExportMetricsServiceRequest` OpenTelemetry data structures. Each data structure starts with a header with an `UnsignedVarInt32` indicating the record length in bytes. Each `ExportMetricsServiceRequest` may contain data from multiple metrics at once.

The following is a string representation of the message of the `ExportMetricsServiceRequest` OpenTelemetry data structure. OpenTelemetry serializes the Google Protocol Buffers binary protocol, and this is not human-readable.

```
resource_metrics {
  resource {
    attributes {
      key: "cloud.provider"
      value {
        string_value: "aws"
      }
    }
    attributes {
      key: "cloud.account.id"
      value {
        string_value: "123456789012"
      }
    }
    attributes {
      key: "cloud.region"
      value {
        string_value: "us-east-1"
      }
    }
    attributes {
      key: "aws.exporter.arn"
      value {
```

```
        string_value: "arn:aws:cloudwatch:us-east-1:123456789012:metric-stream/
MyMetricStream"
      }
    }
  }
  scope_metrics {
    metrics {
      name: "amazonaws.com/AWS/DynamoDB/ConsumedReadCapacityUnits"
      unit: "NoneTranslated"
      summary {
        data_points {
          start_time_unix_nano: 60000000000
          time_unix_nano: 120000000000
          count: 1
          sum: 1.0
          quantile_values {
            value: 1.0
          }
          quantile_values {
            quantile: 0.95
            value: 1.0
          }
          quantile_values {
            quantile: 0.99
            value: 1.0
          }
          quantile_values {
            quantile: 1.0
            value: 1.0
          }
          attributes {
            key: "Namespace"
            value {
              string_value: "AWS/DynamoDB"
            }
          }
          attributes {
            key: "MetricName"
            value {
              string_value: "ConsumedReadCapacityUnits"
            }
          }
          attributes {
            key: "Dimensions"
```

```
            value {
              kvlist_value {
                values {
                  key: "TableName"
                  value {
                    string_value: "MyTable"
                  }
                }
              }
            }
          }
        }
        data_points {
          start_time_unix_nano: 70000000000
          time_unix_nano: 130000000000
          count: 2
          sum: 5.0
          quantile_values {
            value: 2.0
          }
          quantile_values {
            quantile: 1.0
            value: 3.0
          }
          attributes {
            key: "Namespace"
            value {
              string_value: "AWS/DynamoDB"
            }
          }
          attributes {
            key: "MetricName"
            value {
              string_value: "ConsumedReadCapacityUnits"
            }
          }
          attributes {
            key: "Dimensions"
            value {
              kvlist_value {
                values {
                  key: "TableName"
                  value {
                    string_value: "MyTable"
```

```
                    }
                  }
                }
              }
            }
          }
        }
      }
    }
  }
}
```

Top-level object to serialize OpenTelemetry metric data

`ExportMetricsServiceRequest` is the top-level wrapper to serialize an OpenTelemetry exporter payload. It contains one or more `ResourceMetrics`.

```
message ExportMetricsServiceRequest {
  // An array of ResourceMetrics.
  // For data coming from a single resource this array will typically contain one
  // element. Intermediary nodes (such as OpenTelemetry Collector) that receive
  // data from multiple origins typically batch the data before forwarding further and
  // in that case this array will contain multiple elements.
  repeated opentelemetry.proto.metrics.v1.ResourceMetrics resource_metrics = 1;
}
```

`ResourceMetrics` is the top-level object to represent MetricData objects.

```
// A collection of ScopeMetrics from a Resource.
message ResourceMetrics {
  reserved 1000;

  // The resource for the metrics in this message.
  // If this field is not set then no resource info is known.
  opentelemetry.proto.resource.v1.Resource resource = 1;

  // A list of metrics that originate from a resource.
  repeated ScopeMetrics scope_metrics = 2;

  // This schema_url applies to the data in the "resource" field. It does not apply
  // to the data in the "scope_metrics" field which have their own schema_url field.
  string schema_url = 3;
}
```

The Resource object

A `Resource` object is a value-pair object that contains some information about the resource that generated the metrics. For metrics created by AWS, the data structure contains the Amazon Resource Name (ARN) of the resource related to the metric, such as an EC2 instance or an S3 bucket.

The `Resource` object contains an attribute called `attributes`, which store a list of key-value pairs.

- `cloud.account.id` contains the account ID
- `cloud.region` contains the Region
- `aws.exporter.arn` contains the metric stream ARN
- `cloud.provider` is always `aws`.

```
// Resource information.
message Resource {
  // Set of attributes that describe the resource.
  // Attribute keys MUST be unique (it is not allowed to have more than one
  // attribute with the same key).
  repeated opentelemetry.proto.common.v1.KeyValue attributes = 1;

  // dropped_attributes_count is the number of dropped attributes. If the value is 0,
 then
  // no attributes were dropped.
  uint32 dropped_attributes_count = 2;
}
```

The ScopeMetrics object

The `scope` field will not be filled. We fill only the metrics field that we are exporting.

```
// A collection of Metrics produced by an Scope.
message ScopeMetrics {
  // The instrumentation scope information for the metrics in this message.
  // Semantically when InstrumentationScope isn't set, it is equivalent with
  // an empty instrumentation scope name (unknown).
  opentelemetry.proto.common.v1.InstrumentationScope scope = 1;

  // A list of metrics that originate from an instrumentation library.
```

```
  repeated Metric metrics = 2;

  // This schema_url applies to all metrics in the "metrics" field.
  string schema_url = 3;
}
```

The Metric object

The metric object contains some metadata and a `Summary` data field that contains a list of `SummaryDataPoint`.

For metric streams, the metadata is as follows:

- name will be `amazonaws.com/`*`metric_namespace`*`/`*`metric_name`*
- `description` will be blank
- `unit` will be filled by mapping the metric datum's unit to the case-sensitive variant of the Unified code for Units of Measure. For more information, see Translations with OpenTelemetry 1.0.0 format in CloudWatch and The Unified Code For Units of Measure.
- `type` will be `SUMMARY`

```
message Metric {
  reserved 4, 6, 8;

  // name of the metric, including its DNS name prefix. It must be unique.
  string name = 1;

  // description of the metric, which can be used in documentation.
  string description = 2;

  // unit in which the metric value is reported. Follows the format
  // described by http://unitsofmeasure.org/ucum.html.
  string unit = 3;

  // Data determines the aggregation type (if any) of the metric, what is the
  // reported value type for the data points, as well as the relatationship to
  // the time interval over which they are reported.
  oneof data {
    Gauge gauge = 5;
    Sum sum = 7;
    Histogram histogram = 9;
```

```
    ExponentialHistogram exponential_histogram = 10;
    Summary summary = 11;
  }
}

message Summary {
  repeated SummaryDataPoint data_points = 1;
}
```

The SummaryDataPoint object

The SummaryDataPoint object contains the value of a single data point in a time series in a DoubleSummary metric.

```
// SummaryDataPoint is a single data point in a timeseries that describes the
// time-varying values of a Summary metric.
message SummaryDataPoint {
  reserved 1;

  // The set of key/value pairs that uniquely identify the timeseries from
  // where this point belongs. The list may be empty (may contain 0 elements).
  // Attribute keys MUST be unique (it is not allowed to have more than one
  // attribute with the same key).
  repeated opentelemetry.proto.common.v1.KeyValue attributes = 7;

  // StartTimeUnixNano is optional but strongly encouraged, see the
  // the detailed comments above Metric.
  //
  // Value is UNIX Epoch time in nanoseconds since 00:00:00 UTC on 1 January
  // 1970.
  fixed64 start_time_unix_nano = 2;

  // TimeUnixNano is required, see the detailed comments above Metric.
  //
  // Value is UNIX Epoch time in nanoseconds since 00:00:00 UTC on 1 January
  // 1970.
  fixed64 time_unix_nano = 3;

  // count is the number of values in the population. Must be non-negative.
  fixed64 count = 4;

  // sum of the values in the population. If count is zero then this field
  // must be zero.
```

```
  //
  // Note: Sum should only be filled out when measuring non-negative discrete
  // events, and is assumed to be monotonic over the values of these events.
  // Negative events *can* be recorded, but sum should not be filled out when
  // doing so.  This is specifically to enforce compatibility w/ OpenMetrics,
  // see: https://github.com/OpenObservability/OpenMetrics/blob/main/specification/
OpenMetrics.md#summary
  double sum = 5;

  // Represents the value at a given quantile of a distribution.
  //
  // To record Min and Max values following conventions are used:
  // - The 1.0 quantile is equivalent to the maximum value observed.
  // - The 0.0 quantile is equivalent to the minimum value observed.
  //
  // See the following issue for more context:
  // https://github.com/open-telemetry/opentelemetry-proto/issues/125

}
```

For more information, see [Translations with OpenTelemetry 1.0.0 format in CloudWatch].

Translations with OpenTelemetry 1.0.0 format in CloudWatch

CloudWatch performs some transformations to put CloudWatch data into OpenTelemetry format.

Translating namespace, metric name, and dimensions

These attributes are key-value pairs encoded in the mapping.

- One attribute has the key `Namespace` and its value is the namespace of the metric
- One attribute has the key `MetricName` and its value is the name of the metric
- One pair has the key `Dimensions` and its value is a nested list of key-value pairs. Each pair in this list maps to a CloudWatch metric dimension, where the pair's key is the name of the dimension and its value is the value of the dimension.

Translating Average, Sum, SampleCount, Min and Max

The Summary datapoint enables CloudWatch to export all of these statistics using one datapoint.

- `startTimeUnixNano` contains the CloudWatch `startTime`
- `timeUnixNano` contains the CloudWatch `endTime`
- `sum` contains the Sum statistic.
- `count` contains the SampleCount statistic.
- `quantile_values` contains two `valueAtQuantile.value` objects:
  - `valueAtQuantile.quantile = 0.0` with `valueAtQuantile.value = Min value`
  - `valueAtQuantile.quantile = 0.99` with `valueAtQuantile.value = p99 value`
  - `valueAtQuantile.quantile = 0.999` with `valueAtQuantile.value = p99.9 value`
  - `valueAtQuantile.quantile = 1.0` with `valueAtQuantile.value = Max value`

Resources that consume the metric stream can calculate the Average statistic as **Sum/SampleCount**.

Translating units

CloudWatch units are mapped to the case-sensitive variant of the Unified code for Units of Measure, as shown in the following table. For more information, see The Unified Code For Units of Measure.

CloudWatch	OpenTelemetry
Second	s
Second or Seconds	s

CloudWatch	OpenTelemetry
Microseconds	us
Milliseconds	ms
Bytes	By
Kilobytes	kBy
Megabytes	MBy
Gigabytes	GBy
Terabytes	TBy
Bits	bit
Kilobits	kbit
Megabits	MBit
Gigabits	GBit
Terabits	Tbit
Percent	%
Count	{Count}
None	1

Units that are combined with a slash are mapped by applying the OpenTelemetry conversion of both the units. For example, Bytes/Second is mapped to By/s.

How to parse OpenTelemetry 1.0.0 messages

This section provides information to help you get started with parsing OpenTelemetry 1.0.0.

First, you should get language-specific bindings, which enable you to parse OpenTelemetry 1.0.0 messages in your preferred language.

To get language-specific bindings

- The steps depend on your preferred language.
  - To use Java, add the following Maven dependency to your Java project: OpenTelemetry Java >> 0.14.1.
  - To use any other language, follow these steps:

    a. Make sure that your language is supported by checking the list at Generating Your Classes.

    b. Install the Protobuf compiler by following the steps at Download Protocol Buffers.

    c. Download the OpenTelemetry 1.0.0 ProtoBuf definitions at Release version 1.0.0.

    d. Confirm that you are in the root folder of the downloaded OpenTelemetry 1.0.0 ProtoBuf definitions. Then create a `src` folder and then run the command to generate language-specific bindings. For more information, see Generating Your Classes.

    The following is an example for how to generate Javascript bindings.

```
protoc --proto_path=./ --js_out=import_style=commonjs,binary:src \
opentelemetry/proto/common/v1/common.proto \
opentelemetry/proto/resource/v1/resource.proto \
opentelemetry/proto/metrics/v1/metrics.proto \
opentelemetry/proto/collector/metrics/v1/metrics_service.proto
```

The following section includes examples of using the language-specific bindings that you can build using the previous instructions.

Java

```
package com.example;

import io.opentelemetry.proto.collector.metrics.v1.ExportMetricsServiceRequest;

import java.io.IOException;
import java.io.InputStream;
import java.util.ArrayList;
import java.util.List;

public class MyOpenTelemetryParser {
```

```
    public List<ExportMetricsServiceRequest> parse(InputStream inputStream) throws
 IOException {
        List<ExportMetricsServiceRequest> result = new ArrayList<>();

        ExportMetricsServiceRequest request;
        /* A Kinesis record can contain multiple `ExportMetricsServiceRequest`
           records, each of them starting with a header with an
           UnsignedVarInt32 indicating the record length in bytes:
            ------ -------------------------- ------ ----------------------
           |UINT32|ExportMetricsServiceRequest|UINT32|ExportMetricsService...
            ------ -------------------------- ------ ----------------------
         */
        while ((request =
 ExportMetricsServiceRequest.parseDelimitedFrom(inputStream)) != null) {
            // Do whatever we want with the parsed message
            result.add(request);
        }

        return result;
    }
}
```

Javascript

This example assumes that the root folder with the bindings generated is `./`

The data argument of the function `parseRecord` can be one of the following types:

- `Uint8Array` this is optimal
- `Buffer` optimal under node
- `Array.number` 8-bit integers

```
const pb = require('google-protobuf')
const pbMetrics =
    require('./opentelemetry/proto/collector/metrics/v1/metrics_service_pb')

function parseRecord(data) {
    const result = []

    // Loop until we've read all the data from the buffer
```

```
    while (data.length) {
        /* A Kinesis record can contain multiple `ExportMetricsServiceRequest`
           records, each of them starting with a header with an
           UnsignedVarInt32 indicating the record length in bytes:
            ------ -------------------------- ------ ----------------------
           |UINT32|ExportMetricsServiceRequest|UINT32|ExportMetricsService...
            ------ -------------------------- ------ ----------------------
         */
        const reader = new pb.BinaryReader(data)
        const messageLength = reader.decoder_.readUnsignedVarint32()
        const messageFrom = reader.decoder_.cursor_
        const messageTo = messageFrom + messageLength

        // Extract the current `ExportMetricsServiceRequest` message to parse
        const message = data.subarray(messageFrom, messageTo)

        // Parse the current message using the ProtoBuf library
        const parsed =
            pbMetrics.ExportMetricsServiceRequest.deserializeBinary(message)

        // Do whatever we want with the parsed message
        result.push(parsed.toObject())

        // Shrink the remaining buffer, removing the already parsed data
        data = data.subarray(messageTo)
    }

    return result
}
```

Python

You must read the `var-int` delimiters yourself or use the internal methods `_VarintBytes(size)` and `_DecodeVarint32(buffer, position)`. These return the position in the buffer just after the size bytes. The read-side constructs a new buffer that is limited to reading only the bytes of the message.

```
size = my_metric.ByteSize()
f.write(_VarintBytes(size))
f.write(my_metric.SerializeToString())
msg_len, new_pos = _DecodeVarint32(buf, 0)
msg_buf = buf[new_pos:new_pos+msg_len]
request = metrics_service_pb.ExportMetricsServiceRequest()
```

```
request.ParseFromString(msg_buf)
```

Go

Use `Buffer.DecodeMessage()`.

C#

Use `CodedInputStream`. This class can read size-delimited messages.

C++

The functions described in `google/protobuf/util/delimited_message_util.h` can read size-delimited messages.

Other languages

For other languages, see Download Protocol Buffers.

When implementing the parser, consider that a Kinesis record can contain multiple `ExportMetricsServiceRequest` Protocol Buffers messages, each of them starting with a header with an `UnsignedVarInt32` that indicates the record length in bytes.

CloudWatch metric stream output in OpenTelemetry 0.7.0 format

OpenTelemetry is a collection of tools, APIs, and SDKs. You can use it to instrument, generate, collect, and export telemetry data (metrics, logs, and traces) for analysis. OpenTelemetry is part of the Cloud Native Computing Foundation. For more information, see OpenTelemetry.

For information about the full OpenTelemetry 0.7.0 specification, see v0.7.0 release.

A Kinesis record can contain one or more `ExportMetricsServiceRequest` OpenTelemetry data structures. Each data structure starts with a header with an `UnsignedVarInt32` indicating the record length in bytes. Each `ExportMetricsServiceRequest` may contain data from multiple metrics at once.

The following is a string representation of the message of the `ExportMetricsServiceRequest` OpenTelemetry data structure. OpenTelemetry serializes the Google Protocol Buffers binary protocol, and this is not human-readable.

```
resource_metrics {
  resource {
    attributes {
```

```
      key: "cloud.provider"
      value {
        string_value: "aws"
      }
    }
    attributes {
      key: "cloud.account.id"
      value {
        string_value: "2345678901"
      }
    }
    attributes {
      key: "cloud.region"
      value {
        string_value: "us-east-1"
      }
    }
    attributes {
      key: "aws.exporter.arn"
      value {
        string_value: "arn:aws:cloudwatch:us-east-1:123456789012:metric-stream/
MyMetricStream"
      }
    }
  }
  instrumentation_library_metrics {
    metrics {
      name: "amazonaws.com/AWS/DynamoDB/ConsumedReadCapacityUnits"
      unit: "1"
      double_summary {
        data_points {
          labels {
            key: "Namespace"
            value: "AWS/DynamoDB"
          }
          labels {
            key: "MetricName"
            value: "ConsumedReadCapacityUnits"
          }
          labels {
            key: "TableName"
            value: "MyTable"
          }
          start_time_unix_nano: 1604948400000000000
```

```
      time_unix_nano: 1604948460000000000
      count: 1
      sum: 1.0
      quantile_values {
        quantile: 0.0
        value: 1.0
      }
      quantile_values {
        quantile: 0.95
        value: 1.0
      }
      quantile_values {
        quantile: 0.99
        value: 1.0
      }
      quantile_values {
        quantile: 1.0
        value: 1.0
      }
    }
    data_points {
      labels {
        key: "Namespace"
        value: "AWS/DynamoDB"
      }
      labels {
        key: "MetricName"
        value: "ConsumedReadCapacityUnits"
      }
      labels {
        key: "TableName"
        value: "MyTable"
      }
      start_time_unix_nano: 1604948460000000000
      time_unix_nano: 1604948520000000000
      count: 2
      sum: 5.0
      quantile_values {
        quantile: 0.0
        value: 2.0
      }
      quantile_values {
        quantile: 1.0
        value: 3.0
```

```
          }
        }
      }
    }
  }
}
```

Top-level object to serialize OpenTelemetry metric data

`ExportMetricsServiceRequest` is the top-level wrapper to serialize an OpenTelemetry exporter payload. It contains one or more `ResourceMetrics`.

```
message ExportMetricsServiceRequest {
  // An array of ResourceMetrics.
  // For data coming from a single resource this array will typically contain one
  // element. Intermediary nodes (such as OpenTelemetry Collector) that receive
  // data from multiple origins typically batch the data before forwarding further and
  // in that case this array will contain multiple elements.
  repeated opentelemetry.proto.metrics.v1.ResourceMetrics resource_metrics = 1;
}
```

`ResourceMetrics` is the top-level object to represent MetricData objects.

```
// A collection of InstrumentationLibraryMetrics from a Resource.
message ResourceMetrics {
  // The resource for the metrics in this message.
  // If this field is not set then no resource info is known.
  opentelemetry.proto.resource.v1.Resource resource = 1;

  // A list of metrics that originate from a resource.
  repeated InstrumentationLibraryMetrics instrumentation_library_metrics = 2;
}
```

The Resource object

A `Resource` object is a value-pair object that contains some information about the resource that generated the metrics. For metrics created by AWS, the data structure contains the Amazon Resource Name (ARN) of the resource related to the metric, such as an EC2 instance or an S3 bucket.

The `Resource` object contains an attribute called `attributes`, which store a list of key-value pairs.

- `cloud.account.id` contains the account ID
- `cloud.region` contains the Region
- `aws.exporter.arn` contains the metric stream ARN
- `cloud.provider` is always `aws`.

```
// Resource information.
message Resource {
  // Set of labels that describe the resource.
  repeated opentelemetry.proto.common.v1.KeyValue attributes = 1;

  // dropped_attributes_count is the number of dropped attributes. If the value is 0,
  // no attributes were dropped.
  uint32 dropped_attributes_count = 2;
}
```

The InstrumentationLibraryMetrics object

The instrumentation_library field will not be filled. We will fill only the metrics field that we are exporting.

```
// A collection of Metrics produced by an InstrumentationLibrary.
message InstrumentationLibraryMetrics {
  // The instrumentation library information for the metrics in this message.
  // If this field is not set then no library info is known.
  opentelemetry.proto.common.v1.InstrumentationLibrary instrumentation_library = 1;
  // A list of metrics that originate from an instrumentation library.
  repeated Metric metrics = 2;
}
```

The Metric object

The metric object contains a `DoubleSummary` data field that contains a list of `DoubleSummaryDataPoint`.

```
message Metric {
  // name of the metric, including its DNS name prefix. It must be unique.
  string name = 1;

  // description of the metric, which can be used in documentation.
  string description = 2;
```

```
  // unit in which the metric value is reported. Follows the format
  // described by http://unitsofmeasure.org/ucum.html.
  string unit = 3;

  oneof data {
    IntGauge int_gauge = 4;
    DoubleGauge double_gauge = 5;
    IntSum int_sum = 6;
    DoubleSum double_sum = 7;
    IntHistogram int_histogram = 8;
    DoubleHistogram double_histogram = 9;
    DoubleSummary double_summary = 11;
  }
}

message DoubleSummary {
  repeated DoubleSummaryDataPoint data_points = 1;
}
```

The MetricDescriptor object

The MetricDescriptor object contains metadata. For more information, see metrics.proto on GitHub.

For metric streams, the MetricDescriptor has the following contents:

- name will be amazonaws.com/*metric_namespace*/*metric_name*
- `description` will be blank.
- `unit` will be filled by mapping the metric datum's unit to the case-sensitive variant of the Unified code for Units of Measure. For more information, see Translations with OpenTelemetry 0.7.0 format in CloudWatch and The Unified Code For Units of Measure.
- `type` will be SUMMARY.

The DoubleSummaryDataPoint object

The DoubleSummaryDataPoint object contains the value of a single data point in a time series in a DoubleSummary metric.

```
// DoubleSummaryDataPoint is a single data point in a timeseries that describes the
// time-varying values of a Summary metric.
message DoubleSummaryDataPoint {
```

```
  // The set of labels that uniquely identify this timeseries.
  repeated opentelemetry.proto.common.v1.StringKeyValue labels = 1;

  // start_time_unix_nano is the last time when the aggregation value was reset
  // to "zero". For some metric types this is ignored, see data types for more
  // details.
  //
  // The aggregation value is over the time interval (start_time_unix_nano,
  // time_unix_nano].
  //
  // Value is UNIX Epoch time in nanoseconds since 00:00:00 UTC on 1 January
  // 1970.
  //
  // Value of 0 indicates that the timestamp is unspecified. In that case the
  // timestamp may be decided by the backend.
  fixed64 start_time_unix_nano = 2;

  // time_unix_nano is the moment when this aggregation value was reported.
  //
  // Value is UNIX Epoch time in nanoseconds since 00:00:00 UTC on 1 January
  // 1970.
  fixed64 time_unix_nano = 3;

  // count is the number of values in the population. Must be non-negative.
  fixed64 count = 4;

  // sum of the values in the population. If count is zero then this field
  // must be zero.
  double sum = 5;

  // Represents the value at a given quantile of a distribution.
  //
  // To record Min and Max values following conventions are used:
  // - The 1.0 quantile is equivalent to the maximum value observed.
  // - The 0.0 quantile is equivalent to the minimum value observed.
  message ValueAtQuantile {
    // The quantile of a distribution. Must be in the interval
    // [0.0, 1.0].
    double quantile = 1;

    // The value at the given quantile of a distribution.
    double value = 2;
  }
```

```
  // (Optional) list of values at different quantiles of the distribution calculated
  // from the current snapshot. The quantiles must be strictly increasing.
  repeated ValueAtQuantile quantile_values = 6;
}
```

For more information, see Translations with OpenTelemetry 0.7.0 format in CloudWatch.

Translations with OpenTelemetry 0.7.0 format in CloudWatch

CloudWatch performs some transformations to put CloudWatch data into OpenTelemetry format.

Translating namespace, metric name, and dimensions

These attributes are key-value pairs encoded in the mapping.

- One pair contains the namespace of the metric
- One pair contains the name of the metric
- For each dimension, CloudWatch stores the following pair: `metricDatum.Dimensions[i].Name, metricDatum.Dimensions[i].Value`

Translating Average, Sum, SampleCount, Min and Max

The Summary datapoint enables CloudWatch to export all of these statistics using one datapoint.

- `startTimeUnixNano` contains the CloudWatch `startTime`
- `timeUnixNano` contains the CloudWatch `endTime`
- `sum` contains the Sum statistic.
- `count` contains the SampleCount statistic.
- `quantile_values` contains two `valueAtQuantile.value` objects:
  - `valueAtQuantile.quantile = 0.0` with `valueAtQuantile.value = Min value`
  - `valueAtQuantile.quantile = 0.99` with `valueAtQuantile.value = p99 value`
  - `valueAtQuantile.quantile = 0.999` with `valueAtQuantile.value = p99.9 value`
  - `valueAtQuantile.quantile = 1.0` with `valueAtQuantile.value = Max value`

Resources that consume the metric stream can calculate the Average statistic as **Sum/SampleCount**.

Translating units

CloudWatch units are mapped to the case-sensitive variant of the Unified code for Units of Measure, as shown in the following table. For more information, see The Unified Code For Units of Measure.

CloudWatch	OpenTelemetry
Second	s
Second or Seconds	s
Microsecond	us
Milliseconds	ms
Bytes	By
Kilobytes	kBy
Megabytes	MBy
Gigabytes	GBy
Terabytes	TBy
Bits	bit
Kilobits	kbit
Megabits	MBit
Gigabits	GBit
Terabits	Tbit
Percent	%
Count	{Count}
None	1

Units that are combined with a slash are mapped by applying the OpenTelemetry conversion of both the units. For example, Bytes/Second is mapped to By/s.

How to parse OpenTelemetry 0.7.0 messages

This section provides information to help you get started with parsing OpenTelemetry 0.7.0.

First, you should get language-specific bindings, which enable you to parse OpenTelemetry 0.7.0 messages in your preferred language.

To get language-specific bindings

- The steps depend on your preferred language.
  - To use Java, add the following Maven dependency to your Java project: OpenTelemetry Java >> 0.14.1.
  - To use any other language, follow these steps:

    a. Make sure that your language is supported by checking the list at Generating Your Classes.

    b. Install the Protobuf compiler by following the steps at Download Protocol Buffers.

    c. Download the OpenTelemetry 0.7.0 ProtoBuf definitions at v0.7.0 release.

    d. Confirm that you are in the root folder of the downloaded OpenTelemetry 0.7.0 ProtoBuf definitions. Then create a `src` folder and then run the command to generate language-specific bindings. For more information, see Generating Your Classes.

    The following is an example for how to generate Javascript bindings.

```
protoc --proto_path=./ --js_out=import_style=commonjs,binary:src \
opentelemetry/proto/common/v1/common.proto \
opentelemetry/proto/resource/v1/resource.proto \
opentelemetry/proto/metrics/v1/metrics.proto \
opentelemetry/proto/collector/metrics/v1/metrics_service.proto
```

The following section includes examples of using the language-specific bindings that you can build using the previous instructions.

Java

```
package com.example;

import io.opentelemetry.proto.collector.metrics.v1.ExportMetricsServiceRequest;

import java.io.IOException;
import java.io.InputStream;
import java.util.ArrayList;
import java.util.List;

public class MyOpenTelemetryParser {

    public List<ExportMetricsServiceRequest> parse(InputStream inputStream) throws
 IOException {
        List<ExportMetricsServiceRequest> result = new ArrayList<>();

        ExportMetricsServiceRequest request;
        /* A Kinesis record can contain multiple `ExportMetricsServiceRequest`
           records, each of them starting with a header with an
           UnsignedVarInt32 indicating the record length in bytes:
            ------ -------------------------- ------ ----------------------
           |UINT32|ExportMetricsServiceRequest|UINT32|pExportMetricsService...
            ------ -------------------------- ------ ----------------------
         */
        while ((request =
 ExportMetricsServiceRequest.parseDelimitedFrom(inputStream)) != null) {
            // Do whatever we want with the parsed message
            result.add(request);
        }

        return result;
    }
}
```

Javascript

This example assumes that the root folder with the bindings generated is `./`

The data argument of the function `parseRecord` can be one of the following types:

- `Uint8Array` this is optimal
- `Buffer` optimal under node
- `Array.number` 8-bit integers

```
const pb = require('google-protobuf')
const pbMetrics =
    require('./opentelemetry/proto/collector/metrics/v1/metrics_service_pb')

function parseRecord(data) {
    const result = []

    // Loop until we've read all the data from the buffer
    while (data.length) {
        /* A Kinesis record can contain multiple `ExportMetricsServiceRequest`
           records, each of them starting with a header with an
           UnsignedVarInt32 indicating the record length in bytes:
            ------ -------------------------- ------ ----------------------
           |UINT32|ExportMetricsServiceRequest|UINT32|ExportMetricsService...
            ------ -------------------------- ------ ----------------------
         */
        const reader = new pb.BinaryReader(data)
        const messageLength = reader.decoder_.readUnsignedVarint32()
        const messageFrom = reader.decoder_.cursor_
        const messageTo = messageFrom + messageLength

        // Extract the current `ExportMetricsServiceRequest` message to parse
        const message = data.subarray(messageFrom, messageTo)

        // Parse the current message using the ProtoBuf library
        const parsed =
            pbMetrics.ExportMetricsServiceRequest.deserializeBinary(message)

        // Do whatever we want with the parsed message
        result.push(parsed.toObject())

        // Shrink the remaining buffer, removing the already parsed data
        data = data.subarray(messageTo)
    }

    return result
}
```

Python

You must read the `var-int` delimiters yourself or use the internal methods `_VarintBytes(size)` and `_DecodeVarint32(buffer, position)`. These return the position

in the buffer just after the size bytes. The read-side constructs a new buffer that is limited to reading only the bytes of the message.

```
size = my_metric.ByteSize()
f.write(_VarintBytes(size))
f.write(my_metric.SerializeToString())
msg_len, new_pos = _DecodeVarint32(buf, 0)
msg_buf = buf[new_pos:new_pos+msg_len]
request = metrics_service_pb.ExportMetricsServiceRequest()
request.ParseFromString(msg_buf)
```

Go

Use `Buffer.DecodeMessage()`.

C#

Use `CodedInputStream`. This class can read size-delimited messages.

C++

The functions described in `google/protobuf/util/delimited_message_util.h` can read size-delimited messages.

Other languages

For other languages, see Download Protocol Buffers.

When implementing the parser, consider that a Kinesis record can contain multiple `ExportMetricsServiceRequest` Protocol Buffers messages, each of them starting with a header with an `UnsignedVarInt32` that indicates the record length in bytes.

Troubleshooting metric streams in CloudWatch

If you're not seeing metric data at your final destination, check the following:

- Check that the metric stream is in the running state. For steps on how to use the CloudWatch console to do this, see Metric stream operation and maintenance.
- Metrics published more than two days in the past are not streamed. To determine whether a particular metric will be streamed, graph the metric in the CloudWatch console and check how

old the last visible datapoint is. If it is more than two days in the past, then it won't be picked up by metric streams.

- Check the metrics emitted by the metric stream. In the CloudWatch console, under **Metrics**, look at the **AWS/CloudWatch/MetricStreams** namespace for the **MetricUpdate**, **TotalMetricUpdate**, and **PublishErrorRate** metrics.
- If the **PublishErrorRate** metric is high, confirm that the destination that is used by the Firehose delivery stream exists and that the IAM role specified in the metric stream's configuration grants the `CloudWatch` service principal permissions to write to it. For more information, see Trust between CloudWatch and Firehose.
- Check that the Firehose delivery stream has permission to write to the final destination.
- In the Firehose console, view the Firehose delivery stream that is used for the metric stream and check the **Monitoring** tab to see whether the Firehose delivery stream is receiving data.
- Confirm that you have configured your Firehose delivery stream with the correct details.
- Check any available logs or metrics for the final destination that the Firehose delivery stream writes to.
- Ensure that CloudWatch Logs decompression is disabled on your Firehose delivery stream. Only requests from CloudWatch Logs are supported when decompression is enabled.
- To get more detailed information, enable CloudWatch Logs error logging on the Firehose delivery stream. For more information, see Monitoring Amazon Data Firehose Using CloudWatch Logs.

> **Note**
>
> After a data point for a specific metric and timestamp has been sent, it won't be sent again even if the value of the data point changes later.

Math expressions with metrics

Metric math enables you to query multiple CloudWatch metrics and use math expressions to create new time series based on these metrics. You can visualize the resulting time series on the CloudWatch console and add them to dashboards. Using AWS Lambda metrics as an example, you could divide the `Errors` metric by the `Invocations` metric to get an error rate. Then add the resulting time series to a graph on your CloudWatch dashboard.

You can also perform metric math programmatically, using the `GetMetricData` API operation. For more information, see GetMetricData.

Add a math expression to a CloudWatch graph

You can add a math expression to a graph on your CloudWatch dashboard. Each graph is limited to using a maximum of 500 metrics and expressions, so you can add a math expression only if the graph has 499 or fewer metrics. This applies even if not all the metrics are displayed on the graph.

To add a math expression to a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Create or edit a graph. There needs to be at least one metric in the graph.
3. Choose **Graphed metrics**.
4. Choose **Math expression**, **Start with empty expression**. A new line appears for the expression.
5. In the new line, under the **Details** column, enter the math expression. The tables in the **Metric Math Syntax and Functions** section list the functions that you can use in the expression.

   To use a metric or the result of another expression as part of the formula for this expression, use the value shown in the **Id** column: for example, **m1+m2** or **e1-MIN(e1)**.

   You can change the value of **Id**. It can include numbers, letters, an underscore, and must start with a lowercase letter. Changing the value of **Id** to a more meaningful name can also make a graph easier to understand;for example, changing **m1** and **m2** to **errors** and **requests**.

   > **Tip**
   >
   > Choose the down arrow next to **Math Expression** to see a list of supported functions, which you can use when creating your expression.

6. For the **Label** column of the expression, enter a name that describes what the expression is calculating.

   If the result of an expression is an array of time series, each of those time series is displayed on the graph with a separate line, with different colors. Immediately under the graph is a legend for each line in the graph. For a single expression that produces multiple time series, the legend captions for those time series are in the format ***`Expression-Label Metric-Label`***. For example, if the graph includes a metric with a label of **Errors** and an expression

FILL(METRICS(), 0) that has a label of **Filled With 0:**, one line in the legend would be **Filled With 0: Errors**. To have the legend show only the original metric labels, set *`Expression-Label`* to be empty.

When one expression produces an array of time series on the graph, you can't change the colors used for each of those time series.

7. After you have added the desired expressions, you can simplify the graph by hiding some of the original metrics. To hide a metric or expression, clear the check box to the left of the **Id** field.

Metric math syntax and functions

The following sections explain the functions available for metric math. All functions must be written in uppercase letters (such as **AVG**), and the **Id** field for all metrics and math expressions must start with a lowercase letter.

The final result of any math expression must be a single time series or an array of time series. Some functions produce a scalar number. You can use these functions within a larger function that ultimately produces a time series. For example, taking the **AVG** of a single time series produces a scalar number, so it can't be the final expression result. But you could use it in the function **m1-AVG(m1)** to display a time series of the difference between each individual data point and the average value in the time series.

Data type abbreviations

Some functions are valid for only certain types of data. The abbreviations in the following list are used in the tables of functions to represent the types of data supported for each function:

- **S** represents a scalar number, such as 2, -5, or 50.25.
- **TS** is a time series (a series of values for a single CloudWatch metric over time): for example, the `CPUUtilization` metric for instance `i-1234567890abcdef0` over the last three days.
- **TS[]** is an array of time series, such as the time series for multiple metrics.
- **String[]** is an array of strings.

The METRICS() function

The **METRICS()** function returns all the metrics in the request. Math expressions aren't included.

You can use **METRICS()** within a larger expression that produces a single time series or an array of time series. For example, the expression **SUM(METRICS())** returns a time series (TS) that is the sum of the values of all the graphed metrics. **METRICS()/100** returns an array of time series, each of which is a time series showing each data point of one of the metrics divided by 100.

You can use the **METRICS()** function with a string to return only the graphed metrics that contain that string in their **Id** field. For example, the expression **SUM(METRICS("errors"))** returns a time series that is the sum of the values of all the graphed metrics that have 'errors' in their **Id** field. You can also use **SUM([METRICS("4xx"), METRICS("5xx")])** to match multiple strings.

Basic arithmetic functions

The following table lists the basic arithmetic functions that are supported. Missing values in a time series are treated as 0. If the value of a data point causes a function to attempt to divide by zero, the data point is dropped.

Operation	Arguments	Examples
Arithmetic operators: + - * / ^	S, S	PERIOD(m1)/60
	S, TS	**5 * m1**
	TS, TS	**m1 - m2**
	S, TS[]	**SUM(100/[m1, m2])**
	TS, TS[]	**AVG(METRICS())**
		METRICS()*100
Unary subtraction -	S	**-5*m1**
	TS	**-m1**
	TS[]	**SUM(-[m1, m2])**

Comparison and logical operators

You can use comparison and logical operators with either a pair of time series or a pair of single scalar values. When you use a comparison operator with a pair of time series, the operators return

a time series where each data point is either 0 (false) or 1 (true). If you use a comparison operator on a pair of scalar values, a single scalar value is returned, either 0 or 1.

When comparison operators are used between two time series, and only one of the time series has a value for a particular time stamp, the function treats the missing value in the other time series as **0**.

You can use logical operators in conjunction with comparison operators, to create more complex functions.

The following table lists the operators that are supported.

Type of operator	Supported operators
Comparison operators	== != <= >= < >
Logical operators	AND or && OR or ||

To see how these operators are used, suppose you have two time series: **metric1** has values of `[30, 20, 0, 0]` and **metric2** has values of `[20, -, 20, -]` where `-` indicates that there is no value for that timestamp.

Expression	Output
(metric1 < metric2)	**0, 0, 1, 0**
(metric1 >= 30)	**1, 0, 0, 0**

Expression	Output
(metric1 > 15 AND metric2 > 15)	**1, 0, 0, 0**

Functions supported for metric math

The following table describes the functions that you can use in math expressions. Enter all functions in uppercase letters.

The final result of any math expression must be a single time series or an array of time series. Some functions in tables in the following sections produce a scalar number. You can use these functions within a larger function that ultimately produces a time series. For example, taking the **AVG** of a single time series produces a scalar number, so it can't be the final expression result. But you could use it in the function **m1-AVG(m1)** to display a time series of the difference between each individual data point and the average value of that data point.

In the following table, every example in the **Examples** column is an expression that results in a single time series or an array of time series. These examples show how functions that return scalar numbers can be used as part of a valid expression that produces a single time series.

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
ABS	TS TS[]	TS TS[]	Returns the absolute value of each data point.	**ABS(m1-m2)** **MIN(ABS([m1, m2]))** **ABS(METRICS())**	✓
ANOMALY_DETECTION_BAND	TS TS, S	TS[]	Returns an anomaly detection band for the specified metric. The band consists of two time series, one representing the upper	**ANOMALY_DETECTION_BAND(m1)** **ANOMALY_DETECTION_BAND(m1,4)**	

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			limit of the "normal" expected value of the metric, and the other representing the lower limit. The function can take two arguments . The first is the ID of the metric to create the band for. The second argument is the number of standard deviations to use for the band. If you don't specify this argument, the default of 2 is used. For more information, see Using CloudWatch anomaly detection.		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
AVG	TS TS[]	S TS	The **AVG** of a single time series returns a scalar representing the average of all the data points in the metric. The **AVG** of an array of time series returns a single time series. Missing values are treated as 0. **Note** We recommend that you do not use this function in CloudWatch alarms if you want the function to return a scalar. For example, `AVG(m2)`. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher	**SUM([m1,m2])/AVG(m2)** **AVG(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			number of data points than the number specified as Evaluation Periods. This function acts differently when extra data is requested. To use this function with alarms, especially alarms that have Auto Scaling actions, we recommend that you set the alarm to use M out of N datapoints, where M < N.		
CEIL	TS TS[]	TS TS[]	Returns the ceiling of each metric. The ceiling is the smallest integer greater than or equal to each value.	**CEIL(m1)** **CEIL(METRICS())** **SUM(CEIL(METRICS()))**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
DATAPOINT_COUNT	TS TS[]	S TS	Returns a count of the data points that reported values. This is useful for calculating averages of sparse metrics. **Note** We recommend that you do not use this function in CloudWatch alarms. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts differently when	**SUM(m1) / DATAPOINT_COUNT(m1)** **DATAPOINT_COUNT(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			extra data is requested.		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
DB_PERF_INSIGHTS	String, String, String String, String, String[]	TS (if given a single string) TS[] (if given an array of strings)	Returns Performance Insights Counter metrics for databases such as Amazon Relational Database Service and Amazon DocumentDB (with MongoDB compatibility). This function returns the same amount of data that you can get by directly querying the Performance Insights APIs. You can use these metrics in CloudWatch for graphing and creating alarms. **Important** When you use this function, you must specify the Unique Database Resource ID of the database. This is different than	**DB_PERF_INSIGHTS('RDS', 'db-ABCDEFGHIJKLMNOPQRSTUVWXY1', 'os.cpuUtilization.user.avg')** **DB_PERF_INSIGHTS('DOCDB', 'db-ABCDEFGHIJKLMNOPQRSTUVWXY1', ['os.cpuUtilization.idle.avg', 'os.cpuUtilization.user.max'])**	

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			the database identifier. To find the database resource ID in the Amazon RDS console, choose the DB instance to see its details. Then choose the **Configuration** tab. The **Resource ID** is displayed in the **Configuration** section. **DB_PERF_INSIGHTS** also brings in the DBLoad metric at sub-minute intervals. Performance Insights metrics retrieved with this function are not stored in CloudWatch. Therefore, some CloudWatch features such as cross-acc		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			ount observability, anomaly detection, metric streams, metrics explorer, and Metric Insights don't work with Performance Insights metrics that you retrieve with **DB_PERF_INSIGHTS**. A single request using the **DB_PERF_INSIGHTS** function can retrieve the following numbers of data points. • 1080 data points for high-resolution periods (1s, 10s, 30s) • 1440 data points for standard-resolution periods (1m, 5m, 1hr, 1d) The **DB_PERF_INSIGHTS** function supports only the following period lengths: • 1 second		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			• 10 seconds • 30 seconds • 1 minute • 5 minutes • 1 hour • 1 day For more information about Amazon RDS Performance Insights counter metrics, see Performance Insights counter metrics. For more informati on about Amazon DocumentDB Performance Insights counter metrics, see Performance Insights for counter metrics. **Note** High-resolution metrics with sub-minute granularity retrieved by **DB_PERF_I**		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			NSIGHTS are only applicable to the **DBLoad** metric, or for operating system metrics if you have enabled Enhanced Monitoring at a higher resolution. For more information about Amazon RDS enhanced monitoring, see Monitoring OS metrics with Enhanced Monitoring. You can create a high-resolution alarm using the **DB_PERF_INSIGHTS** function for a maximum time range of three hours. You can use the CloudWatc		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			h console to graph metrics retrieved with the **DB_PERF_INSIGHTS** function for any time range.		
DIFF	TS TS[]	TS TS[]	Returns the difference between each value in the time series and the preceding value from that time series.	**DIFF(m1)**	✓
DIFF_TIME	TS TS[]	TS TS[]	Returns the difference in seconds between the timestamp of each value in the time series and the timestamp of the preceding value from that time series.	**DIFF_TIME(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
FILL	TS, [S | REPEAT | LINEAR] TS[], [TS | S | REPEAT | LINEAR]	TS TS[]	Fills the missing values of a time series. There are several options for the values to use as the filler for missing values: • You can specify a value to use as the filler value. • You can specify a metric to use as the filler value. • You can use the **REPEAT** keyword to fill missing values with the most recent actual value of the metric before the missing value. • You can use the **LINEAR** keyword to fill the missing values with values that create a linear interpolation between the values at the beginning and the end of the gap.	**FILL(m1,10)** **FILL(METRICS(), 0)** **FILL(METRICS(), m1)** **FILL(m1, MIN(m1))** **FILL(m1, REPEAT)** **FILL(METRICS(), LINEAR)**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			Note When you use this function in an alarm, you can encounter an issue if your metrics are being published with a slight delay, and the most recent minute never has data. In this case, **FILL** replaces that missing data point with the requested value. That causes the latest data point for the metric to always be the FILL value, which can result in the alarm being stuck in either OK state or ALARM state. You can work		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			around this by using a M out of N alarm. For more informati on, see Alarm evaluation.		
FIRST **LAST**	TS[]	TS	Returns the first or last time series from an array of time series. This is useful when used with the **SORT** function. It can also be used to get the high and low thresholds from the **ANOMALY_D ETECTION_BAND** function.	**IF(FIRST(SORT(METR ICS(), AVG, DESC))>10 0, 1, 0)** Looks at the top metric from an array, which is sorted by AVG. It then returns a 1 or 0 for each data point, depending on whether that data point value is more than 100. **LAST(ANOM ALY_DETEC TION_BAND(m1))** returns the upper bound of the anomaly prediction band.	✓
FLOOR	TS TS[]	TS TS[]	Returns the floor of each metric. The floor is the largest integer less than or equal to each value.	**FLOOR(m1)** **FLOOR(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
IF	**IF** expressi n	TS	Use **IF** along with a comparison operator to filter out data points from a time series, or create a mixed time-series composed of multiple collated time series. For more information, see Using IF expressions.	For examples, see Using IF expressions.	✓
INSIGHT_RULE_METRIC	**INSIGHT ULE_MI C(ruleN e, metricN e)**	TS	Use **INSIGHT_RULE_METRIC** to extract statistics from a rule in Contributor Insights. For more information, see Graphing metrics generated by rules in CloudWatch.		
LAMBDA	**LAMBD mbdaFu ionNam [, optiona arg]*)**	TS TS[]	Calls a Lambda function to query metrics from a data source that is not CloudWatch. For more information, see How to pass arguments to your Lambda function.		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
LOG	TS TS[]	TS TS[]	The **LOG** of a time series returns the natural logarithm value of each value in the time series.	**LOG(METRICS())**	✓
LOG10	TS TS[]	TS TS[]	The **LOG10** of a time series returns the base-10 logarithm value of each value in the time series.	**LOG10(m1)**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
MAX	TS TS[]	S TS	The **MAX** of a single time series returns a scalar representing the maximum value of all data points in the metric. If you input an array of time series, the **MAX** function creates and returns a time series that consists of the highest value for each data point, among the time series that were used as the input. **Note** We recommend that you do not use this function in CloudWatch alarms if you want the function to return a scalar. For example, `MAX(m2)` Whenever an	**MAX(m1)/m1** **MAX(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.		
METRIC_COUNT	TS[]	S	Returns the number of metrics in the time series array.	**m1/METRIC_COUNT(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
METRICS	null string	TS[]	The **METRICS()** function returns all CloudWatch metrics in the request. Math expressions aren't included. You can use **METRICS()** within a larger expression that produces a single time series or an array of time series. You can use the **METRICS()** function with a string to return only the graphed metrics that contain that string in their **Id** field. For example, the expression **SUM(METRICS("errors"))** returns a time series that is the sum of the values of all the graphed metrics that have 'errors' in their **Id** field. You can also use **SUM([METRICS("4xx"), METRICS("5xx")])** to match multiple strings.	**AVG(METRICS())** **SUM(METRICS("errors"))**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
MIN	TS TS[]	S TS	The **MIN** of a single time series returns a scalar representing the minimum value of all data points in the metric. If you input an array of time series, the **MIN** function creates and returns a time series that consists of the lowest value for each data point, among the time series that were used as the input. **Note** We recommend that you do not use this function in CloudWatch alarms if you want the function to return a scalar. For example, `MIN(m2)` Whenever an	**m1-MIN(m1)** **MIN(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
MINUTE **HOUR** **DAY** **DATE** **MONTH** **YEAR** **EPOCH**	TS	TS	These functions take the period and range of the time series and return a new non-sparse time series where each value is based on its timestamp. • **MINUTE** returns a non-sparse time series of integers between 0 and 59 that represent the UTC minute of each timestamp in the original time series. • **HOUR** returns a non-sparse time series of integers between 0 and 23 that represent the UTC hour of each timestamp in the original time series. • **DAY** returns a non-sparse time series of integers between 1 and 7 that represent the UTC day of the week of each timestamp in the	**MINUTE(m1)** **IF(DAY(m1)<6,m1)** returns metrics only from weekdays, Monday to Friday. **IF(MONTH(m1) == 4,m1)** returns only metrics published in April.	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			original time series. 1 represents Monday and 7 represents Sunday. • **DATE** returns a non-sparse time series of integers between 1 and 31 that represent the UTC day of the month of each timestamp in the original time series. • **MONTH** returns a non-sparse time series of integers between 1 and 12 that represent the UTC month of each timestamp in the original time series. 1 represents January and 12 represents December. • **YEAR** returns a non-sparse time series of integers that represent the UTC year of each timestamp in the original time series.		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			• **EPOCH** returns a non-sparse time series of integers that represent the UTC time in seconds since the Epoch of each timestamp in the original time series. The Epoch is January 1, 1970.		
PERIOD	TS	S	Returns the period of the metric in seconds. Valid input is metrics, not the results of other expressions.	**m1/PERIOD(m1)**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
RATE	TS TS[]	TS TS[]	Returns the rate of change of the metric per second. This is calculated as the difference between the latest data point value and the previous data point value, divided by the time difference in seconds between the two values. **Important** Setting alarms on expressions that use the RATE function on metrics with sparse data can behave unpredictably, because the range of data points fetched when evaluating the alarm can vary based on when the data	**RATE(m1)** **RATE(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			points were last published.		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
REMOVE_EMPTY	TS[]	TS[]	Removes any time series that have no data points from an array of time series. The result is an array of time series where each time series contains at least one data point. **Note** We recommend that you do not use this function in CloudWatch alarms. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts	**REMOVE_EMPTY(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			differently when extra data is requested.		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
RUNNING_SUM	TS TS[]	TS TS[]	Returns a time series with the running sum of the values in the original time series. **Note** We recommend that you do not use this function in CloudWatch alarms. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.	**RUNNING_SUM([m1,m2])**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
SEARCH	Search expressi n	One or more TS	Returns one or more time series that match a search criteria that you specify. The **SEARCH** function enables you to add multiple related time series to a graph with one expression. The graph is dynamically updated to include new metrics that are added later and match the search criteria. For more information, see Use search expressions in graphs. You can't create an alarm based on a **SEARCH** expression. This is because search expressions return multiple time series, and an alarm based on a math expression can watch only one time series. If you are signed in to a monitoring account in CloudWatch cross-		✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			account observability, the **SEARCH** function finds metrics in the source accounts and the monitoring account.		
SERVICE_QUOTA	TS that is a usage metric	TS	Returns the service quota for the given usage metric. You can use this to visualize how your current usage compares to the quota, and to set alarms that warn you when you approach the quota. For more information, see AWS usage metrics.		✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
SLICE	(TS[], S, S) or (TS[], S)	TS[] TS	Retrieves part of an array of time series. This is especially useful when combined with **SORT**. For example, you can exclude the top result from an array of time series. You can use two scalar arguments to define the set of time series that you want returned. The two scalars define the start (inclusive) and end (exclusive) of the array to return. The array is zero-indexed, so the first time series in the array is time series 0. Alternatively, you can specify just one value, and CloudWatch returns all time series starting with that value.	**SLICE(SORT(METRICS(), SUM, DESC), 0, 10)** returns the 10 metrics from the array of metrics in the request that have the highest SUM value. **SLICE(SORT(METRICS(), AVG, ASC), 5)** sorts the array of metrics by the AVG statistic, then returns all the time series except for the 5 with the lowest AVG.	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
SORT	(TS[], FUNCTI SORT_C R) (TS[], FUNCTI SORT_C R, S)	TS[]	Sorts an array of time series according to the function you specify. The function you use can be **AVG**, **MIN**, **MAX**, or **SUM**. The sort order can be either **ASC** for ascending (lowest values first) or **DESC** to sort the higher values first. You can optionall y specify a number after the sort order which acts as a limit. For example, specifying a limit of 5 returns only the top 5 time series from the sort. When this math function is displayed on a graph, the labels for each metric in the graph are also sorted and numbered.	**SORT(METRICS(), AVG, DESC, 10)** calculates the average value of each time series, sorts the time series with the highest values at the beginning of the sort, and returns only the 10 time series with the highest averages. **SORT(METRICS(), MAX, ASC)** sorts the array of metrics by the MAX statistic, then returns all of them in ascending order.	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
STDDEV	TS TS[]	S TS	The **STDDEV** of a single time series returns a scalar representing the standard deviation of all data points in the metric. The **STDDEV** of an array of time series returns a single time series. **Note** We recommend that you do not use this function in CloudWatch alarms if you want the function to return a scalar. For example, `STDDEV(m2)` Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data	**m1/STDDEV(m1)** **STDDEV(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.		

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
SUM	TS TS[]	S TS	The **SUM** of a single time series returns a scalar representing the sum of the values of all data points in the metric. The **SUM** of an array of time series returns a single time series. **Note** We recommend that you do not use this function in CloudWatch alarms if you want the function to return a scalar. For example, `SUM(m1)`. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data	**SUM(METRICS())/SUM(m1)** **SUM([m1,m2])** **SUM(METRICS("errors"))/SUM(METRICS("requests"))*100**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-account?
			points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.		
TIME_SERIES	S	TS	Returns a non-sparse time series where every value is set to a scalar argument.	**TIME_SERIES(MAX(m1))** **TIME_SERIES(5*AVG(m1))** **TIME_SERIES(10)**	✓

*Using a function that returns only a scalar number is not valid, as all final results of expressions must be a single time series or an array of time series. Instead, use these functions as part of a larger expression that returns a time series.

Using IF expressions

Use **IF** along with a comparison operator to filter out data points from a time series, or create a mixed time-series composed of multiple collated time series.

IF uses the following arguments:

```
IF(condition, trueValue, falseValue)
```

The condition evaluates to FALSE if the value of the condition data point is 0, and to TRUE if the value of the condition is any other value, whether that value is positive or negative. If the condition is a time series, it is evaluated separately for every timestamp.

The following lists the valid syntax's. For each of these syntax's, the output is a single time series.

- **IF(TS *Comparison Operator* S, S | TS, *S* / *TS*)**

  > **Note**
  >
  > If the `TS comparison operator S` is TRUE but `metric2` doesn't have a corresponding data point, the output will be 0.

- **IF(TS, TS, *TS*)**
- **IF(TS, S, *TS*)**
- **IF(TS, TS, S)**
- **IF(TS, S, S)**
- **IF(S, TS, *TS*)**

The following sections provide more details and examples for these syntax's.

IF(TS *Comparison Operator* S, scalar2 | metric2, scalar3 | metric3)

The corresponding output time series value:

- has the value of **scalar2** or **metric2**, if **TS *Comparison Operator* S** is TRUE
- has the value of **scalar3** or **metric3**, if **TS *Comparison Operator* S** is FALSE
- has the value of **0** if the **TS *Comparison Operator*** is TRUE and the corresponding data point in **metric2** doesn't exist.
- has the value of **0** if the **TS *Comparison Operator*** is FALSE and the corresponding data point in **metric3** doesn't exist.
- is an empty time series, if the corresponding data point of does not exist in **metric3**, or if **scalar3**/**metric3** is omitted from the expression

IF(metric1, metric2, *metric3*)

For each data point of **metric1**, the corresponding output time series value:

- has the value of **metric2**, if the corresponding data point of **metric1** is TRUE.
- has the value of **metric3**, if the corresponding data point of **metric1** is FALSE.
- has the value of **0**, if the corresponding data point of **metric1** is TRUE and the corresponding data point does not exist in **metric2**.
- has the value of **0**, if the corresponding data point of **metric1** is FALSE and the corresponding data point does not exist in **metric3**
- is dropped, if the corresponding data point of **metric1** is FALSE and **metric3** is omitted from the expression.
- is dropped, if the corresponding data point of **metric1** is missing.

The following table shows an example for this syntax.

Metric or function	Values
(metric1)	**[1, 1, 0, 0, -]**
(metric2)	**[30, -, 0, 0, 30]**
(metric3)	**[0, 0, 20, -, 20]**
IF(metric1, metric2, metric3)	**[30, 0, 20, 0, -]**

IF(metric1, scalar2, metric3)

For each data point of **metric1**, the corresponding output time series value:

- has the value of **scalar2**, if the corresponding data point of **metric1** is TRUE.
- has the value of **metric3**, if the corresponding data point of **metric1** is FALSE.
- is dropped, if the corresponding data point of **metric1** is FALSE and the corresponding data point does not exist on **metric3**, or if **metric3** is omitted from the expression.

Metric or function	Values
(metric1)	**[1, 1, 0, 0, -]**

Metric or function	Values
scalar2	**5**
(metric3)	**[0, 0, 20, -, 20]**
IF(metric1, scalar2, metric3)	**[5, 5, 20, -, -]**

IF(metric1, metric2, scalar3)

For each data point of **metric1**, the corresponding output time series value:

- has the value of **metric2**, if the corresponding data point of **metric1** is TRUE.
- has the value of **scalar3**, if the corresponding data point of **metric1** is FALSE.
- has the value of **0**, if the corresponding data point of **metric1** is TRUE and the corresponding data point does not exist in **metric2**.
- is dropped if the corresponding data point in **metric1** does not exist.

Metric or function	Values
(metric1)	**[1, 1, 0, 0, -]**
(metric2)	**[30, -, 0, 0, 30]**
scalar3	**5**
IF(metric1, metric2, scalar3)	**[30, 0, 5, 5, -]**

IF(scalar1, metric2, *metric3*)

The corresponding output time series value:

- has the value of **metric2**, if **scalar1** is TRUE.
- has the value of **metric3**, if **scalar1** is FALSE.
- is an empty time series, if **metric3** is omitted from the expression.

Use case examples for IF expressions

The following examples illustrate the possible uses of the **IF** function.

- To display only the low values of a metric:

  IF(metric1<400, metric1)
- To change each data point in a metric to one of two values, to show relative highs and lows of the original metric:

  IF(metric1<400, 10, 2)
- To display a 1 for each timestamp where latency is over the threshold, and display a 0 for all other data points:

  IF(latency>threshold, 1, 0)

Use metric math with the GetMetricData API operation

You can use `GetMetricData` to perform calculations using math expressions, and also retrieve large batches of metric data in one API call. For more information, see GetMetricData.

Anomaly detection on metric math

Anomaly detection on metric math is a feature that you can use to create anomaly detection alarms on single metrics and the outputs of metric math expressions. You can use these expressions to create graphs that visualize anomaly detection bands. The feature supports basic arithmetic functions, comparison and logical operators, and most other functions.

Anomaly detection on metric math doesn't support the following functions:

- Expressions that contain more than one **ANOMALY_DETECTION_BAND** in the same line.
- Expressions that contain more than 10 metrics or math expressions.
- Expressions that contain the **METRICS** expression.
- Expressions that contain the **SEARCH** function.
- Expressions that use the **DB_PERF_INSIGHTS** function.
- Expressions that use metrics with different periods.
- Expressions that use periods longer than one hour as input.
- Expressions that use high-resolution metrics as input.

For more information about this feature, see Using CloudWatch anomaly detection in the *Amazon CloudWatch User Guide*.

Using CloudWatch anomaly detection

When you enable *anomaly detection* for a metric, CloudWatch applies statistical and machine learning algorithms. These algorithms continuously analyze metrics of systems and applications, determine normal baselines, and surface anomalies with minimal user intervention.

The algorithms generate an anomaly detection model. The model generates a range of expected values that represent normal metric behavior.

You can enable anomaly detection using the AWS Management Console, the AWS CLI, CloudFormation, or the AWS SDK. You can enable anomaly detection on metrics vended by AWS and also on custom metrics. In an account set up as a monitoring account for CloudWatch cross-account observability, you can create anomaly detectors on metrics in source accounts in addition to metrics in the monitoring account.

You can use the model of expected values in two ways:

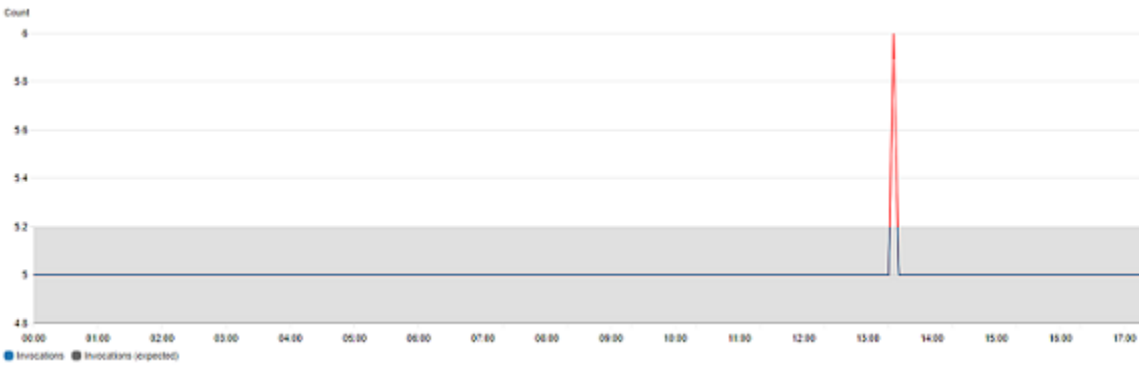
- Create anomaly detection alarms based on a metric's expected value. These types of alarms don't have a static threshold for determining alarm state. Instead, they compare the metric's value to the expected value based on the anomaly detection model.

  You can choose whether the alarm is triggered when the metric value is above the band of expected values, below the band, or both.

  For more information, see Create a CloudWatch alarm based on anomaly detection.
- When viewing a graph of metric data, overlay the expected values onto the graph as a band. This makes it visually clear which values in the graph are out of the normal range. For more information, see Creating a graph.

  You can also retrieve the upper and lower values of the model's band by using the `GetMetricData` API request with the `ANOMALY_DETECTION_BAND` metric math function. For more information, see GetMetricData.

In a graph with anomaly detection, the expected range of values is shown as a gray band. If the metric's actual value goes beyond this band, it is shown as red during that time.



Anomaly detection algorithms account for the seasonality and trend changes of metrics. The seasonality changes could be hourly, daily, or weekly, as shown in the following examples.

The longer-range trends could be downward or upward.

Anomaly detection also works well with metrics with flat patterns.

How CloudWatch anomaly detection works

When you enable anomaly detection for a metric, CloudWatch applies machine learning algorithms to the metric's past data to create a model of the metric's expected values. The model assesses both trends and hourly, daily, and weekly patterns of the metric. The algorithm trains on up to two weeks of metric data, but you can enable anomaly detection on a metric even if the metric does not have a full two weeks of data.

You specify a value for the anomaly detection threshold that CloudWatch uses along with the model to determine the "normal" range of values for the metric. A higher value for the anomaly detection threshold produces a thicker band of "normal" values.

The machine learning model is specific to a metric and a statistic. For example, if you enable anomaly detection for a metric using the `AVG` statistic, the model is specific to the `AVG` statistic.

When CloudWatch creates a model for many common metrics from AWS services, it ensures that the band doesn't extend outside of logical values. For example, the band for `MemoryUtilization` of an EC2 instance will stay between 0 and 100, and the bands tracking CloudFront `Requests`, which can't be negative, will never extend below zero.

After you create a model, CloudWatch anomaly detection continually evaluates the model and makes adjustments to it to make sure that it is as accurate as possible. This includes re-training the model to adjust if the metric values evolve over time or have sudden changes, and also includes predictors to improve the models of metrics that are seasonal, spiky, or sparse.

After you enable anomaly detection on a metric, you can choose to exclude specified time periods of the metric from being used to train the model. This way, you can exclude deployments or other unusual events from being used for model training, ensuring the most accurate model is created.

Using anomaly detection models for alarms incurs charges on your AWS account. For more information, see Amazon CloudWatch Pricing.

Anomaly detection on metric math

Anomaly detection on metric math is a feature that you can use to create anomaly detection alarms on the output metric math expressions. You can use these expressions to create graphs that visualize anomaly detection bands. The feature supports basic arithmetic functions, comparison and logical operators, and most other functions. For information about functions that are not supported, see Using metric math in the *Amazon CloudWatch User Guide*.

You can create anomaly detection models based on metric math expressions similar to how you already create anomaly detection models. From the CloudWatch console, you can apply anomaly detection to metric math expressions and select anomaly detection as a threshold type for these expressions.

> **Note**
>
> Anomaly detection on metric math only can be enabled and edited in the latest version of the metrics user interface. When you create anomaly detectors based on metric math expressions in the new version of the interface, you can view them in the old version, but not edit them.

For information about how to create, edit, and delete alarms and models for anomaly detection and metric math, see the following sections:

- Create a CloudWatch alarm based on anomaly detection
- Editing an anomaly detection model
- Deleting an anomaly detection model
- Improving anomaly detection alarm accuracy with feedback
- Creating a CloudWatch alarm based on a metric math expression

You also can create, delete, and discover anomaly detection models based on metric math expressions using the CloudWatch API with `PutAnomalyDetector`, `DeleteAnomalyDetector`, and `DescribeAnomalyDetectors`. For information about these API actions, see the following sections in the *Amazon CloudWatch API Reference*.

- PutAnomalyDetector
- DeleteAnomalyDetector

- DescribeAnomalyDetectors

For information about how anomaly detection alarms are priced, see Amazon CloudWatch pricing.

Query metrics from other data sources

You can use CloudWatch to query, visualize, and create alarms for metrics from other data sources. To do so, you connect CloudWatch to the other data sources. This gives you a single, consolidated monitoring experience within the CloudWatch console. You can have a unified view of your infrastructure and application metrics regardless of where the data is stored, helping you identify and resolve issues faster.

After you connect to a data source using a CloudWatch wizard, CloudWatch creates an AWS CloudFormation stack that deploys and configures an AWS Lambda function. This Lambda function runs on demand every time you query the data source. The CloudWatch query builder shows you in real time a list of elements that can be queried, such as metrics, tables, fields, or labels. As you make choices, the query builder pre-populates a query in the native language of the selected source.

CloudWatch provides guided wizards for you to connect to the following data sources. For these data sources, you provide basic information to identify the data source and credentials. You can also manually create connectors to other data sources by creating your own Lambda functions.

- Amazon OpenSearch Service– Derive metrics from your OpenSearch Service logs and traces.
- Amazon Managed Service for Prometheus– Query these metrics using PromQL.
- Amazon RDS for MySQL – Use SQL to convert data stored in your Amazon RDS tables into metrics.
- Amazon RDS for PostgreSQL– Use SQL to convert data stored in your Amazon RDS tables into metrics.
- Amazon S3 CSV files– Display metrics data from a CSV file stored in an Amazon S3 bucket.
- Microsoft Azure Monitor– Query metrics from your Microsoft Azure Monitor account.
- Prometheus– Query these metrics using PromQL.

After you create connectors to data sources, see Creating a graph of metrics from another data source for information about graphing a metric from a data source. For information about setting an alarm on a metric from a data source, see Create an alarm based on a connected data source.

Topics

- Managing access to data sources
- Connect to a prebuilt data source with a wizard
- Create a custom connector to a data source
- Use your custom data source
- Delete a connector to a data source

Managing access to data sources

CloudWatch uses CloudFormation to create the required resources in your account. We recommend that you use the `cloudformation:TemplateUrl` condition to control access to CloudFormation templates when you grant `CreateStack` permissions to IAM users.

> **Warning**
>
> Any user that you grant data source invoke permission to can query metrics from that data source even if that user does not have direct IAM permissions to the data source. For example, if you grant `lambda:InvokeFunction` permissions on a Amazon Managed Service for Prometheus data source Lambda function to a user, that user will be able to query metrics from the corresponding Amazon Managed Service for Prometheus workspace even if you didn't grant them direct IAM access to that workspace.

You can find template URLs for data sources on the **Create stack** page in the CloudWatch Settings Console.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCloudFormationCreateStack",
            "Effect": "Allow",
            "Action": [
```

```
                "cloudformation:CreateStack"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "cloudformation:TemplateUrl": [
                        "https://s3.us-east-1.amazonaws.com/amzn-s3-demo-bucket/
template.json"
                    ]
                }
            }
        }
    ]
}
```

For more information about controlling CloudFormation access, see Controlling access with AWS Identity and Access Management

Connect to a prebuilt data source with a wizard

This topic provides instructions for using the wizard to connect CloudWatch to the following data sources.

- Amazon OpenSearch Service
- Amazon Managed Service for Prometheus
- Amazon RDS for MySQL
- Amazon RDS for PostgreSQL
- Amazon S3 CSV files
- Microsoft Azure Monitor
- Prometheus

The subsections in this topic include notes about managing and querying with each of these data sources.

To create a connector to a data source

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Settings**.
3. Choose the **Metrics data sources** tab.
4. Choose **Create data source**.
5. Select the source that you want, then choose **Next**.
6. Enter a name for the data source.
7. Enter the other required information, depending on the data source that you chose. This can include credentials to access the data source and data source identifying information such as Prometheus workspace name, database name, or Amazon S3 bucket name. For AWS services, the wizard discovers the resources and populates them into the selection dropdown.

   For more notes about the data source you are using, see the sections after this procedure.
8. To have CloudWatch connect to the data source in a VPC, choose **Use a VPC** and select the VPC to use. Then select the subnet and security group.
9. Choose **I acknowledge that CloudFormation will create IAM resources**. This resource is the Lambda function execution role.
10. Choose **Create data source**.

    The new source that you just added doesn't appear until the CloudFormation stack is done creating it. To check progress, you can choose **View the status of my CloudFormation stack**. Or you can choose the refresh icon to update this list.

    When your new data source appears in this list, it is ready to use. You can choose **Query from CloudWatch metrics** to begin querying with it. For more information, see Creating a graph of metrics from another data source.

Amazon Managed Service for Prometheus

Updating the data source configuration

- You can update your data source manually by doing the following:
  - To update the Amazon Managed Service for Prometheus workspace ID, update the `AMAZON_PROMETHEUS_WORKSPACE_ID` environment variable for the data source connector Lambda function.
  - To update the VPC configuration, see Configuring VPC access (console) for more information.

Querying the data source

- When querying Amazon Managed Service for Prometheus, after you select the data source in the **Multi source query** tab and select an Amazon Managed Service for Prometheus connector, you can use the **Query helper** to discover metrics and labels and provide simple PromQL queries. You can also use the PromQL query editor to build a PromQL query.
- Multi-line queries are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid. For example, if your query contains a single line comment it will not be valid. If you try to create a dashboard or alarm with a multi-line query from the command line or Infrastructure as Code, the API will reject the action with a parse error.

Amazon OpenSearch Service

Creating the data source

If the OpenSearch domain is enabled for FGAC, you must map the execution role of the connector Lambda function to a user in OpenSearch Service. For more information, see the **Mapping users to roles** section in Managing permissions in the OpenSearch Service documentation.

If your OpenSearch domain is only accessible within a Virtual Private Cloud (VPC), you need to manually include a new environment variable in the Lambda function called `AMAZON_OPENSEARCH_ENDPOINT`. The value for this variable should be the root domain of the OpenSearch endpoint. You can obtain this root domain by removing `https://` and `<region>.es.amazonaws.com` from the domain endpoint listed in the OpenSearch Service console. For example, if your domain endpoint is `https://sample-domain.us-east-1.es.amazonaws.com`, the root domain would be `sample-domain`.

Updating the data source

- You can update your data source manually by doing the following:
  - To update the OpenSearch Service domain, update the `AMAZON_OPENSEARCH_DOMAIN_NAME` environment variable for the data source connector Lambda function.
  - To update the VPC configuration, see Configuring VPC access (console) for more information.

Querying the data source

- When querying OpenSearch Service, after you select the data source in the **Multi source query** tab, do the following:

- Select the Index to query.
- Select the Metric name (Any numeric field in the document) and Stat.
- Select the Time axis (Any date field in the document).
- Select Filters to apply (Any String field in the document).
- Choose **Graph query**.

Amazon RDS for PostgreSQL and Amazon RDS for MySQL

Creating the data source

- If your data source is only accessible in a VPC, you must include the VPC configuration for the connector, as described in Connect to a prebuilt data source with a wizard. If the data source is to connect to the VPC for credentials, the endpoint must be configured in the VPC. For more information, see Using an AWS Secrets Manager VPC endpoint.

  Additionally, you must create a VPC endpoint for the Amazon RDS service. For more information, see Amazon RDS API and interface VPC endpoints (AWS PrivateLink).

Updating the data source

- You can update your data source manually by doing the following:
  - To update the database instance, update the `RDS_INSTANCE` environment variable for the data source connector Lambda function.
  - To update the username and password used to connect to Amazon RDS, use AWS Secrets Manager. You can find the ARN of the secret used for the data source in the environment variable `RDS_SECRET` on the data source Lambda function. For more information about updating the secret in AWS Secrets Manager, see Modify an AWS Secrets Manager secret.
  - To update the VPC configuration, see Configuring VPC access (console) for more information.

Querying the data source

- When querying Amazon RDS, after you select the data source in the **Multi source query** tab and select an Amazon RDS connector, you can use the database discoverer to view available databases, tables, and columns. You can also use the SQL editor to create an SQL query.

  You can use the following variables in the query:

- `$start.iso` – The start time in ISO date format
- `$end.iso` – The end time in ISO date format
- `$period` – The selected period in seconds

  For example, you can query `SELECT value, timestamp FROM table WHERE timestamp BETWEEN $start.iso and $end.iso`
- Multi-line queries are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid. For example, if your query contains a single line comment it will not be valid. If you try to create a dashboard or alarm with a multi-line query from the command line or Infrastructure as Code, the API will reject the action with a parse error.

> **Note**
>
> If no date field is found in the results, the values for each numeric field are summed to single values and plotted across the provided time range. If the timestamps don't align with the selected period in CloudWatch, the data is automatically aggregated using `SUM` and aligned with the period in CloudWatch.

Amazon S3 CSV files

Querying the data source

- When querying Amazon S3 CSV files, after you select the data source in the **Multi source query** tab and select an Amazon S3 connector, you select the Amazon S3 bucket and key.

  The CSV file must be formatted in the following ways:
  - The time stamp must be the first column.
  - The table must have a header row. The headers are used to name your metrics. The title of the time stamp column will be ignored, only the titles of the metrics columns are used.
  - The time stamps must be in ISO date format.
  - The metrics must be numeric fields.

```
Timestamp, Metric-1, Metric-2, ...
```

The following is an example:

timestamp	CPU (%)	Memory (%)	Storage (%)
2023-11-23T17:09:41+00:00	1	2	3
2023-11-23T17:04:41+00:00	4	5	6
2023-11-23T16:59:41+00:00	7	8	9
2023-11-23T16:54:41+00:00	10	11	12

Note

If no timestamp is provided, the values for each metric are summed to single values and plotted across the provided time range. If the timestamps don't align with the selected period in CloudWatch, the data is automatically aggregated using `SUM` and aligned with the period in CloudWatch.

Microsoft Azure Monitor

Creating the data source

- You must provide your tenant ID, client ID, and client secret to connect to Microsoft Azure Monitor. The credentials will be stored in AWS Secrets Manager. For more information, see Create a Microsoft Entra application and service principal that can access resources in the Microsoft documentation.

Updating the data source

- You can update your data source manually by doing the following:

- To update the tenant ID, client ID, and client secret used to connect to Azure Monitor, you can find the ARN of the secret used for the data source as the `AZURE_CLIENT_SECRET` environment variable on the data source Lambda function. For more information about updating the secret in AWS Secrets Manager, see Modify an AWS Secrets Manager secret.

Querying the data source

- When querying Azure Monitor, after you select the data source in the **Multi source query** tab and select an Azure Monitor connector, you specify the Azure subscription, and the resource group and resource. You can then select the metric namespace, metric, and aggregation, and filter by dimensions.

Prometheus

Creating the data source

- You must provide the Prometheus endpoint and the user and password required to query Prometheus. The credentials will be stored in AWS Secrets Manager.
- If your data source is only accessible in a VPC, you must include the VPC configuration for the connector, as described in Connect to a prebuilt data source with a wizard. If the data source is to connect to for credentials, the endpoint must be configured in the VPC. For more information, see Using an AWS Secrets Manager VPC endpoint.

Updating data source configuration

- You can update your data source manually by doing the following:
  - To update the Prometheus endpoint, specify the new endpoint as the `PROMETHEUS_API_ENDPOINT` environment variable on the data source Lambda function.
  - To update the username and password used to connect to Prometheus, you can find the ARN of the secret used for the data source as the `PROMETHEUS_API_SECRET` environment variable on the data source Lambda function. For more information about updating the secret in AWS Secrets Manager, see Modify an AWS Secrets Manager secret.
  - To update the VPC configuration, see Configuring VPC access (console) for more information.

Querying the data source

Important

Prometheus metric types are different than CloudWatch metrics and many metrics available through Prometheus are cumulative by design. When you query Prometheus metrics, CloudWatch doesn't apply any additional transformation to the data: if you specify only the metric name or label, the displayed value will be cumulative. For more information, see Metric types in the Prometheus documentation.
To see Prometheus metrics data as discrete values, like CloudWatch metrics, you need to edit the query before you run it. For example, you might need to add a call to the rate function over your Prometheus metric name. For documentation about the rate function and other Prometheus functions, see rate() in the Prometheus documentation.

Multi-line queries are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid. For example, if your query contains a single line comment it will not be valid. If you try to create a dashboard or alarm with a multi-line query from the command line or Infrastructure as Code, the API will reject the action with a parse error.

Notification of Available Updates

From time to time, Amazon might notify you that we recommend that you update your connectors with a newer available version and will provide instructions for how to do so.

Create a custom connector to a data source

This topic describes how to connect a custom data source to CloudWatch. You can connect a custom data source to CloudWatch in two ways:

- Using a sample template that CloudWatch provides. You can use either JavaScript or Python with this template. These templates include sample Lambda code that will be useful to you when you create your Lambda function. You can then modify the Lambda function from the template to connect to your custom data source.
- Creating an AWS Lambda function from scratch that implements the data source connector, the data query, and the preparation of the time series for use by CloudWatch. This function must pre-aggregate or merge datapoints if needed, and also align the period and timestamps to be compatible with CloudWatch.

Contents

- Use a template
- Create a custom data source from scratch
  - Step 1: Create the function
    - GetMetricData event
    - DescribeGetMetricData event
    - Important considerations for CloudWatch alarms
    - (Optional) Use AWS Secrets Manager to store credentials
    - (Optional) Connect to a data source in a VPC
  - Step 2: Create a Lambda permissions policy
  - Step 3: Attach a resource tag to the Lambda function

Use a template

Using a template creates a sample Lambda function, and can help you get your custom connector built faster. These sample functions provide sample code for many common scenarios involved with building a custom connector. You can examine the Lambda code after you create a connector with a template, then modify it to use to connect to your data source.

Additionally, if you use the template, CloudWatch takes care of creating the Lambda permissions policy and attaching resource tags to the Lambda function.

To use the template to create a connector to a custom data source

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Metrics data sources** tab.
4. Choose **Create data source**.
5. Choose the radio button for **Custom - getting started template** and then choose **Next**.
6. Enter a name for the data source.
7. Select the one of the listed templates.
8. Select either Node.js or Python.
9. Choose **Create data source**.

The new custom source that you just added doesn't appear until the CloudFormation stack finishes creating it. To check progress, you can choose **View the status of my CloudFormation stack**. Or you can choose the refresh icon to update this list.

When your new data source appears in this list, it is ready for you to test in the console and modify.

10. (Optional) To query the test data from this source in the console, follow the instructions in Creating a graph of metrics from another data source.
11. Modify the Lambda function for your needs.

    a. In the navigation pane, choose **Settings**.

    b. Choose the **Metrics data sources** tab.

    c. Choose **View in Lambda console** for the source that you want to modify.

    You can now modify the function to access your data source. For more information, see Step 1: Create the function.

    > **Note**
    >
    > By using the template, when you write your Lambda function you don't need to follow the instructions in Step 2: Create a Lambda permissions policy or Step 3: Attach a resource tag to the Lambda function. These steps were performed by CloudWatch because you used the template.

Create a custom data source from scratch

Follow the steps in this section to create a Lambda function that connects CloudWatch to a data source.

Step 1: Create the function

A custom data source connector must support `GetMetricData` events from CloudWatch. Optionally, you can also implement a `DescribeGetMetricData` event to provide documentation to users in the CloudWatch console for how to use the connector. The `DescribeGetMetricData` response can also be used to set defaults that are used in the CloudWatch custom query builder.

CloudWatch provides code snippets as samples to help you get started. For more information, see the samples repository at https://github.com/aws-samples/cloudwatch-data-source-samples.

Constraints

- The response from Lambda must be smaller than 6 Mb. If the response exceeds 6 Mb, the `GetMetricData` response marks the Lambda function as `InternalError` and no data is returned.
- The Lambda function must complete its execution within 10 seconds for visualization and dashboarding purposes, or within 4.5 seconds for alarms usage. If the execution time exceeds that time, the `GetMetricData` response marks the Lambda function as `InternalError` and no data is returned.
- The Lambda function must send its output using epoch timestamps in seconds.
- If the Lambda function doesn't resample the data and instead returns data that doesn't correspond to the start time and period length that was requested by the CloudWatch user, that data is ignored by CloudWatch. The extra data is discarded from any visualization or alarming. Any data that is not between the start time and end time is also discarded.

  For example, if a user asks for data from 10:00 to 11:00 with a period of 5 min, then "10:00:00 to 10:04:59" and "10:05:00 to 10:09:59" are the valid time ranges for data to be returned. You must return a time series that includes `10:00 value1`, `10:05 value2`, and so on. If the function returns `10:03 valueX`, for example, it gets dropped because 10:03 does not correspond to the requested start time and period.
- Multi-line queries are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid.

GetMetricData event

Request payload

The following is an example of a `GetMetricData` request payload sent as input to the Lambda function.

```
{
  "EventType": "GetMetricData",
  "GetMetricDataRequest": {
    "StartTime": 1697060700,
```

```
    "EndTime": 1697061600,
    "Period": 300,
    "Arguments": ["serviceregistry_external_http_requests{host_cluster!=\"prod\"}"]
  }
}
```

- **StartTime**– The timestamp specifying the earliest data to return. The **Type** is timestamp epoch seconds.
- **EndTime**– The timestamp specifying the latest data to return. The **Type** is timestamp epoch seconds.
- **Period**– The number of seconds that each aggregation of the metrics data represents. The minimum is 60 seconds. The **Type** is Seconds.
- **Arguments**– An array of arguments to pass to the Lambda metric math expression. For more information about passing arguments, see How to pass arguments to your Lambda function.

Response payload

The following is an example of a `GetMetricData` response payload returned by the Lambda function.

```
{
   "MetricDataResults": [
      {
         "StatusCode": "Complete",
         "Label": "CPUUtilization",
         "Timestamps": [ 1697060700, 1697061000, 1697061300 ],
         "Values": [ 15000, 14000, 16000 ]
      }
   ]
}
```

The response payload will contain either a `MetricDataResults` field or an `Error` field, but not both.

A `MetricDataResults` field is a list of time-series fields of type `MetricDataResult`. Each of those time-series fields can include the following fields.

- **StatusCode**– (Optional) `Complete` indicates that all data points in the requested time range were returned. `PartialData` means that an incomplete set of data points were returned. If this is omitted, the default is `Complete`.

  Valid Values: `Complete` | `InternalError` | `PartialData` | `Forbidden`
- **Messages**– Optional list of messages with additional information about the data returned.

  Type: Array of MessageData objects with `Code` and `Value` strings.
- **Label**– The human-readable label associated with the data.

  Type: String
- **Timestamps**– The timestamps for the data points, formatted in epoch time. The number of timestamps always matches the number of values and the value for `Timestamps[x]` is `Values[x]`.

  Type: Array of timestamps
- **Values**– The data point values for the metric, corresponding to `Timestamps`. The number of values always matches the number of timestamps and the value for `Timestamps[x]` is `Values[x]`.

  Type: Array of doubles

For more information about `Error` objects, see the following sections.

Error response formats

You can optionally use the error response to provide more information about errors. We recommend that you return an error with Code Validation when a validation error occurs, such as when a parameter is missing or is the wrong type.

The following is an example of the response when the Lambda function wants to raise a `GetMetricData` validation exception.

```
{
   "Error": {
      "Code": "Validation",
      "Value": "Invalid Prometheus cluster"
   }
}
```

The following is an example of the response when the Lambda function indicates that it's unable to return data because of an access issue. The response is translated into a single time series with a status code of `Forbidden`.

```
{
   "Error": {
      "Code": "Forbidden",
      "Value": "Unable to access ..."
   }
}
```

The following is an example of when the Lambda function raises an overall `InternalError` exception, which is translated into a single time series with a status code of `InternalError` and a message. Whenever an error code has a value other than `Validation` or `Forbidden`, CloudWatch assumes that it's a generic internal error.

```
{
   "Error": {
      "Code": "PrometheusClusterUnreachable",
      "Value": "Unable to communicate with the cluster"
   }
}
```

DescribeGetMetricData event

Request payload

The following is an example of a `DescribeGetMetricData` request payload.

```
{
  "EventType": "DescribeGetMetricData"
}
```

Response payload

The following is an example of a `DescribeGetMetricData` response payload.

```
{
    "Description": "Data source connector",
    "ArgumentDefaults": [{
        Value: "default value"
```

```
    }]
}
```

- **Description**– A description of how to use the data source connector. This description will appear in the CloudWatch console. Markdown is supported.

  Type: String

- **ArgumentDefaults**– Optional array of argument default values used pre-populate the custom data source builder.

  If `[{ Value: "default value 1"}, { Value: 10}]`, is returned, the query builder in the CloudWatch console displays two inputs, the first with “default value 1” and the second with 10.

  If `ArgumentDefaults` is not provided, a single input is displayed with type default set to `String`.

  Type: Array of objects containing Value and Type.

- **Error**– (Optional) An error field can be included in any response. You can see examples in GetMetricData event.

Important considerations for CloudWatch alarms

If you are going to use the data source to set CloudWatch alarms, you should set it up to report data with timestamps every minute to CloudWatch. For more information and other considerations for creating alarms on metrics from connected data sources, see Create an alarm based on a connected data source.

(Optional) Use AWS Secrets Manager to store credentials

If your Lambda function needs to use credentials to access the data source, use AWS Secrets Manager to store these credentials instead of hardcoding them into your Lambda function. For more information about using AWS Secrets Manager with Lambda, see Use AWS Secrets Manager secrets in AWS Lambda functions.

(Optional) Connect to a data source in a VPC

If your data source is in a VPC managed by Amazon Virtual Private Cloud, you must configure your Lambda function to access it. For more information, see Connecting outbound networking to resources in a VPC.

You might also need to configure VPC service endpoints to access services such as AWS Secrets Manager. For more information, see Access an AWS service using an interface VPC endpoint.

Step 2: Create a Lambda permissions policy

You must use create a policy statement that grants CloudWatch permission to use the Lambda function that you created. You can use the AWS CLI or the Lambda console to create the policy statement.

To use the AWS CLI to create the policy statement

- Enter the following command. Replace *123456789012* with your account ID, replace *my-data-source-function* with the name of your Lambda function, and replace *MyDataSource-DataSourcePermission1234* with an arbitrary unique value.

```
aws lambda add-permission --function-name my-data-source-function --statement-
id MyDataSource-DataSourcePermission1234 --action lambda:InvokeFunction --principal
 lambda.datasource.cloudwatch.amazonaws.com --source-account 123456789012
```

Step 3: Attach a resource tag to the Lambda function

The CloudWatch console determines which of your Lambda functions are data source connectors by using a tag. When you create a data source using one of the wizards, the tag is automatically applied by the CloudFormation stack that configures it. When you create a data source yourself, you can use the following tag for your Lambda function. This makes your connector appear in the **Data source** dropdown in the CloudWatch console when you query metrics.

- A tag with `cloudwatch:datasource` as the key and `custom` as the value.

Use your custom data source

After you create a data source, you can use it to query and visualize data from that source, as well as to set alarms. If you used a template to create your custom data source connector or you added the tag listed in Step 3: Attach a resource tag to the Lambda function, you can follow the steps in Creating a graph of metrics from another data source to query it. You can also use the metric math function LAMBDA to query it, as explained in the following section. For information about creating alarms on metrics from your data source, see Create an alarm based on a connected data source. This topic describes how to pass arguments to your Lambda function to your custom data source.

How to pass arguments to your Lambda function

The recommended way for you to pass arguments to your custom data source is to use the query builder in the CloudWatch console when you query the data source.

You can also use your Lambda function to retrieve data from your data source by using the new LAMBDA expression in CloudWatch metric math.

```
LAMBDA("LambdaFunctionName" [, optional-arg]*)
```

`optional-arg` is up to 20 strings, numbers, or Booleans. For example, `param`, `3.14`, or `true`.

> **Note**
>
> Multi-line strings are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid.

When you use the LAMBDA metric math function, you can provide the function name (`"MyFunction"`). If your resource policy allows, you can also use a specific version of the function (`"MyFunction:22"`), or a Lambda function alias (`"MyFunction:MyAlias"`). You can't use *

The following are some examples of calling the LAMBDA function.

```
LAMBDA("AmazonOpenSearchDataSource", "MyDomain", "some-query")
```

```
LAMBDA("MyCustomDataSource", true, "fuzzy", 99.9)
```

The LAMBDA metric math function returns a list of time series that can be returned to the requester or combined with other metric math functions. The following is an example of combining LAMBDA with other metric math functions.

```
FILL(LAMBDA("AmazonOpenSearchDataSource", "MyDomain", "some-query"), 0)
```

Delete a connector to a data source

The instructions in this section describe how to delete a connector to a data source.

To delete a connector to a data source

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Metrics data sources** tab.
4. Choose **Manage in CloudFormation** in the row of the data source that you want to delete.

   You are taken to the CloudFormation console.
5. In the section with the name of your data source, choose **Delete**.
6. In the confirmation pop-up, choose **Delete**.

Grafana integration

You can use Grafana version 6.5.0 and later to contextually advance through the CloudWatch console and query a dynamic list of metrics by using wildcards. This can help you monitor metrics for AWS resources, such as Amazon Elastic Compute Cloud instances or containers. When new instances are created as part of an Auto Scaling event, they appear in the graph automatically. You don't need to track the new instance IDs. Prebuilt dashboards help simplify the getting started experience for monitoring Amazon EC2, Amazon Elastic Block Store, and AWS Lambda resources.

You can use Grafana version 7.0 and later to perform CloudWatch Logs Insights queries on log groups in CloudWatch Logs. You can visualize your query results in bar, line, and stacked graphs and in a table format. For more information about CloudWatch Logs Insights, see Analyzing Log Data with CloudWatch Logs Insights.

For more information about how to get started, see Using AWS CloudWatch in Grafana in the Grafana Labs documentation.

AWS services that publish CloudWatch metrics

You can use the following table to learn which AWS services publish metrics to CloudWatch. For information about the metrics and dimensions, see the specified documentation.

Service	Namespace	Documentation
AWS Amplify	`AWS/AmplifyHosting`	Monitoring

Service	Namespace	Documentation
Amazon API Gateway	AWS/ApiGateway	Monitor API Execution with Amazon CloudWatch
Amazon AppFlow	AWS/AppFlow	Monitoring Amazon AppFlow with Amazon CloudWatch
AWS Application Migration Service	AWS/MGN	Monitoring Application Migration Service with Amazon CloudWatch
AWS App Runner	AWS/AppRunner	Viewing App Runner service metrics reported to CloudWatch
WorkSpaces Applications	AWS/AppStream	Monitoring Amazon AppStream 2.0 Resources
AWS AppSync	AWS/AppSync	CloudWatch Metrics
Amazon Athena	AWS/Athena	Monitoring Athena Queries with CloudWatch Metrics
Amazon Aurora	AWS/RDS	Amazon Aurora metrics
AWS Backup	AWS/Backup	Monitoring AWS Backup Metrics with CloudWatch
Amazon Bedrock Guardrails	AWS/Bedrock/Guardrails	Monitoring Amazon Bedrock Guardrails using CloudWatch Metrics
AWS Billing and Cost Management	AWS/Billing	Monitoring Charges with Alerts and Notifications
Amazon Braket	AWS/Braket/By Device	Monitoring Amazon Braket with Amazon CloudWatch
AWS Certificate Manager	AWS/CertificateManager	Supported CloudWatch Metrics

Service	Namespace	Documentation
AWS Private CA	`AWS/ACMPrivateCA`	Supported CloudWatch Metrics
Amazon Q Developer in chat applications	`AWS/Chatbot`	Monitoring Amazon Q Developer in chat applications with Amazon CloudWatch
Amazon Chime	`AWS/ChimeVoiceConnector`	Monitoring Amazon Chime with Amazon CloudWatch
Amazon Chime SDK	`AWS/ChimeSDK`	Service metrics
AWS Client VPN	`AWS/ClientVPN`	Monitoring with Amazon CloudWatch
Amazon CloudFront	`AWS/CloudFront`	Monitoring CloudFront Activity Using CloudWatch
AWS CloudHSM	`AWS/CloudHSM`	Getting CloudWatch Metrics
Amazon CloudSearch	`AWS/CloudSearch`	Monitoring an Amazon CloudSearch Domain with Amazon CloudWatch
AWS CloudTrail	`AWS/CloudTrail`	Supported CloudWatch metrics
CloudWatch agent	`CWAgent` or a custom namespace	Metrics collected by the CloudWatch agent
CloudWatch Application Signals	`ApplicationSignals`	Metrics collected by Application Signals

Service	Namespace	Documentation
CloudWatch metric streams	`AWS/CloudWatch/MetricStreams`	Monitoring your metric streams with CloudWatch metrics
CloudWatch RUM	`AWS/RUM`	CloudWatch metrics that you can collect with CloudWatch RUM
CloudWatch Synthetics	`CloudWatchSynthetics`	CloudWatch metrics published by canaries
Amazon CloudWatch Logs	`AWS/Logs`	Monitoring Usage with CloudWatch Metrics
AWS CodeBuild	`AWS/CodeBuild`	Monitoring AWS CodeBuild
Amazon CodeGuru Reviewer		Monitoring CodeGuru Reviewer with Amazon CloudWatch
AWS CodePipeline		AWS CodePipeline CloudWatch metrics
Amazon Kendra		Monitoring Amazon Kendra with Amazon CloudWatch
Amazon Cognito	`AWS/Cognito`	Monitoring Amazon Cognito
Amazon Comprehend	`AWS/Comprehend`	Monitoring Amazon Comprehend endpoints
AWS Config	`AWS/Config`	AWS Config Usage and Success Metrics
Connect Customer	`AWS/Connect`	Monitoring Connect Customer in Amazon CloudWatch Metrics

Service	Namespace	Documentation
Amazon Data Lifecycle Manager	AWS/DataLifecycleManager	Monitor your policies using Amazon CloudWatch
AWS DataSync	AWS/DataSync	Monitoring Your Task
Amazon DataZone		Monitoring Amazon DataZone with Amazon CloudWatch
Amazon DevOps Guru	AWS/DevOps-Guru	Monitoring Amazon DevOps Guru with Amazon CloudWatch
AWS Database Migration Service	AWS/DMS	Monitoring AWS DMS Tasks
Direct Connect	AWS/DX	Monitoring with Amazon CloudWatch
AWS Directory Service	AWS/DirectoryService	Use Amazon CloudWatch metrics to determine when to add domain controllers
Amazon DocumentDB	AWS/DocDB	Monitoring Amazon DocumentDB with CloudWatch
Amazon DynamoDB	AWS/DynamoDB	DynamoDB Metrics and Dimensions
DynamoDB Accelerator (DAX)	AWS/DAX	Viewing DAX Metrics and Dimensions
Amazon EC2	AWS/EC2	Monitoring Your Instances Using CloudWatch
Amazon EC2 Elastic Graphics	AWS/ElasticGPUs	Using CloudWatch metrics to monitor Elastic Graphics

Service	Namespace	Documentation
Amazon EC2 Spot Fleet	AWS/EC2Spot	CloudWatch Metrics for Spot Fleet
Amazon EC2 Auto Scaling	AWS/AutoScaling	Monitoring Your Auto Scaling Groups and Instances Using CloudWatch
AWS Elastic Beanstalk	AWS/ElasticBeanstalk	Publishing Amazon CloudWatch Custom Metrics for an Environment
Amazon Elastic Block Store	AWS/EBS	Amazon CloudWatch Metrics for Amazon EBS
Amazon Elastic Container Registry	AWS/ECR	Amazon ECR repository metrics
Amazon Elastic Container Service	AWS/ECS	Amazon ECS CloudWatch Metrics
Amazon ECS through CloudWatch Container Insights	ECS/ContainerInsights	Amazon ECS Container Insights metrics
Amazon ECS Cluster auto scaling	AWS/ECS/ManagedScaling	Amazon ECS cluster auto scaling

Amazon WorkSpaces Web	`AWS/WorkSpacesWeb`	Monitoring Amazon WorkSpaces Web with Amazon CloudWatch

Using Amazon CloudWatch alarms

You can create alarms that watch metrics and send notifications or automatically make changes to the resources you are monitoring when a threshold is breached. For example, you can monitor the CPU usage and disk reads and writes of your Amazon EC2 instances and then use that data to determine whether you should launch additional instances to handle increased load. You can also use this data to stop under-used instances to save money.

You can create both *metric* and *composite* alarms in Amazon CloudWatch.

You can create alarms on Metrics Insights queries that use AWS resource tags to filter and group metrics. To use tags with alarms, on the CloudWatch console, choose **Settings**. On the **CloudWatch Settings** page, under **Enable resource tags on telemetry**, choose **Enable**. For context-aware monitoring that automatically adapts to your tagging strategy, create alarms on Metrics Insights queries using AWS resource tags. This allows you to monitor all resources tagged with specific applications or environments.

- A *metric alarm* watches a single CloudWatch metric or the result of a math expression based on CloudWatch metrics. The alarm performs one or more actions based on the value of the metric or expression relative to a threshold over a number of time periods. The action can be sending a notification to an Amazon SNS topic, performing an Amazon EC2 action or an Amazon EC2 Auto Scaling action, starting an investigation in CloudWatch investigations, or creating an OpsItem or incident in Systems Manager.
- A *PromQL alarm* monitors metrics using a Prometheus Query Language (PromQL) instant query on metrics ingested through the CloudWatch OTLP endpoint. The alarm tracks individual breaching time series as contributors and uses duration-based pending and recovery periods to control state transitions. For more information, see PromQL alarms.
- A *log alarm* monitors the results of a CloudWatch Logs Insights query that runs on a schedule. The alarm evaluates aggregated query results against a threshold using M-out-of-N evaluation on recent query executions. Use log alarms to detect patterns, errors, or threshold breaches directly in your log data without creating metric filters. For more information, see Create a Log Alarm.
- A *composite alarm* includes a rule expression that takes into account the alarm states of other alarms that you have created. The composite alarm goes into ALARM state only if all conditions of the rule are met. The alarms specified in a composite alarm's rule expression can include metric alarms and other composite alarms.

Using composite alarms can reduce alarm noise. You can create multiple metric alarms, and also create a composite alarm and set up alerts only for the composite alarm. For example, a composite might go into ALARM state only when all of the underlying metric alarms are in ALARM state.

Composite alarms can send Amazon SNS notifications when they change state, and can create investigations, Systems Manager OpsItems, or incidents when they go into ALARM state, but can't perform EC2 actions or Auto Scaling actions.

> **Note**
>
> You can create as many alarms as you want in your AWS account.

You can add alarms to dashboards, so you can monitor and receive alerts about your AWS resources and applications across multiple regions. After you add an alarm to a dashboard, the alarm turns gray when it's in the `INSUFFICIENT_DATA` state and red when it's in the `ALARM` state. The alarm is shown with no color when it's in the `OK` state.

You also can favorite recently visited alarms from the *Favorites and recents* option in the CloudWatch console navigation pane. The *Favorites and recents* option has columns for your favorited alarms and recently visited alarms.

An alarm invokes actions only when the alarm changes state. The exception is for alarms with Auto Scaling actions. For Auto Scaling actions, the alarm continues to invoke the action once per minute that the alarm remains in the new state.

An alarm can watch a metric in the same account. If you have enabled cross-account functionality in your CloudWatch console, you can also create alarms that watch metrics in other AWS accounts. Creating cross-account composite alarms is not supported. Creating cross-account alarms that use math expressions is supported, except that the `ANOMALY_DETECTION_BAND`, `INSIGHT_RULE`, and `SERVICE_QUOTA` functions are not supported for cross-account alarms.

> **Note**
>
> CloudWatch doesn't test or validate the actions that you specify, nor does it detect any Amazon EC2 Auto Scaling or Amazon SNS errors resulting from an attempt to invoke nonexistent actions. Make sure that your alarm actions exist.

Concepts

CloudWatch alarms monitor metrics and trigger actions when thresholds are breached. Understanding how alarms evaluate data and respond to conditions is essential for effective monitoring.

Topics

- Alarm data queries

- PromQL alarms
- Log alarms
- Composite alarms
- Alarm actions
- Alarm Mute Rules
- Limits

Alarm data queries

CloudWatch alarms can monitor various data sources. Choose the appropriate query type based on your monitoring needs.

Metrics

Monitor a single CloudWatch metric. This is the most common alarm type for tracking resource performance. For more information about metrics, see CloudWatch Metrics concepts.

For more information, see Create a CloudWatch alarm based on a static threshold.

Metric math

You can set an alarm on the result of a math expression that is based on one or more CloudWatch metrics. A math expression used for an alarm can include as many as 10 metrics. Each metric must be using the same period.

For an alarm based on a math expression, you can specify how you want CloudWatch to treat missing data points. In this case, the data point is considered missing if the math expression doesn't return a value for that data point.

Alarms based on math expressions can't perform Amazon EC2 actions.

For more information about metric math expressions and syntax, see Math expressions with metrics.

For more information, see Create a CloudWatch alarm based on a metric math expression.

Metrics Insights

A CloudWatch Metrics Insights query helps you query metrics at scale using SQL-like syntax. You can create an alarm on any Metrics Insights query, including queries that return multiple time series. This capability significantly expands your monitoring options. When you create an alarm based on a Metrics Insights query, the alarm automatically adjusts as resources are added to or removed from your monitored group. Create the alarm once, and any resource that matches your query definition and filters joins the alarm monitoring scope when its corresponding metric becomes available. For multi-time series queries, each returned time series becomes a contributor to the alarm, allowing for more granular and dynamic monitoring.

Here are two primary use cases for CloudWatch Metrics Insights alarms:

- Anomaly Detection and Aggregate Monitoring

  Create an alarm on a Metrics Insights query that returns a single aggregated time series. This approach works well for dynamic alarms that monitor aggregated metrics across your infrastructure or applications. For example, you can monitor the maximum CPU utilization across all your instances, with the alarm automatically adjusting as you scale your fleet.

  To create an aggregate monitoring alarm, use this query structure:

```
SELECT FUNCTION(metricName)
```

```
                    FROM SCHEMA(...)
                    WHERE condition;
```

- Per-Resource Fleet Monitoring

  Create an alarm that monitors multiple time series, where each time series functions as a contributor with its own state. The alarm activates when any contributor enters the ALARM state, triggering resource-specific actions. For example, monitor database connections across multiple RDS instances to prevent connection rejections.

  To monitor multiple time series, use this query structure:

```
SELECT AVG(DatabaseConnections)
                    FROM AWS/RDS
                    WHERE condition
                    GROUP BY DBInstanceIdentifier
                    ORDER BY AVG() DESC;
```

  When creating multi-time series alarms, you must include two key clauses in your query:

  - A `GROUP BY` clause that defines how to structure the time series and determines how many time series the query will produce
  - An `ORDER BY` clause that establishes a deterministic sorting of your metrics, enabling the alarm to evaluate the most important signals first

  These clauses are essential for proper alarm evaluation. The `GROUP BY` clause splits your data into separate time series (for example, by instance ID), while the `ORDER BY` clause ensures consistent and prioritized processing of these time series during alarm evaluation.

For more information on how to create a multi time series alarm, see Create an alarm based on Metrics Insights.

Log group-metric filters

You can create an alarm based on a log group-metric filter. With metric filters, you can look for terms and patterns in log data as the data is sent to CloudWatch. For more information, see Create metrics from log events using filters in the *Amazon CloudWatch Logs User Guide*.

For more information on how to create an alarm based on log group-metric filter, see Alarming on logs.

Log Insights query

You can create an alarm that uses a CloudWatch Logs Insights query to monitor log data directly. The query runs on a schedule using a Scheduled Query, and the alarm evaluates the aggregated results against a threshold. When the aggregation expression includes a by clause, each unique combination of field values is tracked as a contributor.

For more information about how Log Alarms work, see Log alarms.

For more information about how to create a Log Alarm, see Create a Log Alarm.

PromQL

You can create an alarm that uses a Prometheus Query Language (PromQL) instant query to monitor metrics ingested through the CloudWatch OTLP endpoint.

For more information about how PromQL alarms work, see PromQL alarms.

For more information on how to create a PromQL alarm, see Create an alarm using a PromQL query.

External data source

You can create alarms that watch metrics from data sources that aren't in CloudWatch. For more information about creating connections to these other data sources, see Query metrics from other data sources.

For more information on how to create an alarm based on a connected data source, see Create an alarm based on a connected data source.

Alarm evaluation

Metric alarm states

A metric alarm has the following possible states:

- `OK` – The metric or expression is within the defined threshold.
- `ALARM` – The metric or expression is outside of the defined threshold.
- `INSUFFICIENT_DATA` – The alarm has just started, the metric is not available, or not enough data is available for the metric to determine the alarm state.

Alarm evaluation state

In addition to the alarm state, each alarm has an evaluation state that provides information about the alarm evaluation process. The following states may occur:

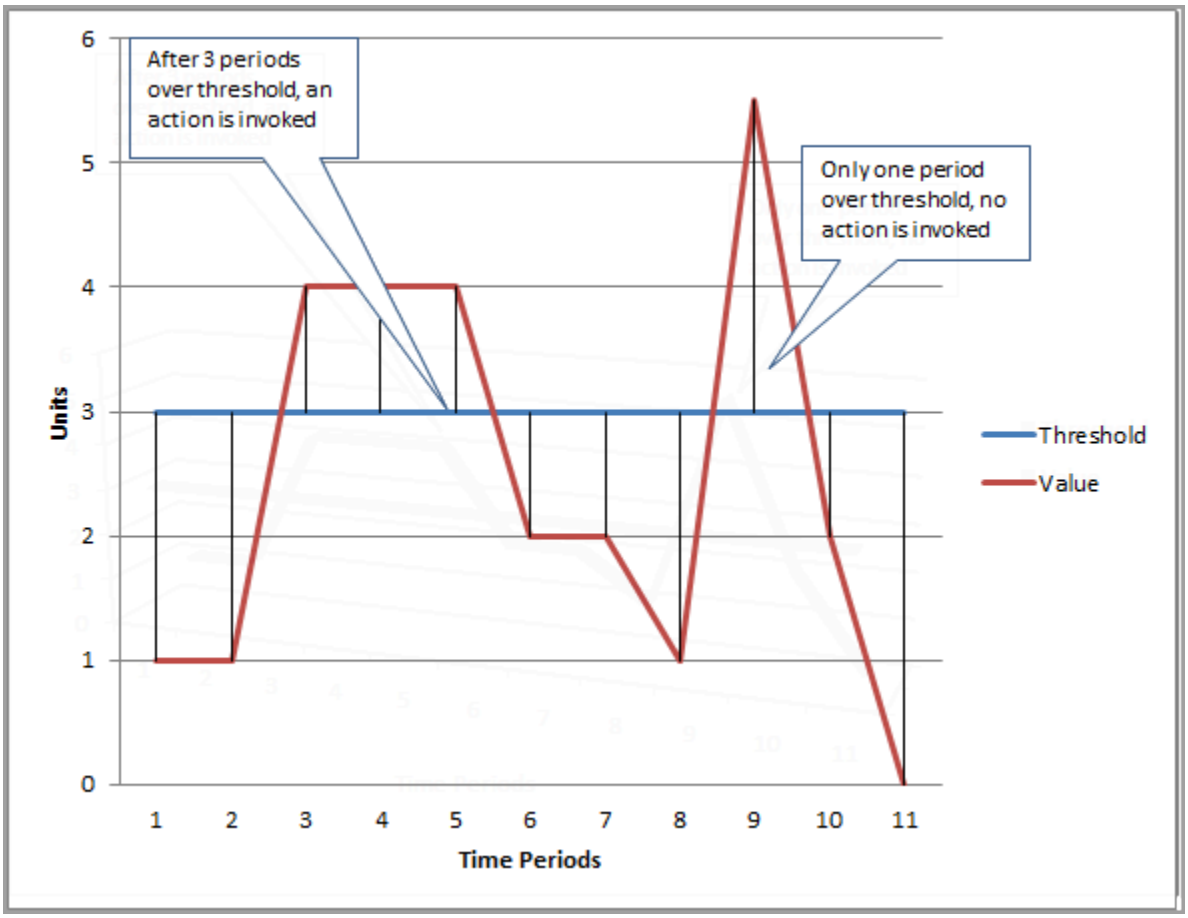
- `PARTIAL_DATA` – Indicates that not all the available data was able to be retrieved due to quota limitations. For more information, see How partial data is handled.
- `IN_WARM_UP` – Indicates that the alarm is in its warm-up period and does not yet evaluate. The alarm remains in `INSUFFICIENT_DATA` and does not perform alarm actions until the warm-up period ends. For more information, see Alarm warm-up periods.
- `EVALUATION_ERROR` – Indicates configuration errors in alarm setup that require review and correction. Refer to StateReason field of the alarm for more details.
- `EVALUATION_FAILURE` – Indicates temporary CloudWatch issues. We recommend manual monitoring until the issue is resolved

You can view the evaluation state in the alarm details in the console, or by using the `describe-alarms` CLI command or `DescribeAlarms` API.

Alarm evaluation settings

When you create an alarm, you specify 3 settings to enable CloudWatch to evaluate when to change the alarm state:

- **Period** is the length of time to use to evaluate the metric or expression to create each individual data point for an alarm. It is expressed in seconds.
- **Evaluation Periods** is the number of the most recent periods, or data points, to evaluate when determining alarm state.
- **Datapoints to Alarm** is the number of data points within the Evaluation Periods that must be breaching to cause the alarm to go to the `ALARM` state. The breaching data points don't have to be consecutive, but they must all be within the last number of data points equal to **Evaluation Period**.



For any period of one minute or longer, an alarm is evaluated every minute and the evaluation is based on the window of time defined by the **Period** and **Evaluation Periods**. For example, if the **Period** is 5 minutes (300 seconds) and **Evaluation Periods** is 1, then at the end of minute 5

the alarm evaluates based on data from minutes 1 to 5. Then at the end of minute 6, the alarm is evaluated based on the data from minutes 2 to 6.

If the alarm period is 10 seconds, 20 seconds, or 30 seconds, the alarm is evaluated every 10 seconds. For more information, see High-resolution alarms.

If the number of evaluation periods multiplied by the length of each evaluation period exceeds one day, the alarm is evaluated once per hour. For more details about how these multi-day alarms are evaluated, see Example of evaluating a multi-day alarm.

In the following figure, the alarm threshold for a metric alarm is set to 3 units. Both **Evaluation Period** and **Datapoints to Alarm** are 3. That is, when all existing data points in the most recent 3 consecutive periods are above the threshold, the alarm goes to ALARM state. In the figure, this happens in the third through fifth time periods. At period six, the value dips below the threshold, so one of the periods being evaluated is not breaching, and the alarm state changes back to OK. During the ninth time period, the threshold is breached again, but for only 1 period. Consequently, the alarm state remains OK.

When you configure **Evaluation Periods** and **Datapoints to Alarm** as different values, you're setting an "M out of N" alarm. **Datapoints to Alarm** is ("M") and **Evaluation Periods** is ("N").The evaluation interval is the number of evaluation periods multiplied by the period length. For example, if you configure 4 out of 5 data points with a period of 1 minute, the evaluation interval is 5 minutes. If you configure 3 out of 3 data points with a period of 10 minutes, the evaluation interval is 30 minutes.

> **Note**
>
> If data points are missing soon after you create an alarm, and the metric was being reported to CloudWatch before you created the alarm, CloudWatch retrieves the most recent data points from before the alarm was created when evaluating the alarm.

By default, CloudWatch uses a *sliding window* for alarm evaluation. Each time the alarm is evaluated, the window advances by one minute, and the boundaries of the window are not aligned to the wall clock. You can instead align the evaluation window to wall clock boundaries and time zones. For more information, see Alarm evaluation window.

High-resolution alarms

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds, 20 seconds, or 30 seconds. There is a higher charge for high-resolution alarms. For more information about high-resolution metrics, see Publish custom metrics (PutMetricData / EMF).

Example of evaluating a multi-day alarm

An alarm is a multi-day alarm if the number of evaluation periods multiplied by the length of each evaluation period exceeds one day. Multi-day alarms are evaluated once per hour. When multi-day alarms are evaluated, CloudWatch takes into account only the metrics up to the current hour at the :00 minute when evaluating. This top-of-the-hour behavior, and the following example, apply to alarms that use a sliding evaluation window, which is the default.

For example, consider an alarm that monitors a job that runs every 3 days at 10:00.

1. At 10:02, the job fails
2. At 10:03, the alarm evaluates and stays in OK state, because the evaluation considers data only up to 10:00.

3. At 11:03, the alarm considers data up to 11:00 and goes into ALARM state.
4. At 11:43, you correct the error and the job now runs successfully.
5. At 12:03, the alarm evaluates again, sees the successful job, and returns to OK state.

If the alarm instead uses a wall clock evaluation window, CloudWatch aligns the evaluation window to the wall clock boundary that matches the period in the alarm's selected time zone, rather than clamping to the top of each hour. For example, a multi-day alarm with a one-day period evaluates complete calendar days that end at midnight in the selected time zone, and an alarm with a one-week period evaluates complete calendar weeks. The window advances by one full period when each boundary is reached, so the alarm considers a newly completed calendar period only after that period ends. For more information, see Alarm evaluation window.

Alarm evaluation window

When CloudWatch evaluates a metric alarm, it retrieves metric data for a time range called the *evaluation window*. The length of the window is `Period` multiplied by `Evaluation Periods`. Where the boundaries of that window fall is controlled by the `EvaluationWindow` parameter on the PutMetricAlarm API. `EvaluationWindow` accepts one of two configurations:

- `SlidingWindow` – the default. The window advances each time the alarm is evaluated, forming a rolling time window.
- `WallClockWindow` – the window is aligned to clock boundaries that match the period (such as the top of the hour, midnight, or the start of the calendar week) and, optionally, to a specific time zone.

If you don't specify `EvaluationWindow` when you create or update a metric alarm, the alarm uses a sliding window. You can switch an existing alarm to a wall clock window at any time by updating the alarm.

Both configurations are supported on all types of metric alarms except alarms that are based on a PromQL query.

Choosing between a sliding window and a wall clock window

A sliding window continuously incorporates the most recent data, so it detects breaches as soon as data points cross your threshold. Choose a sliding window for real-time monitoring where calendar alignment doesn't matter, such as performance, latency, or resource-exhaustion workloads.

A wall clock window evaluates complete, calendar-aligned periods such as each hour, day, or week. Choose a wall clock window when monitoring is tied to a business or calendar period. It also avoids false alarms that can occur when events span rolling window boundaries. For example, a daily backup alarm with a sliding window can enter `ALARM` if consecutive backups are more than 24 hours apart, even though each calendar day had a backup. A wall clock window evaluates each day independently and avoids this.

The trade-off is detection timing. A wall clock window reflects a data point only after the period that contains it ends. If you need to detect a problem while it is still in progress, use a sliding window.

Sliding window

With a sliding window, the evaluation window moves forward each time the alarm is evaluated, forming a rolling time window. For example, an alarm with a 1-hour period and 1 evaluation period might evaluate the time range 13:07–14:07 on one evaluation and 13:08–14:08 on the next.

Because the window always incorporates the most recent data points, a sliding window is the better choice for alarms that trigger Auto Scaling actions.

A sliding window has no additional configuration options. To configure one explicitly through the API, set `EvaluationWindow` to `{"SlidingWindow":{}}`. Omitting `EvaluationWindow` has the same effect.

Wall clock window

Evaluation periods align to fixed time boundaries (for example, each hour or day) in your selected time zone. Best for scheduled workloads like daily reports, batch jobs, or backups.

Boundaries align to the start of the matching calendar period in the selected time zone: the top of the hour for a 1-hour period, midnight for a 1-day period, and Monday at 00:00 (the start of the ISO 8601 week) for a 1-week period. These alignment points are fixed and can't be changed.

When to use a wall clock window

Choose a wall clock window when you want alarm evaluations to align with time-of-day or calendar boundaries. Common scenarios include:

- Daily batch jobs that should complete by midnight in a specific time zone.
- Weekly compliance or business reports that summarize a calendar week.

> **Note**
>
> We don't recommend using a wall clock window for alarms that trigger Auto Scaling actions. The alarm reflects new data only after the current period ends, so it can't track load closely enough for responsive scaling. Use a sliding window instead.

Supported periods

You can use a wall clock window with metric alarms that have one of the following periods:

- 1 minute (60 seconds)
- 5 minutes (300 seconds)
- 1 hour (3600 seconds)
- 1 day (86400 seconds)
- 1 week (604800 seconds)

Wall clock windows are not supported for high-resolution alarms (periods of 10, 20, or 30 seconds).

If you specify a period that wall clock windows don't support, `PutMetricAlarm` returns a validation error that lists the supported periods.

For metric math and Metrics Insights alarms, every metric in the `Metrics` array must use one of the supported wall clock periods.

> **Note**
>
> A Metrics Insights alarm can evaluate a time range of no more than 3 hours (**Period** multiplied by **Evaluation Periods**). When a Metrics Insights alarm uses a wall clock window, CloudWatch automatically reserves one additional period to align the window to wall clock boundaries. As a result, the effective limit becomes **Period** multiplied by (**Evaluation Periods** + 1), which must still be 3 hours or less. This means a Metrics Insights alarm that uses a wall clock window can span one fewer evaluation period than the same alarm with a sliding window. For example, with a 1-hour period, a sliding window supports up to 3 evaluation periods, but a wall clock window supports up to 2. If you exceed this limit, `PutMetricAlarm` returns a validation error.

Time zones and daylight saving time

You can optionally specify a time zone for the wall clock window. If you don't specify a time zone, CloudWatch uses UTC. The time zone determines where wall clock boundaries fall: for example, an alarm with a 1-day period in `America/New_York` evaluates each calendar day from local midnight to local midnight in New York, while the same alarm in UTC evaluates from 00:00 UTC to 00:00 UTC. Time zones with non-whole-hour offsets such as `Asia/Kolkata` (`+05:30`) shift the boundaries even for hourly and sub-hourly periods.

You can specify the time zone in any of the following forms:

- An IANA time zone identifier, such as `America/New_York`, `Europe/London`, or `Asia/Kolkata`.
- A fixed UTC offset, such as `+05:30`, `-08:00`, or `Z` (equivalent to UTC).
- An offset-prefixed identifier, such as `UTC+05:30` or `GMT-08:00`.

The time zone you specify must resolve to a UTC offset that is a multiple of 5 minutes. For example, `+01:00`, `+05:30`, and `+01:05` are accepted, but `+01:03` is rejected. CloudWatch rejects time zones that don't meet this requirement with a validation error at alarm creation.

When you specify an IANA time zone, CloudWatch automatically handles daylight saving time transitions. The evaluation window remains aligned to the local wall clock in the specified time zone, even on the days when clocks change. Fixed UTC offsets and offset-prefixed identifiers don't observe daylight saving time.

How often the alarm is evaluated

An alarm with a wall clock window is evaluated at the same frequency as an alarm with a sliding window. Choosing a wall clock window changes only the *boundaries* of the window that CloudWatch uses to retrieve metric data, not how often the alarm runs.

For example, an alarm with a 1-hour period and a wall clock window evaluates every minute. Each evaluation looks at the data for the most recently completed clock hour. As a new clock hour begins, the window advances to the new hour boundary.

To create a metric alarm that uses a wall clock window, see Create a metric alarm that uses a wall clock evaluation window.

Alarm warm-up periods

A warm-up period delays alarm evaluation after you create or update an alarm. This reduces noise from missing data while a new resource or service starts to publish data. During warm-up, the alarm stays in `INSUFFICIENT_DATA` and does not perform alarm actions.

Use a warm-up period when you deploy alarms with a new application or service that takes time to emit metrics. Without a warm-up period, the alarm can transition and run actions on missing data during startup, and cause false notifications.

Warm-up periods work with metric alarms and log alarms.

Warm-up period configuration

Set the `WarmUpConfiguration` parameter when you create or update an alarm. This parameter includes the following settings:

- `WarmUpPeriodDurationInMinutes` (required) – The warm-up duration, in minutes. Specify a value from 1 to 2,880 minutes (2 days).
- `OnlyStartEvaluatingAfterWarmUpPeriodEnds` (optional, default is `false`) – Controls when evaluation begins. When set to `false` (default), the alarm ends warm-up early. Evaluation begins as soon as enough data fills its evaluation window. When set to `true`, the alarm waits the full warm-up duration before it evaluates, even if data arrives sooner. Use this setting when startup fluctuations, such as a CPU spike, could cause premature alarm transitions.

When `OnlyStartEvaluatingAfterWarmUpPeriodEnds` is `false`, the alarm ends warm-up as soon as it can fill its evaluation window. The evaluation window spans `Period` multiplied by `Evaluation Periods` and is full when a datapoint exists for the most recent period.

For example, an alarm with a 5-minute period and 3 evaluation periods has a 15-minute evaluation window. Suppose that you create this alarm at 10:00 and the resource starts to publish at 10:04. The alarm stays in `INSUFFICIENT_DATA` until a full 15-minute window is available. This happens at about 10:19, and then the alarm begins to evaluate. The `Datapoints to Alarm` setting does not affect when warm-up ends.

Change or end a warm-up period

You can change the warm-up configuration while the alarm is still in its warm-up period. You can also end warm-up early when you update the configuration. Warm-up applies only once at alarm creation and does not restart.

After the warm-up period ends, you can update the warm-up configuration. However, the update does not start a new warm-up period. The alarm continues to evaluate normally.

View warm-up status

During warm-up, the alarm state remains `INSUFFICIENT_DATA` and the evaluation state is `IN_WARM_UP`. View the alarm configuration and state with the DescribeAlarms API. For more information about evaluation states, see Alarm evaluation state.

For instructions on creating an alarm with a warm-up period, see Create an alarm that uses a warm-up period.

Configuring how CloudWatch alarms treat missing data

Sometimes, not every expected data point for a metric gets reported to CloudWatch. For example, this can happen when a connection is lost, a server goes down, or when a metric reports data only intermittently by design.

CloudWatch enables you to specify how to treat missing data points when evaluating an alarm. This helps you to configure your alarm so that it goes to `ALARM` state only when appropriate for the type of data being monitored. You can avoid false positives when missing data doesn't indicate a problem.

Similar to how each alarm is always in one of three states, each specific data point reported to CloudWatch falls under one of three categories:

- Not breaching (within the threshold)
- Breaching (violating the threshold)
- Missing

For each alarm, you can specify CloudWatch to treat missing data points as any of the following:

- `notBreaching` – Missing data points are treated as "good" and within the threshold
- `breaching` – Missing data points are treated as "bad" and breaching the threshold
- `ignore` – The current alarm state is maintained
- `missing` – If all data points in the alarm evaluation range are missing, the alarm transitions to INSUFFICIENT_DATA.

The best choice depends on the type of metric and the purpose of the alarm. For example, if you are creating an application rollback alarm using a metric that continually reports data, you might want to treat missing data points as breaching, because it might indicate that something is wrong. But for a metric that generates data points only when an error occurs, such as `ThrottledRequests` in Amazon DynamoDB, you would want to treat missing data as `notBreaching`. The default behavior is `missing`.

> **Important**
>
> Alarms configured on Amazon EC2 metrics can temporarily enter the INSUFFICIENT_DATA state if there are missing metric data points. This is rare, but can happen when the metric reporting is interrupted, even when the Amazon EC2 instance is healthy. For alarms on Amazon EC2 metrics that are configured to take stop, terminate, reboot, or recover actions, we recommend that you configure those alarms to treat missing data as `missing`, and to have these alarms trigger only when in the ALARM state.

Choosing the best option for your alarm prevents unnecessary and misleading alarm condition changes, and also more accurately indicates the health of your system.

> **Important**
>
> Alarms that evaluate metrics in the `AWS/DynamoDB` namespace default to ignore missing data. You can override this if you choose a different option for how the alarm should treat missing data. When an `AWS/DynamoDB` metric has missing data, alarms that evaluate that metric remain in their current state.

How alarm state is evaluated when data is missing

Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as **Evaluation Periods**. The exact number of data points it attempts to retrieve depends on the length of the alarm period and whether it is based on a metric with standard resolution or high resolution. The time frame of the data points that it attempts to retrieve is the *evaluation range*.

> **Note**
>
> This wider evaluation range applies only to alarms that use a sliding evaluation window, which is the default. Alarms that use a wall clock evaluation window retrieve exactly the data points in the aligned window (**Period** multiplied by **Evaluation Periods**) and do not query additional data points from farther back. For more information, see Alarm evaluation window.

Once CloudWatch retrieves these data points, the following happens:

- If no data points in the evaluation range are missing, CloudWatch evaluates the alarm based on the most recent data points collected. The number of data points evaluated is equal to the **Evaluation Periods** for the alarm. The extra data points from farther back in the evaluation range are not needed and are ignored.
- If some data points in the evaluation range are missing, but the total number of existing data points that were successfully retrieved from the evaluation range is equal to or more than the alarm's **Evaluation Periods**, CloudWatch evaluates the alarm state based on the most recent real data points that were successfully retrieved, including the necessary extra data points from farther back in the evaluation range. In this case, the value you set for how to treat missing data is not needed and is ignored.
- If some data points in the evaluation range are missing, and the number of actual data points that were retrieved is lower than the alarm's number of **Evaluation Periods**, CloudWatch fills in the missing data points with the result you specified for how to treat missing data, and then evaluates the alarm. However, all real data points in the evaluation range are included in the evaluation. CloudWatch uses missing data points only as few times as possible.

> **Note**
>
> A particular case of this behavior is that CloudWatch alarms might repeatedly re-evaluate the last set of data points for a period of time after the metric has stopped flowing. This re-evaluation might cause the alarm to change state and re-execute actions, if it had changed state immediately before the metric stream stopping. To mitigate this behavior, use shorter periods.

The following tables illustrate examples of the alarm evaluation behavior. In the first table, **Datapoints to Alarm** and **Evaluation Periods** are both 3. CloudWatch retrieves the 5 most recent data points when evaluating the alarm, in case some of the most recent 3 data points are missing. 5 is the evaluation range for the alarm.

Column 1 shows the 5 most recent data points, because the evaluation range is 5. These data points are shown with the most recent data point on the right. 0 is a non-breaching data point, X is a breaching data point, and - is a missing data point.

Column 2 shows how many of the 3 necessary data points are missing. Even though the most recent 5 data points are evaluated, only 3 (the setting for **Evaluation Periods**) are necessary to evaluate the alarm state. The number of data points in Column 2 is the number of data points that must be "filled in", using the setting for how missing data is being treated.

In columns 3-6, the column headers are the possible values for how to treat missing data. The rows in these columns show the alarm state that is set for each of these possible ways to treat missing data.

Data points	# of data points that must be filled	Missing	Ignore	Breaching	Not breaching
0 - X - X	0	OK	OK	OK	OK
0 - - - -	2	OK	OK	OK	OK
- - - - -	3	INSUFFICIENT_DATA	Retain current state	ALARM	OK
0 X X - X	0	ALARM	ALARM	ALARM	ALARM
- - X - -	2	ALARM	Retain current state	ALARM	OK

In the second row of the preceding table, the alarm stays OK even if missing data is treated as breaching, because the one existing data point is not breaching. This is evaluated along with two missing data points which are treated as breaching. The next time this alarm is evaluated, if the

data is still missing it will go to ALARM, as that non-breaching data point will no longer be in the evaluation range.

The third row, where all five of the most recent data points are missing, illustrates how the various settings for how to treat missing data affect the alarm state. If missing data points are considered breaching, the alarm goes into ALARM state, while if they are considered not breaching, then the alarm goes into OK state. If missing data points are ignored, the alarm retains the current state it had before the missing data points. And if missing data points are just considered as missing, then the alarm does not have enough recent real data to make an evaluation, and goes into INSUFFICIENT_DATA.

In the fourth row, the alarm goes to ALARM state in all cases because the three most recent data points are breaching. The alarm's **Evaluation Periods** and **Datapoints to Alarm** are both set to 3. In this case, the missing data point is ignored and the setting for how to evaluate missing data is not needed, because there are 3 real data points to evaluate.

Row 5 represents a special case of alarm evaluation called *premature alarm state*. For more information, see Avoiding premature transitions to alarm state.

In the next table, the **Period** is again set to 5 minutes, and **Datapoints to Alarm** is only 2 while **Evaluation Periods** is 3. This is a 2 out of 3, M out of N alarm.

The evaluation range is 5. This is the maximum number of recent data points that are retrieved and can be used in case some data points are missing.

Data points	# of missing data points	Missing	Ignore	Breaching	Not breaching
0 - X - X	0	ALARM	ALARM	ALARM	ALARM
0 0 X 0 X	0	ALARM	ALARM	ALARM	ALARM
0 - X - -	1	OK	OK	ALARM	OK
- - - - 0	2	OK	OK	ALARM	OK
- - - X -	2	ALARM	Retain current state	ALARM	OK

In rows 1 and 2, the alarm always goes to ALARM state because 2 of the 3 most recent data points are breaching. In row 2, the two oldest data points in the evaluation range are not needed because none of the 3 most recent data points are missing, so these two older data points are ignored.

In rows 3 and 4, the alarm goes to ALARM state only if missing data is treated as breaching, in which case the two most recent missing data points are both treated as breaching. In row 4, these two missing data points that are treated as breaching provide the two necessary breaching data points to trigger the ALARM state.

Row 5 represents a special case of alarm evaluation called *premature alarm state*. For more information, see the following section.

Avoiding premature transitions to alarm state

CloudWatch alarm evaluation includes logic to try to avoid false alarms, where the alarm goes into ALARM state prematurely when data is intermittent. The example shown in row 5 in the tables in the previous section illustrate this logic. In those rows, and in the following examples, the **Evaluation Periods** is 3 and the evaluation range is 5 data points. **Datapoints to Alarm** is 3, except for the M out of N example, where **Datapoints to Alarm** is 2.

Suppose an alarm's most recent data is - - - - X, with four missing data points and then a breaching data point as the most recent data point. Because the next data point may be non-breaching, the alarm does not go immediately into ALARM state when the data is either - - - - X or - - - X - and **Datapoints to Alarm** is 3. This way, false positives are avoided when the next data point is non-breaching and causes the data to be - - - X 0 or - - X - 0.

However, if the last few data points are - - X - -, the alarm goes into ALARM state even if missing data points are treated as missing. This is because alarms are designed to always go into ALARM state when the oldest available breaching datapoint during the **Evaluation Periods** number of data points is at least as old as the value of **Datapoints to Alarm**. All other more recent data points are breaching or missing. In this case, the alarm goes into ALARM state even if the total number of datapoints available is lower than M (**Datapoints to Alarm**).

This alarm logic applies to M out of N alarms as well. If the oldest breaching data point during the evaluation range is at least as old as the value of **Datapoints to Alarm**, and all of the more recent data points are either breaching or missing, the alarm goes into ALARM state no matter the value of M (**Datapoints to Alarm**).

Missing Data in CloudWatch Metrics Insights alarms

Alarms based on Metrics Insights queries that aggregate to a single time series

The missing data scenarios and their effects upon alarm evaluation are the same as a standard metric alarm in terms of the configured missing data treatment. See, Configuring how CloudWatch alarms treat missing data.

Alarms based on Metrics Insights queries that produce multiple time series

Missing data scenarios for Metrics Insights alarms occur when:

- Individual datapoints within a time series are not present.
- One or more time series disappear when evaluating upon multiple time series.
- No time series are retrieved by the query.

Missing data scenarios affect the alarm evaluation in the following manner:

- For the evaluation of a time series, the treat missing data treatment is applied for individual datapoints within the time series. For example, if 3 datapoints were queried for the time series but only 1 was received, 2 datapoints would follow the configured missing data configuration.
- If a time series is not retrieved by the query anymore, it will transition to `OK` no matter the treat missing data treatment. Alarm actions associated with the `OK` transition at the contributor level are executed and the `StateReason` specifies that the aforementioned contributor was not found with the message, "No data was returned for this contributor". The state of the alarm will depend on the state of the other contributors that were retrieved by the query.
- At alarm level, if the query returns an empty result (no time series at all), the treat missing data treatment is applied. For example, if the treat missing data was set as `BREACHING`, the alarm will transition to `ALARM`.

How partial data is handled

How partial data from a Metrics Insights query is evaluated

If the Metrics Insights query used for the alarm matches more than 10,000 metrics, the alarm is evaluated based on the first 10,000 metrics that the query finds. This means that the alarm is being evaluated on partial data.

You can use the following methods to find whether a Metrics Insights alarm is currently evaluating its alarm state based on partial data:

- In the console, if you choose an alarm to see the **Details** page, the message **Evaluation warning: Not evaluating all data** appears on that page.
- You see the value `PARTIAL_DATA` in the `EvaluationState` field when you use the describe-alarms AWS CLI command or the DescribeAlarms API.

Alarms also publish events to Amazon EventBridge when it goes into the partial data state, so you can create an EventBridge rule to watch for these events. In these events, the `evaluationState` field has the value `PARTIAL_DATA`. The following is an example.

```
{
    "version": "0",

            "timestamp": "2022-11-08T11:25:51.227+0000"
        },
        "configuration": {
```

```
            "metrics": [
                {
                    "id": "m2",
                    "expression": "SELECT SUM(PartialDataTestMetric) FROM
 partial_data_test",
                    "returnData": true,
                    "period": 60
                }
            ]
        }
    }
}
```

If the query for the alarm includes a GROUP BY statement that initially returns more than 500 time series, the alarm is evaluated based on the first 500 time series that the query finds. However, if you use an ORDER BY clause, then all the time series that the query finds are sorted. The 500 that have the highest or lowest values according to your ORDER BY clause are used to evaluate the alarm.

How partial data from a multi data source alarm is evaluated

If the Lambda function returns partial data:

- The alarm continues to be evaluated on the data points that are returned.
- You can use the following methods to find whether an alarm on a Lambda function is currently evaluating its alarm state based on partial data:
  - In the console, choose an alarm and choose the **Details** page. If you see the message **Evaluation warning: Not evaluating all data appears on that page**, it is evaluating on partial data.
  - If you see the value `PARTIAL_DATA` in the `EvaluationState` field when you use the `describe-alarms` AWS CLI command or the DescribeAlarms API, it is evaluating on partial data.
- An alarm also publishes events to Amazon EventBridge when it goes into the partial data state.

Percentile-based alarms and low data samples

When you set a percentile as the statistic for an alarm, you can specify what to do when there is not enough data for a good statistical assessment. You can choose to have the alarm evaluate the statistic anyway and possibly change the alarm state. Or, you can have the alarm ignore the metric

while the sample size is low, and wait to evaluate it until there is enough data to be statistically significant.

For percentiles between 0.5 (inclusive) and 1.00 (exclusive), this setting is used when there are fewer than 10/(1-percentile) data points during the evaluation period. For example, this setting would be used if there were fewer than 1000 samples for an alarm on a p99 percentile. For percentiles between 0 and 0.5 (exclusive), the setting is used when there are fewer than 10/percentile data points.

PromQL alarms

A PromQL alarm monitors metrics using a Prometheus Query Language (PromQL) instant query. The query selects metrics ingested through the CloudWatch OTLP endpoint, and all matching time series returned by the query are considered to be breaching. The alarm evaluates the query at a regular interval and tracks each breaching time series independently as a *contributor*.

For information about ingesting metrics using OpenTelemetry, see OpenTelemetry.

How PromQL alarms work

A PromQL alarm evaluates a PromQL instant query on a recurring schedule defined by the `EvaluationInterval`. The query returns only the time series that satisfy the condition. Each returned time series is a *contributor*, identified by its unique set of attributes.

The alarm uses duration-based state transitions:

- When a contributor is returned by the query, it is considered *breaching*. If the contributor continues breaching for the duration specified by `PendingPeriod`, the contributor transitions to `ALARM` state.
- When a contributor stops being returned by the query, it is considered *recovering*. If the contributor remains absent for the duration specified by `RecoveryPeriod`, the contributor transitions back to `OK` state.

The alarm is in `ALARM` state when at least one contributor has been breaching for longer than the pending period. The alarm returns to `OK` state when all contributors have recovered.

> **Note**
>
> You can reference a PromQL alarm as a child alarm in a CloudWatch composite alarm's rule expression, the same as any other alarm type. For more information, see Create a composite alarm.

PromQL alarm configuration

A PromQL alarm is configured with the following parameters:

- **PendingPeriod** is the duration in seconds that a contributor must continuously breach before the contributor transitions to `ALARM` state. This is equivalent to the Prometheus alert rule's `for` duration.
- **RecoveryPeriod** is the duration in seconds that a contributor must stop breaching before the contributor transitions back to `OK` state. This is equivalent to the Prometheus alert rule's `keep_firing_for` duration.
- **EvaluationInterval** is how frequently, in seconds, the alarm evaluates the PromQL query.

To create a PromQL alarm, see Create an alarm using a PromQL query.

Log alarms

A Log Alarm monitors the results of a CloudWatch Logs Insights query that runs on a schedule using a Scheduled Query. The alarm applies an aggregation expression to the query results to produce a numeric value, and when that aggregated value breaches a configured threshold, the alarm transitions to `ALARM` state and runs configured actions.

Unlike metric alarms that require metric filters as an intermediate step, Log Alarms evaluate directly on log data using the same Logs Insights query language you use for ad-hoc analysis.

How Log Alarms work

The following steps describe how a Log Alarm works:

1. You create a Log Alarm with a query, aggregation expression, schedule, and threshold.
2. CloudWatch automatically creates an AWS managed Scheduled Query that runs your query on the specified schedule.

3. Each query execution produces aggregated results (a single value or multiple contributor values).
4. CloudWatch evaluates the aggregated results against your threshold using M-out-of-N evaluation on recent query executions.
5. If the threshold is breached, the alarm transitions to `ALARM` state and runs your configured actions (such as Amazon SNS notifications).

> **Note**
>
> Log Alarms evaluate the last N query executions. The alarm transitions to `ALARM` when M of those N executions breach the threshold.

To create a Log Alarm, see Create a Log Alarm.

Managed Scheduled Query lifecycle

When you create a Log Alarm, CloudWatch automatically creates an AWS managed Scheduled Query that runs your query on the specified schedule. You do not need to create the Scheduled Query separately.

The AWS managed Scheduled Query has the following characteristics:

- It is visible in the CloudWatch Logs console under Scheduled Queries.
- You cannot modify it directly. To change the query or its configuration, update the Log Alarm.
- CloudWatch deletes the AWS managed Scheduled Query when you delete the alarm.

Log Alarm configuration

A Log Alarm is configured with the following parameters:

- **QueryString** is the CloudWatch Logs Insights query to run.
- **LogGroupIdentifiers** are the log groups to query. Specify either log group names or log group ARNs.
- **ScheduledQueryRoleARN** is the ARN of the IAM role that allows CloudWatch Logs to run the scheduled query on your behalf.
- **AggregationExpression** defines how query results are aggregated into a numeric value for threshold evaluation.

- **ScheduleExpression** defines how frequently the query runs (for example, `rate(5 minutes)`).
- **StartTimeOffset** defines the lookback window in seconds for each query execution.
- **EndTimeOffset** defines the end of the query time range as an offset in seconds from the current time.
- **ComparisonOperator** is how aggregated results are compared to the threshold. Valid values: `GreaterThanThreshold`, `GreaterThanOrEqualToThreshold`, `LessThanThreshold`, `LessThanOrEqualToThreshold`.
- **Threshold** is the numeric value to compare against.
- **QueryResultsToEvaluate** is the number of recent query executions to evaluate (N in M-out-of-N).
- **QueryResultsToAlarm** is the number of breaching results required to trigger `ALARM` (M in M-out-of-N).
- **TreatMissingData** defines how missing query results are treated during evaluation.

For the full list of parameters and creation instructions, see Create a Log Alarm.

Logs query

The Log Alarm query is a CloudWatch Logs Insights query that selects and filters the log data to evaluate. The query runs on the log groups specified in `LogGroupIdentifiers` over the time range defined by `StartTimeOffset` and `EndTimeOffset`.

The query uses CloudWatch Logs Insights query syntax. For guidelines on writing efficient queries for Log Alarms, see Best practices and troubleshooting.

Aggregation expressions

The aggregation expression defines how CloudWatch summarizes query results into a numeric value for threshold evaluation. The expression uses the same syntax as the `stats` command in CloudWatch Logs Insights.

The syntax for an aggregation expression is as follows:

```
statistic_func_expression [by field1, field2, ...] [| sort asc|desc]
```

You can specify only a single aggregation expression. The following table lists the supported aggregation functions.

Function	Description	Example
`count(*)`	Count of all matched log lines.	`count(*)`
`avg(field)`	Average value of the specified field.	`avg(duration)`
`sum(field)`	Sum of the specified field.	`sum(bytesSent)`
`min(field)`	Minimum value of the specified field.	`min(latency)`
`max(field)`	Maximum value of the specified field.	`max(latency)`

The `bin()` function is not supported in the aggregation expression `by` clause. However, you can use `bin()` in the query string itself.

Multi-contributor alarms

When you include a `by` clause in your aggregation expression, the alarm evaluates each unique combination of field values (called a *contributor*) independently. The alarm transitions to `ALARM` state if any contributor breaches the threshold.

For example, the following expression groups error counts by service name:

```
count(*) by serviceName
```

Each unique value of `serviceName` is evaluated independently against the threshold. If any service exceeds the threshold in M out of N query executions, the alarm enters `ALARM` state.

The following limits apply to multi-contributor alarms:

- Maximum 5 fields in the `by` clause.
- Maximum 500 contributor results returned per query execution.
- Maximum 100 contributors tracked in `ALARM` state simultaneously.

By default, contributors are sorted alphabetically and only the first 500 are returned per query execution. To sort contributors by their aggregated value instead, specify `| sort asc` or `| sort`

`desc` in your aggregation expression (for example, `avg(latency) by serviceName | sort desc`). Value-based sorting ensures that the most significant contributors are evaluated first when the total number exceeds 500.

For multi-contributor alarms, Amazon SNS and Lambda actions run at the contributor level (once per breaching contributor). Systems Manager OpsItem actions run at the alarm level.

> **Note**
>
> Systems Manager Incident Manager and investigation actions are not supported for Log Alarms.

If a contributor disappears from query results (for example, an ephemeral resource is terminated), that contributor transitions to OK state regardless of the missing data treatment setting.

Missing data treatment

Missing data occurs when a scheduled query execution does not produce a value that can be evaluated against the threshold. This happens in the following cases:

No logs present — The log group contains no log events in the query time range.

Query returns no applicable results — Logs are present but the aggregation expression cannot produce a value. This happens when:

- Matching query results were not present as per the query filter.
- The field referenced in the aggregation expression was not present in the query results. For example, `count(error-codes)` where `error-codes` does not exist in the returned log events.

Note that `count(*)` on an empty result set returns 0, which is a valid datapoint and is not treated as missing.

You can configure how the alarm treats missing data using the `TreatMissingData` parameter. The following table describes the available options.

Value	Behavior
`missing`	Treat the datapoint as missing. This is the default.

Value	Behavior
notBreaching	Treat the missing datapoint as not breaching the threshold.
breaching	Treat the missing datapoint as breaching the threshold.
ignore	Ignore the missing datapoint and evaluate only available data.

Evaluation states

In addition to the standard OK, ALARM, and INSUFFICIENT_DATA states, Log Alarms can report the following evaluation states in the EvaluationState field. These states provide additional context about why the alarm is in its current state.

State	Description
EVALUATION_FAILURE	A transient CloudWatch service issue prevented evaluation. This can occur when the service experiences issues in evaluating query results due to service errors, or when some (but not all) query results failed. The alarm transitions to INSUFFICIENT_DATA . We recommend manual monitoring until the issue is resolved.
EVALUATION_ERROR	A client configuration error prevented evaluation. This can occur due to insufficient permissions, an invalid query, or when all query results have failed. The alarm transitions to INSUFFICIENT_DATA immediately. Refer to the StateReason field for details.
PARTIAL_DATA	The query returned the maximum 500 contributor groups but more matched. The alarm evaluates the available contributors, but results might be incomplete.

Alarm update

When you update the query, aggregation expression, schedule, or log groups of a Log Alarm, the alarm transitions to `INSUFFICIENT_DATA` until sufficient new datapoints are collected. Changes to the threshold or M-out-of-N values do not trigger this reset.

Actions and notifications

Log Alarms support the following actions:

- Amazon SNS notifications
- Lambda function invocations
- Systems Manager OpsItem creation

For the full actions support matrix, see Alarm actions.

When a Log Alarm transitions state, the action notification includes the following information:

- Standard alarm configuration change information (alarm name, description, configuration details).
- State change information (new state, state reason, timestamp).
- Amazon SNS email notifications also include a deep link to the CloudWatch Logs Insights console showing the full query results.

The following example shows an Amazon SNS email notification for a single-value Log Alarm (without a BY clause):

```
{
    "AlarmName": "HighErrorCount",
    "NewStateValue": "ALARM",
    "NewStateReason": "Threshold Crossed: 3 out of the last 5 query results
 [142.0 (10/06/26 12:15:00), 135.0 (10/06/26 12:10:00), 120.0 (10/06/26 12:05:00)]
 were greater than the threshold (100.0) (minimum 3 datapoints for OK -> ALARM
 transition).",
    "NewStateReasonData": {
        "version": "1.0",
        "queryDate": "2026-06-10T12:15:30.000+0000",
        "threshold": 100.0,
        "queryResultsToEvaluate": 5,
```

```
        "queryResultsToAlarm": 3,
        "results": [
            {
                "queryResultId": "scheduled-query-execution-id-3",
                "status": "COMPLETE",
                "timestamp": "2026-06-10T12:15:00.000+0000",
                "value": 142.0
            }
            // Additional results...
        ]
    },
    "StateChangeTime": "2026-06-10T12:15:30.000+0000",
    "OldStateValue": "OK"
    // Additional fields...
}
```

The following example shows an Amazon SNS email notification for a multi-contributor Log Alarm (with a BY clause). Each breaching contributor generates a separate notification:

```
{
    "AlarmName": "EndpointLatency",
    "NewStateValue": "ALARM",
    "NewStateReason": "5 out of 10 contributors evaluated to ALARM",
    "StateChangeTime": "2026-06-10T12:20:15.000+0000",
    "OldStateValue": "OK",
    "AlarmContributorId": "a1b2c3d4e5f6g7h8",
    "AlarmContributorAttributes": {
        "endpoint": "/api/orders"
    }
    // Additional fields...
}
```

Including log lines in notifications

You can optionally include raw query result log lines in alarm notifications by setting the `ActionLogLineCount` parameter to a value between 1 and 50. These are the underlying log events on which the aggregation expression is evaluated, not the aggregated values. The default value is 0, which means no log lines are included.

> **Note**
>
> Log lines are included only in Amazon SNS email notifications. Lambda actions do not include log lines in their payloads. CloudWatch also does not include log lines for multi-contributor alarms, even when you set `ActionLogLineCount`. CloudWatch includes log lines only for single-value Log Alarms that do not use a by clause.

> **Important**
>
> Including log lines in notifications might expose sensitive data from your logs in Amazon SNS messages. Review your log content before you enable this feature.

To include log lines, the log lines role must have the `logs:GetQueryResults` permission. The number of log lines included in a notification is limited by the requested count, the total results available, and the Amazon SNS payload size limit.

Best practices and troubleshooting

Best practices

Query optimization

- Test queries manually in CloudWatch Logs Insights before using them in a Log Alarm to verify performance and expected results.
- Use filter commands early in your query to reduce the volume of data processed.
- Limit query time ranges (StartTimeOffset) to avoid timeouts with high-volume log groups.
- Use field indexes to optimize query performance.

Schedule planning

- Choose a schedule frequency that allows queries to complete before the next execution. For high-volume log groups, use longer intervals (for example, 10 minutes instead of 5).
- Account for log ingestion delays when setting StartTimeOffset. A small gap between EndTimeOffset and the current time helps avoid evaluating incomplete data.

- Spread out Log Alarm schedules across your account to avoid hitting Scheduled Query concurrency limits. Concurrent query executions across your account cannot exceed 100. Factor in this quota when creating multiple Log Alarms with overlapping schedules.

Threshold tuning

- Start with higher QueryResultsToEvaluate (N) values to reduce alarm noise from transient spikes.
- For sparse events (such as errors that rarely occur), set TreatMissingData to `notBreaching` to keep the alarm in OK state when no logs match.
- For continuous signals (such as traffic logs), consider setting TreatMissingData to `breaching` to detect when expected log data stops arriving.

Multi-contributor design

- Choose meaningful fields for the BY clause that represent distinct resources or dimensions you want to monitor independently.
- Be aware that only the first 500 contributors are returned per query execution. If you expect more, narrow your query or use fewer BY clause fields.
- Use the `| sort desc` or `| sort asc` suffix in your aggregation expression to prioritize the highest or lowest values based on your comparison operator when the 500 contributor limit is reached.

Troubleshooting

Alarm stays in INSUFFICIENT_DATA

Possible cause	Resolution
Scheduled query execution role lacks permissions	Verify the role has `logs:StartQuery` , `logs:StopQuery` , `logs:GetQueryResults` , and `logs:DescribeLogGroups` permissions scoped to the correct log groups.
Log group does not exist or was deleted	Verify the log group ARNs in the alarm configuration are correct and accessible.

Possible cause	Resolution
Recently created or updated alarm	After creation or configuration update, the alarm remains in INSUFFICIENT_DATA until enough query executions complete to satisfy the M-out-of-N evaluation window.
Scheduled query is not running	Check the AWS managed Scheduled Query in the CloudWatch Logs console to verify it is executing on schedule.
Aggregation field not present in query results	The field referenced in the aggregation expression must be present in the query results. For example, if your aggregation is `avg(latency)` , make sure the query produces a `latency` field. If the field is not present, the result is treated as missing data.
Log ingestion delay	A scheduled query can only evaluate log events that have been ingested by the time it runs. `StartTimeOffset` and `EndTimeOffset` define the query window relative to execution time T — [T − StartTimeOffset, T − EndTimeOffset] — but they do not account for ingestion delay. If events are still being ingested for the window you query, the query runs before they are available and skips them. Use `EndTimeOffset` to shift the window back far enough that ingestion is complete for the entire range. Example: Suppose logs take up to 2 minutes to become queryable after the events occur. • `StartTimeOffset=60, EndTimeOffset=0` — window [T−60s, T]. The window ends at execution time, so recent events are not yet ingested and are missed. • `StartTimeOffset=180, EndTimeOffset=120` — window [T−180s, T−120s]. The window ends 2 minutes in the past, by which point all events are ingested and evaluable.

Alarm shows EVALUATION_ERROR

This indicates a client configuration issue. Check the StateReason field for details. Common causes:

- Invalid or malformed query syntax.
- Insufficient permissions on the scheduled query execution role.
- All query executions failed (for example, log group permissions revoked).

Alarm shows EVALUATION_FAILURE

This indicates a transient CloudWatch service issue. The alarm automatically recovers when the issue resolves. If it persists beyond a few minutes, check the CloudWatch service health dashboard.

Alarm shows PARTIAL_DATA

The query returned the maximum 500 contributor groups but more matched. The alarm evaluates available contributors, but results might be incomplete. Consider narrowing your query or reducing the number of BY clause fields.

Log lines not appearing in notifications

- Verify `ActionLogLineCount` is set to a value between 1 and 50.
- Verify the log lines role has `logs:GetQueryResults` permission scoped to the correct log groups.
- Log lines are included only in Amazon SNS email notifications. Other action types do not include log lines.
- Queries using `unmask()` cannot include log lines in notifications (rejected at creation time).

For additional best practices on query optimization, monitoring, and authorization, see Scheduled Queries best practices in the *Amazon CloudWatch Logs User Guide*.

Composite alarms

With CloudWatch, you can combine several alarms into one *composite alarm* to create a summarized, aggregated health indicator over a whole application or group of resources. Composite alarms are alarms that determine their state by monitoring the states of other alarms. You define rules to combine the status of those monitored alarms using Boolean logic.

You can use composite alarms to reduce alarm noise by taking actions only at an aggregated level. For example, you can create a composite alarm to send a notification to your web server team if any alarm related to your web server triggers. When any of those alarms goes into the ALARM state, the composite alarm goes itself in the ALARM state and sends a notification to your team. If other alarms related to your web server also go into the ALARM state, your team does not get overloaded with new notifications since the composite alarm has already notified them about the existing situation.

You can also use composite alarms to create complex alarming conditions and take actions only when many different conditions are met. For example, you can create a composite alarm that combines a CPU alarm and a memory alarm, and would only notify your team if both the CPU and the memory alarms have triggered.

Using composite alarms

When you use composite alarms, you have two options:

- Configure the actions you want to take only at the composite alarm level, and create the underlying monitored alarms without actions
- Configure a different set of actions at the composite alarm level. For example, the composite alarm actions could engage a different team in case of a widespread issue.

Composite alarms can take only the following actions:

- Notify Amazon SNS topics
- Invoke Lambda functions
- Create OpsItems in Systems Manager Ops Center
- Create incidents in Systems Manager Incident Manager

> **Note**
>
> All the underlying alarms in your composite alarm must be in the same account and the same Region as your composite alarm. However, if you set up a composite alarm in a CloudWatch cross-account observability monitoring account, the underlying alarms can watch metrics in different source accounts and in the monitoring account itself. For more information, see CloudWatch cross-account observability.

A single composite alarm can monitor 100 underlying alarms, and 150 composite alarms can monitor a single underlying alarm.

Rule expressions

All composite alarms contain rule expressions. Rule expressions tell composite alarms which other alarms to monitor and determine their states from. Rule expressions can refer to metric alarms and composite alarms. When you reference an alarm in a rule expression, you designate a function to the alarm that determines which of the following three states the alarm will be in:

- ALARM

  ALARM ("alarm-name or alarm-ARN") is TRUE if the alarm is in ALARM state.
- OK

  OK ("alarm-name or alarm-ARN") is TRUE if the alarm is in OK state.
- INSUFFICIENT_DATA

  INSUFFICIENT_DATA ("alarm-name or alarm-ARN") is TRUE if the named alarm is in INSUFFICIENT_DATA state.

Note

TRUE always evaluates to TRUE, and FALSE always evaluates to FALSE.

Alarm references

When referencing an alarm, using either the alarm name or ARN, the rule syntax can support referencing the alarm with or without quotation marks (") around the alarm name or ARN.

- If specified without quotes, alarm names or ARNs must not contain spaces, round brackets, or commas.
- If specified within quotes, alarm names or ARNs that *include* double quotes (") must enclose the " using backslash escape (\) characters for correct interpretation of the reference.

Syntax

The syntax of the expression you use to combine several alarms into one composite alarm uses boolean logic and functions. The following table describes the operators and functions available in rule expressions:

Operator/Function	Description
`AND`	Logical AND operator. Returns TRUE when all specified conditions are TRUE.
`OR`	Logical OR operator. Returns TRUE when at least one of the specified conditions is TRUE.
`NOT`	Logical NOT operator. Returns TRUE when the specified condition is FALSE.
`AT_LEAST`	Function that returns TRUE when a minimum number or percentag e of specified alarms are in the required state. Format: `AT_LEAST( M, STATE_CONDITION, (alarm1, alarm2, ...alarmN))` where M can be an absolute number or percentage (for example, 50%), and STATE_CONDITION can be ALARM, OK, INSUFFICIENT_DATA, NOT ALARM, NOT OK, or NOT INSUFFICIENT_DATA.

You can use parentheses to group conditions and control the order of evaluation in complex expressions.

Example expressions

The request parameter `AlarmRule` supports the use of the logical operators `AND`, `OR`, and `NOT`, as well as the `AT_LEAST` function, so you can combine multiple functions into a single expressions. The following example expressions show how you can configure the underlying alarms in your composite alarm:

- `ALARM(CPUUtilizationTooHigh) AND ALARM(DiskReadOpsTooHigh)`

  The expression specifies that the composite alarm goes into `ALARM` only if `CPUUtilizationTooHigh` and `DiskReadOpsTooHigh` are in `ALARM`.
- `AT_LEAST(2, ALARM, (WebServer1CPU, WebServer2CPU, WebServer3CPU, WebServer4CPU))`

The expression specifies that the composite alarm goes into ALARM when at least 2 out of the 4 web server CPU alarms are in ALARM state. This allows you to trigger alerts based on a threshold of affected resources rather than requiring all or just one to be in alarm state.

- `AT_LEAST(50%, OK, (DatabaseConnection1, DatabaseConnection2, DatabaseConnection3, DatabaseConnection4))`

  The expression specifies that the composite alarm goes into ALARM when at least 50% of the database connection alarms are in OK state. Using percentages allows the rule to adapt dynamically as you add or remove monitored alarms.

- `ALARM(CPUUtilizationTooHigh) AND NOT ALARM(DeploymentInProgress)`

  The expression specifies that the composite alarm goes into ALARM if CPUUtilizationTooHigh is in ALARM and DeploymentInProgress is not in ALARM. This is an example of a composite alarm that reduces alarm noise during a deployment window.

- `AT_LEAST(2, ALARM, (AZ1Health, AZ2Health, AZ3Health)) AND NOT ALARM(MaintenanceWindow)`

  The expression specifies that the composite alarm goes into ALARM when at least 2 out of 3 availability zone health alarms are in ALARM state and the maintenance window alarm is not in ALARM. This combines the AT_LEAST function with other logical operators for more complex monitoring scenarios.

Alarm suppression

Composite alarm action suppression allows you to temporarily disable alarm actions without deleting or modifying the alarm configuration. This is useful during planned maintenance, deployments, or when investigating known issues.

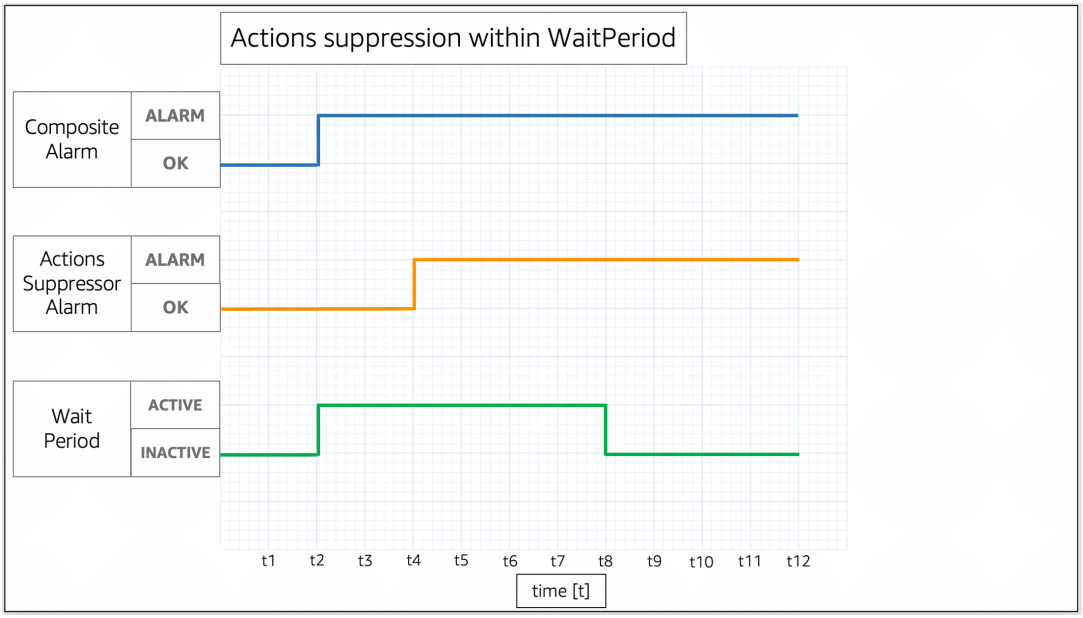
With composite alarm action suppression, you define alarms as suppressor alarms. Suppressor alarms prevent composite alarms from taking actions. For example, you can specify a suppressor alarm that represents the status of a supporting resource. If the supporting resource is down, the suppressor alarm prevents the composite alarm from sending notifications.

When to use alarm suppression

Common situations where alarm suppression is useful:

- Maintenance windows of your application

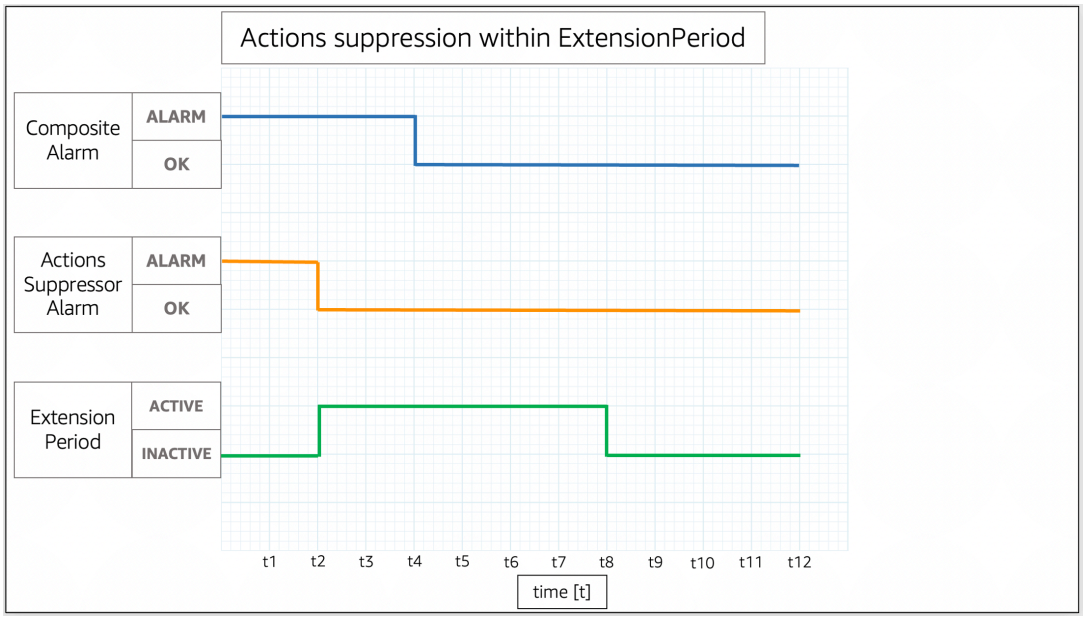
- Application deployments
- Ongoing incident investigation
- Testing and development activities



How suppressor alarms work

You specify suppressor alarms when you configure composite alarms. Any alarm can function as a suppressor alarm. When a suppressor alarm changes states from `OK` to `ALARM`, its composite alarm stops taking actions. When a suppressor alarm changes states from `ALARM` to `OK`, its composite alarm resumes taking actions.

Because composite alarms allow you to get an aggregated view of your health across multiple alarms, there are common situations where it is expected for those alarms to trigger. For example, during a maintenance window of your application or when you investigate an ongoing incident. In such situations, you may want to suppress the actions of your composite alarms, to prevent unwanted notifications or the creation of new incident tickets



`WaitPeriod` and `ExtensionPeriod`

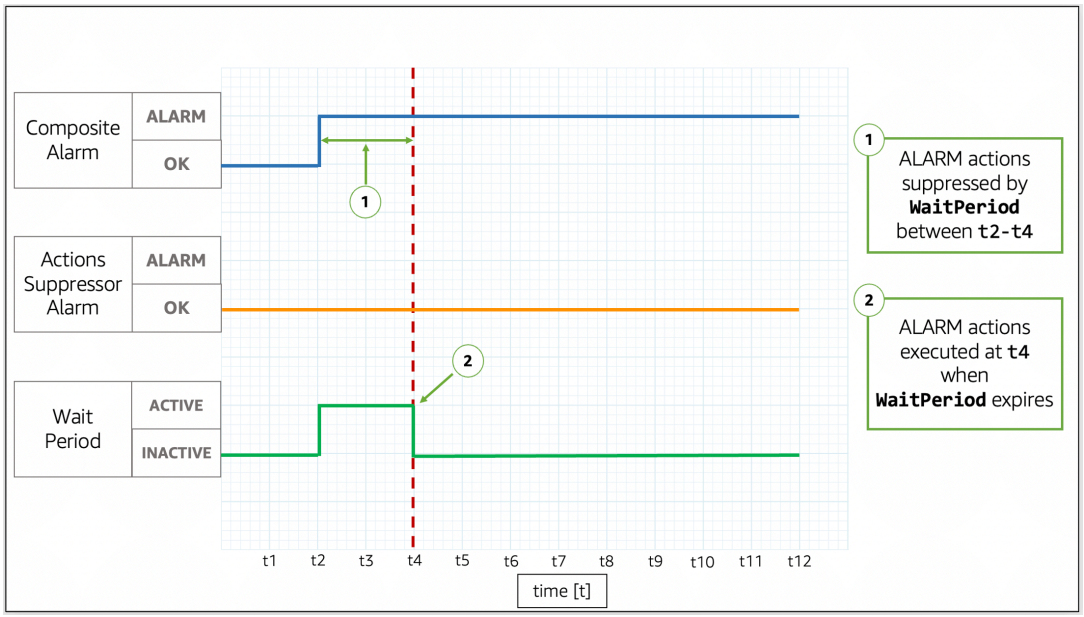
When you specify a suppressor alarm, you set the parameters `WaitPeriod` and `ExtensionPeriod`. These parameters prevent composite alarms from taking actions unexpectedly while suppressor alarms change states. Use `WaitPeriod` to compensate for any delays that can occur when a suppressor alarm changes from `OK` to `ALARM`. For example, if a suppressor alarm changes from `OK` to `ALARM` within 60 seconds, set `WaitPeriod` to 60 seconds.

In the image, the composite alarm changes from OK to ALARM at t2. A `WaitPeriod` starts at t2 and ends at t8. This gives the suppressor alarm time to change states from OK to ALARM at t4 before it suppresses the composite alarm's actions when the `WaitPeriod` expires at t8.

Use `ExtensionPeriod` to compensate for any delays that can occur when a composite alarm changes to OK following a suppressor alarm changing to OK. For example, if a composite alarm changes to OK within 60 seconds of a suppressor alarm changing to OK, set `ExtensionPeriod` to 60 seconds.

In the image, the suppressor alarm changes from ALARM to OK at t2. An `ExtensionPeriod` starts at t2 and ends at t8. This gives the composite alarm time to change from ALARM to OK before the `ExtensionPeriod` expires at t8.

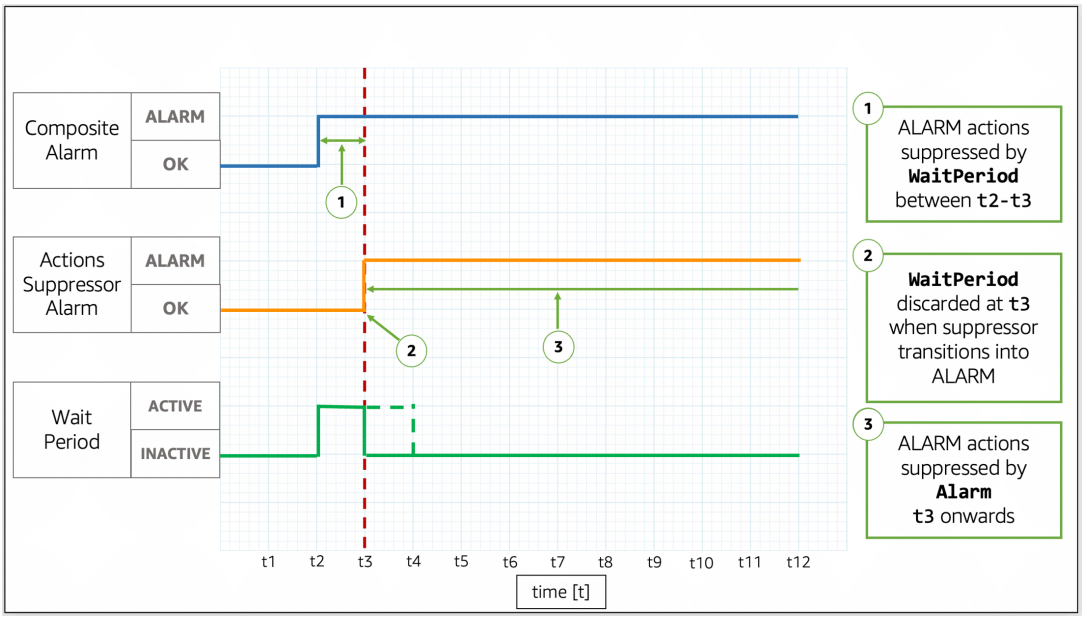
Composite alarms don't take actions when `WaitPeriod` and `ExtensionPeriod` become active. Composite alarms take actions that are based on their currents states when `ExtensionPeriod` and `WaitPeriod` become inactive. We recommend that you set the value for each parameter to 60 seconds, as evaluates metric alarms every minute. You can set the parameters to any integer in seconds.



The following examples describe in more detail how `WaitPeriod` and `ExtensionPeriod` prevent composite alarms from taking actions unexpectedly.

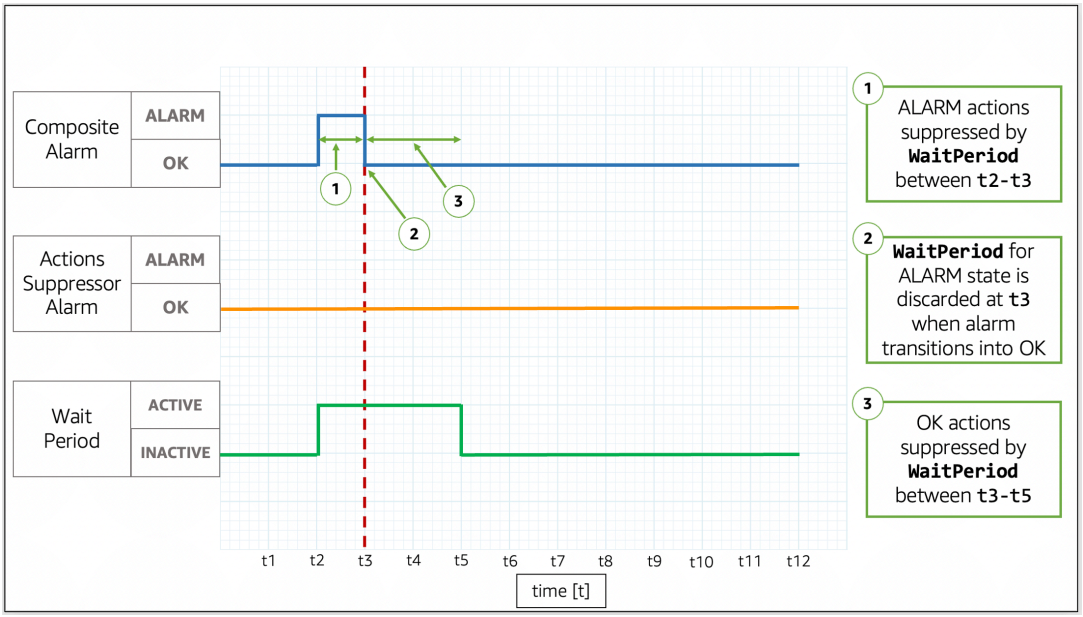
Note

In the following examples, `WaitPeriod` is configured as 2 time units, and `ExtensionPeriod` is configured as 3 time units.



Examples

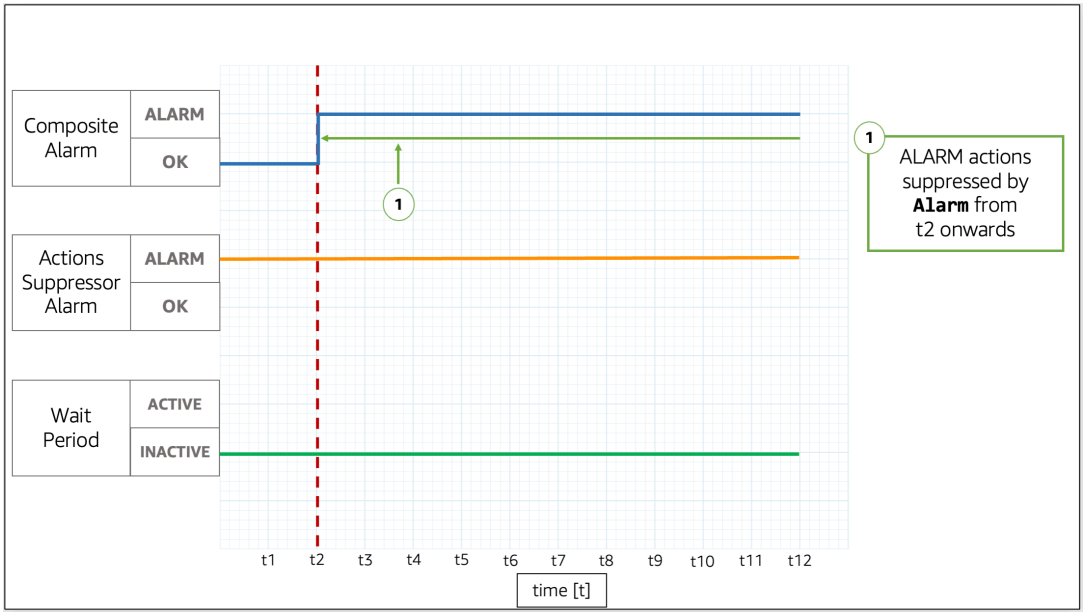
Example 1: Actions are not suppressed after `WaitPeriod`



In the image, the composite alarm changes states from `OK` to `ALARM` at t2. A `WaitPeriod` starts at t2 and ends at t4, so it can prevent the composite alarm from taking actions. After the `WaitPeriod` expires at t4, the composite alarm takes its actions because the suppressor alarm is still in `OK`.

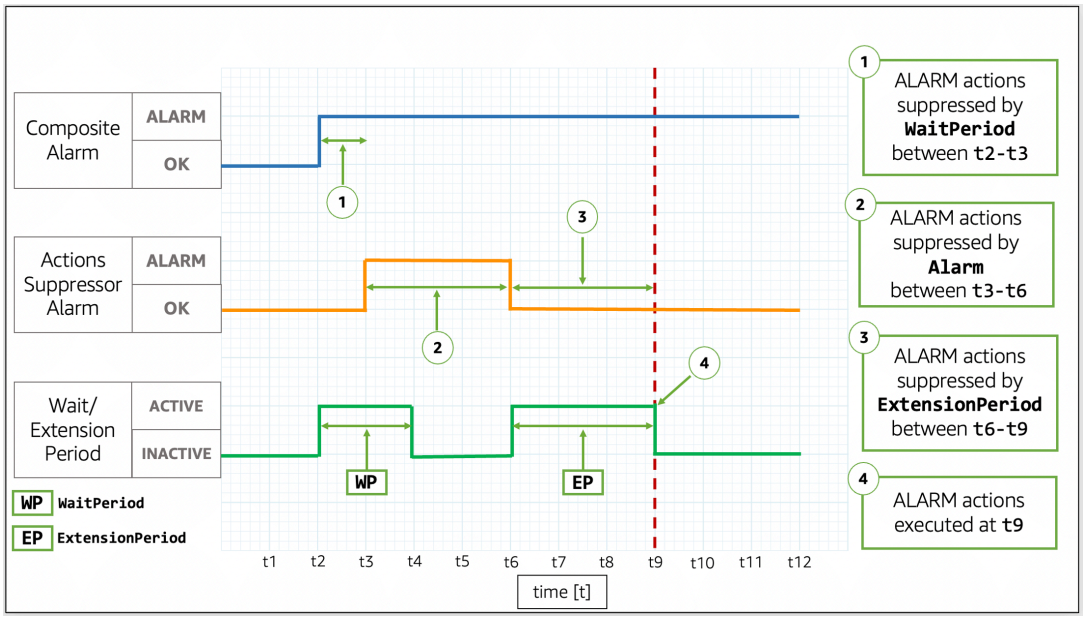
Example 2: Actions are suppressed by alarm before `WaitPeriod` expires

In the image, the composite alarm changes states from OK to ALARM at t2. A `WaitPeriod` starts at t2 and ends at t4. This gives the suppressor alarm time to change states from OK to ALARM at t3. Because the suppressor alarm changes states from OK to ALARM at t3, the `WaitPeriod` that started at t2 is discarded, and the suppressor alarm now stops the composite alarm from taking actions.



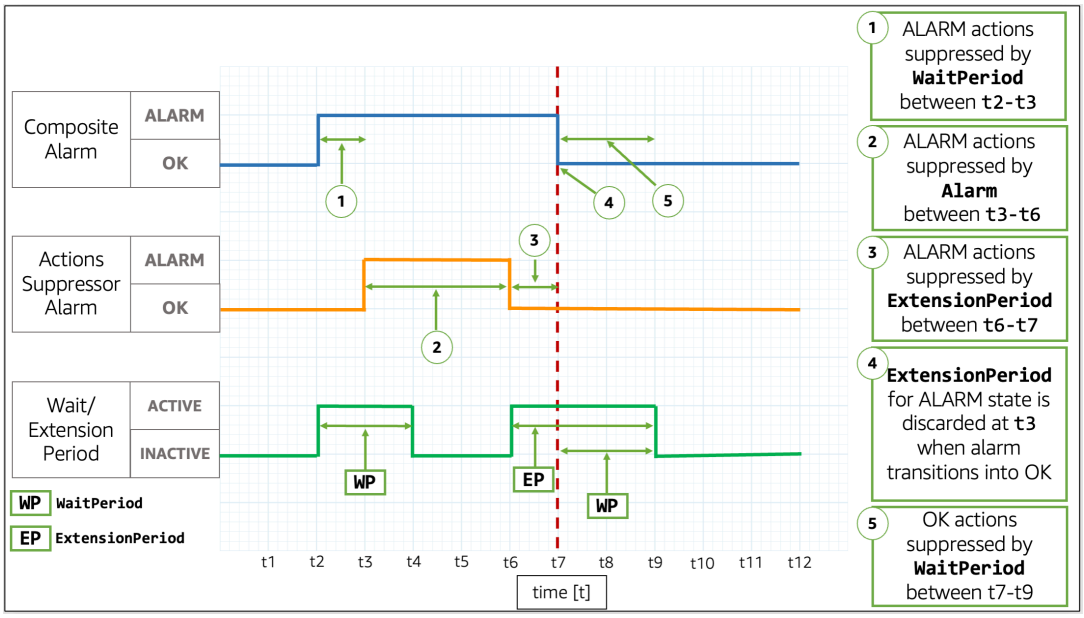
Example 3: State transition when actions are suppressed by `WaitPeriod`

In the image, the composite alarm changes states from OK to ALARM at t2. A `WaitPeriod` starts at t2 and ends at t4. This gives the suppressor alarm time to change states. The composite alarm



changes back to OK at t3, so the `WaitPeriod` that started at t2 is discarded. A new `WaitPeriod` starts at t3 and ends at t5. After the new `WaitPeriod` expires at t5, the composite alarm takes its actions.

Example 4: State transition when actions are suppressed by alarm



In the image, the composite alarm changes states from OK to ALARM at t2. The suppressor alarm is already in ALARM. The suppressor alarm stops the composite alarm from taking actions.

Example 5: Actions are not suppressed after `ExtensionPeriod`

In the image, the composite alarm changes states from OK to ALARM at t2. A `WaitPeriod` starts at t2 and ends at t4. This gives the suppressor alarm time to change states from OK to ALARM at t3 before it suppresses the composite alarm's actions until t6. Because the suppressor alarm changes states from OK to ALARM at t3, the `WaitPeriod` that started at t2 is discarded. At t6, the suppressor alarm changes to OK. An `ExtensionPeriod` starts at t6 and ends at t9. After the `ExtensionPeriod` expires, the composite alarm takes its actions.

Example 6: State transition when actions are suppressed by `ExtensionPeriod`

In the image, the composite alarm changes states from OK to ALARM at t2. A `WaitPeriod` starts at t2 and ends at t4. This gives the suppressor alarm time to change states from OK to ALARM at t3 before it suppresses the composite alarm's actions until t6. Because the suppressor alarm changes states from OK to ALARM at t3, the `WaitPeriod` that started at t2 is discarded. At t6, the suppressor alarm changes back to OK. An `ExtensionPeriod` starts at t6 and ends at t9. When the composite alarm changes back to OK at t7, the `ExtensionPeriod` is discarded, and a new `WaitPeriod` starts at t7 and ends at t9.

> **Tip**
>
> If you replace the action suppressor alarm, any active `WaitPeriod` or `ExtensionPeriod` is discarded.

Action Suppression and Mute Rules

When both action suppression and alarm mute rules are active for a composite alarm, mute rules take precedence and suppress all alarm actions. After the mute window ends, the composite alarm's action suppression configuration determines whether actions are executed based on the suppressor alarm state and configured wait or extension periods. For more information about alarm mute rules, see the section called “Alarm Mute Rules”.

Alarm actions

You can specify what actions an alarm takes when it changes state between the OK, ALARM, and INSUFFICIENT_DATA states.

Most actions can be set for the transition into each of the 3 states. Except for Auto Scaling actions, the actions happen only on state transitions, and are not performed again if the condition persists for hours or days.

The following are supported as alarm actions:

- Notify one or more subscribers by using an Amazon Simple Notification Service topic. Subscribers can be applications as well as persons.
- Invoke a Lambda function. This is the easiest way for you to automate custom actions on alarm state changes.
- Alarms based on EC2 metrics can also perform EC2 actions, such as stopping, terminating, rebooting, or recovering an EC2 instance.
- Alarms can scale an Auto Scaling group or an Application Auto Scaling target. For more information, see Auto Scaling actions.
- Alarms can create OpsItems in Systems Manager Ops Center or create incidents in AWS Systems Manager Incident Manager. These actions are performed only when the alarm goes into ALARM state.
- An alarm can start an investigation when it goes into ALARM state.

Alarms also emit events to Amazon EventBridge when they change state, and you can set up Amazon EventBridge to trigger other actions for these state changes.

Alarm actions and notifications

The following table shows the actions executed for alarms along with their behavior for multiple time series (or contributors) alarms:

Action Type	Standard metric alarm	Metrics Insights Multiple Time Series Alarm	PromQL Alarm	Log Alarm	More Information
SNS notifications	Supported	Contributor Level	Contributor Level	Contributor Level	Amazon SNS event destinations
EC2 actions (stop, terminate, reboot, recover)	Supported	Not supported	Not supported	Not supported	Stop, terminate, reboot, or recover an EC2 instance
Auto Scaling group actions	Simple, step, and target tracking	Not supported	Not supported	Not supported	Auto Scaling actions
Application Auto Scaling actions	Step and target tracking	Not supported	Step	Not supported	Auto Scaling actions
Systems Manager OpsItem creation	Supported	Alarm Level	Not supported	Alarm Level	Configure CloudWatch alarms to create OpsItems
Systems Manager Incident Manager incidents	Supported	Alarm Level	Not supported	Not supported	Creating incidents automatically with CloudWatch alarms

Action Type	Standard metric alarm	Metrics Insights Multiple Time Series Alarm	PromQL Alarm	Log Alarm	More Information
Lambda function invocation	Supported	Contributor Level	Contributor Level	Contributor Level	Invoke a Lambda function from an alarm
CloudWatch investigations investigation	Supported	Alarm Level	Not supported	Not supported	Start a CloudWatch investigations from an alarm

The content of alarm notifications differs depending on the alarm type:

- Single-metric alarms include both a state reason and detailed state reason data, showing the specific datapoints that caused the state change.
- Multi-time series Metrics Insights alarms provide a simplified state reason for each contributor, without the detailed state reason data block.
- PromQL alarms do not include a state reason or state reason data in their notifications.
- Log alarms without contributors (single-value) include both a state reason and detailed state reason data, showing the query results evaluated.
- Log alarms with contributors (using a BY clause) provide a simplified state reason for each contributor, without the detailed state reason data block.

Example Notification Content Examples

Single-metric alarm notification includes detailed data:

```
{
  "stateReason": "Threshold Crossed: 3 out of the last 3 datapoints [32.6 (03/07/25
 08:29:00), 33.8 (03/07/25 08:24:00), 41.0 (03/07/25 08:19:00)] were greater than the
 threshold (31.0)...",
  "stateReasonData": {
    "version": "1.0",
```

```
    "queryDate": "2025-07-03T08:34:06.300+0000",
    "startDate": "2025-07-03T08:19:00.000+0000",
    "statistic": "Average",
    "period": 300,
    "recentDatapoints": [41, 33.8, 32.6],
    "threshold": 31,
    "evaluatedDatapoints": [
      {
        "timestamp": "2025-07-03T08:29:00.000+0000",
        "sampleCount": 5,
        "value": 32.6
      }
      // Additional datapoints...
    ]
  }
}
```

Multiple time series Metrics Insights Alarm SNS notification for Contributor example:

```
{
  "AlarmName": "DynamoDBInsightsAlarm",
  "NewStateValue": "ALARM",
  "NewStateReason": "Threshold Crossed: 1 datapoint was less than the threshold (1.0).
 The most recent datapoint which crossed the threshold: [0.0 (01/12/25 13:34:00)].",
  "StateChangeTime": "2025-12-01T13:42:04.919+0000",
  "OldStateValue": "OK",
  "AlarmContributorId": "6d442278dba546f6",
  "AlarmContributorAttributes": {
    "TableName": "example-dynamodb-table-name"
  }
  // Additional information...
}
```

PromQL Alarm SNS notification for Contributor example:

```
{
  "AlarmName": "HighCPUUsageAlarm",
  "NewStateValue": "ALARM",
  "StateChangeTime": "2025-12-01T13:42:04.919+0000",
  "OldStateValue": "OK",
  "AlarmContributorId": "1d502278dcd546a1",
  "AlarmContributorAttributes": {
```

```
    "team": "example-team-name"
  }
  // Additional information...
}
```

Auto Scaling actions

A CloudWatch metric alarm can trigger an Auto Scaling scaling policy to add or remove capacity. Composite alarms can't trigger Auto Scaling actions.

Scaling policies belong to one of two services:

- Amazon EC2 Auto Scaling scales the EC2 instances in an Auto Scaling group.
- Application Auto Scaling scales other resources, such as Amazon ECS services, Amazon DynamoDB tables, Amazon Aurora replicas, and Spot Fleets.

How the alarm is created depends on the policy type:

- For simple scaling and step scaling, you create a CloudWatch metric alarm and attach it to the scaling policy.
- For target tracking, the Auto Scaling service creates and manages the alarms for you (a high alarm and a low alarm). Don't edit or delete them.

For more information, see Step and simple scaling policies for Amazon EC2 Auto Scaling. For Application Auto Scaling, see Step scaling policies and Target tracking scaling policies.

Alarm tags in action payloads

You can include a CloudWatch alarm's tags in the payloads it sends when the alarm changes state. Recipients can then route, filter, or add context by using tags such as team, environment, or cost center. This applies to Amazon SNS notifications, Lambda function invocations, and the alarm state change events that CloudWatch sends to EventBridge.

To enable this, see Alarm tags in action payloads.

Muting Alarm Actions

Alarm mute rules allow you to automatically mute alarm actions during predefined time windows, such as maintenance periods or operational events. CloudWatch continues monitoring alarm states

while preventing unwanted notifications. For more information, see the section called “Alarm Mute Rules”.

Mute rules versus disabling alarm actions

Alarm mute rules temporarily mute actions during scheduled time windows and automatically unmute when the window ends. In contrast, the `DisableAlarmActions` API permanently disables alarm actions until you manually call `EnableAlarmActions`. The `EnableAlarmActions` API does not unmute alarms that are muted by active mute rules.

Note

Muting an alarm does not stop CloudWatch from sending alarm events for alarm create, update, delete, and state changes to Amazon EventBridge.

Alarm Mute Rules

Alarm Mute Rules is a CloudWatch feature that provides you a mechanism to automatically mute alarm actions during predefined time windows. When you create a mute rule, you define specific time periods and target alarms whose actions will be muted. CloudWatch will continue monitoring and evaluating alarm states while preventing unwanted notifications or automated alarm actions during expected operational events.

Alarm Mute Rules help you manage critical operational scenarios where alarm actions would be unnecessary or disruptive. For example, during planned maintenance windows, you can prevent automated alarm actions while your systems are intentionally offline or experiencing expected issues, allowing you to perform maintenance without interruptions. For operations during non-business hours such as weekends or holidays, you can mute non-critical alarm actions when immediate response is not required, reducing alarm noise and unnecessary notifications to your operations team. In testing environments, mute rules allow you to temporarily mute alarm actions during scenarios such as load testing where high resource usage or error rates are expected and don't require immediate attention. When your team is actively troubleshooting issues, mute rules allow you to prevent duplicate alarm actions from being triggered, helping you focus on resolution without being distracted by redundant alarm notifications.

Defining alarm mute rules

Alarm mute rules can be defined using: **rules** and **targets**.

- **Rules** - define the time windows when alarm actions should be muted. Rules are composed of three attributes:
  - **Expression** – Defines when the mute period begins and how it repeats. You can use two types of expressions:
    - **Cron expressions** – Use standard cron syntax to create recurring mute windows. This approach is ideal for regular maintenance schedules, such as weekly system updates or daily backup operations. Cron expressions allow you to specify complex recurring patterns, including specific days of the week, months, or times.

      Syntax for cron expression

      ```
      ############## minute (0 - 59)
      # ############## hour (0 - 23)
      # # ############## day of the month (1 - 31)
      # # # ############## month (1 - 12) (or JAN-DEC)
      # # # # ############## day of the week (0 - 6) (0 or 7 is Sunday, or MON-SUN)
      # # # # #
      # # # # #
      * * * * *
      ```

      - The following characters are supported in each field:
        - `Minute`: `* , - /`
        - `Hour`: `* , - /`
        - `Day of month`: `* ? , - / L`
        - `Month`: `* , - /`
        - `Day of week`: `* ? , - L #`

        For example, `cron(0 9 * * SUN#4)` activates on the fourth Sunday of every month at 9:00 AM.
      - English names can be used for the `month` (JAN-DEC) and `day of week` (SUN-SAT) fields
    - **At expressions** – Use at expressions for one-time mute windows. This approach works well for planned operational events that occur once at a known time.

```
Syntax: `at(yyyy-MM-ddThh:mm)`
```

- **Duration** – Specifies how long the mute rule lasts once activated. Duration must be specified in ISO-8601 format with a minimum of 1 minute (PT1M) and maximum of 15 days (P15D).
- **Timezone** – Specifies the timezone in which the mute window will be applied according to the expressions, using standard timezone identifiers such as "America/Los_Angeles" or "Europe/London".

- **Targets** - specify the list of alarm names whose actions will be muted during the defined time windows. You can include both metric alarms and composite alarms in your target list.

You can optionally include start and end timestamps to provide additional boundaries for your mute windows. Start timestamps make sure that mute rules don't activate before a specific date and time, while end timestamps prevent rules from being applied beyond the specified date and time.

For more information about creating alarm mute rules programmatically, see PutAlarmMuteRule.

Note

- The targeted alarms must be present in the same AWS account and same AWS Region in which the mute rule is created.
- A single alarm mute rule can target up to 100 alarms by alarm names.

The CloudWatch console includes a dedicated "Alarm Mute Rules" tab that provides centralized management of all your mute rules within your AWS account. You can search for specific mute rules using the mute rule attributes such as rule name.

Mute Rule Status

Once created, an alarm mute rule can be in one of the below three statuses:

- **SCHEDULED** – The mute rule will become active at some time in the future according to the configured time window expression.

- **ACTIVE** – The mute rule is currently active as per the configured time window expression and actively muting targeted alarm actions.
- **EXPIRED** – The mute rule will not be SCHEDULED/ACTIVE anymore in the future. This occurs for one-time mute rules after the mute window has ended, or for recurring mute rules when an end timestamp is configured and that time has passed.

Effects of mute rules on alarms

During an active mute window, when a targeted alarm changes state and has actions configured, CloudWatch mutes those actions from executing. Mutes are applied only to alarm actions, meaning that alarms continue to be evaluated and state changes are visible in the CloudWatch console. However, configured actions such as Amazon Simple Notification Service notifications, Amazon Elastic Compute Cloud Auto Scaling actions, or Amazon EC2 actions are prevented from executing. CloudWatch continues to evaluate alarm states normally throughout the mute period, and you can view this information through alarm history.

When a mute window ends, CloudWatch compares the current state of each targeted alarm with the state that the alarm was in when the mute window started. If the two states are different, CloudWatch automatically executes the actions configured for the alarm's current state. This ensures that your alarm actions are executed for ongoing issues after the planned mute period ends, maintaining the integrity of your monitoring system.

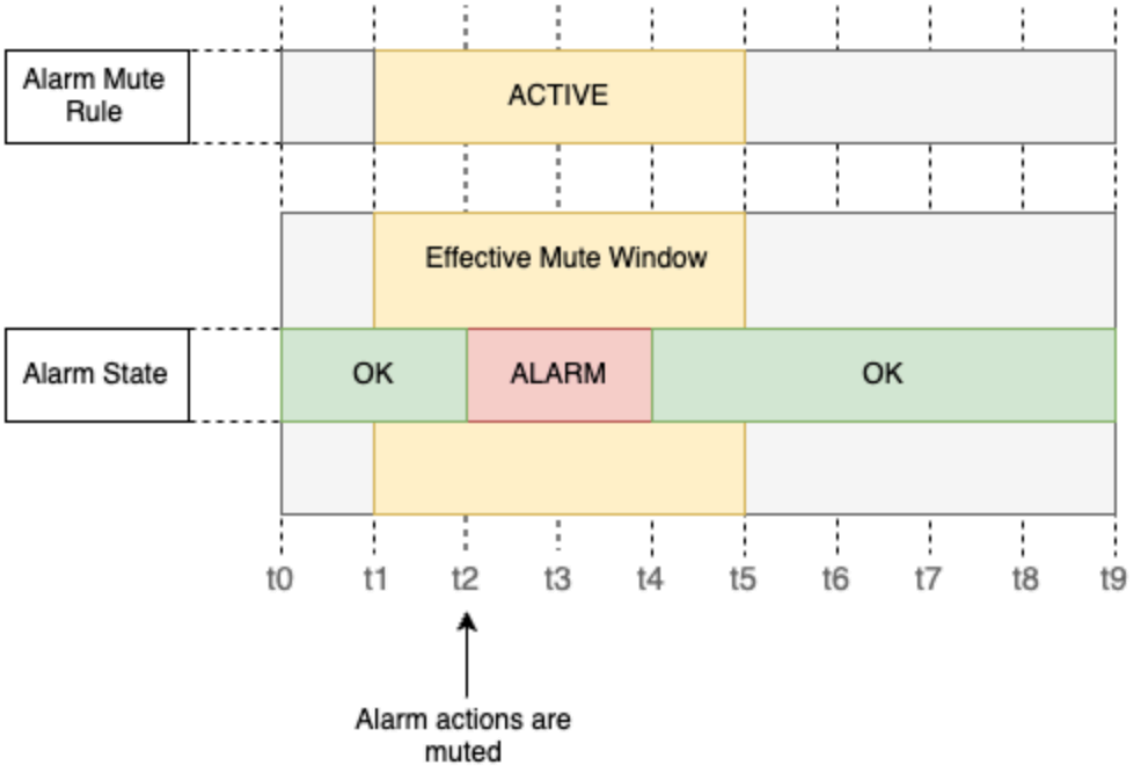
If the alarm is in the same state as it was when the mute window started, no actions are executed when the window ends. This is true even if the alarm changed state during the window and then returned to its original state before the window ended. The state in which an individual action was muted is not used for this comparison. A state change that happens after the mute window has ended is not affected by the mute rule, and its actions are executed as usual.

> **Note**
>
> When you mute an alarm:
>
> - All the actions associated with the targeted alarms are muted
> - Actions associated with all alarm states (OK, ALARM, and INSUFFICIENT_DATA) are muted

Viewing and managing muted alarms

For information about viewing and managing muted alarms, see Viewing and managing muted alarms.

How alarm mute rules work



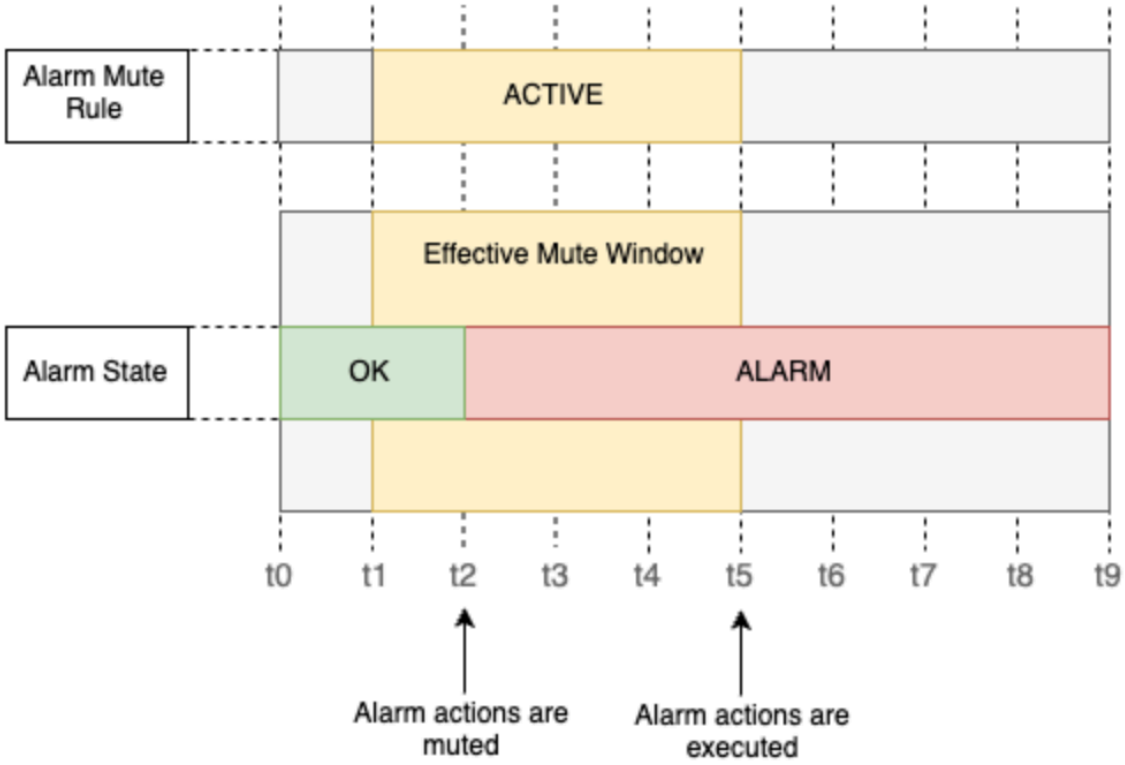
The following scenarios illustrate how alarm mute rules affect the targeted alarms and how the alarm actions are muted or executed.

> **Note**
>
> - Muting an alarm will mute actions associated with all alarm states, including OK, ALARM, and INSUFFICIENT_DATA. The behaviours illustrated below apply to actions associated with all alarm states.
> - When a mute window ends, CloudWatch compares the alarm's current state with the state the alarm was in when the mute window started. Actions are executed only if these two states are different, and the actions executed are those configured for the alarm's current state.
> - When you mute a Metrics Insights alarm, all contributor metric series for that alarm are automatically muted as well.

Scenario: Alarm actions are muted when a mute rule is active

Consider that,

- An Alarm has actions configured for its ALARM state
- An alarm mute rule is scheduled to be active from t1 to t5 that targets the Alarm



- At **t0** - Alarm is in OK state, mute rule status is SCHEDULED
- At **t1** - Mute rule status becomes ACTIVE
- At **t2** - Alarm transitions to ALARM state, action is muted as the alarm is effectively muted by the mute rule.
- At **t4** - Alarm returns to OK state while mute rule is still active
- At **t5** - Mute rule becomes inactive, but no ALARM action is executed because the alarm is in OK state, the same state it was in when the mute window started

Scenario: Alarm action muted when mute rule is active and re-triggered after mute window

Consider that,

- An Alarm has actions configured for its ALARM state
- An alarm mute rule is scheduled to be active from t1 to t5 that targets the Alarm

- At **t0** - Alarm is in OK state, mute rule status is SCHEDULED
- At **t1** - Mute rule status becomes ACTIVE
- At **t2** - Alarm transitions to ALARM state, action is muted as the alarm is effectively muted by the mute rule.
- At **t4** - Mute window becomes inactive, alarm is still in ALARM state
- At **t5** - Alarm action is executed because the mute window has ended and the alarm is in a different state (ALARM) from the state it was in when the mute window started (OK)

Scenario: Alarm is already in ALARM state when the mute window starts and is in ALARM state when it ends

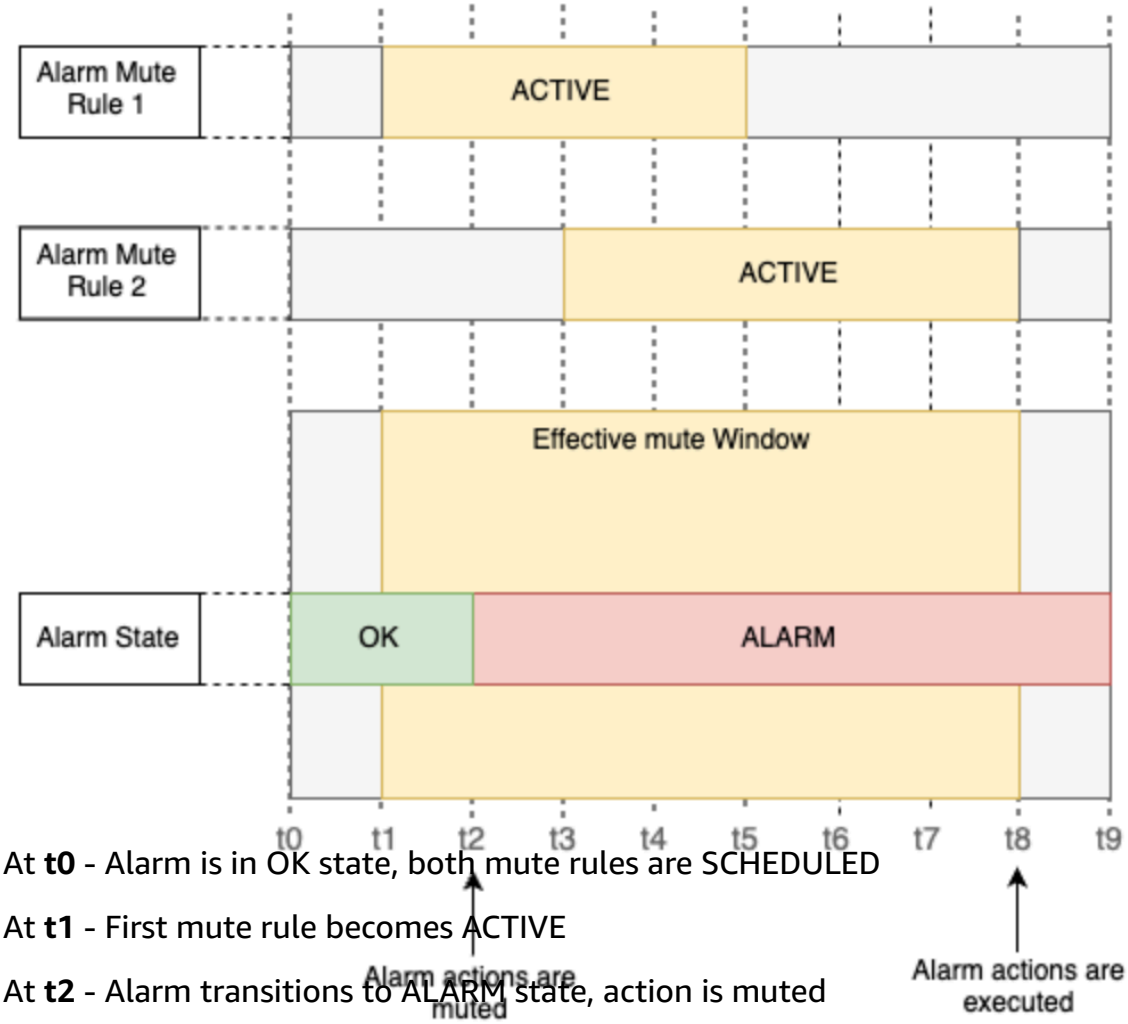
Consider that,

- An Alarm has actions configured for its ALARM state and no actions configured for its OK state
- An alarm mute rule is scheduled to be active from t1 to t5 that targets the Alarm

- At **t0** - Alarm is in ALARM state, mute rule status is SCHEDULED. The ALARM action was executed when the alarm transitioned to ALARM state.

- At **t1** - Mute rule status becomes ACTIVE. The alarm is in ALARM state when the mute window starts.
- At **t2** - Alarm transitions to OK state. No OK action is configured, so there is nothing to mute.
- At **t3** - Alarm transitions back to ALARM state, the ALARM action is muted because the alarm is effectively muted by the mute rule.
- At **t5** - Mute rule becomes inactive. No ALARM action is executed, because the alarm is in the same state (ALARM) as it was when the mute window started. The fact that the ALARM action was muted at t3 does not cause it to be executed at the end of the window.

> **Note**
>
> If the alarm had instead been in OK state at t5, the OK actions (if any) would have been executed, because OK is a different state from the state the alarm was in when the mute window started.



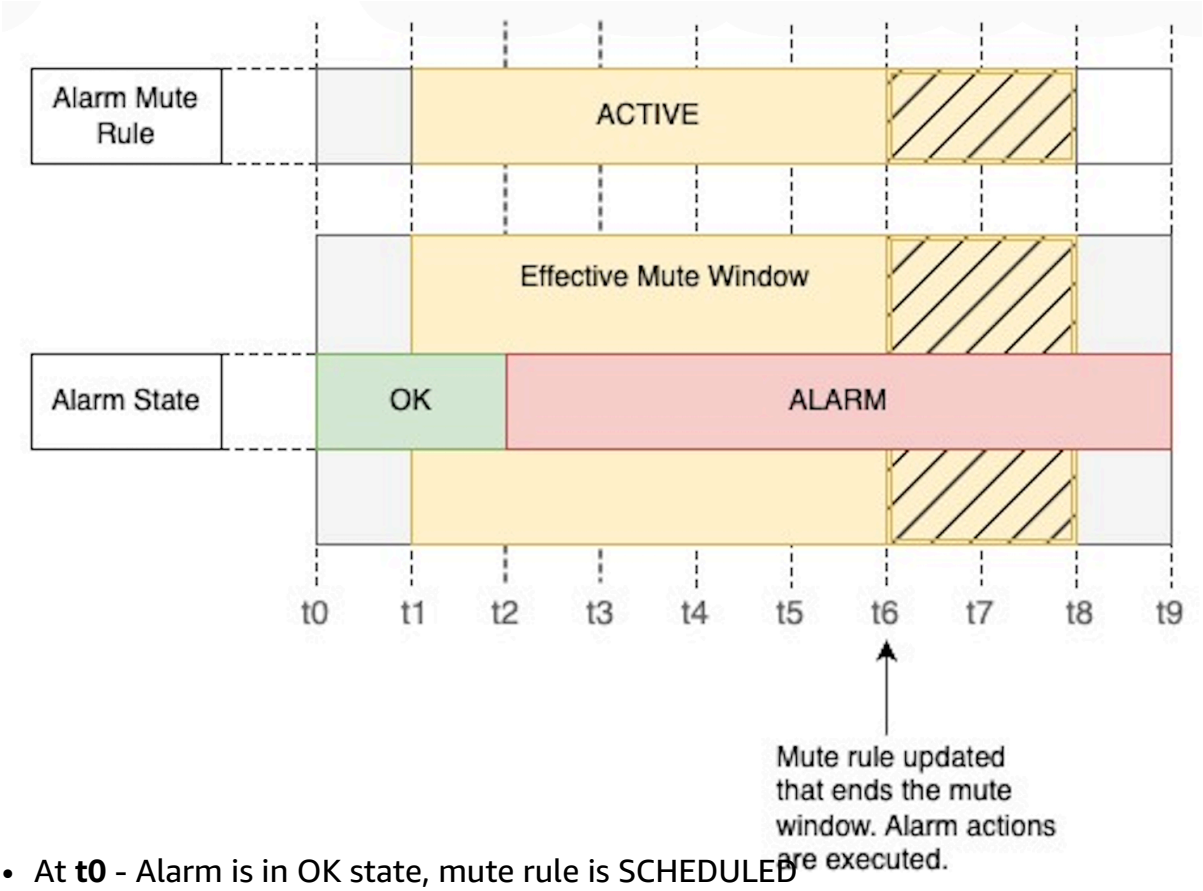
Scenario: Multiple overlapping alarm mute rules

Consider that,

- An Alarm has actions configured for its ALARM state

Consider that there are two mute rules,

- Alarm Mute Rule 1 - mutes Alarm from t1 to t5
- Alarm Mute Rule 2 - mutes Alarm from t3 to t9

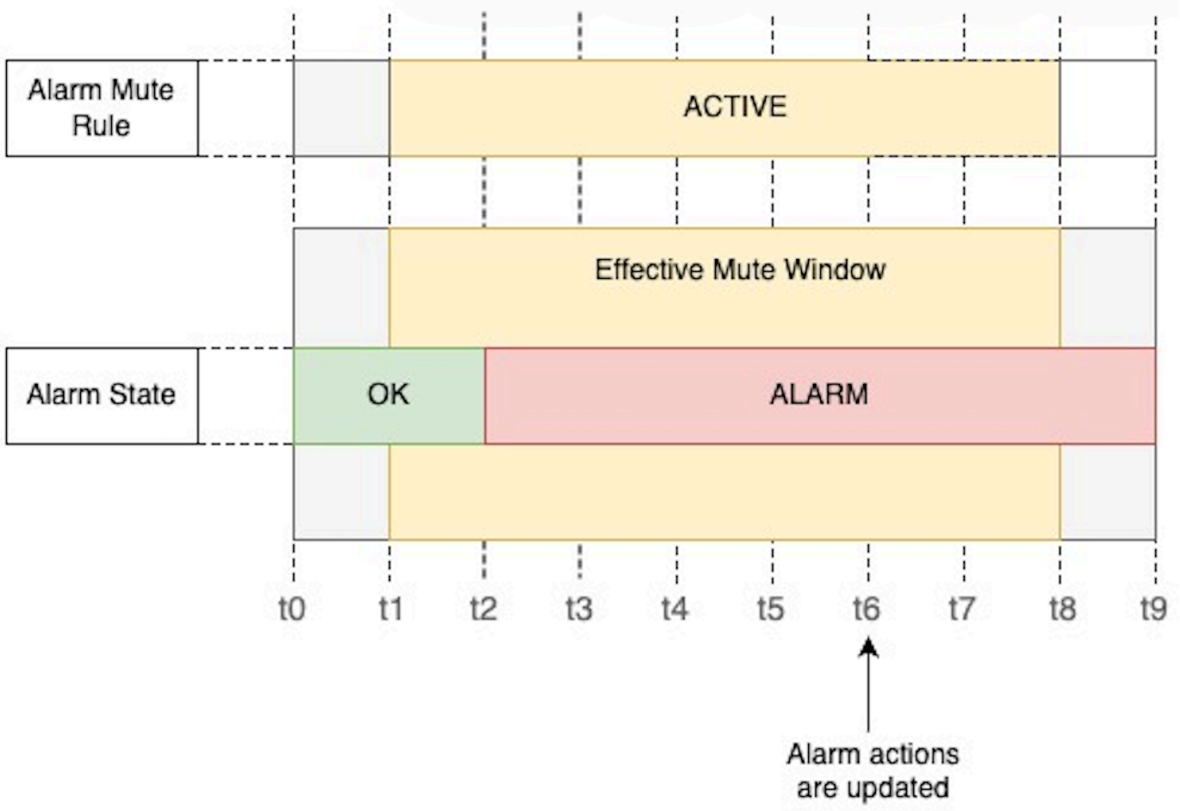


- At **t0** - Alarm is in OK state, both mute rules are SCHEDULED
- At **t1** - First mute rule becomes ACTIVE
- At **t2** - Alarm transitions to ALARM state, action is muted
- At **t3** - Second mute rule becomes ACTIVE
- At **t5** - First mute rule becomes inactive, but alarm action remains muted because second mute rule is still active
- At **t8** - Alarm action is executed because the second mute window has ended and the alarm is in a different state (ALARM) from the state it was in when the effective mute window started at t1 (OK)

Scenario: Muted alarm actions are executed when mute rule update ends the mute window

Consider that,

- An Alarm has actions configured for its ALARM state
- An alarm mute rule is scheduled to be active from t1 to t8 that targets the Alarm



- At **t0** - Alarm is in OK state, mute rule is SCHEDULED
- At **t1** - Mute rule becomes ACTIVE
- At **t2** - Alarm transitions to ALARM state, actions are muted
- At **t6** - The mute rule configuration is updated such that the time window ends at t6. Alarm actions are immediately executed at t6 because the mute rule is no longer active.

> **Note**
>
> The same behaviour applies,
>
> - If the mute rule is deleted at t6. Deleting the mute rule immediately unmutes the alarm.
> - If the alarm is removed from the mute rule targets (at t6) then the alarm will be unmuted immediately.

Scenario: New actions are executed if alarm actions are updated during mute window

Consider that,

- An Alarm has actions configured for its ALARM state
- An alarm mute rule is scheduled to be active from t1 to t8 that targets the Alarm

- At **t0** - Alarm is in OK state, mute rule is SCHEDULED. An SNS action is configured with the alarm state ALARM.
- At **t1** - Mute rule becomes ACTIVE
- At **t2** - Alarm transitions to ALARM state, the configured SNS action is muted
- At **t6** - Alarm configuration is updated to remove SNS action and add Lambda action
- At **t8** - The lambda action configured to the Alarm is executed because the mute window has ended and the alarm is in a different state (ALARM) from the state it was in when the mute window started (OK). The actions executed are those configured for the alarm's current state at the end of the window.

> **Note**
>
> If all the alarm actions are removed during the mute window (at t6 in above example) then no actions will be executed at the end of mute window (at t8 above)

Example schedules for common use cases

The following examples show how to configure time window expressions for common use cases.

Scenario 1: Muting alarm actions during scheduled maintenance windows – Regular maintenance activities that occur on a predictable schedule, such as system or database updates when services are intentionally unavailable or operating in degraded mode.

- Cron expression `0 2 * * SUN` with duration `PT4H` - Mutes alarms every Sunday from 2:00 AM to 6:00 AM for weekly system maintenance.
- Cron expression `0 1 1 * *` with duration `PT6H` - Mutes alarms on the first day of each month from 1:00 AM to 7:00 AM for monthly database maintenance.

Scenario 2: Muting non-critical alarms during non-business hours – Reducing alert fatigue during weekends or holidays when immediate attention is not required.

- Cron expression `0 18 * * FRI` with duration `P2DT12H` - Mutes alarms every weekend from Friday 6:00 PM to Monday 6:00 AM.

Scenario 3: Muting performance alarms during daily backup operations – Daily automated backup processes that temporarily increase resource utilization and may trigger performance-related alarms during predictable time windows.

- Cron expression `0 23 * * *` with duration `PT2H` - Mutes alarms every day from 11:00 PM to 1:00 AM during nightly backup operations that temporarily increase disk I/O and CPU utilization.

Scenario 4: Muting duplicate alarms during active troubleshooting sessions – Temporary muting of alarm actions while teams are actively investigating and resolving issues, preventing notification noise and allowing focused problem resolution.

- At expression `at(2024-05-10T14:00)` with duration `PT4H` - Mutes alarms on May 10, 2024 from 2:00 PM to 6:00 PM during an active incident response session.

Scenario 5: Muting alarm actions during planned company shutdowns – One-time extended maintenance periods or company-wide shutdowns where all systems are intentionally offline for extended periods.

- At expression `at(2024-12-23T00:00)` with duration `P7D` - Mutes alarms for the entire week of December 23-29, 2024 during annual company shutdown.

Limits

General CloudWatch quotas

For information about general CloudWatch service quotas that apply to alarms, see CloudWatch service quotas.

Limits that apply to alarms based on metric math expressions

Alarms based on metric math expressions can reference a maximum of 10 metrics. This is a hard limit that cannot be increased. If you need to monitor more than 10 metrics in a single alarm, consider one of the following approaches:

- If the metrics are in the same namespace, use a Metrics Insights query in your alarm instead of a metric math expression. Metrics Insights can aggregate across many metrics with a single query.
- Pre-aggregate metrics into custom metrics using a Lambda function, then reference the aggregated metrics in your alarm expression.
- Split your logic across multiple alarms and combine them using a composite alarm.

Limits that apply to alarms based on Metrics Insights queries

When working with CloudWatch Metrics Insights alarms, be aware of these functional limits:

- A default of 200 alarms using the Metrics Insights query per account per Region
- Only the latest 3 hours of data can be used for evaluating the alarm's conditions. However, you can visualize up to two weeks of data on the alarm's detail page graph
- Alarms evaluating multiple time series will limit the number of contributors in ALARM to 100

- Assuming the query retrieves 150 time series:
  - If there are fewer than 100 contributors in ALARM (for example 95), the `StateReason` will be "95 out of 150 time series evaluated to ALARM"
  - If there are more than 100 contributors in ALARM (for example 105), the `StateReason` will be "100+ time series evaluated to ALARM"
- Furthermore, if the volume of attributes is too large, the number of contributors in ALARM can be limited to less than 100.
- Metrics Insights limits on the maximum number of time series analyzed or returned apply
- During alarm evaluation, the `EvaluationState` will be set to `PARTIAL_DATA` for the following limits:
  - If the Metrics Insights query returns more than 500 time series.
  - If the Metrics Insights query matches more than 10,000 metrics.

For more information on CloudWatch service quotas and limits, see CloudWatch Metrics Insights service quotas.

Limits that apply to Log Alarms

When working with CloudWatch Log Alarms, be aware of the following limits:

Resource	Limit	Adjustable
PutLogAlarm requests per second	3 (burst: 5)	No
Maximum Log Alarms per account	~1000 (limited by CloudWatch Logs AWS managed Scheduled Query quota)	No
Maximum contributors per query execution	500	No
Maximum contributors tracked in ALARM	100	No
Maximum fields in BY clause	5	No
Maximum log lines in SNS email notification	50 (also limited by SNS notification payload limit of 256 KB)	No

- Alarms evaluating multiple contributors limit the number of contributors in ALARM to 100.
  - If there are fewer than 100 contributors in ALARM (for example 95), the `StateReason` is "95 out of 100 contributors evaluated to ALARM."
  - If there are more than 100 contributors in ALARM (for example 105), the `StateReason` is "100+ contributors evaluated to ALARM."
  - If the volume of attributes is too large, the number of contributors in ALARM can be limited to fewer than 100.
- During alarm evaluation, the `EvaluationState` is set to `PARTIAL_DATA` if the query returns more than 500 contributor groups.
- The total log lines included in a notification are limited by the requested count, the total results available, and the SNS payload size limit. If the log lines exceed the payload limit, fewer lines are included.

Limits that apply to alarms based on PromQL queries

When working with CloudWatch alarms that use Prometheus Query Language (PromQL) queries, be aware of these functional limits:

- Your account can have up to 15,000 PromQL alarms in each AWS Region by default.
- Alarms evaluating multiple time series will limit the number of contributors in ALARM to 100.
  - If there are fewer than 100 contributors in ALARM (for example 95), the `StateReason` will be "95 time series evaluated to ALARM"
  - If there are more than 100 contributors in ALARM (for example 105), the `StateReason` will be "100+ time series evaluated to ALARM"
  - Furthermore, if the volume of attributes is too large, the number of contributors in ALARM can be limited to less than 100.
- PromQL query limits apply to the maximum number of time series that are analyzed or returned.
- During alarm evaluation, the `EvaluationState` will be set to `PARTIAL_DATA` if the PromQL query returns more than 500 time series.

Limits that apply to alarms based on connected data sources

- When CloudWatch evaluates an alarm, it does so every minute, even if the period for the alarm is longer than one minute. For the alarm to work, the Lambda function must be able to return

a list of timestamps starting on any minute, not only on multiples of the period length. These timestamps must be spaced one period length apart.

Therefore, if the data source queried by the Lambda can only return timestamps that are multiples of the period length, the function should "re-sample" the fetched data to match the timestamps expected by the `GetMetricData` request.

For example, an alarm with a five-minute period is evaluated every minute using five-minute windows that shift by one minute each time. In this case:

- For the alarm evaluation at 12:15:00, CloudWatch expects data points with timestamps of `12:00:00`, `12:05:00`, and `12:10:00`.
- Then for the alarm evaluation at 12:16:00, CloudWatch expects data points with timestamps of `12:01:00`, `12:06:00`, and `12:11:00`.

- When CloudWatch evaluates an alarm, any data points returned by the Lambda function that don't align with the expected timestamps are dropped, and the alarm is evaluated using the remaining expected data points. For example, when the alarm is evaluated at `12:15:00` it expects data with timestamps of `12:00:00`, `12:05:00`, and `12:10:00`. If it receives data with timestamps of `12:00:00`, `12:05:00`, `12:06:00`, and `12:10:00`, the data from `12:06:00` is dropped and CloudWatch evaluates the alarm using the other timestamps.

  Then for the next evaluation at `12:16:00`, it expects data with timestamps of `12:01:00`, `12:06:00`, and `12:11:00`. If it only has the data with timestamps of `12:00:00`, `12:05:00`, and `12:10:00`, all of these data points are ignored at 12:16:00 and the alarm transitions into the state according to how you specified the alarm to treat missing data. For more information, see Alarm evaluation.
- We recommend that you create these alarms to take actions when they transition to the `INSUFFICIENT_DATA` state, because several Lambda function failure use cases will transition the alarm to `INSUFFICIENT_DATA` regardless of the way that you set the alarm to treat missing data.
- If the Lambda function returns an error:
  - If there is a permission problem with calling the Lambda function, the alarm begins having missing data transitions according to how you specified the alarm to treat missing data when you created it.
  - Any other error coming from the Lambda function causes the alarm to transition to `INSUFFICIENT_DATA`.

- If the metric requested by the Lambda function has some delay so that the last data point is always missing, you should use a workaround. You can create an M out of N alarm or increase the evaluation period of the alarm. For more information about M out of N alarms, see Alarm evaluation.

Getting started

Topics

- Create alarms
- Acting on alarm changes
- Configure alarm mute rules

Create alarms

Topics

- Create an alarm using a PromQL query
- Create a CloudWatch alarm based on a static threshold
- Create a CloudWatch alarm based on a metric math expression
- Create a CloudWatch alarm based on anomaly detection
- Create an alarm based on Metrics Insights
- Create an alarm based on a connected data source
- Create a metric alarm that uses a wall clock evaluation window
- Create an alarm that uses a warm-up period
- Alarming on logs
- Create a composite alarm

Create an alarm using a PromQL query

You can create a CloudWatch alarm that uses a PromQL instant query to monitor metrics ingested through the CloudWatch OTLP endpoint. All matching time series returned by the query are considered breaching, and the alarm tracks each breaching time series as a contributor. For more information about how PromQL alarms work, see PromQL alarms.

Creating a PromQL alarm using the AWS Management Console

This example creates an alarm that monitors the HTTP 5xx server-error rate for the checkout-api service and alerts you when the error rate exceeds 5 percent.

To create a PromQL alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **PromQL** for the metric type.
5. In **Editor** mode, enter the PromQL query:

```
sum(rate({"http.server.request.count", "@resource.service.name"="checkout-api",
 "http.response.status_code"=~"5.."}[5m])) / sum(rate({"http.server.request.count",
 "@resource.service.name"="checkout-api"}[5m])) * 100 > 5
```

6. Under **Conditions**, specify the following:
   - For **Evaluation interval**, choose **`1 minute`**. This value defines how often CloudWatch evaluates the PromQL query.
   - For **Pending period**, enter **`120`**. This value is the number of seconds that a contributor must breach before it enters the ALARM state.
   - For **Recovery period**, enter **`300`**. This value is the number of seconds that a contributor must stop breaching before it enters the OK state.
7. Configure notifications and actions as needed.
8. Add a name and description for your alarm.
9. Choose **Next**.
10. Choose **Create alarm**.

Creating a PromQL alarm (AWS CLI)

Use the PutMetricAlarm API action to create a PromQL alarm.

Example: PromQL alarm that triggers when the 5xx error rate for a service exceeds 5 percent

This alarm notifies an Amazon SNS topic when the 5xx error rate exceeds 5 percent. It waits 60 seconds (the pending period) before entering the `ALARM` state, and 300 seconds (the recovery period) before returning to `OK`.

```
aws cloudwatch put-metric-alarm \
  --alarm-name MyPromQLAlarm \
  --evaluation-criteria '{"PromQLCriteria":
{"Query":"sum(rate({\"http.server.request.count\", \"@resource.service.name
\"=\"checkout-api\", \"http.response.status_code\"=~\"5..\"}[5m])) /
 sum(rate({\"http.server.request.count\", \"@resource.service.name\"=\"checkout-api\"}
[5m])) * 100 > 5","PendingPeriod":60,"RecoveryPeriod":300}}' \
  --evaluation-interval 60 \
  --alarm-actions arn:aws:sns:us-east-1:123456789012:MyTopic
```

Example: PromQL alarm for p99 request latency with a pending period

This alarm waits 300 seconds (5 minutes) before transitioning to the `ALARM` state, and waits 600 seconds (10 minutes) before recovering.

```
aws cloudwatch put-metric-alarm \
  --alarm-name HighLatencyAlarm \
  --evaluation-criteria '{"PromQLCriteria":{"Query":"histogram_quantile(0.99,
 {\"http.server.request.duration\", \"@resource.service.name\"=\"checkout-api\"}) >
 0.5","PendingPeriod":300,"RecoveryPeriod":600}}' \
  --evaluation-interval 60
```

Example Create a PromQL alarm with an SNS notification action

```
aws cloudwatch put-metric-alarm \
  --alarm-name MyPromQLAlarmWithAction \
  --evaluation-criteria '{"PromQLCriteria":{"Query":"avg by (\"@resource.k8s.pod.name
\") (rate(container_cpu_usage_seconds_total{\"@resource.k8s.namespace.name\"=
\"production\"}[5m])) * 100 > 80","PendingPeriod":0,"RecoveryPeriod":0}}' \
  --evaluation-interval 60 \
  --alarm-actions arn:aws:sns:us-east-1:123456789012:MyTopic
```

Example: PromQL anomaly-detection alarm using a statistical band

A PromQL alarm can detect anomalies without a separate anomaly detector. Instead of the `ANOMALY_DETECTION_BAND` metric-math function that standard metric alarms use, you build

the expected range directly in the query with functions such as `quantile_over_time` and `stddev_over_time`. The following query alerts when the request count for the checkout-api service moves more than three standard deviations from its one-hour median in either direction. The `clamp_min` function keeps the lower bound from going negative.

```
aws cloudwatch put-metric-alarm \
  --alarm-name RequestCountAnomaly \
  --evaluation-criteria '{"PromQLCriteria":{"Query":"1 * {\"http.server.request.count
\", \"@resource.service.name\"=\"checkout-api\"} > quantile_over_time(0.5,
 {\"http.server.request.count\", \"@resource.service.name\"=\"checkout-api
\"}[60m] offset 1m) + 3 * stddev_over_time({\"http.server.request.count
\", \"@resource.service.name\"=\"checkout-api\"}[60m] offset 1m) or 1 *
 {\"http.server.request.count\", \"@resource.service.name\"=\"checkout-
api\"} < clamp_min(quantile_over_time(0.5, {\"http.server.request.count
\", \"@resource.service.name\"=\"checkout-api\"}[60m] offset 1m) - 3 *
 stddev_over_time({\"http.server.request.count\", \"@resource.service.name\"=
\"checkout-api\"}[60m] offset 1m), 0)"}}' \
  --evaluation-interval 60
```

Example: PromQL alarm that triggers an Application Auto Scaling step scaling policy

You can attach a PromQL alarm to an Application Auto Scaling step scaling policy. First, create the step scaling policy with the `put-scaling-policy` command. The command returns a policy ARN.

```
aws application-autoscaling put-scaling-policy \
  --service-namespace ecs \
  --scalable-dimension ecs:service:DesiredCount \
  --resource-id service/my-cluster/my-service \
  --policy-name promql-5xx-scale-out \
  --policy-type StepScaling \
  --step-scaling-policy-configuration
 '{"AdjustmentType":"ChangeInCapacity","StepAdjustments":
[{"MetricIntervalLowerBound":0,"ScalingAdjustment":1}],"Cooldown":60}'
```

Then create the PromQL alarm, setting `--alarm-actions` to the policy ARN from the previous output. This alarm scales out the service when the 5xx error rate for the checkout-api service exceeds 5 percent. When a PromQL alarm triggers an Auto Scaling action, the query must return a single time series and include a comparison. Wrap the expression in an aggregation function such as `avg`, `sum`, `max`, or `min`, followed by the comparison, as shown in the following command.

```
aws cloudwatch put-metric-alarm \
```

```
  --alarm-name checkout-5xx-scale-out \
  --evaluation-criteria '{"PromQLCriteria":
{"Query":"avg(sum(rate({\"http.server.request.count\", \"@resource.service.name
\"=\"checkout-api\", \"http.response.status_code\"=~\"5..\"}[5m])) /
 sum(rate({\"http.server.request.count\", \"@resource.service.name\"=\"checkout-api\"}
[5m])) * 100) > 5","PendingPeriod":60,"RecoveryPeriod":300}}' \
  --evaluation-interval 60 \
  --alarm-actions arn:aws:autoscaling:us-
east-1:123456789012:scalingPolicy:abcd1234-5678-90ab-cdef-example11111:resource/ecs/
service/my-cluster/my-service:policyName/promql-5xx-scale-out
```

Creating a PromQL alarm from Query Studio

This example shows how to create a PromQL alarm from Query Studio that alerts you when the average HTTP request duration for a service exceeds 500 milliseconds.

Unlike standard CloudWatch alarms where the threshold is configured as a separate step, PromQL alarms define the alarm condition (threshold) as part of the query itself. For example, the comparison operator (>) and threshold value (`0.5`) are embedded directly in the PromQL expression.

To create a PromQL alarm from Query Studio

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane below **Metrics**, choose **Query Studio**.
3. Select **PromQL** from the query language drop-down menu.
4. Build your query using one of the following modes:
   - In **Builder** mode, select a metric name from the **Metric** field (for example, `http.server.request.duration`). Add label filters as needed (for example, `@resource.service.name` = `my-api`). To define the alarm threshold, select a **Basic Operation** (for example, >) and enter a **Number** (for example, `0.5`).
   - In **Code** mode, enter the PromQL expression directly, for example:

     ```
     histogram_avg({"http.server.request.duration", "@resource.service.name"="my-
     api"}) > 0.5
     ```
5. Choose **Run** to execute the query and verify it returns the expected results.
6. Choose **Create alarm** from the actions menu.

7. You are redirected to the CloudWatch alarm creation page with your PromQL query pre-populated.
8. Under **Conditions**, specify the following:
   - For **Evaluation interval**, choose **`1 minute`**, to define how often the PromQL query is evaluated.
   - For **Pending period**, enter **`60`**, duration in seconds the query must be breaching before entering ALARM state. This means the latency must exceed the threshold for at least 60 seconds before the alarm fires.
   - For **Recovery period**, enter **`120`**, duration in seconds the query must not be breaching before entering OK state. This means the latency must stay below the threshold for at least 120 seconds before the alarm recovers.
9. Configure notifications and actions as needed.
10. Add a name and description for your alarm.
11. Choose **Next**.
12. Choose **Create alarm**.

> **Note**
>
> The PromQL query must return a single time series to create an alarm. If your query returns multiple time series, use aggregation functions such as `sum`, `avg`, or `topk` to reduce the result to a single series before creating the alarm.

Create a CloudWatch alarm based on a static threshold

You choose a CloudWatch metric for the alarm to watch, and the threshold for that metric. The alarm goes to `ALARM` state when the metric breaches the threshold for a specified number of evaluation periods.

If you are creating an alarm in an account set up as a monitoring account in CloudWatch cross-account observability, you can set up the alarm to watch a metric in a source account linked to this monitoring account. For more information, see CloudWatch cross-account observability.

To create an alarm based on a single metric

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select Metric**.
5. Do one of the following:
   - Choose the service namespace that contains the metric that you want. Continue choosing options as they appear to narrow the choices. When a list of metrics appears, select the check box next to the metric that you want.
   - In the search box, enter the name of a metric, account ID, account label, dimension, or resource ID. Then, choose one of the results and continue until a list of metrics appears. Select the check box next to the metric that you want.
6. Choose the **Graphed metrics** tab.
   a. Under **Statistic** , choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, **p95.45**).
   b. Under **Period**, choose the evaluation period for the alarm. When evaluating the alarm, each period is aggregated into one data point.

      You can also choose whether the y-axis legend appears on the left or right while you're creating the alarm. This preference is used only while you're creating the alarm.
   c. Choose **Select metric**.

      The **Specify metric and conditions** page appears, showing a graph and other information about the metric and statistic that you selected.
7. Under **Conditions**, specify the following:
   a. For **Whenever *`metric`* is**, specify whether the metric must be greater than, less than, or equal to the threshold. Under **than...**, specify the threshold value.
   b. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

      To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Alarm evaluation.

c. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.

d. If the alarm uses a percentile as the monitored statistic, a **Percentiles with low samples** box appears. Use it to choose whether to evaluate or ignore cases with low sample rates. If you choose **ignore (maintain alarm state)**, the current alarm state is always maintained when the sample size is too low. For more information, see Percentile-based alarms and low data samples.

8. Choose **Next**.

9. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

   To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

   In CloudWatch cross-account observability, you can choose to have notifications sent to multiple AWS accounts. For example, to both the monitoring account and the source account.

   To have the alarm not send notifications, choose **Remove**.

10. To have the alarm perform Auto Scaling, EC2, Lambda, investigation, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. Alarms can perform Systems Manager actions and investigation actions only when they go into ALARM state. For more information about Systems Manager actions, see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

    To have the alarm start an investigation, choose **Add investigation action** and then select your investigation group. For more information about , see CloudWatch investigations.

    > **Note**
    >
    > To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for AWS Systems Manager Incident Manager.

11. When finished, choose **Next**.

12. Enter a name and description for the alarm. The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting,

which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources. Then choose **Next**.

13. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

You can also add alarms to a dashboard. For more information, see Adding an alarm to a CloudWatch dashboard.

Create a CloudWatch alarm based on a metric math expression

Metric alarms are designed to evaluate time series that you define from either a single metric, or a metric math expression that combines or transforms one or more metrics into a time series that deliver insights more closely aligned to your unique needs. To create an alarm based on a metric math expression, choose one or more CloudWatch metrics to use in the expression. Then, specify the expression, threshold, and evaluation periods.

You can't create an alarm based on the **SEARCH** expression. Only alarms based on Metrics Insights SQL queries can operate on multiple time series.

To create an alarm that's based on a metric math expression

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select Metric**, and then perform one of the following actions:
   - Select a namespace from the **AWS namespaces** dropdown or **Custom namespaces** dropdown. After you select a namespace, you continue choosing options until a list of metrics appears, where you select the checkbox next to the correct metric.
   - Use the search box to find a metric, account ID, dimension, or resource ID. After you enter the metric, dimension, or resource ID, you continue choosing options until a list of metrics appears, where you select the check box next to the correct metric.
5. (Optional) If you want to add another metric to a metric math expression, you can use the search box to find a specific metric. You can add as many as 10 metrics to a metric math expression.
6. Select the **Graphed metrics** tab. For each of the metrics that you previously added, perform the following actions:

a. Under the **Statistic** column, select the dropdown menu. In the dropdown menu, choose one of the predefined statistics or percentiles. Use the search box in the dropdown menu to specify a custom percentile.

b. Under the **Period** column, select the dropdown menu. In the dropdown menu, choose one of the predefined evaluation periods.

   While you're creating your alarm, you can specify whether the Y-axis legend appears on the left or right side of your graph.

> **Note**
>
> When CloudWatch evaluates alarms, periods are aggregated into single data points.

7. Choose the **Add math** dropdown, and then select **Start with an empty expression** from the list of predefined metric math expressions.

   After you choose **Start with an empty expression**, a math expression box appears where you apply or edit math expressions.

8. In the math expression box, enter your math expression, and then choose **Apply**.

   After you choose **Apply**, an **ID** column appears next to the **Label** column.

   To use a metric or the result of another metric math expression as part of your current math expression's formula, you use the value that's shown under the **ID** column. To change the value of **ID**, you select the pen-and-paper icon next to the current value. The new value must begin with a lowercase letter and can include numbers, letters, and the underscore symbol. Changing the value of **ID** to a more significant name can make your alarm graph easier to understand.

   For information about the functions that are available for metric math, see Metric math syntax and functions.

9. (Optional) Add more math expressions, using both metrics and the results of other math expressions in the formulas of the new math expressions.

10. When you have the expression to use for the alarm, clear the check boxes to the left of every other expression and every metric on the page. Only the check box next to the expression to use for the alarm should be selected. The expression that you choose for the alarm must produce a single time series and show only one line on the graph. Then choose **Select metric**.

The **Specify metric and conditions** page appears, showing a graph and other information about the math expression that you have selected.

11. For **Whenever *`expression`* is**, specify whether the expression must be greater than, less than, or equal to the threshold. Under **than...**, specify the threshold value.
12. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

    To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Alarm evaluation.
13. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.
14. Choose **Next**.
15. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

    To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    To have the alarm not send notifications, choose **Remove**.
16. To have the alarm perform Auto Scaling, Amazon EC2, Lambda, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. If you choose a Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

    Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

> **Note**
>
> To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for AWS Systems Manager Incident Manager.

17. When finished, choose **Next**.
18. Enter a name and description for the alarm. Then choose **Next**.

    The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.
19. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

You can also add alarms to a dashboard. For more information, see Adding an alarm to a CloudWatch dashboard.

Create a CloudWatch alarm based on anomaly detection

You can create an alarm based on CloudWatch anomaly detection, which analyzes past metric data and creates a model of expected values. The expected values take into account the typical hourly, daily, and weekly patterns in the metric.

You set a value for the anomaly detection threshold, and CloudWatch uses this threshold with the model to determine the "normal" range of values for the metric. A higher value for the threshold produces a thicker band of "normal" values.

You can choose whether the alarm is triggered when the metric value is above the band of expected values, below the band, or either above or below the band.

You also can create anomaly detection alarms on single metrics and the outputs of metric math expressions. You can use these expressions to create graphs that visualize anomaly detection bands.

In an account set up as a monitoring account for CloudWatch cross-account observability, you can create anomaly detectors on metrics in source accounts in addition to metrics in the monitoring account.

For more information, see Using CloudWatch anomaly detection.

> **Note**
>
> If you're already using anomaly detection for visualization purposes on a metric in the Metrics console and you create an anomaly detection alarm on that same metric, then the

threshold that you set for the alarm doesn't change the threshold that you already set for visualization. For more information, see Creating a graph.

To create an alarm that's based on anomaly detection

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select Metric**.
5. Do one of the following:
   - Choose the service namespace that contains your metric, and then continue choosing options as they appear to narrow down your options. When a list of metrics appears, select the check box that's next to your metric.
   - In the search box, enter the name of a metric, dimension, or resource ID. Select one of the results, and then continue choosing options as they appear until a list of metrics appears. Select the check box that's next to your metric.
6. Choose **Graphed metric**.
   a. (Optional) For *Statistic*, choose the dropdown, and then select one of the predefined statistics or percentiles. You can use the search box in the dropdown to specify a custom percentile, such as **p95.45**.
   b. (Optional) For *Period*, choose the dropdown, and then select one of the predefined evaluation periods.

   > **Note**
   >
   > When CloudWatch evaluates your alarm, it aggragates the period into a single datapoint. For an anomaly detection alarm, the evaluation period must be one minute or longer.

7. Choose **Next**.
8. Under ***Conditions***, specify the following:
   a. Choose **Anomaly detection**.

If the model for this metric and statistic already exists, CloudWatch displays a preview of the anomaly detection band in the graph at the top of the screen. After you create your alarm, it can take up to 15 minutes for the actual anomaly detection band to appear in the graph. Before that, the band that you see is an approximation of the anomaly detection band.

> **Tip**
>
> To see the graph at the top of the screen in a longer time frame, choose **Edit** at the top-right of the screen.

If the model for this metric and statistic doesn't already exist, CloudWatch generates the anomaly detection band after you finish creating your alarm. For new models, it can take up to 3 hours for the actual anomaly detection band to appear in your graph. It can take up to two weeks for the new model to train, so the anomaly detection band shows more accurate expected values.

b. For **Whenever *`metric`* is**, specify when to trigger the alarm. For example, when the metric is greater than, lower than, or outside the band (in either direction).

c. For **Anomaly detection threshold**, choose the number to use for the anomaly detection threshold. A higher number creates a thicker band of "normal" values that is more tolerant of metric changes. A lower number creates a thinner band that will go to `ALARM` state with smaller metric deviations. The number does not have to be a whole number.

d. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

   To create an M out of N alarm, specify a number for the first value that is lower than the number for the second value. For more information, see Alarm evaluation.

e. For **Missing data treatment**, choose how the alarm behaves when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.

f. If the alarm uses a percentile as the monitored statistic, a **Percentiles with low samples** box appears. Use it to choose whether to evaluate or ignore cases with low sample rates.

If you choose **Ignore (maintain alarm state)**, the current alarm state is always maintained when the sample size is too low. For more information, see Percentile-based alarms and low data samples.

9. Choose **Next**.
10. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

    To send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    Choose **Remove** if you don't want the alarm to send notifications.
11. You can set up the alarm to perform EC2 actions or invoke a Lambda function when it changes state, or to create a Systems Manager OpsItem or incident when it goes into ALARM state. To do this, choose the appropriate button and then choose the alarm state and action to perform.

    If you choose a Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

    For more information about Systems Manager actions, see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

    > **Note**
    >
    > To create an alarm that performs an AWS Systems Manager Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for AWS Systems Manager Incident Manager.
12. Choose **Next**.
13. Under ***Name and description***, enter a name and description for your alarm, and choose **Next**. The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

> **Tip**
>
> The alarm name must contain only UTF-8 characters, and can't contain ASCII control characters

14. Under ***Preview and create***, confirm that your alarm's information and conditions are correct, and choose **Create alarm**.

Creating an anomaly detection alarm using the AWS CLI

You can also create an anomaly detection alarm with the AWS CLI. First create the anomaly detector, and then create an alarm that uses an `ANOMALY_DETECTION_BAND` metric math expression to define the expected range.

To create an anomaly detection alarm

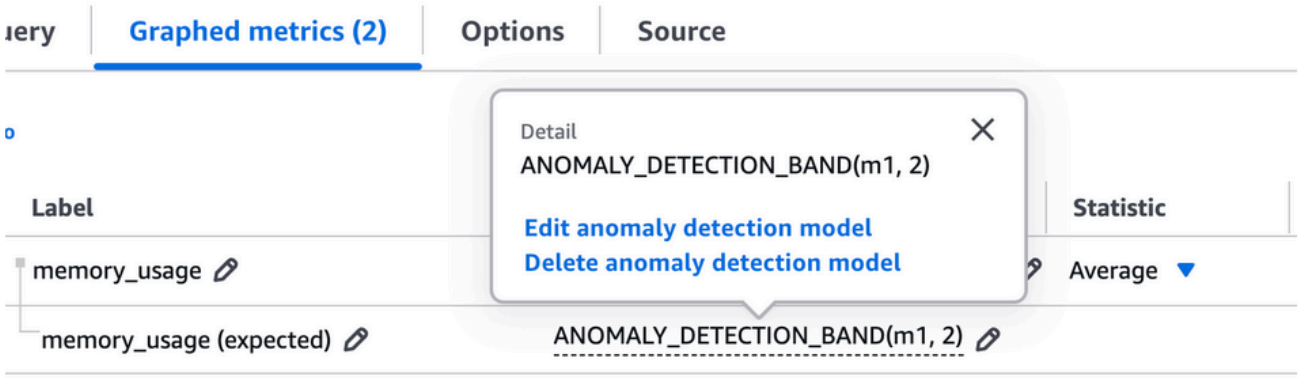
1. Create the anomaly detector using the put-anomaly-detector command.

```
aws cloudwatch put-anomaly-detector --single-metric-anomaly-detector
 '{"Namespace":"AWS/EC2","MetricName":"CPUUtilization","Dimensions":
[{"Name":"InstanceId","Value":"instance-id"}],"Stat":"Average"}'
```

   If the command succeeds, it returns no output.

2. Create the alarm with a metric-math band using the put-metric-alarm command. The `ANOMALY_DETECTION_BAND` expression defines the expected range.

```
aws cloudwatch put-metric-alarm --alarm-name cpu-anomaly --comparison-
operator LessThanLowerOrGreaterThanUpperThreshold --evaluation-periods 1
 --threshold-metric-id ad1 --metrics '[{"Id":"m1","MetricStat":{"Metric":
{"Namespace":"AWS/EC2","MetricName":"CPUUtilization","Dimensions":
[{"Name":"InstanceId","Value":"instance-
id"}]},"Period":300,"Stat":"Average"},"ReturnData":true},
{"Id":"ad1","Expression":"ANOMALY_DETECTION_BAND(m1, 2)","ReturnData":true}]'
```



Editing an anomaly detection model

After you create an alarm, you can adjust the anomaly detection model. You can exclude certain time periods from being used in the model creation. It is critical that you exclude unusual events

such as system outages, deployments, and holidays from the training data. You can also specify whether to adjust the model for Daylight Savings Time changes.

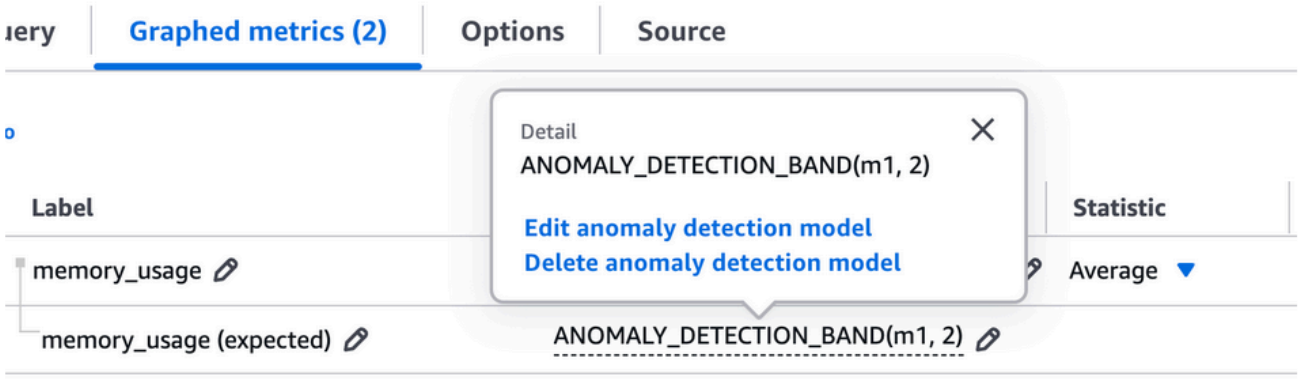
To edit the anomaly detection model for an alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose the name of the alarm. If necessary, use the search box to find the alarm.
4. Choose **View**, **In metrics**.
5. In the **Details** column, choose the **ANOMALY_DETECTION_BAND** keyword, and then choose **Edit anomaly detection model** in the popup.

6. To exclude a time period from being used to produce the model, choose the calendar icon by **End date**. Then, select or enter the days and times to exclude from training and choose **Apply**.
7. If the metric is sensitive to Daylight Savings Time changes, select the appropriate time zone in the **Metric timezone** box.
8. Choose **Update**.

Deleting an anomaly detection model

Using anomaly detection for an alarm accrues charges. As a best practice, if your alarm no longer needs an anomaly detection model, delete the alarm first and the model second. When anomaly detection alarms are evaluated, any missing anomaly detectors are created on your behalf. If you delete the model without deleting the alarm, the alarm automatically recreates the model.



To delete an alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose the name of the alarm.
4. Choose **Actions**, **Delete**.
5. In the confirmation box, choose **Delete**.

To delete an anomaly detection model that was used for an alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**.
3. Choose **Browse**, and then select the metric that includes the anomaly detection model. You can search for your metric in the search box or select your metric by choosing through the options.
   - (Optional) If you're using the original interface, choose **All metrics**, and then choose the metric that includes the anomaly detection model. You can search for your metric in the search box or select your metric by choosing through the options.
4. Choose **Graphed metrics**.
5. In the **Graphed metrics** tab, in the **Details** column, choose the **ANOMALY_DETECTION_BAND** keyword, and then choose **Delete anomaly detection model** in the popup.

   - (Optional) If you're using the original interface, choose **Edit model**. You're directed to a new screen. On the new screen, choose **Delete model**, and then choose **Delete**.

Improving anomaly detection alarm accuracy with feedback

After you create an anomaly detection alarm, you can provide feedback to help CloudWatch improve the accuracy of the anomaly detection model. CloudWatch uses your feedback to adjust

how the model learns from your metric's behavior, which can result in more accurate anomaly detection bands over time.

You can provide feedback when you notice that:

- The alarm triggered correctly, and you want to confirm that the detection was accurate.
- The alarm triggered, but the metric behavior was actually normal (a false alarm).
- The alarm did not trigger, but the metric behavior was anomalous (a missed detection).

To submit feedback on an anomaly detection alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**.
3. Choose the name of the anomaly detection alarm that you want to provide feedback for.
4. Choose the **Improve this alarm** button.
5. In the feedback dialog box, specify a **Start time** and **End time** for the time range that your feedback applies to. This should cover the period where you observed the alarm behavior you want to report.
6. For **Feedback type**, choose one of the following:

   - **Correct** – The alarm correctly detected an anomaly (or correctly did not trigger). This confirms that the model is performing well for this time range. No model adjustments are made.
   - **False alarm** – The alarm triggered, but the metric behavior was actually normal. CloudWatch adjusts the anomaly detection model to reduce false positives.
   - **Missed** – The alarm did not trigger, but the metric behavior was anomalous and should have been detected. CloudWatch adjusts the anomaly detection model to improve sensitivity.
7. For **Reason**, choose the reason that best describes why the alarm behavior was incorrect:

   - **Bands learning too fast** – The anomaly detection bands are adapting too quickly to recent changes in metric behavior, treating new patterns as normal too soon.
   - **Bands learning too slow** – The anomaly detection bands are not adapting quickly enough to legitimate changes in metric behavior.
   - **Bands too wide** – The expected range of normal values is too broad, causing the alarm to miss anomalies.

- **Bands too narrow** – The expected range of normal values is too tight, causing the alarm to trigger on normal metric variations.
- **Band level off** – The anomaly detection bands are not aligned with the expected baseline level of the metric.
- **Planned deployment** – The alarm fired due to a planned deployment or change.
- **Scaling event** – The alarm fired due to an expected scaling event (such as auto-scaling).
- **Other** – The alarm behavior was incorrect for a reason not listed above.

8. Choose **Submit**.

CloudWatch processes your feedback and adjusts the anomaly detection model accordingly. For false alarm and missed feedback, CloudWatch automatically tunes the model's learning rate or band width based on the reason that you provide.

> **Note**
>
> You can submit feedback multiple times for different time ranges. Each piece of feedback is processed independently and contributes to improving the model's accuracy over time.

> **Note**
>
> When you submit feedback, the CloudWatch console calls the `SubmitAlarmFeedback` API on your behalf. This API is used by the CloudWatch console only and is not intended to be called directly.

Create an alarm based on Metrics Insights

You can create an alarm that monitors multiple time series across a fleet of resources. Unlike single-instance alarms that trigger actions on individual instances, fleet monitoring alarms let you aggregate metrics across multiple resources and trigger based on fleet-wide conditions.

Setting up a Multi Time Series alarm using the AWS Management Console

This example shows how to create an alarm that monitors memory utilization across a fleet of instances and alerts you when more than two instances exceed a threshold.

To create a multi time series alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**.
5. Under **Metrics**, enter a Metrics Insights query:

```
SELECT MAX(mem_used_percent)
FROM "CWAgent"
GROUP BY InstanceId
ORDER BY MAX() DESC
```

6. Choose **Next**.
7. Under **Conditions**, specify the following:
   - For **Threshold type**, choose **Static**.
   - For **When metric is**, choose **Greater than** and enter **80**.
   - For **Datapoints to alarm**, enter **2**.
8. Configure notifications and actions as needed.
9. Add a name and description for your alarm.
10. Choose **Create alarm**.

This alarm differs from single-instance alarms in several ways:

- It monitors multiple time series simultaneously through the use of a metrics query. The metrics query is refreshed every time the alarm evaluates, thus your alarm automatically adapts as resources are created, paused, or deleted.
- For each contributor that breaches the threshold, the alarm sends a contributor state change event, which has a different event type in EventBridge than an alarm state change event. The alarm itself also changes state: as soon as at least one contributor is in alarm, the alarm also enters the alarm state.
- Some actions however, such as SSM Incident, are triggered at the alarm level. Such actions are not repeated when the list of contributors in alarm changes.

This alarm differs from aggregated metric-query alarms in several ways:

- It monitors time series individually instead of an aggregate, using the `GROUP BY` clause.
- It follows the level of granularity that you set according to your needs: for example, it can alarm on every Amazon EC2 instance (most granular level of Amazon EC2 metrics) or per Amazon RDS table (aggregated across various operations on a table), depending on which fields you set in the `GROUP BY` clause
- It prioritizes evaluation using the `ORDER BY` clause.
- For each contributor that breaches the threshold, the alarm sends a contributor state change event, which has a different event type in EventBridge than an alarm state change event. The alarm itself also changes state: as soon as at least one contributor is in alarm, the alarm also enters the alarm state.
- Some actions however, such as SSM Incident, are triggered at the alarm level. Such actions are not repeated when the list of contributors in alarm changes.

Create an alarm based on a connected data source

You can create alarms that watch metrics from data sources that aren't in CloudWatch. For more information about creating connections to these other data sources, see Query metrics from other data sources.

To create an alarm on metrics from a data source that you have connected to

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Choose the **Multi source query** tab.
4. For **Data source**, select the data source that you want to use.
5. The query builder prompts you for the information necessary for the query to retrieve the metrics to use for the alarm. The workflow is different for each data source, and is tailored to the data source. For example, for Amazon Managed Service for Prometheus and Prometheus data sources, a PromQL query editor box with a query helper appears.
6. When you have finished constructing the query, choose **Graph query**.
7. If the sample graph looks the way that you expect, choose **Create alarm**.

8. The **Specify metric and conditions** page appears. If the query you are using produces more than one time series, you see a warning banner at the top of the page. If you do, select a function to use to aggregate the time series in **Aggregation function**.
9. (Optional) Add a **Label** for the alarm.
10. For **Whenever *`your-metric-name`* is . . .**, choose **Greater**, **Greater/Equal**, **Lower/Equal**, or **Lower**. Then for **than . . .**, specify a number for your threshold value.
11. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

    To create an M out of N alarm, specify a number for the first value that is lower than the number for the second value. For more information, see Alarm evaluation.
12. For **Missing data treatment**, choose how the alarm behaves when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.
13. Choose **Next**.
14. For **Notification**, specify an Amazon SNS topic to notify when your alarm transitions to the `ALARM`, `OK`, or `INSUFFICIENT_DATA` state.

    a. (Optional) To send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    > **Note**
    >
    > We recommend that you set the alarm to take actions when it goes into **Insufficient data** state in addition to when it goes into **Alarm** state. This is because many issues with the Lambda function that connects to the data source can cause the alarm to transition to **Insufficient data**.

    b. (Optional) To not send Amazon SNS notifications, choose **Remove**.
15. To have the alarm perform Auto Scaling, Lambda, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. If you choose a Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

> **Note**
>
> To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for AWS Systems Manager Incident Manager.

16. Choose **Next**.
17. Under **Name and description**, enter a name and description for your alarm, and choose **Next**. The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

> **Tip**
>
> The alarm name must contain only UTF-8 characters. It can't contain ASCII control characters.

18. Under **Preview and create**, confirm that your alarm's information and conditions are correct, and choose **Create alarm**.

Create a metric alarm that uses a wall clock evaluation window

You can create a metric alarm that aligns its evaluation window to wall clock boundaries instead of a sliding window. For information about how wall clock windows work and when to use them, see Wall clock window.

Creating a wall clock alarm using the AWS Management Console

This example shows how to create an alarm that uses a 1-hour wall clock window.

To create a wall clock alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**, choose the metric you want to monitor, and then choose **Select metric**.
5. Under **Metric**, for **Period**, choose a period that supports wall clock windows: **`1 minute`**, **`5 minutes`**, **`1 hour`**, **`1 day`**, or **`1 week`**.
6. Under **Conditions**, configure the threshold and comparison operator for your alarm.
7. For **Evaluation window**, choose **Wall clock window**.

> **Note**
>
> If you don't see the **Evaluation window** option, the metric type or period you selected does not support wall clock windows. Wall clock windows are not available for high-resolution alarms, composite alarms, or PromQL alarms, and are only available for periods of 1 minute, 5 minutes, 1 hour, 1 day, or 1 week.

8. Optionally, choose a time zone for **Time zone**. The alarm aligns its evaluation window to clock boundaries in this time zone. If you don't choose a time zone, CloudWatch uses UTC. For details about how time zones affect wall clock boundaries, see Time zones and daylight saving time.
9. Configure notifications and actions as needed, then choose **Next**.
10. Add a name and description for your alarm, then choose **Next**.
11. Review the alarm configuration and choose **Create alarm**.

Creating a wall clock alarm (AWS CLI)

Use the PutMetricAlarm API action to create or update a metric alarm with an `EvaluationWindow`. Set `WallClockWindow` to align the alarm to wall clock boundaries, or set `SlidingWindow` to use the default sliding behavior. If you omit the `EvaluationWindow` parameter, the alarm uses a sliding window.

Example Create an alarm that uses a 1-hour wall clock window

This alarm evaluates the most recently completed clock hour in UTC. To align to a different time zone, set `Timezone` on the `WallClockWindow`.

```
aws cloudwatch put-metric-alarm \
```

```
  --alarm-name HourlyCpuAlarm \
  --metric-name CPUUtilization \
  --namespace AWS/EC2 \
  --statistic Average \
  --period 3600 \
  --evaluation-periods 1 \
  --threshold 80 \
  --comparison-operator GreaterThanThreshold \
  --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
  --evaluation-window '{"WallClockWindow":{}}'
```

Example Create a daily alarm aligned to a specific time zone

This alarm evaluates each calendar day in the `America/New_York` time zone. Daylight saving time transitions are handled automatically.

```
aws cloudwatch put-metric-alarm \
  --alarm-name DailyBackupCheck \
  --metric-name SuccessfulBackups \
  --namespace MyApplication \
  --statistic Sum \
  --period 86400 \
  --evaluation-periods 1 \
  --threshold 1 \
  --comparison-operator LessThanThreshold \
  --evaluation-window '{"WallClockWindow":{"Timezone":"America/New_York"}}'
```

Example Create a weekly alarm in UTC

This alarm evaluates each calendar week (Monday 00:00 UTC through the following Monday 00:00 UTC).

```
aws cloudwatch put-metric-alarm \
  --alarm-name WeeklyComplianceCheck \
  --metric-name ComplianceFailures \
  --namespace MyApplication \
  --statistic Sum \
  --period 604800 \
  --evaluation-periods 1 \
  --threshold 0 \
  --comparison-operator GreaterThanThreshold \
  --evaluation-window '{"WallClockWindow":{}}'
```

Example Switch an existing alarm back to a sliding window

Set `EvaluationWindow` to `SlidingWindow` to make the change explicit. You can also omit the parameter, which has the same effect.

```
aws cloudwatch put-metric-alarm \
  --alarm-name HourlyCpuAlarm \
  --metric-name CPUUtilization \
  --namespace AWS/EC2 \
  --statistic Average \
  --period 3600 \
  --evaluation-periods 1 \
  --threshold 80 \
  --comparison-operator GreaterThanThreshold \
  --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
  --evaluation-window '{"SlidingWindow":{}}'
```

View the evaluation window for an existing alarm

Use the DescribeAlarms API action to retrieve the evaluation window configuration of an alarm. The `EvaluationWindow` field is included in the response when the alarm uses a wall clock window. If the field is absent, the alarm uses a sliding window.

```
aws cloudwatch describe-alarms \
  --alarm-names HourlyCpuAlarm
```

You can also view the evaluation window in the AWS Management Console on the alarm details page.

Create an alarm that uses a warm-up period

Create a metric alarm or log alarm with a warm-up period to delay evaluation after creation. For more information about warm-up periods, see Alarm warm-up periods.

Set the warm-up period with the `WarmUpConfiguration` parameter on the PutMetricAlarm API. Log alarms use the PutLogAlarm API.

Creating a warm-up alarm with the AWS CLI

The following examples create and manage alarms with warm-up periods.

Example Create a metric alarm with a 30-minute warm-up period

This alarm uses default early-termination behavior: it ends warm-up and begins to evaluate as soon as enough data fills the evaluation window.

```
aws cloudwatch put-metric-alarm \
  --alarm-name MyServiceStartupAlarm \
  --metric-name CPUUtilization \
  --namespace AWS/EC2 \
  --statistic Average \
  --period 300 \
  --evaluation-periods 1 \
  --threshold 80 \
  --comparison-operator GreaterThanThreshold \
  --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
  --warm-up-configuration '{"WarmUpPeriodDurationInMinutes":30}'
```

Example Wait the entire warm-up period before evaluating

Set `OnlyStartEvaluatingAfterWarmUpPeriodEnds` to `true` to prevent evaluation until the full warm-up duration elapses. The alarm waits the full 60 minutes before it evaluates, even if data arrives sooner.

```
aws cloudwatch put-metric-alarm \
  --alarm-name MyServiceStartupAlarm \
  --metric-name CPUUtilization \
  --namespace AWS/EC2 \
  --statistic Average \
  --period 300 \
  --evaluation-periods 1 \
  --threshold 80 \
  --comparison-operator GreaterThanThreshold \
  --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
  --warm-up-configuration
 '{"WarmUpPeriodDurationInMinutes":60,"OnlyStartEvaluatingAfterWarmUpPeriodEnds":true}'
```

Example Change the warm-up period while the alarm is warming up

You can update the warm-up configuration while the alarm is still in its warm-up period. This example sets the warm-up duration to 45 minutes.

```
aws cloudwatch put-metric-alarm \
```

```
  --alarm-name MyServiceStartupAlarm \
  --metric-name CPUUtilization \
  --namespace AWS/EC2 \
  --statistic Average \
  --period 300 \
  --evaluation-periods 1 \
  --threshold 80 \
  --comparison-operator GreaterThanThreshold \
  --dimensions Name=InstanceId,Value=i-1234567890abcdef0 \
  --warm-up-configuration '{"WarmUpPeriodDurationInMinutes":45}'
```

> **Note**
>
> After the warm-up period ends, you can update the warm-up configuration. However, the update does not start a new warm-up period. The alarm continues to evaluate normally.

View the warm-up configuration

Use the DescribeAlarms API to retrieve an alarm's warm-up configuration.

```
aws cloudwatch describe-alarms \
  --alarm-names MyServiceStartupAlarm
```

During warm-up, the alarm state remains `INSUFFICIENT_DATA` and the evaluation state is `IN_WARM_UP`.

Alarming on logs

You can create CloudWatch alarms that monitor your log data in two ways:

- **Log Alarm approach** — Create a Log Alarm that runs a CloudWatch Logs Insights query on a schedule and evaluates the aggregated results directly against a threshold.
- **Metric filter approach** — Create a metric filter on a log group, then create a standard metric alarm on the resulting metric.

Create a Log Alarm

Create a Log Alarm

You can create a CloudWatch alarm that uses a CloudWatch Logs Insights query to monitor log data directly. The query runs on a schedule using a Scheduled Query, and the alarm evaluates the aggregated results against a threshold. For more information about how Log Alarms work, see Log alarms.

Prerequisites

Before you create a Log Alarm, you must create an IAM role that grants CloudWatch Logs permission to execute the scheduled query. If you also want log lines included in Amazon SNS notifications, you must create a second role.

> **Note**
>
> If you create a Log Alarm from the CloudWatch console, the console helps you create these roles.

Scheduled query execution role

The scheduled query execution role allows CloudWatch Logs to run the query on your behalf. This role is required for all Log Alarms to execute the scheduled query. The role must trust the `logs.amazonaws.com` service principal.

The following example shows the trust policy for the scheduled query execution role.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "logs.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
```

```
}
```

The following example shows the permissions policy. Scope the `Resource` to the log group ARNs that the query targets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "logs:StartQuery",
                "logs:StopQuery",
                "logs:GetQueryResults",
                "logs:DescribeLogGroups"
            ],
            "Resource": "arn:aws:logs:us-east-1:111122223333:log-group:your-log-
group:*"
        }
    ]
}
```

Log lines role (optional)

The log lines role allows CloudWatch to fetch log lines for Amazon SNS email notifications. This role is required only if you set `ActionLogLineCount` to a value greater than 0. The role must trust the `cloudwatch.amazonaws.com` service principal.

The following example shows the trust policy for the log lines role.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "cloudwatch.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

The following example shows the permissions policy for the log lines role. The `logs:GetQueryResults` permission is required to fetch log lines. Scope the `Resource` to the log group ARNs that the query targets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "logs:GetQueryResults"
            ],
            "Resource": "arn:aws:logs:us-east-1:111122223333:log-group:your-log-
group:*"
        }
    ]
}
```

> **Note**
>
> To view Log Alarm query results in the CloudWatch console, the IAM user or role accessing the console must have the `logs:GetScheduledQueryData` permission. This is a console-only API and is not available through the AWS CLI or SDK. CloudTrail logs this API as a data event, so you must configure a trail with data event logging to capture it.

Creating a Log Alarm using the console

The steps in this section explain how to use the CloudWatch console to create a Log Alarm. You can also use the AWS CLI to create a Log Alarm. For more information, see Creating a Log Alarm using the AWS CLI.

To create a Log Alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**.
3. Choose **Create alarm**.
4. For **Data source**, choose **Logs**.
5. Under **Logs Query**:

a. Choose **Create query in Log Analytics**. This opens the Log Analytics page where you build your query.

b. On the Log Analytics page, write your query. When you finish, choose **Continue to Alarms** in the top right to return to the alarm console.

c. For **Aggregation expression**, specify how to aggregate the query results to return a numerical value for alarm evaluation (for example, `count(*)` or `avg(latency) by endpoint`).

6. Under **Alarm Conditions**:

a. For **Whenever the aggregated result is...**, choose a comparison operator.

b. For **than...**, enter the threshold value.

c. (Optional) Under **Additional Configuration**:

i. Modify **Datapoints to alarm** to specify the number of breaching results required to trigger `ALARM` out of last N queries.

ii. Modify **Missing data treatment** to specify how to treat missing data.

7. Under **Schedule**:

a. For **Evaluation Frequency**, choose how often the query runs (for example, every 5 minutes).

b. For **Start time offset**, the lookback window for each query execution.

c. For **End time offset** (optional), the end of the query time range as an offset in seconds from the current time.

8. Under **IAM permission**:

- Specify the role that is required to execute the scheduled query. You can either choose to create a new role or use an existing role.

9. Choose **Next**.

10. Under **Configure actions**, configure actions and notifications as needed.

- To include log lines triggering the alarm transition in Amazon SNS email notifications, under **Include query results in the actions**:

i. Add **Number of query results** to specify the number of log lines to include.

ii. Create or choose an existing role that is used to get the required query results.

11. Choose **Next**.
12. Enter a **Name** and optional **Description** (supports Markdown).
13. (Optional) Add tags.
14. Choose **Next**.
15. Under **Preview and create**, review your configuration, and then choose **Create alarm**.

Creating a Log Alarm using the AWS CLI

You can use the AWS CLI `put-log-alarm` command to create a Log Alarm.

The following example creates a Log Alarm that monitors error counts in a log group and transitions to `ALARM` state when the count exceeds 100 in 3 out of 5 query executions.

```
aws cloudwatch put-log-alarm \
    --alarm-name "HighErrorCount" \
    --alarm-description "Alarm when error count exceeds 100" \
    --comparison-operator GreaterThanThreshold \
    --threshold 100 \
    --query-results-to-evaluate 5 \
    --query-results-to-alarm 3 \
    --treat-missing-data missing \
    --alarm-actions "arn:aws:sns:us-east-1:111122223333:topic-name" \
    --scheduled-query-configuration '{
        "QueryString": "fields @timestamp, @message | filter @message like /ERROR/",
        "LogGroupIdentifiers": ["/aws/lambda/my-function"],
        "ScheduledQueryRoleARN": "arn:aws:iam::111122223333:role/ScheduledQueryRole",
        "AggregationExpression": "count(*)",
        "ScheduleConfiguration": {
            "ScheduleExpression": "rate(10 minutes)",
            "StartTimeOffset": 600
        }
    }' \
    --action-log-line-count 5 \
    --action-log-line-role-arn "arn:aws:iam::111122223333:role/LogLineRole"
```

The following table describes the key parameters for the `put-log-alarm` command.

Parameter	Required	Description
`--alarm-name`	Yes	The name of the alarm. Must contain only UTF-8 characters.
`--comparison-operator`	Yes	The comparison operator for threshold evaluation. Valid values: `GreaterThanThreshold` , `GreaterThanOrEqualToThreshold` , `LessThanThreshold` , `LessThanOrEqualToThreshold` .
`--threshold`	Yes	The numeric threshold value to compare against.
`--query-results-to-evaluate`	Yes	The number of recent query executions to evaluate (N in M-out-of-N).
`--query-results-to-alarm`	Yes	The number of breaching results required to trigger `ALARM` (M in M-out-of-N).
`--treat-missing-data`	No	How to treat missing data. Valid values: `missing` (default), `notBreaching` , `breaching` , `ignore`.
`--scheduled-query-configuration`	Yes	The query configuration including query string, log group identifiers, scheduled query role ARN, aggregation expression, and schedule configuration.
`--action-log-line-count`	No	The number of log lines to include in Amazon SNS email notifications (0–50). Default is 0.
`--action-log-line-role-arn`	No	The ARN of the IAM role that trusts `cloudwatch.amazonaws.com` . Required if `action-log-line-count` is greater than 0.

Creating a Log Alarm using AWS CloudFormation

You can use the `AWS::CloudWatch::LogAlarm` resource type to create a Log Alarm in a AWS CloudFormation template.

The following example template creates a Log Alarm that monitors error counts.

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  HighErrorCountAlarm:
    Type: AWS::CloudWatch::LogAlarm
    Properties:
      AlarmName: HighErrorCount
      AlarmDescription: Alarm when error count exceeds 100
      ComparisonOperator: GreaterThanThreshold
      Threshold: 100
      QueryResultsToEvaluate: 5
      QueryResultsToAlarm: 3
      TreatMissingData: missing
      ActionLogLineCount: 5
      ActionLogLineRoleArn: !GetAtt LogLineRole.Arn
      ScheduledQueryConfiguration:
        QueryString: "fields @timestamp, @message | filter @message like /ERROR/"
        LogGroupIdentifiers:
          - /aws/lambda/my-function
        ScheduledQueryRoleARN: !GetAtt ScheduledQueryRole.Arn
        AggregationExpression: "count(*)"
        ScheduleConfiguration:
          ScheduleExpression: "rate(10 minutes)"
          StartTimeOffset: 600
      AlarmActions:
        - !Ref AlarmSNSTopic
```

Create a CloudWatch alarm based on a log group-metric filter

The procedure in this section describes how to create an alarm based on a log group-metric filter. With metric filters, you can look for terms and patterns in log data as the data is sent to CloudWatch. For more information, see Create metrics from log events using filters in the *Amazon CloudWatch Logs User Guide*. Before you create an alarm based on a log group-metric filter, you must complete the following actions:

- Create a log group. For more information, see Working with log groups and log streams in the *Amazon CloudWatch Logs User Guide*.
- Create a metric filter. For more information, see Create a metric filter for a log group in the *Amazon CloudWatch Logs User Guide*.

To create an alarm based on a log group-metric filter

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. From the navigation pane, choose **Logs**, and then choose **Log groups**.
3. Choose the log group that includes your metric filter.
4. Choose **Metric filters**.
5. In the metric filters tab, select the box for the metric filter that you want to base your alarm on.
6. Choose **Create alarm**.
7. (Optional) Under **Metric**, edit **Metric name**, **Statistic**, and **Period**.
8. Under **Conditions**, specify the following:
   a. For **Threshold type**, choose **Static** or **Anomaly detection**.
   b. For **Whenever *`your-metric-name`* is . . .**, choose **Greater**, **Greater/Equal**, **Lower/Equal** , or **Lower**.
   c. For **than . . .**, specify a number for your threshold value.
9. Choose **Additional configuration**.
   a. For **Data points to alarm**, specify how many data points trigger your alarm to go into the `ALARM` state. If you specify matching values, your alarm goes into the `ALARM` state if that many consecutive periods are breaching. To create an M-out-of-N alarm, specify a number for the first value that's lower than the number you specify for the second value. For more information, see Alarm evaluation.
   b. For **Missing data treatment**, select an option to specify how to treat missing data when your alarm is evaluated.
10. Choose **Next**.
11. For **Notification**, specify an Amazon SNS topic to notify when your alarm is in the `ALARM`, `OK`, or `INSUFFICIENT_DATA` state.

a. (Optional) To send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

b. (Optional) To not send notifications, choose **Remove**.

12. To have the alarm perform Auto Scaling, EC2, Lambda, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. If you choose a Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

    Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

    > **Note**
    >
    > To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for AWS Systems Manager Incident Manager.

13. Choose **Next**.

14. For **Name and description**, enter a name and description for your alarm. The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

15. For **Preview and create**, check that your configuration is correct, and choose **Create alarm**.

Create a composite alarm

The steps in this section explain how to use the CloudWatch console to create a composite alarm. You can also use the API or AWS CLI to create a composite alarm. For more information, see PutCompositeAlarm or put-composite-alarm

> **Note**
>
> A composite alarm's rule expression can reference other alarms as children, including standard metric alarms and PromQL alarms. Composite alarms evaluate only the states of the alarms they reference. They don't evaluate metrics directly.

To create a composite alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. From the list of alarms, select the check box next to each of the existing alarms that you want to reference in your rule expression, and then choose **Create composite alarm**.
4. Under **Specify composite alarm conditions**, specify the rule expression for your new composite alarm.

   > **Note**
   >
   > Automatically, the alarms that you selected from the list of alarms are listed in the **Conditions** box. By default, the `ALARM` function has been designated to each of your alarms, and each of your alarms is joined by the logical operator `OR`.

   You can use the following substeps to modify your rule expression:

   a. You can change the required state for each of your alarms from `ALARM` to `OK` or `INSUFFICIENT_DATA`.

   b. You can change the logical operator in your rule expression from `OR` to `AND` or `NOT`, and you can add parentheses to group your functions.

   c. You can include other alarms in your rule expression or delete alarms from your rule expression.

   Example: Rule expression with conditions

```
(ALARM("CPUUtilizationTooHigh") OR
ALARM("DiskReadOpsTooHigh")) AND
```

```
OK("NetworkOutTooHigh")
```

In the example rule expression where the composite alarm goes into ALARM when ALARM ("CPUUtilizationTooHigh" or ALARM("DiskReadOpsTooHigh") is in ALARM at the same time as OK("NetworkOutTooHigh") is in OK.

5. When finished, choose **Next**.
6. Under **Configure actions**, you can choose from the following:

   For ***Notification***

   - **Select an exisiting SNS topic**, **Create a new SNS topic**, or **Use a topic ARN** to define the SNS topic that will receive the notification.
   - **Add notification**, so your alarm can send multiple notifications for the same alarm state or different alarm states.
   - **Remove** to stop your alarm from sending notifications or taking actions.

   (Optional) To have the alarm invoke a Lambda function when it changes state, choose **Add Lambda action**. Then specify the function name or ARN, and optionally choose a specific version of the function.

   For ***Systems Manager action***

   - **Add Systems Manager action**, so your alarm can perform an SSM action when it goes into ALARM.

   To learn more about Systems Manager actions, see Configuring CloudWatch to create OpsItems from alarms in the *AWS Systems Manager User Guide* and Incident creation in the *Incident Manager User Guide*. To create an alarm that performs an SSM Incident Manager action, you must have the correct permissions. For more information, see Identity-based policy examples for AWS Systems Manager Incident Manager in the *Incident Manager User Guide*.

   To have the alarm start an investigation, choose **Add investigation action** and then select your investigation group. For more information about , see CloudWatch investigations.
7. When finished, choose **Next**.
8. Under **Add name and description**, enter an alarm name and *optional* description for your new composite alarm. The name must contain only UTF-8 characters, and can't contain ASCII

control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

9. When finished, choose **Next**.
10. Under **Preview and create**, confirm your information, and then choose **Create composite alarm**.

> **Note**
>
> You can create a cycle of composite alarms, where one composite alarm and another composite alarm depend on each other. If you find yourself in this scenario, your composite alarms stop being evaluated, and you can't delete your composite alarms because they're dependent on each other. The easiest way to break the cycle of dependecy between your composite alarms is to change the function `AlarmRule` in one of your composite alarms to `False`.

Acting on alarm changes

CloudWatch can notify users on two types of alarm changes: when an alarm changes state, and when the configuration of an alarm gets updated.

When an alarm evaluates, it might change from one state to another, such as ALARM or OK. For Metrics Insights alarms that monitor multiple time series, each time series (contributor) can only be in ALARM or OK state, never in INSUFFICIENT_DATA state. This is because a time series only exists when data is present.

Additionally, CloudWatch sends events to Amazon EventBridge whenever alarms change state, and when alarms are created, deleted, or updated. You can write EventBridge rules to take actions or be notified when EventBridge receives these events.

For more information about alarm actions, see Alarm actions.

Topics

- Notifying users on alarm changes
- Invoke a Lambda function from an alarm
- Start a CloudWatch investigations from an alarm

- Stop, terminate, reboot, or recover an EC2 instance
- Alarm events and EventBridge
- Alarm tags in action payloads

Notifying users on alarm changes

This section explains how you can use AWS User Notifications or Amazon Simple Notification Service to have users be notified of alarm changes.

Setting up AWS User Notifications

You can use AWS User Notifications to set up delivery channels to get notified about CloudWatch alarm state change and configuration change events. You receive a notification when an event matches a rule that you specify. You can receive notifications for events through multiple channels, including email, AWS Chatbot chat notifications, or AWS Console Mobile Application push notifications. You can also see notifications in the at Console Notifications Center. User Notifications supports aggregation, which can reduce the number of notifications you receive during specific events.

The notification configurations you create with AWS User Notifications do not count towards the limit on the number of actions you can configure per target alarm state. As AWS User Notifications matches the events emitted to Amazon EventBridge, it sends notifications for all the alarms in your account and selected Regions, unless you specify an advanced filter to allowlist or denylist specific alarms or patterns.

The following example of an advanced filter matches an alarm state change from OK to ALARM on the alarm named `ServerCpuTooHigh`.

```
{
"detail": {
    "alarmName": ["ServerCpuTooHigh"],
    "previousState": { "value": ["OK"] },
    "state": { "value": ["ALARM"] }
  }
}
```

You can use any of the properties published by an alarm in EventBridge events to create a filter. For more information, see Alarm events and EventBridge.

Setting up Amazon SNS notifications

You can use Amazon Simple Notification Service to send both application-to-application (A2A) messaging and application-to-person (A2P) messaging, including mobile text messaging (SMS) and email messages. For more information, see Amazon SNS event destinations.

For every state that an alarm can take, you can configure the alarm to send a message to an SNS topic. Every Amazon SNS topic you configure for a state on a given alarm counts towards the limit on the number of actions you can configure for that alarm and state. You can send messages to the same Amazon SNS topic from any alarms in your account, and use the same Amazon SNS topic for both application (A2A) and person (A2P) consumers. Because this configuration is done at the alarm level, only the alarms you have configured send messages to the selected Amazon SNS topic.

First, create a topic, then subscribe to it. You can optionally publish a test message to the topic. For an example, see Setting up an Amazon SNS topic using the AWS Management Console. Or for more information, see Getting started with Amazon SNS.

Alternatively, if you plan to use the AWS Management Console to create your CloudWatch alarm, you can skip this procedure because you can create the topic when you create the alarm.

When you create a CloudWatch alarm, you can add actions for any target state the alarm enters. Add an Amazon SNS notification for the state you want to be notified about, and select the Amazon SNS topic you created in the previous step to send an email notification when the alarm enters the selected state.

> **Note**
>
> When you create an Amazon SNS topic, you choose to make it a *standard topic* or a *FIFO topic*. CloudWatch guarantees the publication of all alarm notifications to both types of topics. However, even if you use a FIFO topic, in rare cases CloudWatch sends the notifications to the topic out of order. If you use a FIFO topic, the alarm sets the message group ID of the alarm notifications to be a hash of the ARN of the alarm.

- Setting up an Amazon SNS topic using the AWS Management Console
- Setting up an SNS topic using the AWS CLI

Preventing confused deputy security issues

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

We recommend using the `aws:SourceArn`, `aws:SourceAccount`, `aws:SourceOrgID`, and `aws:SourceOrgPaths` global condition context keys in resource policies to limit the permissions that Amazon SNS gives another service to the resource. Use `aws:SourceArn` to associate only one resource with cross-service access. Use `aws:SourceAccount` to let any resource in that account be associated with the cross-service use. Use `aws:SourceOrgID` to allow any resource from any account within an organization be associated with the cross-service use. Use `aws:SourceOrgPaths` to associate any resource from accounts within an AWS Organizations path with the cross-service use. For more information about using and understanding paths, see aws:SourceOrgPaths in the IAM User Guide.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. If you don't know the full ARN of the resource or if you are specifying multiple resources, use the `aws:SourceArn` global context condition key with wildcard characters (*) for the unknown portions of the ARN. For example, `arn:aws:`*`servicename`*`:*:`*`123456789012`*`:*`.

If the `aws:SourceArn` value does not contain the account ID, such as an Amazon S3 bucket ARN, you must use both `aws:SourceAccount` and `aws:SourceArn` to limit permissions.

To protect against the confused deputy problem at scale, use the `aws:SourceOrgID` or `aws:SourceOrgPaths` global condition context key with the organization ID or organization path of the resource in your resource-based policies. Policies that include the `aws:SourceOrgID` or `aws:SourceOrgPaths` key will automatically include the correct accounts and you don't have to manually update the policies when you add, remove, or move accounts in your organization.

The value of `aws:SourceArn` must be the ARN of the alarm that is sending notifications.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in CloudWatch to prevent the confused deputy problem.

```
{
    "Statement": [{
        "Effect": "Allow",
        "Principal": {
            "Service": "cloudwatch.amazonaws.com"
        },
        "Action": "SNS:Publish",
        "Resource": "arn:aws:sns:us-east-2:444455556666:MyTopic",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:cloudwatch:us-east-2:111122223333:alarm:*"
            },
            "StringEquals": {
                "aws:SourceAccount": "111122223333"
            }
        }
    }]
}
```

If an alarm ARN includes any non-ASCII characters, use only the `aws:SourceAccount` global condition key to limit the permissions.

Setting up an Amazon SNS topic using the AWS Management Console

First, create a topic, then subscribe to it. You can optionally publish a test message to the topic.

To create an SNS topic

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. On the Amazon SNS dashboard, under **Common actions**, choose **Create Topic**.
3. In the **Create new topic** dialog box, for **Topic name**, enter a name for the topic (for example, **`my-topic`**).
4. Choose **Create topic**.
5. Copy the **Topic ARN** for the next task (for example, arn:aws:sns:us-east-1:111122223333:my-topic).

To subscribe to an SNS topic

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation pane, choose **Subscriptions**, **Create subscription**.

3. In the **Create subscription** dialog box, for **Topic ARN**, paste the topic ARN that you created in the previous task.
4. For **Protocol**, choose **Email**.
5. For **Endpoint**, enter an email address that you can use to receive the notification, and then choose **Create subscription**.
6. From your email application, open the message from AWS Notifications and confirm your subscription.

   Your web browser displays a confirmation response from Amazon SNS.

To publish a test message to an SNS topic

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation pane, choose **Topics**.
3. On the **Topics** page, select a topic and choose **Publish to topic**.
4. In the **Publish a message** page, for **Subject**, enter a subject line for your message, and for **Message**, enter a brief message.
5. Choose **Publish Message**.
6. Check your email to confirm that you received the message.

Setting up an SNS topic using the AWS CLI

First, you create an SNS topic, and then you publish a message directly to the topic to test that you have properly configured it.

To set up an SNS topic

1. Create the topic using the create-topic command as follows.

   ```
   aws sns create-topic --name my-topic
   ```

   Amazon SNS returns a topic ARN with the following format:

   ```
   {
       "TopicArn": "arn:aws:sns:us-east-1:111122223333:my-topic"
   }
   ```

2. Subscribe your email address to the topic using the subscribe command. If the subscription request succeeds, you receive a confirmation email message.

```
aws sns subscribe --topic-arn arn:aws:sns:us-east-1:111122223333:my-topic --
protocol email --notification-endpoint my-email-address
```

Amazon SNS returns the following:

```
{
    "SubscriptionArn": "pending confirmation"
}
```

3. From your email application, open the message from AWS Notifications and confirm your subscription.

Your web browser displays a confirmation response from Amazon Simple Notification Service.

4. Check the subscription using the list-subscriptions-by-topic command.

```
aws sns list-subscriptions-by-topic --topic-arn arn:aws:sns:us-
east-1:111122223333:my-topic
```

Amazon SNS returns the following:

```
{
  "Subscriptions": [
    {
        "Owner": "111122223333",
        "Endpoint": "me@mycompany.com",
        "Protocol": "email",
        "TopicArn": "arn:aws:sns:us-east-1:111122223333:my-topic",
        "SubscriptionArn": "arn:aws:sns:us-east-1:111122223333:my-topic:64886986-
bf10-48fb-a2f1-dab033aa67a3"
    }
  ]
}
```

5. (Optional) Publish a test message to the topic using the publish command.

```
aws sns publish --message "Verification" --topic arn:aws:sns:us-
east-1:111122223333:my-topic
```

Amazon SNS returns the following.

```
{
    "MessageId": "42f189a0-3094-5cf6-8fd7-c2dde61a4d7d"
}
```

6. Check your email to confirm that you received the message.

Schema of Amazon SNS notifications when alarms change state

When an alarm has tag propagation enabled, these notification schemas include an `AlarmTags` list and an `AlarmTagsStatus` field. For how to enable tag propagation and what the status values mean, see Alarm tags in action payloads.

This section lists the schemas of the notifications sent to Amazon SNS topics when alarms change their state.

Schema when a metric alarm changes state

```
{
  "AlarmName": "string",
  "AlarmDescription": "string",
  "AWSAccountId": "string",
  "AlarmConfigurationUpdatedTimestamp": "string",
  "NewStateValue": "string",
  "NewStateReason": "string",
  "StateChangeTime": "string",
  "Region": "string",
  "AlarmArn": "string",
  "OldStateValue": "string",
  "OKActions": ["string"],
  "AlarmActions": ["string"],
  "InsufficientDataActions": ["string"],
  "Trigger": {
    "MetricName": "string",
    "Namespace": "string",
    "StatisticType": "string",
    "Statistic": "string",
    "Unit": "string or null",
    "Dimensions": [
      {
```

```
        "value": "string",
        "name": "string"
      }
    ],
    "Period": "integer",
    "EvaluationPeriods": "integer",
    "DatapointsToAlarm": "integer",
    "ComparisonOperator": "string",
    "Threshold": "number",
    "TreatMissingData": "string",
    "EvaluateLowSampleCountPercentile": "string or null"
  },
  "AlarmTags": [
    {
      "Key": "string",
      "Value": "string"
    }
  ],
  "AlarmTagsStatus": "string"
}
```

Schema when a composite alarm changes state

```
{
  "AlarmName": "string",
  "AlarmDescription": "string",
  "AWSAccountId": "string",
  "NewStateValue": "string",
  "NewStateReason": "string",
  "StateChangeTime": "string",
  "Region": "string",
  "AlarmArn": "string",
  "OKActions": [String],
  "AlarmActions": [String],
  "InsufficientDataActions": [String],
  "OldStateValue": "string",
  "AlarmRule": "string",
  "TriggeringChildren": [String],
  "AlarmTags": [
    {
      "Key": "string",
      "Value": "string"
    }
```

```
  ],
  "AlarmTagsStatus": "string"
}
```

Schema when a log alarm changes state

```
{
  "AlarmName": "string",
  "AlarmDescription": "string",
  "AWSAccountId": "string",
  "AlarmConfigurationUpdatedTimestamp": "string",
  "NewStateValue": "string",
  "NewStateReason": "string",
  "StateChangeTime": "string",
  "Region": "string",
  "AlarmArn": "string",
  "OldStateValue": "string",

```

Invoke a Lambda function from an alarm

CloudWatch alarms guarantees an asynchronous invocation of the Lambda function for a given state change, except in the following cases:

- When the function doesn't exist.
- When CloudWatch is not authorized to invoke the Lambda function.

If CloudWatch can't reach the Lambda service or the message is rejected for another reason, CloudWatch retries until the invocation is successful. Lambda queues the message and handles execution retries. For more information about this execution model, including information about how Lambda handles errors, see Asynchronous invocation in the AWS Lambda Developer Guide.

You can invoke a Lambda function in the same account, or in other AWS accounts.

When you specify an alarm to invoke a Lambda function as an alarm action, you can choose to specify the function name, function alias, or a specific version of a function.

When you specify a Lambda function as an alarm action, you must create a resource policy for the function to allow the CloudWatch service principal to invoke the function.

One way to do this is by using the AWS CLI, as in the following example:

```
aws lambda add-permission \
--function-name my-function-name \
--statement-id AlarmAction \
--action 'lambda:InvokeFunction' \
--principal lambda.alarms.cloudwatch.amazonaws.com \
--source-account 111122223333 \
--source-arn arn:aws:cloudwatch:us-east-1:111122223333:alarm:alarm-name
```

Alternatively, you can create a policy similar to one of the following examples and then assign it to the function.

The following example specifies the account where the alarm is located, so that only alarms in that account (111122223333) can invoke the function.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "default",
    "Statement": [{
        "Sid": "AlarmAction",
        "Effect": "Allow",
        "Principal": {
            "Service": "lambda.alarms.cloudwatch.amazonaws.com"
        },
```

```
        "Action": "lambda:InvokeFunction",
        "Resource": "arn:aws:lambda:us-east-1:444455556666:function:function-
name",
        "Condition": {
            "StringEquals": {
                "AWS:SourceAccount": "111122223333"
            }
        }
    }]
}
```

The following example has a narrower scope, allowing only the specified alarm in the specified account to invoke the function.

JSON

```
{
  "Version":"2012-10-17",
  "Id": "default",
  "Statement": [
    {
      "Sid": "AlarmAction",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.alarms.cloudwatch.amazonaws.com"
      },
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:us-east-1:444455556666:function:function-name",
      "Condition": {
        "StringEquals": {
          "AWS:SourceAccount": "111122223333",
          "AWS:SourceArn": "arn:aws:cloudwatch:us-
east-1:111122223333:alarm:alarm-name"
        }
      }
    }]
}
```

We don't recommend creating a policy that doesn't specify a source account, because such policies are vulnerable to confused deputy issues.

Add Lambda metrics to CloudWatch investigations

You can add Lambda metrics to your active CloudWatch investigations. When investigating an issue, Lambda metrics can provide valuable insights about function performance and behavior. For example, if you're investigating an application performance issue, Lambda metrics such as duration, error rates, or throttles might help identify the root cause.

To add Lambda metrics to CloudWatch investigations:

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the **Monitor** section, find the metric.
3. Open the context menu for the metric, choose **Investigate**, **Add to investigation**. Then, in the **Investigate** pane, select the name of the investigation.

Event object sent from CloudWatch to Lambda

When you configure a Lambda function as an alarm action, CloudWatch delivers a JSON payload to the Lambda function when it invokes the function. This JSON payload serves as the event object for the function. You can extract data from this JSON object and use it in your function. The following is an example of an event object from a metric alarm.

When the alarm has tag propagation enabled, the `alarmData` object also includes an `alarmTags` list of key-value objects and an `alarmTagsStatus` field. For information about how to enable this feature and what the status values mean, see Alarm tags in action payloads.

```

Start a CloudWatch investigations from an alarm

Start a CloudWatch investigations from an alarm, or from any point in the last two weeks of a CloudWatch alarm's history.

For more information about CloudWatch investigations, see CloudWatch investigations.

Prerequisites

Before you can start a CloudWatch investigations from a CloudWatch alarm, you must create a resource policy for the function to allow the CloudWatch service principal to start the investigation. To do this using the AWS CLI, use a command similar to the following example:

```
aws aiops put-investigation-group-policy \
    --identifier arn:aws:aiops:us-east-1:111122223333:investigation-group/
investigation_group_id \
    --policy "{\"Version\":\"2008-10-17\",\"Statement\":[{\"Effect\":\"Allow\",
\"Principal\":{\"Service\":\"aiops.alarms.cloudwatch.amazonaws.com\"},\"Action\":
[\"aiops:CreateInvestigation\",\"aiops:CreateInvestigationEvent\"],\"Resource\":\"*\",
\"Condition\":{\"StringEquals\":{\"aws:SourceAccount\":\"111122223333\"},\"ArnLike\":
{\"aws:SourceArn\":\"arn:aws:cloudwatch:us-east-1:111122223333:alarm:*\"}}}]}" \
    --region eu-north-1
```

Replace the example values with your own AWS account ID, region, and investigation group ID.

Start an investigation from a CloudWatch alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the left navigation pane, choose **Alarms**, **All alarms**.
3. Choose the name of the alarm.
4. Choose the time period in the alarm history that you want to investigate.
5. Choose **Investigate**, **Start new investigation**.
6. For **New investigation title**, enter a name for the investigation. Then choose **Start investigation**.

   The CloudWatch investigations assistant starts and scans your telemetry data to find data that might be associated with this situation.
7. In the CloudWatch console's navigation pane, choose **Investigations**, then choose the name of the investigation that you just started.

   The **Findings** section displays a natural-language summary of the alarm's status and the reason that it was triggered.
8. (Optional) In the graph of the alarm, right-click and choose to deep-dive into the alarm or the metric that it watches.
9. On the right side of the screen, choose the **Suggestions** tab.

   A list of other telemetry that CloudWatch investigations has discovered and that might be relevant to the investigation appears. These findings can include other metrics and CloudWatch Logs Insights query results. CloudWatch investigations ran these queries based on the alarm.

   - For each finding, choose **Add to findings** or **Discard**.

     When you choose **Add to findings**, the telemetry is added to the **Findings** section, and CloudWatch investigations uses this information to direct its further scanning and suggestions.
   - For a CloudWatch Logs Insights query result, to change or edit the query and re-run it, open the context (right-click) menu for the results, and then choose **Open in Logs Insights**. For more information, see Analyzing log data with CloudWatch Logs Insights.

     To run a different query, when you get to the Logs Insights page, choose to use query assist to form a query using natural language. For more information, see Use natural language to generate and update CloudWatch Logs Insights queries.
   - (Optional) If you know of telemetry in another AWS service that might apply to this investigation, go to that service's console and add the telemetry to the investigation.

10. CloudWatch investigations might also add hypotheses to the list in the **Suggestions** tab. These hypotheses are generated by the investigation in natural language.

    For each hypothesis, choose **Add to findings** or **Discard**.
11. When you think you have completed the investigation and found the root cause of the issue, choose the **Overview** tab and then choose **Investigation summary**. CloudWatch investigations then creates a natural-language summary of the important findings and hypotheses from the investigation.

Stop, terminate, reboot, or recover an EC2 instance

Using Amazon CloudWatch alarm actions, you can create alarms that automatically stop, terminate, reboot, or recover your EC2 instances. You can use the stop or terminate actions to help you save money when you no longer need an instance to be running. You can use the reboot and recover actions to automatically reboot those instances or recover them onto new hardware if a system impairment occurs.

There are a number of scenarios in which you might want to automatically stop or terminate your instance. For example, you might have instances dedicated to batch payroll processing jobs or scientific computing tasks that run for a period of time and then complete their work. Rather than letting those instances sit idle (and accrue charges), you can stop or terminate them, which helps you to save money. The main difference between using the stop and the terminate alarm actions is that you can easily restart a stopped instance if you need to run it again later. You can also keep the same instance ID and root volume. However, you cannot restart a terminated instance. Instead, you must launch a new instance.

You can add the stop, terminate, or reboot, actions to any alarm that is set on an Amazon EC2 per-instance metric, including basic and detailed monitoring metrics provided by Amazon CloudWatch (in the AWS/EC2 namespace), in addition to any custom metrics that include the "InstanceId=" dimension, as long as the InstanceId value refers to a valid running Amazon EC2 instance. You can also add the recover action to alarms that is set on any Amazon EC2 per-instance metric except for `StatusCheckFailed_Instance`.

> **Important**
>
> Alarms configured on Amazon EC2 metrics can temporarily enter the INSUFFICIENT_DATA state if there are missing metric data points. This is rare, but can happen when the metric reporting is interrupted, even when the Amazon EC2 instance is healthy. For alarms on

Amazon EC2 metrics that are configured to take stop, terminate, reboot, or recover actions, we recommend that you configure those alarms to treat missing data as `missing`, and to have these alarms trigger only when in the ALARM state.
For more information about how you can configure CloudWatch to act on missing metrics that have alarms set on them, see Configuring how CloudWatch alarms treat missing data.

To set up a CloudWatch alarm action that can reboot, stop, or terminate an instance, you must use a service-linked IAM role, *AWSServiceRoleForCloudWatchEvents*. The AWSServiceRoleForCloudWatchEvents IAM role enables AWS to perform alarm actions on your behalf.

To create the service-linked role for CloudWatch Events, use the following command:

```
aws iam create-service-linked-role --aws-service-name events.amazonaws.com
```

Console support

You can create alarms using the CloudWatch console or the Amazon EC2 console. The procedures in this documentation use the CloudWatch console. For procedures that use the Amazon EC2 console, see Create alarms that stop, terminate, reboot, or rcover an instance in the *Amazon EC2 User Guide*.

Permissions

If you are using an AWS Identity and Access Management (IAM) account to create or modify an alarm that performs EC2 actions or Systems Manager OpsItem actions, you must have the `iam:CreateServiceLinkedRole` permission.

Contents

- Adding stop actions to Amazon CloudWatch alarms
- Adding terminate actions to Amazon CloudWatch alarms
- Adding reboot actions to Amazon CloudWatch alarms
- Adding recover actions to Amazon CloudWatch alarms
- Viewing the history of triggered alarms and actions

Adding stop actions to Amazon CloudWatch alarms

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them off. You can create an alarm that is triggered when the average CPU utilization percentage has been lower than 10 percent for 24 hours, signaling that it is idle and no longer in use. You can adjust the threshold, duration, and period to suit your needs, plus you can add an SNS notification, so that you will receive an email when the alarm is triggered.

Amazon EC2 instances that use an Amazon Elastic Block Store volume as the root device can be stopped or terminated, whereas instances that use the instance store as the root device can only be terminated.

To create an alarm to stop an idle instance using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select Metric**.
5. For **AWS namespaces**, choose **EC2**.
6. Do the following:
    a. Choose **Per-Instance Metrics**.
    b. Select the check box in the row with the correct instance and the **CPUUtilization** metric.
    c. Choose the **Graphed metrics** tab.
    d. For the statistic, choose **Average**.
    e. Choose a period (for example, **1 Hour**).
    f. Choose **Select metric**.
7. Under **Conditions**, do the following:
    a. Choose **Static**.
    b. Under **Whenever CPUUtilization is**, choose **Lower**.
    c. For **than**, type **10**.
    d. Choose **Next**.
    e. Under **Notification**, for **Send notification to**, choose an existing SNS topic or create a new one.

To create an SNS topic, choose **New list**. For **Send notification to**, type a name for the SNS topic (for example, Stop_EC2_Instance). For **Email list**, type a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.

f. Choose **Add EC2 Action**.

g. For **Alarm state trigger**, choose **In alarm**. For **Take the following action**, choose **Stop this instance**.

h. Choose **Next**.

i. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.

j. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

Adding terminate actions to Amazon CloudWatch alarms

You can create an alarm that terminates an EC2 instance automatically when a certain threshold has been met (as long as termination protection is not enabled for the instance). For example, you might want to terminate an instance when it has completed its work, and you don't need the instance again. If you might want to use the instance later, you should stop the instance instead of terminating it. For information about enabling and disabling termination protection for an instance, see Enabling Termination Protection for an Instance in the *Amazon EC2 User Guide*.

To create an alarm to terminate an idle instance using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **Create Alarm**.
3. For the **Select Metric** step, do the following:

   a. Under **EC2 Metrics**, choose **Per-Instance Metrics**.

   b. Select the row with the instance and the **CPUUtilization** metric.

   c. For the statistic, choose **Average**.

   d. Choose a period (for example, **1 Hour**).

   e. Choose **Next**.
4. For the **Define Alarm** step, do the following:

a. Under **Alarm Threshold**, type a unique name for the alarm (for example, Terminate EC2 instance) and a description of the alarm (for example, Terminate EC2 instance when CPU is idle for too long). Alarm names must contain only ASCII characters.

b. Under **Whenever**, for **is**, choose **<** and type **10**. For **for**, type **24** consecutive periods.

   A graphical representation of the threshold is shown under **Alarm Preview**.

c. Under **Notification**, for **Send notification to**, choose an existing SNS topic or create a new one.

   To create an SNS topic, choose **New list**. For **Send notification to**, type a name for the SNS topic (for example, Terminate_EC2_Instance). For **Email list**, type a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.

d. Choose **EC2 Action**.

e. For **Whenever this alarm**, choose **State is ALARM**. For **Take this action**, choose **Terminate this instance**.

f. Choose **Create Alarm**.

Adding reboot actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically reboots the instance. The reboot alarm action is recommended for Instance Health Check failures (as opposed to the recover alarm action, which is suited for System Health Check failures). An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it remains on the same physical host, so your instance keeps its public DNS name, private IP address, and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing hour, unlike stopping and restarting your instance. For more information about rebooting an instance, see Reboot Your Instance in the *Amazon EC2 User Guide*.

> **Important**
>
> To avoid a race condition between the reboot and recover actions, avoid setting the same evaluation period for both a reboot alarm and a recover alarm. We recommend that you set reboot alarms to three evaluation periods of one minute each.

To create an alarm to reboot an instance using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **Create Alarm**.
3. For the **Select Metric** step, do the following:
   a. Under **EC2 Metrics**, choose **Per-Instance Metrics**.
   b. Select the row with the instance and the **StatusCheckFailed_Instance** metric.
   c. For the statistic, choose **Minimum**.
   d. Choose a period (for example, **`1 Minute`**).
   e. Choose **Next**.
4. For the **Define Alarm** step, do the following:
   a. Under **Alarm Threshold**, type a unique name for the alarm (for example, Reboot EC2 instance) and a description of the alarm (for example, Reboot EC2 instance when health checks fail). Alarm names must contain only ASCII characters.
   b. Under **Whenever**, for **is**, choose **>** and type **`0`**. For **for**, type **3** consecutive periods.

      A graphical representation of the threshold is shown under **Alarm Preview**.
   c. Under **Notification**, for **Send notification to**, choose an existing SNS topic or create a new one.

      To create an SNS topic, choose **New list**. For **Send notification to**, type a name for the SNS topic (for example, Reboot_EC2_Instance). For **Email list**, type a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.
   d. Choose **EC2 Action**.

e. For **Whenever this alarm**, choose **State is ALARM**. For **Take this action**, choose **Reboot this instance**.

f. Choose **Create Alarm**.

Adding recover actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. Terminated instances cannot be recovered. A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata.

When the `StatusCheckFailed_System` alarm is triggered, and the recover action is initiated, you will be notified by the Amazon SNS topic that you chose when you created the alarm and associated the recover action. During instance recovery, the instance is migrated during an instance reboot, and any data that is in-memory is lost. When the process is complete, information is published to the SNS topic you've configured for the alarm. Anyone who is subscribed to this SNS topic will receive an email notification that includes the status of the recovery attempt and any further instructions. You will notice an instance reboot on the recovered instance.

The recover action can be used only with `StatusCheckFailed_System`, not with `StatusCheckFailed_Instance`.

Examples of problems that cause system status checks to fail include:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

The recover action is supported only on some instance types. For more information about supported instance types and other requirements, see Recover your instance and Requirements.

> **Important**
>
> To avoid a race condition between the reboot and recover actions, avoid setting the same evaluation period for both a reboot alarm and a recover alarm. We recommend that you set

recover alarms to two evaluation periods of one minute each and reboot alarms to three evaluation periods of one minute each.

To create an alarm to recover an instance using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create Alarm**.
4. Choose **Select Metric** and then do the following:
   a. Choose **EC2 Metrics**, **Per-Instance Metrics**.
   b. Select the row with the instance and the **StatusCheckFailed_System** metric, and then choose **Select metric**.
   c. For the statistic, choose **Minimum**.
   d. Choose a period (for example, **`1 Minute`**).

   > **Important**
   >
   > To avoid a race condition between the reboot and recover actions, avoid setting the same evaluation period for both a reboot alarm and a recover alarm. We recommend that you set recover alarms to two evaluation periods of one minute each.

5. For **Conditions**, do the following:
   a. Under **Threshold type**, choose **Static**.
   b. Under **Whenever**, choose **Greater** and enter **`0`** for **than...**.
   c. Choose **Additional configuration**, then for **Datapoints to alarm** specify 2 **out of** 2.
6. Choose **Next**.
7. Under **Notification**, do the following:
   a. For **Alarm state trigger**, choose **In alarm**.
   b. For **Send notification to the following SNS topic**, choose an existing SNS topic or create a new one.
   c. Choose **Add EC2 Action**.

d. For **Alarm state trigger**, choose **In alarm**.

e. For **Take the following action**, choose **Recover this instance**.

f. Choose **Next**.

8. For **Alarm name**, type a unique name for the alarm (for example, **`Recover EC2 instance`**) and a description of the alarm (for example, **`Recover EC2 instance when health checks fail`**). Alarm names must contain only ASCII characters.
9. Choose **Next**.
10. Choose **Create Alarm**.

Viewing the history of triggered alarms and actions

You can view alarm and action history in the Amazon CloudWatch console. Amazon CloudWatch keeps the last 30 days of alarm and action history.

To view the history of triggered alarms and actions

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms** and select an alarm.
3. To view the most recent state transition along with the time and metric values, choose **Details**.
4. To view the most recent history entries, choose **History**.

Alarm events and EventBridge

CloudWatch sends events to Amazon EventBridge whenever a CloudWatch alarm is created, updated, deleted, or changes alarm state. You can use EventBridge and these events to write rules that take actions, such as notifying you, when an alarm changes state. For more information, see What is Amazon EventBridge?

CloudWatch guarantees the delivery of alarm state change events to EventBridge.

Alarm State Change Events

This section shows example events sent to EventBridge when an alarm's state changes. Select a tab to view different types of alarm state change events.

When an alarm has tag propagation enabled, the event `detail` also includes an `alarmTags` object (a set of key-value pairs, which makes event pattern filtering easier) and an

`alarmTagsStatus` field. For how to enable tag propagation and what the status values mean, see Alarm tags in action payloads.

Single Metric Alarm

Events generated when a single metric alarm changes state. These events include `state` and `previousState` fields with the alarm's evaluation results.

```
    }
}
```

Multi Time Series Alarm

Events generated when an Alarm Contributor or an Alarm changes state. Alarm Contributor state change events contain the id and attributes of the Alarm Contributor as well as the most recent datapoint that breached the threshold. Alarm State change events have a summary of the number of contributors that caused the alarm to transition in their state reason.

Alarm Contributor Example

```
{

    }
}
```

Alarm Configuration Change Events

This section shows example events sent to EventBridge when an alarm's configuration changes. Configuration changes include creating, updating, or deleting alarms.

Creation Events

Events generated when new alarms are created. These events include the initial alarm configuration in the `configuration` field, with `operation` set to "create".

Composite Alarm Example

```
{
    "version": "0",
    "id": "91535fdd-1e9c-849d-624b-9a9f2b1d09d0",
    "detail-type": "CloudWatch Alarm Configuration Change",
    "source": "aws.cloudwatch",
    "account": "123456789012",
    "time": "2022-03-03T17:06:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:cloudwatch:us-east-1:123456789012:alarm:ServiceAggregatedAlarm"
    ],
    "detail": {
        "alarmName": "ServiceAggregatedAlarm",
        "operation": "create",
        "state": {
            "value": "INSUFFICIENT_DATA",
            "timestamp": "2022-03-03T17:06:22.289+0000"
        },
        "configuration": {
            "alarmRule": "ALARM(ServerCpuTooHigh) OR
 ALARM(TotalNetworkTrafficTooHigh)",
            "alarmName": "ServiceAggregatedAlarm",
            "description": "Aggregated monitor for instance",
            "actionsEnabled": true,
            "timestamp": "2022-03-03T17:06:22.289+0000",

Alarm tags in action payloads

With CloudWatch, you can include an alarm's tags in the payloads it sends when the alarm changes state. You can then route, filter, or add context to notifications by using tags such as team, environment, or cost center.

You can use alarm tags with the following destinations: Amazon SNS notifications, Lambda function invocations, and the alarm state change events that CloudWatch sends to EventBridge.

CloudWatch sends alarm state change events to EventBridge by default, so configured tags appear in those events even when you don't configure an action on the alarm. For Amazon SNS and Lambda, tags appear only when you configure that action for the alarm. For Amazon SNS, CloudWatch includes the tags in the notification message that it delivers to the topic's subscribers, including those that use the HTTP/HTTPS and email protocols.

> **Note**
>
> CloudWatch doesn't support alarm tags for other actions, such as Systems Manager OpsItems, Systems Manager Incident Manager incidents, Amazon EC2 actions, Amazon EC2 Auto Scaling and Application Auto Scaling actions, or CloudWatch investigations.

Tag keys that begin with `aws:` are reserved for AWS and are never propagated.

Each payload includes a status field (`AlarmTagsStatus` for Amazon SNS, and `alarmTagsStatus` for Lambda and EventBridge) with one of the following values:

- `SUCCESS` – The tags were retrieved and any key filter was applied. The list can be empty if the filter excluded all tags.
- `NO_TAGS` – The alarm has no tags.
- `TRUNCATED` – Some tags were omitted to keep the payload within its size limit. If your tags are truncated, narrow the set of tags that CloudWatch includes by using the include or exclude tag key options.
- `FAILURE` – The tags couldn't be retrieved when the notification was sent. CloudWatch still delivers the notification or event, with no tags.

The representation of the tags differs by destination. Amazon SNS and Lambda include the tags as a list of key-value objects, and EventBridge includes them as key-value pairs to make event pattern filtering easier. For the Amazon SNS schema, see Schema of Amazon SNS notifications when alarms change state. For Lambda, see Invoke a Lambda function from an alarm. For EventBridge, see Alarm events and EventBridge.

Each notification or event reflects the alarm's tags at the time of the state change, including tag changes that you make after you create the alarm.

By default, when tag propagation is enabled, CloudWatch includes all of the alarm's tags (future tags as well if they are added later). To include only the relevant tags, or to exclude sensitive tags that you don't want to send in the payload, provide an include or exclude tag key list:

- Exclude tag keys – CloudWatch includes all of the alarm's tags except the keys that you specify. Any tags that you add later are also included, unless their keys are in the exclude list.

- Include tag keys – CloudWatch includes only the keys that you specify. If you add a new tag later and want it in the payload, you must add its key to the include list.

Prerequisites

A principal that creates or updates an alarm to enable this configuration must have the `cloudwatch:ListTagsForResource` permission for that alarm. CloudWatch also provides the `cloudwatch:AlarmTagsPropagationEnabled` condition key to control whether principals can enable tag propagation.

Enable alarm tag propagation using the console

You enable tag propagation while you create or edit an alarm in the CloudWatch console.

To enable alarm tag propagation

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then start creating an alarm, or edit an existing alarm.
2. On the **Add alarm details** step, under the tag editor, select **Include this alarm's tags in action and event payloads**.
3. To set which tags to include, select **All tags** to include all of the alarm's tags, or select **Select tags** to specify tag keys.
4. If you selected **Select tags**, select **Include tags** to include only the keys that you specify, or select **Exclude tags** to include all tags except the keys that you specify.
5. If you selected **Include tags** or **Exclude tags**, enter the tag keys in **Tag keys to include** or **Tag keys to exclude**.
6. Choose **Preview and create** to review your choice.
7. Finish creating or saving the alarm.

After you complete these steps, the alarm includes its tags in its notifications and events when its state changes.

To view the setting later, open the alarm's **Tags** tab on the alarm details page. To change the setting without the wizard, choose **Manage tags**.

Enable alarm tag propagation using the API

To enable tag propagation with the API, set the `AlarmTagsPropagation` configuration within the `ActionConfiguration` parameter on `PutMetricAlarm`, `PutCompositeAlarm`, or `PutLogAlarm`, and set `Enabled` to `true`. `DescribeAlarms` returns the current configuration.

To include all of the alarm's tags, omit both of the following mutually exclusive lists. To narrow the set of tags, use one of them:

- `IncludedTagKeys` – Include only the listed keys.
- `ExcludedTagKeys` – Include all keys except those listed.

Each list can contain from 1 to 50 tag keys, and each tag key can be from 1 to 128 characters.

For more information, see PutMetricAlarm, PutCompositeAlarm, PutLogAlarm, and DescribeAlarms in the *Amazon CloudWatch API Reference*.

Configure alarm mute rules

The steps in this section explain how to use the CloudWatch console to create an alarm mute rule. You can also use the API or AWS CLI to create an alarm mute rule. For more information, see PutAlarmMuteRule.

To create an alarm mute rule

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **Mute Rules** tab
3. Click **Create Alarm Mute Rule** button, which would open a wizard
4. Under **Alarm mute rule details** section, enter a name and optional description for your alarm mute rule
5. Under **Schedule pattern** section, choose one time or recurring schedule
    a. If you choose one-time occurrence,
        i. Select the Timezone to apply the mute schedules
        ii. Choose a start date and time, to define when the mute rule should become active
        iii. Choose end date and time, to define when the mute rule should expire

b. If you choose Recurring schedule, you will have two options. Either to use the Console form or use cron expression to configure the recurring time schedules.

   i. Under **Schedule creation type** choose "Specify date, time and recurrence" to use the Console form

      A. Choose the Timezone to apply the mute rule

      B. Choose **Start date and time**, to define when the mute rule should become active

      C. Choose **Duration**, to define how long the mute rule should last once becomes active

      D. Choose **Repeat**, to define how the schedule should repeat like every day, every month, every weekend or on specific days during the week.

      E. Choose optional **Until**, to define when the mute schedule should expire. Default option is "Indefinitely"

   ii. Under **Schedule creation type** choose "Set from a cron expression" to configure schedules using cron expressions

      A. Under **Cron expression** section enter the desired cron expression values.

      B. Choose **Duration**, to define how long the mute rule should last once becomes active

      C. Under optional **Timeframe** section, enter optional start and end date and time to define when the mute schedule should become active and expire.

6. Under **Target alarms** section, choose the alarms from the drop down to which you want to apply this mute rule

7. Under **Set tags for your mute rule** section, attach tags to your alarm mute rule. A tag is a key-value pair applied to a resource to hold metadata about that resource. For more information see What are tags?

8. Select **Create alarm mute rule** button to create the mute rule

Quick mutes

Alarms could be added for a short time period as follows,

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Alarms**

3. Select the alarms that you want to mute from the list
4. Under **Actions** menu choose **Mute**
5. Under the **Quick mute** section choose the predefined time periods 15min, 1h, 3h or select **Mute until** to set desired time period
6. Click **Confirm** to mute the alarms immediately until the chosen time period

Add alarms to existing mute rules

Alarms could be added to existing mute rules as follows,

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**
3. Select the alarms that you want to mute from the list
4. Under **Actions** menu choose **Mute**
5. Choose **Apply existing mute rules**, which should open a wizard
6. Select the mute rules from the drop down to which you want to add the alarms
7. Click **Apply**

> **Note**
>
> Quick mute and adding an alarm to existing mute rules options are also available from the alarm details page. **Mute rules** tab in the details page displays all mute rules associated with the alarm.

Managing alarms

Topics

- Edit or delete a CloudWatch alarm
- Hide Auto Scaling alarms
- Alarms and tagging
- Viewing and managing muted alarms

Edit or delete a CloudWatch alarm

You can edit or delete an existing alarm.

You can't change the name of an existing alarm. You can copy an alarm and give the new alarm a different name. To copy an alarm, select the check box next to the alarm name in the alarm list and choose **Action**, **Copy**.

To edit an alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose the name of the alarm.
4. To add or remove tags, choose the **Tags** tab and then choose **Manage tags**.
5. To edit other parts of the alarm, choose **Actions**, **Edit**.

   The **Specify metric and conditions** page appears, showing a graph and other information about the metric and statistic that you selected.
6. To change the metric, choose **Edit**, choose the **All metrics** tab, and do one of the following:
   - Choose the service namespace that contains the metric that you want. Continue choosing options as they appear to narrow the choices. When a list of metrics appears, select the check box next to the metric that you want.
   - In the search box, enter the name of a metric, dimension, or resource ID and press Enter. Then choose one of the results and continue until a list of metrics appears. Select the check box next to the metric that you want.

   Choose **Select metric**.
7. To change other aspects of the alarm, choose the appropriate options. To change how many data points must be breaching for the alarm to go into `ALARM` state or to change how missing data is treated, choose **Additional configuration**.
8. Choose **Next**.
9. Under **Notification**, **Auto Scaling action**, and **EC2 action**, optionally edit the actions taken when the alarm is triggered. Then choose **Next**.
10. Optionally change the alarm description.

You can't change the name of an existing alarm. You can copy an alarm and give the new alarm a different name. To copy an alarm, select the check box next to the alarm name in the alarm list and choose **Action**, **Copy**.

11. Choose **Next**.
12. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Update alarm**.

To update an email notification list that was created using the Amazon SNS console

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation pane, choose **Topics** and then select the ARN for your notification list (topic).
3. Do one of the following:
   - To add an email address, choose **Create subscription**. For **Protocol**, choose **Email**. For **Endpoint**, enter the email address of the new recipient. Choose **Create subscription**.
   - To remove an email address, choose the **Subscription ID**. Choose **Other subscription actions**, **Delete subscriptions**.
4. Choose **Publish to topic**.

To delete an alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**.
3. Select the check box to the left of the name of the alarm, and choose **Actions**, **Delete**.
4. Choose **Delete**.

Hide Auto Scaling alarms

When you view your alarms in the AWS Management Console, you can hide the alarms related to both Amazon EC2 Auto Scaling and Application Auto Scaling. This feature is available only in the AWS Management Console.

To temporarily hide Auto Scaling alarms

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

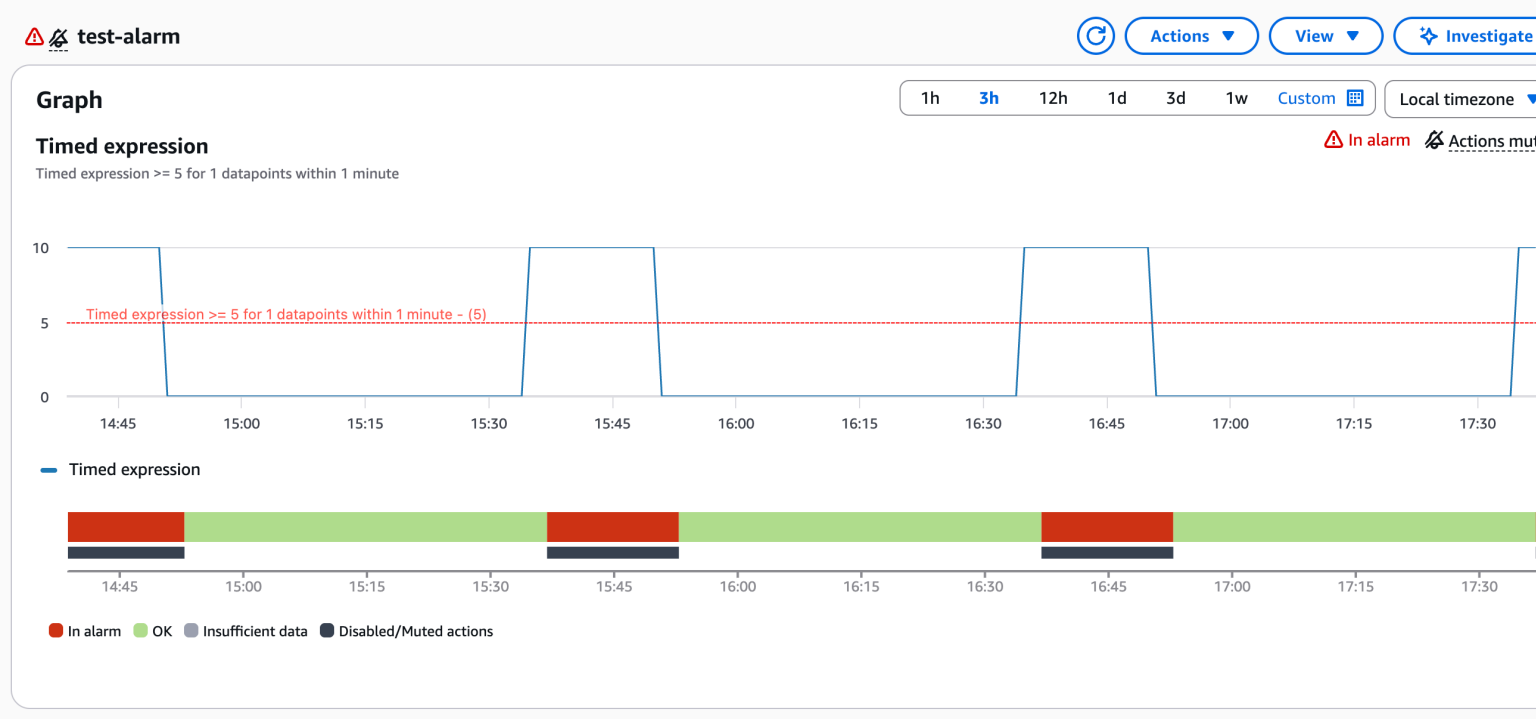
2. In the navigation pane, choose **Alarms**, **All alarms**, and select **Hide Auto Scaling alarms**.

Alarms and tagging

Tags are key-value pairs that can help you organize and categorize your resources. You can also use them to scope user permissions by granting a user permission to access or change only resources with certain tag values. For more general information about tagging resources, see Tagging your AWS resources

The following list explains some details about how tagging works with CloudWatch alarms.

- To be able to set or update tags for a CloudWatch resource, you must be signed on to an account that has the `cloudwatch:TagResource` permission. For example, to create an alarm and set tags for it, you must have the `cloudwatch:TagResource` permission in addition to the `cloudwatch:PutMetricAlarm` (or `cloudwatch:PutLogAlarm` for log alarms) permission. You recommend that you make sure anyone in your organization who will create or update CloudWatch resources has the `cloudwatch:TagResource` permission.
- Tags can be used for tag-based authorization control. For example, IAM user or role permissions can include conditions to limit CloudWatch calls to specific resources based on their tags. However, keep in mind the following
  - Tags with names that start with `aws:` can't be used for tag-based authorization control.
  - Composite alarms do not support tag-based authorization control.



Viewing and managing muted alarms

Viewing muted alarms: You can easily identify which alarms are currently muted through the CloudWatch console. In both the alarms list view and individual alarm detail pages, a mute icon appears next to alarms whose actions are currently being muted by active mute rules. This visual indicator helps you quickly understand which alarms actions are being currently muted until the mute window expires.

Alarms timeline: The CloudWatch alarms console provides a comprehensive timeline view that shows when your alarm actions were muted. This timeline displays mute periods alongside alarm

state changes, giving you a complete historical view of both alarm behaviour and muting activity. You can use this timeline to analyze the effectiveness of your mute rules and understand how they correlate with your operational activities.

Programmatically checking alarm mute status: To programmatically determine if an alarm is currently muted, you can use the ListAlarmMuteRules API with the alarm name as a filter criteria. This API returns all active mute rules that are affecting the specified alarm, allowing you to integrate mute status checks into your automation workflows, monitoring dashboards, or operational tools.

For example: To check if an alarm named "HighCPUAlarm" is currently muted, call the ListAlarmMuteRules API with the filter parameter set to the alarm name. The response will include all mute rules targeting that alarm, along with their current status (SCHEDULED, ACTIVE, or EXPIRED).

Alarm history: Whenever alarm actions are muted due to an active mute rule, CloudWatch writes a history entry to the alarm's history log. This provides a complete audit trail of when your alarms were muted, helping you understand the timeline of muting events and correlate them with operational activities. You can view this history through the CloudWatch console or retrieve it programmatically using the DescribeAlarmHistory API.

Note

- When multiple alarm mute rules are active simultaneously, the most recently created mute rule name is written to the alarm history along with the total number of other active mute rules.
- The timeline displays mute periods only when an alarm state transitions during an active mute window and actions were prevented from executing.

Tip

You can manage alarm mute rules programmatically using the CloudWatch API. For more information, see PutAlarmMuteRule, GetAlarmMuteRule, ListAlarmMuteRules, and DeleteAlarmMuteRule.

Common features of CloudWatch alarms

The following features apply to all CloudWatch alarms:

- There is no limit to the number of alarms that you can create. To create or update an alarm, you use the CloudWatch console, the PutMetricAlarm or PutLogAlarm API actions, or the corresponding commands in the AWS CLI.
- Alarm names must contain only UTF-8 characters, and can't contain ASCII control characters
- You can list any or all of the currently configured alarms, and list any alarms in a particular state by using the CloudWatch console, the DescribeAlarms API action, or the describe-alarms command in the AWS CLI.
- You can disable and enable alarm actions by using the DisableAlarmActions and EnableAlarmActions API actions, or the disable-alarm-actions and enable-alarm-actions commands in the AWS CLI.
- You can test an alarm by setting it to any state using the SetAlarmState API action or the set-alarm-state command in the AWS CLI. This temporary state change lasts only until the next alarm comparison occurs.
- You can create an alarm for a custom metric before you've created that custom metric. For the alarm to be valid, you must include all of the dimensions for the custom metric in addition

to the metric namespace and metric name in the alarm definition. To do this, you can use the PutMetricAlarm API action, or the put-metric-alarm command in the AWS CLI.

- You can view an alarm's history using the CloudWatch console, the DescribeAlarmHistory API action, or the describe-alarm-history command in the AWS CLI. CloudWatch preserves alarm history for 30 days. Each state transition is marked with a unique timestamp. In rare cases, your history might show more than one notification for a state change. The timestamp enables you to confirm unique state changes.
- You can favorite alarms from the *Favorites and recents* option in the CloudWatch console navigation pane by hovering over the alarm that you want to favorite and choosing the star symbol next to it.
- Alarms have an evaluation period quota. The evaluation period is calculated by multiplying the alarm period by the number of evaluation periods used.
  - The maximum evaluation period is seven days for alarms with a period of at least one hour (3600 seconds).
  - The maximum evaluation period is one day for alarms with a shorter period.
  - The maximum evaluation period is one day for alarms that use the custom Lambda data source.

> **Note**
>
> Some AWS resources don't send metric data to CloudWatch under certain conditions. For example, Amazon EBS might not send metric data for an available volume that is not attached to an Amazon EC2 instance, because there is no metric activity to be monitored for that volume. If you have an alarm set for such a metric, you might notice its state change to `INSUFFICIENT_DATA`. This might indicate that your resource is inactive, and might not necessarily mean that there is a problem. You can specify how each alarm treats missing data. For more information, see Configuring how CloudWatch alarms treat missing data.

Best practice alarm recommendations for AWS services

CloudWatch provides out-of-the box alarm recommendations. These are CloudWatch alarms that CloudWatch recommends that you create for metrics that are published by other AWS services. These recommendations can help you identify the metrics that you should set alarms for to follow

best practices for monitoring. The recommendations also suggest the alarm thresholds to set. Following these recommendations can help you not miss important monitoring of your AWS infrastructure.

To find the alarm recommendations, you use the metrics section of the CloudWatch console, and select the alarm recommendations filter toggle. If you navigate to the recommended alarms in the console and then create a recommended alarm, CloudWatch can pre-fill some of the alarm settings. For some recommended alarms, the alarm threshold value is also pre-filled. You can also use the console to download infrastructure-as-code alarm definitions for recommended alarms, and then use this code to create the alarm in AWS CloudFormation, the AWS CLI, or Terraform.

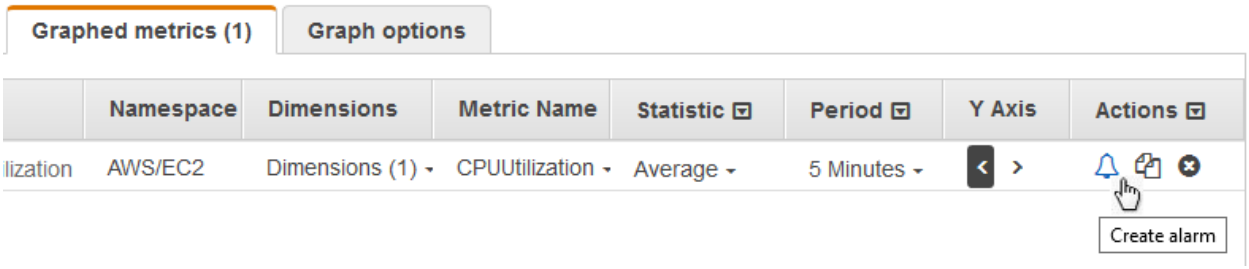
You can also see the list of recommended alarms in Recommended alarms (Classic).

You are charged for the alarms that you create, at the same rate as any other alarms that you create in CloudWatch. Using the recommendations incurs no extra charges. For more information, see Amazon CloudWatch Pricing.

Find and create recommended alarms

Follow these steps to find the metrics that CloudWatch recommends that you set alarms for, and optionally to create one of these alarms. The first procedure explains how to find the metrics that have recommended alarms, and how to create one of these alarms.

You can also get a bulk download of infrastructure-as-code alarm definitions for all recommended alarms in an AWS namespace, such as `AWS/Lambda` or `AWS/S3`. Those instructions are later in this topic.



To find the metrics with recommended alarms, and create a single recommended alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Above the **Metrics** table, Choose **Alarm recommendations**.

   The list of metric namespaces is filtered to include only the metrics that have alarm recommendations and that services in your account are publishing.
4. Choose the namespace for a service.

   The list of metrics under this namespace is filtered to include only those that have alarm recommendations.

5. To see the alarm intent and recommended threshold for a metric, choose **View details**.
6. To create an alarm for one of the metrics, do one of the following:
   - To use the console to create the alarm, do the following:
     a. Select the checkbox for the metric and choose the **Graphed metrics** tab.
     b. Choose the alarm icon.

     The alarm creation wizard appears, with the metric name, statistic, and period filled in based on the alarm recommendation. If the recommendation includes a specific threshold value, that value is also pre-filled.
     c. Choose **Next**.
     d. Under **Notification**, select an SNS topic to notify when the alarm transitions to ALARM state, OK state, or INSUFFICIENT_DATA state.

     To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

     To have the alarm not send notifications, choose **Remove**.
     e. To have the alarm perform Auto Scaling or EC2 actions, choose the appropriate button and choose the alarm state and action to perform.
     f. When finished, choose **Next**.
     g. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.
     h. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.
   - To download an infrastructure-as-code alarm definition to use in either AWS CloudFormation, AWS CLI, or Terraform, choose **Download alarm code** and select the format that you want. The downloaded code will have the recommended settings for the metric name, statistic, and threshold.

To download infrastructure-as-code alarm definitions for all recommended alarms for an AWS service

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Above the **Metrics** table, Choose **Alarm recommendations**.

   The list of metric namespaces is filtered to include only the metrics that have alarm recommendations and that services in your account are publishing.
4. Choose the namespace for a service.

   The list of metrics under this namespace is filtered to include only those that have alarm recommendations.
5. The **Download alarm code** displays how many alarms are recommended for the metrics in this namespace. To download infrastructure-as-code alarm definitions for all recommended alarms, choose **Download alarm code** and then choose the code format that you want.

Recommended PromQL alarms

Use these PromQL alarms as equivalents of the classic recommended alarms. They monitor the same metrics by using PromQL instant queries that are evaluated against metrics ingested through the CloudWatch OTLP endpoint.

PromQL alarms use `EvaluationCriteria` with `PromQLCriteria`. Unlike classic metric alarms, the threshold is embedded directly in the PromQL query expression.

- **Pending period** – The duration in seconds that a time series must continuously breach before the alarm transitions to ALARM state.
- **Recovery period** – The duration in seconds that all time series must stop breaching before the alarm returns to OK state.
- **Evaluation interval** – How often, in seconds, CloudWatch runs the PromQL query.

> **Note**
>
> These alarms require metrics published through the CloudWatch OTLP endpoint. For more information, see PromQL alarms.

You can deploy these alarms by using AWS CloudFormation. Use the `EvaluationCriteria` and `PromQLCriteria` properties on the `AWS::CloudWatch::Alarm` resource.

API Gateway

REST API

4XXError

Labels: ApiName, Stage

Alarm description: Alarm when the average 4XX error rate exceeds 5% for a REST API stage.

Intent: Detect high client error rate indicating request issues.

PromQL criteria: `avg({__name__="4XXError", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiName="your-api-name",Stage="your-stage"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Detects greater than 5% client error rate, which indicates significant request failures.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

5XXError

Labels: ApiName, Stage

Alarm description: Alarm when the average 5XX error rate exceeds 5% for a REST API stage.

Intent: Detect high server error rate indicating backend failures.

PromQL criteria: `avg({__name__="5XXError", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiName="your-api-name",Stage="your-stage"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Detects greater than 5% server error rate, which requires immediate investigation.

Evaluation interval: 60

Pending period: 180

Recovery period: 300

Latency

Labels: ApiName, Stage

Alarm description: Alarm when the p90 latency exceeds 2500 ms for a REST API stage.

Intent: Detect high p90 latency affecting user experience.

PromQL criteria: `histogram_quantile(0.9, {__name__="Latency", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiName="your-api-name",Stage="your-stage"}) > 2500`

Recommended threshold: 2500 (embedded in query)

Threshold justification: A p90 latency above 2500 ms indicates degraded response times for most requests.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

Count

Labels: ApiName, Stage

Alarm description: Alarm when the total request count drops below the expected baseline for a REST API stage.

Intent: Detect low traffic volume that might indicate routing or availability issues.

PromQL criteria: `sum({__name__="Count", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiName="your-api-name",Stage="your-stage"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your expected traffic baseline to detect unexpected drops.

Evaluation interval: 60

Pending period: 600

Recovery period: 300

HTTP API

4xx

Labels: ApiId, Stage

Alarm description: Alarm when the average 4xx error rate exceeds 5% for an HTTP API stage.

Intent: Detect high client error rate on HTTP API endpoints.

PromQL criteria: `avg({__name__="4xx", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiId="your-api-id",Stage="your-stage"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Detects greater than 5% client error rate.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

5xx

Labels: ApiId, Stage

Alarm description: Alarm when the average 5xx error rate exceeds 5% for an HTTP API stage.

Intent: Detect high server error rate on HTTP API endpoints.

PromQL criteria: `avg({__name__="5xx", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiId="your-api-id",Stage="your-stage"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Detects greater than 5% server error rate requiring investigation.

Evaluation interval: 60

Pending period: 180

Recovery period: 300

Latency

Labels: ApiId, Stage

Alarm description: Alarm when the p90 latency exceeds 2500 ms for an HTTP API stage.

Intent: Detect high p90 latency on HTTP API endpoints.

PromQL criteria: `histogram_quantile(0.9, {__name__="Latency", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiId="your-api-id",Stage="your-stage"}) > 2500`

Recommended threshold: 2500 (embedded in query)

Threshold justification: A p90 latency above 2500 ms indicates degraded response times.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

IntegrationLatency

Labels: ApiId, Stage

Alarm description: Alarm when the p90 integration latency exceeds 2000 ms for an HTTP API stage.

Intent: Detect high backend integration latency affecting response times.

PromQL criteria: `histogram_quantile(0.9, {__name__="IntegrationLatency", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiId="your-api-id",Stage="your-stage"}) > 2000`

Recommended threshold: 2000 (embedded in query)

Threshold justification: A p90 integration latency above 2000 ms indicates backend slowness.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

Count

Labels: ApiId, Stage

Alarm description: Alarm when the total request count drops below the expected baseline for an HTTP API stage.

Intent: Detect low traffic volume that might indicate routing or availability issues.

PromQL criteria: `sum({__name__="Count", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiId="your-api-id",Stage="your-stage"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your expected traffic baseline to detect unexpected drops.

Evaluation interval: 60

Pending period: 600

Recovery period: 300

WebSocket API

ClientError

Labels: ApiId, Stage

Alarm description: Alarm when the average client error rate exceeds 5% for a WebSocket API stage.

Intent: Detect high client error rate on WebSocket API connections.

PromQL criteria: `avg({__name__="ClientError", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiId="your-api-id",Stage="your-stage"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Detects greater than 5% client error rate on WebSocket connections.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ExecutionError

Labels: ApiId, Stage

Alarm description: Alarm when the average execution error rate exceeds 5% for a WebSocket API stage.

Intent: Detect high server-side execution error rate on WebSocket APIs.

PromQL criteria: `avg({__name__="ExecutionError", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiId="your-api-id",Stage="your-stage"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Detects greater than 5% execution error rate requiring investigation.

Evaluation interval: 60

Pending period: 180

Recovery period: 300

IntegrationLatency

Labels: ApiId, Stage

Alarm description: Alarm when the p90 integration latency exceeds 2000 ms for a WebSocket API stage.

Intent: Detect high backend integration latency on WebSocket API routes.

PromQL criteria: `histogram_quantile(0.9, {__name__="IntegrationLatency", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiId="your-api-id",Stage="your-stage"}) > 2000`

Recommended threshold: 2000 (embedded in query)

Threshold justification: A p90 integration latency above 2000 ms indicates backend slowness.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

MessageCount

Labels: ApiId, Stage

Alarm description: Alarm when the total message count drops below the expected baseline for a WebSocket API stage.

Intent: Detect low message volume that might indicate connection or routing issues.

PromQL criteria: `sum({__name__="MessageCount", "@instrumentation.@name"="cloudwatch.aws/apigateway", ApiId="your-api-id",Stage="your-stage"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your expected message volume to detect unexpected drops.

Evaluation interval: 60

Pending period: 600

Recovery period: 300

Auto Scaling

GroupInServiceCapacity

Labels: AutoScalingGroupName

Alarm description: Alarm when the average in-service capacity drops below the expected minimum for an Auto Scaling group.

Intent: Detect low availability due to launch failures or terminated instances.

PromQL criteria: `avg({__name__="GroupInServiceCapacity", "@instrumentation.@name"="cloudwatch.aws/autoscaling", AutoScalingGroupName="`*`your-auto-scaling-group-name`*`"}) < `*`THRESHOLD`*

Recommended threshold: *`THRESHOLD`* (embedded in query)

Threshold justification: Set based on your minimum desired capacity to detect launch failures or insufficient instances.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

Certificate Manager

DaysToExpiry

Labels: CertificateArn

Alarm description: Alarm when the minimum days to certificate expiry drops to 44 days or fewer.

Intent: Proactive certificate expiration alert to allow time for renewal.

PromQL criteria: `min({__name__="DaysToExpiry", "@instrumentation.@name"="cloudwatch.aws/certificatemanager", CertificateArn="`*`your-certificate-arn`*`"}) <= 44`

Recommended threshold: 44 (embedded in query)

Threshold justification: Provides sufficient lead time before certificate expiration to complete the renewal process.

Evaluation interval: 86400

Pending period: 86400

Recovery period: 86400

CloudFront

5xxErrorRate

Labels: DistributionId

Alarm description: Alarm when the average 5xx error rate exceeds the threshold for a CloudFront distribution.

Intent: Detect high origin or CloudFront error rate affecting content delivery.

PromQL criteria: `avg({__name__="5xxErrorRate", "@instrumentation.@name"="cloudwatch.aws/cloudfront", DistributionId="`*`your-distribution-id`*`"}) > `*`THRESHOLD`*

Recommended threshold: *`THRESHOLD`* (embedded in query)

Threshold justification: Set based on your acceptable error rate for content delivery.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

OriginLatency

Labels: DistributionId

Alarm description: Alarm when the p90 origin latency exceeds the threshold for a CloudFront distribution.

Intent: Detect high origin response latency affecting content delivery performance.

PromQL criteria: `histogram_quantile(0.9, {__name__="OriginLatency", "@instrumentation.@name"="cloudwatch.aws/cloudfront", DistributionId="your-distribution-id"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your expected origin response time and caching strategy.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

FunctionValidationErrors

Labels: DistributionId, FunctionName

Alarm description: Alarm when any CloudFront function validation errors occur.

Intent: Detect CloudFront function validation failures that prevent function execution.

PromQL criteria: `sum({__name__="FunctionValidationErrors", "@instrumentation.@name"="cloudwatch.aws/cloudfront", DistributionId="your-distribution-id",FunctionName="your-function-name"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any validation error indicates a function configuration problem that requires attention.

Evaluation interval: 60

Pending period: 120

Recovery period: 120

FunctionExecutionErrors

Labels: DistributionId, FunctionName

Alarm description: Alarm when any CloudFront function execution errors occur.

Intent: Detect runtime failures in CloudFront functions that affect request processing.

PromQL criteria: `sum({__name__="FunctionExecutionErrors", "@instrumentation.@name"="cloudwatch.aws/cloudfront", DistributionId="your-distribution-id",FunctionName="your-function-name"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any execution error indicates a runtime problem in the function code.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

FunctionThrottles

Labels: DistributionId, FunctionName

Alarm description: Alarm when any CloudFront function throttling occurs.

Intent: Detect CloudFront function throttling that might degrade request processing.

PromQL criteria: `sum({__name__="FunctionThrottles", "@instrumentation.@name"="cloudwatch.aws/cloudfront", DistributionId="your-distribution-id",FunctionName="your-function-name"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any throttling indicates the function is hitting compute limits.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

Cognito

SignUpThrottles

Labels: UserPool, UserPoolClient

Alarm description: Alarm when sign-up throttle events exceed the threshold for a user pool.

Intent: Detect sign-up throttling that prevents new user registrations.

PromQL criteria: `sum({__name__="SignUpThrottles", "@instrumentation.@name"="cloudwatch.aws/cognito", UserPool="your-user-pool",UserPoolClient="your-user-pool-client"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable throttle rate for sign-up operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

SignInThrottles

Labels: UserPool, UserPoolClient

Alarm description: Alarm when sign-in throttle events exceed the threshold for a user pool.

Intent: Detect sign-in throttling that prevents user authentication.

PromQL criteria: `sum({__name__="SignInThrottles", "@instrumentation.@name"="cloudwatch.aws/cognito", UserPool="your-user-pool",UserPoolClient="your-user-pool-client"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable throttle rate for sign-in operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

TokenRefreshThrottles

Labels: UserPool, UserPoolClient

Alarm description: Alarm when token refresh throttle events exceed the threshold for a user pool.

Intent: Detect token refresh throttling that might cause session interruptions.

PromQL criteria: `sum({__name__="TokenRefreshThrottles", "@instrumentation.@name"="cloudwatch.aws/cognito", UserPool="your-user-pool",UserPoolClient="your-user-pool-client"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable throttle rate for token refresh operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

FederationThrottles

Labels: UserPool, UserPoolClient, IdentityProvider

Alarm description: Alarm when federation throttle events exceed the threshold for a user pool identity provider.

Intent: Detect federation throttling that might prevent federated sign-in.

PromQL criteria: `sum({__name__="FederationThrottles", "@instrumentation.@name"="cloudwatch.aws/cognito", UserPool="your-user-pool",UserPoolClient="your-user-pool-client",IdentityProvider="your-identity-provider"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable throttle rate for federation operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

DynamoDB

AccountProvisionedReadCapacityUtilization

Labels: None

Alarm description: Alarm when the account-level provisioned read capacity utilization exceeds 80%.

Intent: Detect when provisioned read capacity approaches account limits.

PromQL criteria: `max({__name__="AccountProvisionedReadCapacityUtilization", "@instrumentation.@name"="cloudwatch.aws/dynamodb"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: At 80% utilization, you have limited headroom before reaching account limits.

Evaluation interval: 300

Pending period: 600

Recovery period: 600

AccountProvisionedWriteCapacityUtilization

Labels: None

Alarm description: Alarm when the account-level provisioned write capacity utilization exceeds 80%.

Intent: Detect when provisioned write capacity approaches account limits.

PromQL criteria: `max({__name__="AccountProvisionedWriteCapacityUtilization", "@instrumentation.@name"="cloudwatch.aws/dynamodb"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: At 80% utilization, you have limited headroom before reaching account limits.

Evaluation interval: 300

Pending period: 600

Recovery period: 600

AgeOfOldestUnreplicatedRecord

Labels: TableName, DelegatedOperation

Alarm description: Alarm when the age of the oldest unreplicated record exceeds the threshold.

Intent: Detect replication lag that might cause stale data in global tables.

PromQL criteria: `max({__name__="AgeOfOldestUnreplicatedRecord", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name",DelegatedOperation="your-operation"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your replication freshness requirements.

Evaluation interval: 300

Pending period: 900

Recovery period: 900

FailedToReplicateRecordCount

Labels: TableName, DelegatedOperation

Alarm description: Alarm when any records fail to replicate in a global table.

Intent: Detect replication failures that cause data inconsistency across regions.

PromQL criteria: `sum({__name__="FailedToReplicateRecordCount", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name",DelegatedOperation="your-operation"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any failed replication indicates data consistency issues requiring immediate attention.

Evaluation interval: 60

Pending period: 60

Recovery period: 60

ReadThrottleEvents

Labels: TableName

Alarm description: Alarm when read throttle events exceed the threshold for a table.

Intent: Detect read throttling that indicates insufficient provisioned capacity.

PromQL criteria: `sum({__name__="ReadThrottleEvents", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable throttle count for read operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ReadThrottleEvents (GSI)

Labels: TableName, GlobalSecondaryIndexName

Alarm description: Alarm when read throttle events exceed the threshold for a global secondary index.

Intent: Detect read throttling on a GSI that indicates insufficient index capacity.

PromQL criteria: `sum({__name__="ReadThrottleEvents", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name",GlobalSecondaryIndexName="your-index-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable throttle count for GSI read operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ReplicationLatency

Labels: TableName, ReceivingRegion

Alarm description: Alarm when the average replication latency exceeds the threshold for a global table.

Intent: Detect high replication latency that might cause stale reads in replica regions.

PromQL criteria: `avg({__name__="ReplicationLatency", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name",ReceivingRegion="your-receiving-region"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your data freshness requirements for replica regions.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

SuccessfulRequestLatency

Labels: TableName, Operation

Alarm description: Alarm when the average successful request latency exceeds the threshold for a table operation.

Intent: Detect high latency on DynamoDB operations affecting application performance.

PromQL criteria: `avg({__name__="SuccessfulRequestLatency", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name",Operation="your-operation"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your latency SLA for the specific DynamoDB operation.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

SystemErrors

Labels: TableName

Alarm description: Alarm when system errors exceed the threshold for a table.

Intent: Detect DynamoDB service-side errors that affect table availability.

PromQL criteria: `sum({__name__="SystemErrors", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable system error count for the table.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

ThrottledPutRecordCount

Labels: TableName, DelegatedOperation

Alarm description: Alarm when throttled put record count exceeds the threshold for a table.

Intent: Detect throttled puts that might cause data loss in streaming operations.

PromQL criteria: `max({__name__="ThrottledPutRecordCount", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name",DelegatedOperation="your-operation"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable throttle count for streaming put operations.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

UserErrors

Labels: None

Alarm description: Alarm when user errors exceed the threshold across the account.

Intent: Detect high rates of client errors such as validation or conditional check failures.

PromQL criteria: `sum({__name__="UserErrors", "@instrumentation.@name"="cloudwatch.aws/dynamodb"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable error rate for client-side request failures.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

WriteThrottleEvents

Labels: TableName

Alarm description: Alarm when write throttle events exceed the threshold for a table.

Intent: Detect write throttling that indicates insufficient provisioned capacity.

PromQL criteria: `sum({__name__="WriteThrottleEvents", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable throttle count for write operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

WriteThrottleEvents (GSI)

Labels: TableName, GlobalSecondaryIndexName

Alarm description: Alarm when write throttle events exceed the threshold for a global secondary index.

Intent: Detect write throttling on a GSI that indicates insufficient index capacity.

PromQL criteria: `sum({__name__="WriteThrottleEvents", "@instrumentation.@name"="cloudwatch.aws/dynamodb", TableName="your-table-name",GlobalSecondaryIndexName="your-index-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your acceptable throttle count for GSI write operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

EBS

VolumeStalledIOCheck

Labels: VolumeId, InstanceId

Alarm description: Alarm when an EBS volume reports a stalled I/O check failure.

Intent: Detect stalled I/O on EBS volumes that indicates volume impairment.

PromQL criteria: `max({__name__="VolumeStalledIOCheck", "@instrumentation.@name"="cloudwatch.aws/ebs", VolumeId="your-volume-id",InstanceId="your-instance-id"}) >= 1`

Recommended threshold: 1 (embedded in query)

Threshold justification: A value of 1 or greater indicates the volume has stalled I/O, requiring immediate investigation.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

Amazon Elastic Compute Cloud

CPUUtilization

Labels: InstanceId

Alarm description: Alarm when average CPU utilization exceeds 80% for an EC2 instance.

Intent: Detect high CPU utilization.

PromQL criteria: `avg({__name__="CPUUtilization", "@instrumentation.@name"="cloudwatch.aws/ec2", InstanceId="your-instance-id"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% threshold gives headroom before saturation.

Evaluation interval: 300

Pending period: 900

Recovery period: 900

StatusCheckFailed

Labels: InstanceId

Alarm description: Alarm when an instance or system health check fails for an EC2 instance.

Intent: Detect instance or system health issues.

PromQL criteria: `max({__name__="StatusCheckFailed", "@instrumentation.@name"="cloudwatch.aws/ec2", InstanceId="your-instance-id"}) >= 1`

Recommended threshold: 1 (embedded in query)

Threshold justification: Any status check failure requires investigation.

Evaluation interval: 300

Pending period: 600

Recovery period: 600

StatusCheckFailed_AttachedEBS

Labels: InstanceId

Alarm description: Alarm when an attached EBS volume becomes unreachable for an EC2 instance.

Intent: Detect unreachable EBS volumes.

PromQL criteria: `max({__name__="StatusCheckFailed_AttachedEBS", "@instrumentation.@name"="cloudwatch.aws/ec2", InstanceId="your-instance-id"}) >= 1`

Recommended threshold: 1 (embedded in query)

Threshold justification: Unreachable volumes cause I/O failures.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

Amazon ECS

CPUReservation

Labels: ClusterName

Alarm description: Alarm when average CPU reservation exceeds 80% for an ECS cluster.

Intent: Detect cluster approaching CPU capacity.

PromQL criteria: `avg({__name__="CPUReservation", "@instrumentation.@name"="cloudwatch.aws/ecs", ClusterName="your-cluster-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% reservation indicates limited headroom for new tasks.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

CPUUtilization

Labels: ClusterName, ServiceName

Alarm description: Alarm when average CPU utilization exceeds 80% for an ECS service.

Intent: Detect high CPU utilization for ECS service.

PromQL criteria: `avg({__name__="CPUUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

EBSFilesystemUtilization

Labels: ClusterName, ServiceName

Alarm description: Alarm when average EBS filesystem utilization exceeds 80% for an ECS service.

Intent: Detect high EBS storage utilization.

PromQL criteria: `avg({__name__="EBSFilesystemUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

MemoryReservation

Labels: ClusterName

Alarm description: Alarm when average memory reservation exceeds 80% for an ECS cluster.

Intent: Detect cluster approaching memory capacity.

PromQL criteria: `avg({__name__="MemoryReservation", "@instrumentation.@name"="cloudwatch.aws/ecs", ClusterName="your-cluster-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% reservation indicates limited headroom for new tasks.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

MemoryUtilization

Labels: ClusterName, ServiceName

Alarm description: Alarm when average memory utilization exceeds 80% for an ECS service.

Intent: Detect high memory utilization.

PromQL criteria: `avg({__name__="MemoryUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

HTTPCode_Target_5XX_Count

Labels: ClusterName, ServiceName

Alarm description: Alarm when the HTTP 5XX error count exceeds the threshold for an ECS service.

Intent: Detect high server-side error count.

PromQL criteria: `sum({__name__="HTTPCode_Target_5XX_Count", "@instrumentation.@name"="cloudwatch.aws/ecs", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your application's normal error rate baseline.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

TargetResponseTime

Labels: ClusterName, ServiceName

Alarm description: Alarm when average target response time exceeds the threshold for an ECS service.

Intent: Detect high target response time.

PromQL criteria: `avg({__name__="TargetResponseTime", "@instrumentation.@name"="cloudwatch.aws/ecs", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your application's acceptable latency requirements.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

Amazon ECS Container Insights

EphemeralStorageUtilized

Labels: ClusterName, ServiceName

Alarm description: Alarm when average ephemeral storage usage exceeds the threshold for Fargate tasks.

Intent: Detect high ephemeral storage usage for Fargate tasks.

PromQL criteria: `avg({__name__="EphemeralStorageUtilized", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your task's ephemeral storage allocation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

RunningTaskCount

Labels: ClusterName, ServiceName

Alarm description: Alarm when the running task count drops to zero for an ECS service.

Intent: Detect when no tasks are running.

PromQL criteria: `avg({__name__="RunningTaskCount", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name",ServiceName="your-service-name"}) <= 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Zero running tasks indicates a service outage.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

instance_filesystem_utilization

Labels: InstanceId, ContainerInstanceId, ClusterName

Alarm description: Alarm when average filesystem utilization exceeds 90% on a container instance.

Intent: Detect high filesystem utilization.

PromQL criteria: `avg({__name__="instance_filesystem_utilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", InstanceId="your-instance-id",ContainerInstanceId="your-container-instance-id",ClusterName="your-cluster-name"}) > 90`

Recommended threshold: 90 (embedded in query)

Threshold justification: 90% filesystem utilization leaves minimal space for operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

Amazon ECS Container Insights enhanced observability

TaskCpuUtilization (cluster level)

Labels: ClusterName

Alarm description: Alarm when average task CPU utilization exceeds 80% at the cluster level.

Intent: Detect high CPU utilization.

PromQL criteria: `avg({__name__="TaskCpuUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

TaskCpuUtilization (service level)

Labels: ClusterName, ServiceName

Alarm description: Alarm when average task CPU utilization exceeds 80% at the service level.

Intent: Detect high CPU utilization.

PromQL criteria: `avg({__name__="TaskCpuUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

TaskMemoryUtilization (cluster level)

Labels: ClusterName

Alarm description: Alarm when average task memory utilization exceeds 80% at the cluster level.

Intent: Detect high memory utilization.

PromQL criteria: `avg({__name__="TaskMemoryUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

TaskMemoryUtilization (service level)

Labels: ClusterName, ServiceName

Alarm description: Alarm when average task memory utilization exceeds 80% at the service level.

Intent: Detect high memory utilization.

PromQL criteria: `avg({__name__="TaskMemoryUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ContainerCpuUtilization (cluster level)

Labels: ClusterName

Alarm description: Alarm when average container CPU utilization exceeds 80% at the cluster level.

Intent: Detect high CPU utilization.

PromQL criteria: `avg({__name__="ContainerCpuUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ContainerCpuUtilization (container level)

Labels: ContainerName, ClusterName, ServiceName

Alarm description: Alarm when average container CPU utilization exceeds 80% at the container level.

Intent: Detect high CPU utilization.

PromQL criteria: `avg({__name__="ContainerCpuUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ContainerName="your-container-name",ClusterName="your-cluster-name",ServiceName="your-service-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ContainerMemoryUtilization (cluster level)

Labels: ClusterName

Alarm description: Alarm when average container memory utilization exceeds 80% at the cluster level.

Intent: Detect high memory utilization.

PromQL criteria: `avg({__name__="ContainerMemoryUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ContainerMemoryUtilization (container level)

Labels: ContainerName, ClusterName, ServiceName

Alarm description: Alarm when average container memory utilization exceeds 80% at the container level.

Intent: Detect high memory utilization.

PromQL criteria: `avg({__name__="ContainerMemoryUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ContainerName="your-container-name",ClusterName="your-cluster-name",ServiceName="your-service-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

TaskEBSfilesystemUtilization

Labels: ClusterName, ServiceName

Alarm description: Alarm when average EBS filesystem utilization exceeds 80% for tasks.

Intent: Detect high EBS filesystem utilization.

PromQL criteria: `avg({__name__="TaskEBSfilesystemUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

TaskEphemeralStorageUtilization (cluster level)

Labels: ClusterName

Alarm description: Alarm when average ephemeral storage utilization exceeds 80% at the cluster level.

Intent: Detect high ephemeral storage utilization.

PromQL criteria: `avg({__name__="TaskEphemeralStorageUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

TaskEphemeralStorageUtilization (service level)

Labels: ClusterName, ServiceName

Alarm description: Alarm when average ephemeral storage utilization exceeds 80% at the service level.

Intent: Detect high ephemeral storage utilization.

PromQL criteria: `avg({__name__="TaskEphemeralStorageUtilization", "@instrumentation.@name"="cloudwatch.aws/ecs-containerinsights", ClusterName="your-cluster-name",ServiceName="your-service-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

Amazon EFS

PercentIOLimit

Labels: FileSystemId

Alarm description: Alarm when an EFS filesystem reaches 100% of its I/O limit.

Intent: Detect when filesystem reaches I/O limit.

PromQL criteria: `avg({__name__="PercentIOLimit", "@instrumentation.@name"="cloudwatch.aws/efs", FileSystemId="your-filesystem-id"}) >= 100`

Recommended threshold: 100 (embedded in query)

Threshold justification: At 100% the filesystem becomes a bottleneck.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

BurstCreditBalance

Labels: FileSystemId

Alarm description: Alarm when burst credit balance drops to zero for an EFS filesystem.

Intent: Detect depleted burst credits causing throughput slowdown.

PromQL criteria: `avg({__name__="BurstCreditBalance", "@instrumentation.@name"="cloudwatch.aws/efs", FileSystemId="your-filesystem-id"}) <= 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Zero credits causes reduced throughput.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

Amazon EKS Container Insights

node_cpu_utilization

Labels: ClusterName

Alarm description: Alarm when maximum CPU utilization exceeds 80% on EKS worker nodes.

Intent: Detect high CPU on worker nodes.

PromQL criteria: `max({__name__="node_cpu_utilization", "@instrumentation.@name"="cloudwatch.aws/eks-containerinsights", ClusterName="your-cluster-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

node_filesystem_utilization

Labels: ClusterName

Alarm description: Alarm when maximum filesystem utilization exceeds the threshold on EKS worker nodes.

Intent: Detect high filesystem usage on worker nodes.

PromQL criteria: `max({__name__="node_filesystem_utilization", "@instrumentation.@name"="cloudwatch.aws/eks-containerinsights", ClusterName="your-cluster-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on your node's storage capacity and usage patterns.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

node_memory_utilization

Labels: ClusterName

Alarm description: Alarm when maximum memory utilization exceeds 80% on EKS worker nodes.

Intent: Detect high memory on worker nodes.

PromQL criteria: `max({__name__="node_memory_utilization", "@instrumentation.@name"="cloudwatch.aws/eks-containerinsights", ClusterName="your-cluster-name"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

pod_cpu_utilization_over_pod_limit

Labels: ClusterName, Namespace, Service

Alarm description: Alarm when pod CPU utilization exceeds 80% of its limit.

Intent: Detect pods approaching CPU limits.

PromQL criteria: `max({__name__="pod_cpu_utilization_over_pod_limit", "@instrumentation.@name"="cloudwatch.aws/eks-containerinsights", ClusterName="your-cluster-name",Namespace="your-namespace",Service="your-service"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before throttling occurs.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

pod_memory_utilization_over_pod_limit

Labels: ClusterName, Namespace, Service

Alarm description: Alarm when pod memory utilization exceeds 80% of its limit.

Intent: Detect pods approaching memory limits.

PromQL criteria: `max({__name__="pod_memory_utilization_over_pod_limit", "@instrumentation.@name"="cloudwatch.aws/eks-containerinsights", ClusterName="your-cluster-name",Namespace="your-namespace",Service="your-service"}) > 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: 80% gives headroom before OOMKill occurs.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

Amazon ElastiCache

CPUUtilization

Labels: CacheClusterId, CacheNodeId

Alarm description: Alarm when average CPU utilization exceeds the threshold for an ElastiCache node.

Intent: Detect high CPU across the instance.

PromQL criteria: `avg({__name__="CPUUtilization", "@instrumentation.@name"="cloudwatch.aws/elasticache", CacheClusterId="`*`your-cache-cluster-id`*`",CacheNodeId="`*`your-cache-node-id`*`"}) > `*`THRESHOLD`*

Recommended threshold: *`THRESHOLD`* (embedded in query)

Threshold justification: Set based on your node type and workload characteristics.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

CurrConnections

Labels: CacheClusterId, CacheNodeId

Alarm description: Alarm when the connection count exceeds the threshold for an ElastiCache node.

Intent: Detect high connection counts.

PromQL criteria: `avg({__name__="CurrConnections", "@instrumentation.@name"="cloudwatch.aws/elasticache", CacheClusterId="`*`your-cache-cluster-id`*`",CacheNodeId="`*`your-cache-node-id`*`"}) > `*`THRESHOLD`*

Recommended threshold: *`THRESHOLD`* (embedded in query)

Threshold justification: Set based on your expected connection pool size and application needs.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

DatabaseMemoryUsagePercentage

Labels: CacheClusterId

Alarm description: Alarm when database memory usage exceeds the threshold for an ElastiCache cluster.

Intent: Detect high memory usage to prevent write failures.

PromQL criteria: `avg({__name__="DatabaseMemoryUsagePercentage", "@instrumentation.@name"="cloudwatch.aws/elasticache", CacheClusterId="`*`your-cache-cluster-id`*`"}) > `*`THRESHOLD`*

Recommended threshold: *`THRESHOLD`* (embedded in query)

Threshold justification: Set based on your eviction policy and data criticality.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

EngineCPUUtilization

Labels: CacheClusterId

Alarm description: Alarm when Redis engine CPU utilization exceeds 90% for an ElastiCache cluster.

Intent: Detect high Redis engine CPU utilization.

PromQL criteria: `avg({__name__="EngineCPUUtilization", "@instrumentation.@name"="cloudwatch.aws/elasticache", CacheClusterId="`*`your-cache-cluster-id`*`"}) > 90`

Recommended threshold: 90 (embedded in query)

Threshold justification: Redis is single-threaded; greater than 90% indicates saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ReplicationLag

Labels: CacheClusterId

Alarm description: Alarm when replication lag exceeds the threshold for an ElastiCache cluster.

Intent: Detect replication delay affecting data consistency.

PromQL criteria: `avg({__name__="ReplicationLag", "@instrumentation.@name"="cloudwatch.aws/elasticache", CacheClusterId="`*`your-cache-cluster-id`*`"}) > `*`THRESHOLD`*

Recommended threshold: *`THRESHOLD`* (embedded in query)

Threshold justification: Set based on your application's tolerance for stale reads.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

Elastic GPUs

GPUConnectivityCheckFailed

Labels: InstanceId, EGPUId

Alarm description: Alarm when the Elastic Graphics accelerator loses connectivity to the instance.

Intent: Detect connectivity issues to Elastic Graphics accelerator.

PromQL criteria: `max({__name__="GPUConnectivityCheckFailed", "@instrumentation.@name"="cloudwatch.aws/elasticgpus", InstanceId="your-instance-id",EGPUId="your-egpu-id"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any connectivity failure requires investigation.

Evaluation interval: 300

Pending period: 900

Recovery period: 900

GPUHealthCheckFailed

Labels: InstanceId, EGPUId

Alarm description: Alarm when an Elastic Graphics accelerator health check fails.

Intent: Detect unhealthy Elastic Graphics accelerator.

PromQL criteria: `max({__name__="GPUHealthCheckFailed", "@instrumentation.@name"="cloudwatch.aws/elasticgpus", InstanceId="your-instance-id",EGPUId="your-egpu-id"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Health check failures indicate accelerator problems.

Evaluation interval: 300

Pending period: 900

Recovery period: 900

Amazon EventBridge Scheduler

TargetErrorThrottledCount

Alarm description: Alarm when schedule target invocations are throttled.

Intent: Detect target throttling causing schedule delays.

PromQL criteria: `sum({__name__="TargetErrorThrottledCount", "@instrumentation.@name"="cloudwatch.aws/scheduler"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any throttling indicates target capacity issues.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

InvocationThrottleCount

Alarm description: Alarm when Scheduler invocations are throttled.

Intent: Detect Scheduler invocation throttling.

PromQL criteria: `sum({__name__="InvocationThrottleCount", "@instrumentation.@name"="cloudwatch.aws/scheduler"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Throttling delays scheduled executions.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

InvocationDroppedCount

Alarm description: Alarm when scheduled invocations are dropped.

Intent: Detect dropped invocations.

PromQL criteria: `sum({__name__="InvocationDroppedCount", "@instrumentation.@name"="cloudwatch.aws/scheduler"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Dropped invocations represent lost scheduled events.

Evaluation interval: 60

Pending period: 60

Recovery period: 60

InvocationsFailedToBeSentToDeadLetterCount

Alarm description: Alarm when failed invocations cannot be sent to the dead-letter queue.

Intent: Detect DLQ delivery failures.

PromQL criteria: `sum({__name__="InvocationsFailedToBeSentToDeadLetterCount", "@instrumentation.@name"="cloudwatch.aws/scheduler"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Failed DLQ delivery means lost error information.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

Amazon Kinesis Data Streams

GetRecords.IteratorAgeMilliseconds

Labels: StreamName

Alarm description: Alarm when consumer iterator age exceeds the threshold for a Kinesis stream.

Intent: Detect data falling behind retention period risking data loss.

PromQL criteria: `max({__name__="GetRecords.IteratorAgeMilliseconds", "@instrumentation.@name"="cloudwatch.aws/kinesis", StreamName="`*`your-stream-name`*`"}) > `*`THRESHOLD`*

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on stream retention period percentage.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

GetRecords.Success

Labels: StreamName

Alarm description: Alarm when the GetRecords success rate drops below the threshold for a Kinesis stream.

Intent: Detect consumer retrieval failures.

PromQL criteria: `avg({__name__="GetRecords.Success", "@instrumentation.@name"="cloudwatch.aws/kinesis", StreamName="your-stream-name"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on expected success rate.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

PutRecord.Success

Labels: StreamName

Alarm description: Alarm when the PutRecord success rate drops below the threshold for a Kinesis stream.

Intent: Detect producer ingestion failures.

PromQL criteria: `avg({__name__="PutRecord.Success", "@instrumentation.@name"="cloudwatch.aws/kinesis", StreamName="your-stream-name"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on expected success rate.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

PutRecords.FailedRecords

Labels: StreamName

Alarm description: Alarm when batch put operations produce failed records for a Kinesis stream.

Intent: Detect batch put failures.

PromQL criteria: `sum({__name__="PutRecords.FailedRecords", "@instrumentation.@name"="cloudwatch.aws/kinesis", StreamName="your-stream-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable failure count.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ReadProvisionedThroughputExceeded

Labels: StreamName

Alarm description: Alarm when consumer reads exceed provisioned throughput for a Kinesis stream.

Intent: Detect consumer read throttling.

PromQL criteria: `avg({__name__="ReadProvisionedThroughputExceeded", "@instrumentation.@name"="cloudwatch.aws/kinesis", StreamName="your-stream-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Any sustained throttling indicates capacity needs.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

SubscribeToShardEvent.MillisBehindLatest

Labels: StreamName, ConsumerName

Alarm description: Alarm when an enhanced fan-out consumer falls behind the latest record.

Intent: Detect enhanced fan-out consumer processing lag.

PromQL criteria: `avg({__name__="SubscribeToShardEvent.MillisBehindLatest", "@instrumentation.@name"="cloudwatch.aws/kinesis", StreamName="`*your-stream-name*`",ConsumerName="`*your-consumer-name*`"}) > `*THRESHOLD*

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable processing delay.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

WriteProvisionedThroughputExceeded

Labels: StreamName

Alarm description: Alarm when producer writes exceed provisioned throughput for a Kinesis stream.

Intent: Detect producer write throttling.

PromQL criteria: `avg({__name__="WriteProvisionedThroughputExceeded", "@instrumentation.@name"="cloudwatch.aws/kinesis", StreamName="`*your-stream-name*`"}) > `*THRESHOLD*

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Sustained throttling indicates capacity needs.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

AWS Lambda

ClaimedAccountConcurrency

Alarm description: Alarm when claimed account concurrency exceeds the threshold.

Intent: Detect account approaching concurrency quota.

PromQL criteria: `max({__name__="ClaimedAccountConcurrency", "@instrumentation.@name"="cloudwatch.aws/lambda"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set to percentage of regional concurrency limit.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

Errors

Labels: FunctionName

Alarm description: Alarm when function error count exceeds the threshold for a Lambda function.

Intent: Detect high function error count.

PromQL criteria: `sum({__name__="Errors", "@instrumentation.@name"="cloudwatch.aws/lambda", FunctionName="your-function-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable error volume.

Evaluation interval: 60

Pending period: 180

Recovery period: 300

Throttles

Labels: FunctionName

Alarm description: Alarm when function invocations are throttled for a Lambda function.

Intent: Detect function invocation throttling.

PromQL criteria: `sum({__name__="Throttles", "@instrumentation.@name"="cloudwatch.aws/lambda", FunctionName="`*your-function-name*`"}) > `*THRESHOLD*

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Throttling indicates concurrency limit reached.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

Duration

Labels: FunctionName

Alarm description: Alarm when p90 function duration exceeds the threshold for a Lambda function.

Intent: Detect long-running function invocations.

PromQL criteria: `histogram_quantile(0.9, {__name__="Duration", "@instrumentation.@name"="cloudwatch.aws/lambda", FunctionName="`*your-function-name*`"}) > `*THRESHOLD*

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set relative to function timeout.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

ConcurrentExecutions

Labels: FunctionName

Alarm description: Alarm when concurrent executions exceed the threshold for a Lambda function.

Intent: Detect function approaching concurrency limits.

PromQL criteria: `max({__name__="ConcurrentExecutions", "@instrumentation.@name"="cloudwatch.aws/lambda", FunctionName="`*your-function-name*`"}) > `*THRESHOLD*

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set to percentage of reserved concurrency.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

AWS Lambda Insights

memory_utilization

Labels: function_name

Alarm description: Alarm when average memory utilization exceeds 90% for a Lambda function.

Intent: Detect function approaching configured memory limit.

PromQL criteria: `avg({__name__="memory_utilization", "@instrumentation.@name"="cloudwatch.aws/lambda-insights", function_name="your-function-name"}) > 90`

Recommended threshold: 90 (embedded in query)

Threshold justification: Above 90% risks out-of-memory failures.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

NAT Gateway

ErrorPortAllocation

Labels: NatGatewayId

Alarm description: Alarm when the NAT gateway fails to allocate a port for new connections.

Intent: Detect port allocation failures preventing new connections.

PromQL criteria: `sum({__name__="ErrorPortAllocation", "@instrumentation.@name"="cloudwatch.aws/natgateway", NatGatewayId="your-nat-gateway-id"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any allocation failure impacts connectivity.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

PacketsDropCount

Labels: NatGatewayId

Alarm description: Alarm when the NAT gateway drops packets exceeding the threshold.

Intent: Detect packet drops indicating capacity or connectivity issues.

PromQL criteria: `sum({__name__="PacketsDropCount", "@instrumentation.@name"="cloudwatch.aws/natgateway", NatGatewayId="your-nat-gateway-id"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable drop rate.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

AWS PrivateLink endpoints

PacketsDropped

Labels: VpcId, VpcEndpointId, EndpointType, SubnetId, ServiceName

Alarm description: Alarm when a VPC endpoint drops packets exceeding the threshold.

Intent: Detect unhealthy endpoint or endpoint service.

PromQL criteria: `sum({__name__="PacketsDropped", "@instrumentation.@name"="cloudwatch.aws/privatelinkendpoints", VpcId="your-vpc-id",VpcEndpointId="your-vpc-endpoint-id",EndpointType="your-endpoint-type",SubnetId="your-subnet-id",ServiceName="your-service-name"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable drop rate.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

AWS PrivateLink services

RstPacketsSent

Labels: ServiceId, LoadBalancerArn, Az

Alarm description: Alarm when the RST packet rate exceeds the threshold for an endpoint service.

Intent: Detect unhealthy targets of endpoint service.

PromQL criteria: `sum({__name__="RstPacketsSent", "@instrumentation.@name"="cloudwatch.aws/privatelinkservices", ServiceId="SVC",LoadBalancerArn="LB",Az="AZ"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable RST packet rate.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

RDS

CPUUtilization

Labels: DBInstanceIdentifier

Alarm description: Alarm when average CPU utilization exceeds 90% for an RDS instance.

Intent: Detect high CPU preventing performance degradation.

PromQL criteria: `avg({__name__="CPUUtilization", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) > 90`

Recommended threshold: 90 (embedded in query)

Threshold justification: 90% indicates near saturation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

DatabaseConnections

Labels: DBInstanceIdentifier

Alarm description: Alarm when database connections exceed the threshold for an RDS instance.

Intent: Prevent rejected connections at maximum limit.

PromQL criteria: `avg({__name__="DatabaseConnections", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set to percentage of max_connections parameter.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

EBSByteBalance%

Labels: DBInstanceIdentifier

Alarm description: Alarm when EBS byte balance drops below 10% for an RDS instance.

Intent: Detect low throughput credits causing bottlenecks.

PromQL criteria: `avg({__name__="EBSByteBalance%", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) < 10`

Recommended threshold: 10 (embedded in query)

Threshold justification: Below 10% risks throughput degradation.

Evaluation interval: 60

Pending period: 180

Recovery period: 180

EBSIOBalance%

Labels: DBInstanceIdentifier

Alarm description: Alarm when EBS IO balance drops below 10% for an RDS instance.

Intent: Detect low IOPS credits causing bottlenecks.

PromQL criteria:
```
avg({__name__="EBSIOBalance%",
"@instrumentation.@name"="cloudwatch.aws/rds",
DBInstanceIdentifier="DB"}) < 10
```

Recommended threshold: 10 (embedded in query)

Threshold justification: Below 10% risks IOPS degradation.

Evaluation interval: 60

Pending period: 180

Recovery period: 180

FreeableMemory

Labels: DBInstanceIdentifier

Alarm description: Alarm when freeable memory drops below the threshold for an RDS instance.

Intent: Prevent out-of-memory causing rejected connections.

PromQL criteria:
```
avg({__name__="FreeableMemory",
"@instrumentation.@name"="cloudwatch.aws/rds",
DBInstanceIdentifier="DB"}) < THRESHOLD
```

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on instance class memory.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

FreeLocalStorage

Labels: DBInstanceIdentifier

Alarm description: Alarm when free local storage drops below the threshold for an Aurora instance.

Intent: Prevent Aurora local storage exhaustion.

PromQL criteria: `avg({__name__="FreeLocalStorage", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on minimum required for operations.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

FreeStorageSpace

Labels: DBInstanceIdentifier

Alarm description: Alarm when free storage space drops below the threshold for an RDS instance.

Intent: Prevent storage-full downtime.

PromQL criteria: `min({__name__="FreeStorageSpace", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on storage growth rate and provisioned size.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

MaximumUsedTransactionIDs

Labels: DBInstanceIdentifier

Alarm description: Alarm when maximum used transaction IDs exceed 1 billion for an RDS instance.

Intent: Prevent PostgreSQL transaction ID wraparound.

PromQL criteria: `avg({__name__="MaximumUsedTransactionIDs", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) > 1000000000`

Recommended threshold: 1000000000 (embedded in query)

Threshold justification: 1 billion indicates approaching wraparound danger.

Evaluation interval: 60

Pending period: 60

Recovery period: 60

ReadLatency

Labels: DBInstanceIdentifier

Alarm description: Alarm when p90 read latency exceeds the threshold for an RDS instance.

Intent: Detect high read latency indicating disk issues.

PromQL criteria: `histogram_quantile(0.9, {__name__="ReadLatency", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable application latency.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

ReplicaLag

Labels: DBInstanceIdentifier

Alarm description: Alarm when replication lag exceeds 60 seconds for an RDS read replica.

Intent: Detect replication delay risking data loss.

PromQL criteria:
```
max({__name__="ReplicaLag",
"@instrumentation.@name"="cloudwatch.aws/rds",
DBInstanceIdentifier="DB"}) > 60
```

Recommended threshold: 60 (embedded in query)

Threshold justification: 60 seconds represents significant lag for most workloads.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

WriteLatency

Labels: DBInstanceIdentifier

Alarm description: Alarm when p90 write latency exceeds the threshold for an RDS instance.

Intent: Detect high write latency indicating disk issues.

PromQL criteria:
```
histogram_quantile(0.9, {__name__="WriteLatency",
"@instrumentation.@name"="cloudwatch.aws/rds",
DBInstanceIdentifier="DB"}) > THRESHOLD
```

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable application latency.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

DBLoad

Labels: DBInstanceIdentifier

Alarm description: Alarm when average database load exceeds the threshold for an RDS instance.

Intent: Detect high database load degrading performance.

PromQL criteria: `avg({__name__="DBLoad", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set to multiple of vCPU count.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

AuroraVolumeBytesLeftTotal

Labels: DBClusterIdentifier

Alarm description: Alarm when Aurora cluster storage bytes remaining drops below the threshold.

Intent: Prevent Aurora cluster storage exhaustion.

PromQL criteria: `avg({__name__="AuroraVolumeBytesLeftTotal", "@instrumentation.@name"="cloudwatch.aws/rds", DBClusterIdentifier="CLUSTER"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on growth rate.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

AuroraBinlogReplicaLag

Labels: DBClusterIdentifier

Alarm description: Alarm when Aurora binlog replica lag indicates an error state.

Intent: Detect writer instance replication errors.

PromQL criteria: `avg({__name__="AuroraBinlogReplicaLag", "@instrumentation.@name"="cloudwatch.aws/rds", DBClusterIdentifier="CLUSTER"}) <= -1`

Recommended threshold: -1 (embedded in query)

Threshold justification: -1 indicates error state.

Evaluation interval: 60

Pending period: 120

Recovery period: 120

BlockedTransactions

Labels: DBInstanceIdentifier

Alarm description: Alarm when blocked transaction count exceeds the threshold for an RDS instance.

Intent: Detect transaction blocking causing performance degradation.

PromQL criteria: `avg({__name__="BlockedTransactions", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable blocked transaction count.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

BufferCacheHitRatio

Labels: DBInstanceIdentifier

Alarm description: Alarm when buffer cache hit ratio drops below 80% for an RDS instance.

Intent: Detect low cache efficiency causing performance decrease.

PromQL criteria: `avg({__name__="BufferCacheHitRatio", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) < 80`

Recommended threshold: 80 (embedded in query)

Threshold justification: Below 80% indicates excessive disk I/O.

Evaluation interval: 60

Pending period: 600

Recovery period: 600

EngineUptime

Labels: DBClusterIdentifier

Alarm description: Alarm when engine uptime drops to zero indicating an Aurora writer restart.

Intent: Detect Aurora writer instance downtime or crash.

PromQL criteria: `avg({__name__="EngineUptime", "@instrumentation.@name"="cloudwatch.aws/rds", DBClusterIdentifier="CLUSTER"}) <= 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Zero uptime indicates instance restart.

Evaluation interval: 60

Pending period: 120

Recovery period: 120

RollbackSegmentHistoryListLength

Labels: DBInstanceIdentifier

Alarm description: Alarm when rollback segment history list length exceeds 1 million for an Aurora instance.

Intent: Detect high rollback history causing CPU degradation.

PromQL criteria: `avg({__name__="RollbackSegmentHistoryListLength", "@instrumentation.@name"="cloudwatch.aws/rds", DBInstanceIdentifier="DB"}) > 1000000`

Recommended threshold: 1000000 (embedded in query)

Threshold justification: Above 1M causes performance issues.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

StorageNetworkThroughput

Labels: DBClusterIdentifier

Alarm description: Alarm when storage network throughput exceeds the threshold for an Aurora cluster.

Intent: Detect high throughput risking network packet drops.

PromQL criteria: `avg({__name__="StorageNetworkThroughput", "@instrumentation.@name"="cloudwatch.aws/rds", DBClusterIdentifier="CLUSTER"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on instance network capacity.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

Route 53

HealthCheckStatus

Labels: HealthCheckId

Alarm description: Alarm when a Route 53 health check reports an unhealthy endpoint.

Intent: Detect unhealthy endpoints by using Route 53 health checkers.

PromQL criteria: `avg({__name__="HealthCheckStatus", "@instrumentation.@name"="cloudwatch.aws/route53", HealthCheckId="HC"}) < 1`

Recommended threshold: 1 (embedded in query)

Threshold justification: Below 1 indicates endpoint is failing health checks.

Evaluation interval: 60

Pending period: 180

Recovery period: 180

S3

4xxErrors

Labels: BucketName, FilterId

Alarm description: Alarm when the 4xx error rate exceeds 5% for an S3 bucket.

Intent: Detect abnormal client error rates.

PromQL criteria: `avg({__name__="4xxErrors", "@instrumentation.@name"="cloudwatch.aws/s3", BucketName="BUCKET",FilterId="FILTER"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Above 5% indicates setup or access issues.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

5xxErrors

Labels: BucketName, FilterId

Alarm description: Alarm when the 5xx error rate exceeds 5% for an S3 bucket.

Intent: Detect server-side errors affecting application.

PromQL criteria: `avg({__name__="5xxErrors", "@instrumentation.@name"="cloudwatch.aws/s3", BucketName="BUCKET",FilterId="FILTER"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Above 5% indicates S3 service issues.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

OperationsFailedReplication

Labels: SourceBucket, DestinationBucket, RuleId

Alarm description: Alarm when S3 replication operations fail for a bucket.

Intent: Detect replication failures risking data inconsistency.

PromQL criteria: `max({__name__="OperationsFailedReplication", "@instrumentation.@name"="cloudwatch.aws/s3", SourceBucket="SRC",DestinationBucket="DST",RuleId="RULE"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any failed replication requires investigation.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

S3 Object Lambda

4xxErrors

Labels: AccessPointName, DataSourceARN

Alarm description: Alarm when the 4xx error rate exceeds 5% for an S3 Object Lambda access point.

Intent: Detect abnormal client error rates for Object Lambda.

PromQL criteria: `avg({__name__="4xxErrors", "@instrumentation.@name"="cloudwatch.aws/s3objectlambda", AccessPointName="AP",DataSourceARN="ARN"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Above 5% indicates setup issues.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

5xxErrors

Labels: AccessPointName, DataSourceARN

Alarm description: Alarm when the 5xx error rate exceeds 5% for an S3 Object Lambda access point.

Intent: Detect server-side errors in Object Lambda.

PromQL criteria: `avg({__name__="5xxErrors", "@instrumentation.@name"="cloudwatch.aws/s3objectlambda", AccessPointName="AP",DataSourceARN="ARN"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Above 5% indicates Lambda or S3 issues.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

LambdaResponse4xx

Labels: AccessPointName, DataSourceARN

Alarm description: Alarm when the Lambda function 4xx response rate exceeds 5% for an S3 Object Lambda access point.

Intent: Detect Lambda function client errors.

PromQL criteria: `avg({__name__="LambdaResponse4xx", "@instrumentation.@name"="cloudwatch.aws/s3objectlambda", AccessPointName="AP",DataSourceARN="ARN"}) > 0.05`

Recommended threshold: 0.05 (embedded in query)

Threshold justification: Above 5% indicates Lambda function issues.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

SNS

NumberOfMessagesPublished

Labels: TopicName

Alarm description: Alarm when the number of messages published drops below the threshold for an SNS topic.

Intent: Detect significant drop in publishing volume.

PromQL criteria: `sum({__name__="NumberOfMessagesPublished", "@instrumentation.@name"="cloudwatch.aws/sns", TopicName="TOPIC"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on minimum expected traffic.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

NumberOfNotificationsDelivered

Labels: TopicName

Alarm description: Alarm when the number of notifications delivered drops below the threshold for an SNS topic.

Intent: Detect drop in notification delivery volume.

PromQL criteria: `sum({__name__="NumberOfNotificationsDelivered", "@instrumentation.@name"="cloudwatch.aws/sns", TopicName="TOPIC"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on minimum expected deliveries.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

NumberOfNotificationsFailed

Labels: TopicName

Alarm description: Alarm when failed notification delivery count exceeds the threshold for an SNS topic.

Intent: Detect delivery failures.

PromQL criteria: `sum({__name__="NumberOfNotificationsFailed", "@instrumentation.@name"="cloudwatch.aws/sns", TopicName="TOPIC"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable failure rate.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

NumberOfNotificationsFilteredOut-InvalidAttributes

Labels: TopicName

Alarm description: Alarm when notifications are filtered out due to invalid message attributes.

Intent: Detect invalid message attributes.

PromQL criteria: `sum({__name__="NumberOfNotificationsFilteredOut-InvalidAttributes", "@instrumentation.@name"="cloudwatch.aws/sns", TopicName="TOPIC"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any invalid filter indicates misconfiguration.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

NumberOfNotificationsFilteredOut-InvalidMessageBody

Labels: TopicName

Alarm description: Alarm when notifications are filtered out due to invalid message bodies.

Intent: Detect invalid message bodies.

PromQL criteria: `sum({__name__="NumberOfNotificationsFilteredOut-InvalidMessageBody", "@instrumentation.@name"="cloudwatch.aws/sns", TopicName="TOPIC"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any invalid filter indicates misconfiguration.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

NumberOfNotificationsRedrivenToDlq

Labels: TopicName

Alarm description: Alarm when notifications are sent to the dead-letter queue for an SNS topic.

Intent: Detect messages sent to dead-letter queue.

PromQL criteria: `sum({__name__="NumberOfNotificationsRedrivenToDlq", "@instrumentation.@name"="cloudwatch.aws/sns", TopicName="TOPIC"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Any DLQ message indicates delivery issues.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

NumberOfNotificationsFailedToRedriveToDlq

Labels: TopicName

Alarm description: Alarm when notifications fail to be sent to the dead-letter queue for an SNS topic.

Intent: Detect DLQ delivery failures.

PromQL criteria: `sum({__name__="NumberOfNotificationsFailedToRedriveToDlq", "@instrumentation.@name"="cloudwatch.aws/sns", TopicName="TOPIC"}) > 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Failed DLQ means lost error tracking.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

SMSMonthToDateSpentUSD

Labels: TopicName

Alarm description: Alarm when SMS spending approaches the account quota for an SNS topic.

Intent: Detect SMS spend approaching quota.

PromQL criteria: `max({__name__="SMSMonthToDateSpentUSD", "@instrumentation.@name"="cloudwatch.aws/sns", TopicName="TOPIC"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on account SMS quota.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

SMSSuccessRate

Labels: TopicName

Alarm description: Alarm when the SMS delivery success rate drops below the threshold for an SNS topic.

Intent: Detect failing SMS deliveries.

PromQL criteria: `avg({__name__="SMSSuccessRate", "@instrumentation.@name"="cloudwatch.aws/sns", TopicName="TOPIC"}) < THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable delivery rate.

Evaluation interval: 60

Pending period: 300

Recovery period: 300

SQS

ApproximateAgeOfOldestMessage

Labels: QueueName

Alarm description: Alarm when the oldest message age exceeds the threshold for an SQS queue.

Intent: Detect messages not processed quickly enough.

PromQL criteria: `max({__name__="ApproximateAgeOfOldestMessage", "@instrumentation.@name"="cloudwatch.aws/sqs", QueueName="QUEUE"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on acceptable message processing time.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

ApproximateNumberOfMessagesNotVisible

Labels: QueueName

Alarm description: Alarm when the number of in-flight messages exceeds the threshold for an SQS queue.

Intent: Detect high in-flight messages indicating consumer issues.

PromQL criteria: `avg({__name__="ApproximateNumberOfMessagesNotVisible", "@instrumentation.@name"="cloudwatch.aws/sqs", QueueName="QUEUE"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on expected processing volume.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

ApproximateNumberOfMessagesVisible

Labels: QueueName

Alarm description: Alarm when the number of visible messages exceeds the threshold for an SQS queue.

Intent: Detect message backlog indicating slow consumers.

PromQL criteria: `avg({__name__="ApproximateNumberOfMessagesVisible", "@instrumentation.@name"="cloudwatch.aws/sqs", QueueName="QUEUE"}) > THRESHOLD`

Recommended threshold: *THRESHOLD* (embedded in query)

Threshold justification: Set based on expected queue depth.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

NumberOfMessagesSent

Labels: QueueName

Alarm description: Alarm when no messages are sent to an SQS queue.

Intent: Detect producers stopped sending messages.

PromQL criteria: `sum({__name__="NumberOfMessagesSent", "@instrumentation.@name"="cloudwatch.aws/sqs", QueueName="QUEUE"}) <= 0`

Recommended threshold: 0 (embedded in query)

Threshold justification: Zero messages indicates producer failure.

Evaluation interval: 60

Pending period: 900

Recovery period: 900

VPN

TunnelState (VPN level)

Labels: VpnId

Alarm description: Alarm when at least one VPN tunnel is in a DOWN state.

Intent: Detect at least one tunnel in DOWN state.

PromQL criteria: `min({__name__="TunnelState", "@instrumentation.@name"="cloudwatch.aws/vpn", VpnId="VPN"}) < 1`

Recommended threshold: 1 (embedded in query)

Threshold justification: Below 1 means tunnel is down.

Evaluation interval: 300

Pending period: 900

Recovery period: 900

TunnelState (Tunnel level)

Labels: TunnelIpAddress

Alarm description: Alarm when a specific VPN tunnel is in a DOWN state.

Intent: Detect specific tunnel in DOWN state.

PromQL criteria: `min({__name__="TunnelState", "@instrumentation.@name"="cloudwatch.aws/vpn", TunnelIpAddress="IP"}) < 1`

Recommended threshold: 1 (embedded in query)

Threshold justification: Below 1 means tunnel is down.

Evaluation interval: 300

Pending period: 900

Recovery period: 900

Recommended alarms (Classic)

The following sections list the metrics that we recommend that you set best practice alarms for. For each metric, the dimensions, alarm intent, recommended threshold, threshold justification, and the period length and number of datapoints is also displayed.

Some metrics might appear twice in the list. This happens when different alarms are recommended for different combinations of dimensions of that metric.

Datapoints to alarm is the number of data points that must be breaching to send the alarm into ALARM state. **Evaluation periods** is the number of periods that are taken into account when the alarm is evaluated. If these numbers are the same, the alarm goes into ALARM state only when that number of consecutive periods have values that breach the threshold. If **Datapoints to alarm** is lower than **Evaluation periods**, then it is an "M out of N" alarm and the alarm goes into ALARM state if at least **Datapoints to alarm** data points are breaching within any **Evaluation periods** set of data points. For more information, see Alarm evaluation.

Amazon API Gateway

4XXError

Dimensions: ApiName, Stage

Alarm description: This alarm detects a high rate of client-side errors. This can indicate an issue in the authorization or client request parameters. It could also mean that a resource was removed or a client is requesting one that doesn't exist. Consider enabling CloudWatch Logs and checking for any errors that may be causing the 4XX errors. Moreover, consider enabling

detailed CloudWatch metrics to view this metric per resource and method and narrow down the source of the errors. Errors could also be caused by exceeding the configured throttling limit. If the responses and logs are reporting high and unexpected rates of 429 errors, follow this guide to troubleshoot this issue.

Intent: This alarm can detect high rates of client-side errors for the API Gateway requests.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: The suggested threshold detects when more than 5% of total requests are getting 4XX errors. However, you can tune the threshold to suit the traffic of the requests as well as acceptable error rates. You can also analyze historical data to determine the acceptable error rate for the application workload and then tune the threshold accordingly. Frequently occurring 4XX errors need to be alarmed on. However, setting a very low value for the threshold can cause the alarm to be too sensitive.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

5XXError

Dimensions: ApiName, Stage

Alarm description: This alarm helps to detect a high rate of server-side errors. This can indicate that there is something wrong on the API backend, the network, or the integration between the API gateway and the backend API. This documentation can help you troubleshoot the cause of 5xx errors.

Intent: This alarm can detect high rates of server-side errors for the API Gateway requests.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: The suggested threshold detects when more than 5% of total requests are getting 5XX errors. However, you can tune the threshold to suit the traffic of the requests as

well as acceptable error rates. you can also analyze historical data to determine the acceptable error rate for the application workload and then tune the threshold accordingly. Frequently occurring 5XX errors need to be alarmed on. However, setting a very low value for the threshold can cause the alarm to be too sensitive.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: GREATER_THAN_THRESHOLD

Count

Dimensions: ApiName, Stage

Alarm description: This alarm helps to detect low traffic volume for the REST API stage. This can be an indicator of an issue with the application calling the API such as using incorrect endpoints. It could also be an indicator of an issue with the configuration or permissions of the API making it unreachable for clients.

Intent: This alarm can detect unexpectedly low traffic volume for the REST API stage. We recommend that you create this alarm if your API receives a predictable and consistent number of requests under normal conditions. If you have detailed CloudWatch metrics enabled and you can predict the normal traffic volume per method and resource, we recommend that you create alternative alarms to have more fine-grained monitoring of traffic volume drops for each resource and method. This alarm is not recommended for APIs that don't expect constant and consistent traffic.

Statistic: SampleCount

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold based on historical data analysis to determine what the expected baseline request count for your API is. Setting the threshold at a very high value might cause the alarm to be too sensitive at periods of normal and expected low traffic. Conversely, setting it at a very low value might cause the alarm to miss anomalous smaller drops in traffic volume.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

Count

Dimensions: ApiName, Stage, Resource, Method

Alarm description: This alarm helps to detect low traffic volume for the REST API resource and method in the stage. This can indicate an issue with the application calling the API such as using incorrect endpoints. It could also be an indicator of an issue with the configuration or permissions of the API making it unreachable for clients.

Intent: This alarm can detect unexpectedly low traffic volume for the REST API resource and method in the stage. We recommend that you create this alarm if your API receives a predictable and consistent number of requests under normal conditions. This alarm is not recommended for APIs that don't expect constant and consistent traffic.

Statistic: SampleCount

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold based on historical data analysis to determine what the expected baseline request count for your API is. Setting the threshold at a very high value might cause the alarm to be too sensitive at periods of normal and expected low traffic. Conversely, setting it at a very low value might cause the alarm to miss anomalous smaller drops in traffic volume.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

Count

Dimensions: ApiId, Stage

Alarm description: This alarm helps to detect low traffic volume for the HTTP API stage. This can indicate an issue with the application calling the API such as using incorrect endpoints. It

could also be an indicator of an issue with the configuration or permissions of the API making it unreachable for clients.

Intent: This alarm can detect unexpectedly low traffic volume for the HTTP API stage. We recommend that you create this alarm if your API receives a predictable and consistent number of requests under normal conditions. If you have detailed CloudWatch metrics enabled and you can predict the normal traffic volume per route, we recommend that you create alternative alarms to this in order to have more fine-grained monitoring of traffic volume drops for each route. This alarm is not recommended for APIs that don't expect constant and consistent traffic.

Statistic: SampleCount

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold value based on historical data analysis to determine what the expected baseline request count for your API is. Setting the threshold at a very high value might cause the alarm to be too sensitive at periods of normal and expected low traffic. Conversely, setting it at a very low value might cause the alarm to miss anomalous smaller drops in traffic volume.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

Count

Dimensions: ApiId, Stage, Resource, Method

Alarm description: This alarm helps to detect low traffic volume for the HTTP API route in the stage. This can indicate an issue with the application calling the API such as using incorrect endpoints. It could also indicate an issue with the configuration or permissions of the API making it unreachable for clients.

Intent: This alarm can detect unexpectedly low traffic volume for the HTTP API route in the stage. We recommend that you create this alarm if your API receives a predictable and consistent number of requests under normal conditions. This alarm is not recommended for APIs that don't expect constant and consistent traffic.

Statistic: SampleCount

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold value based on historical data analysis to determine what the expected baseline request count for your API is. Setting the threshold at a very high value might cause the alarm to be too sensitive at periods of normal and expected low traffic. Conversely, setting it at a very low value might cause the alarm to miss anomalous smaller drops in traffic volume.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

IntegrationLatency

Dimensions: ApiId, Stage

Alarm description: This alarm helps to detect if there is high integration latency for the API requests in a stage. You can correlate the `IntegrationLatency` metric value with the corresponding latency metric of your backend such as the `Duration` metric for Lambda integrations. This helps you determine whether the API backend is taking more time to process requests from clients due to performance issues, or if there is some other overhead from initialization or cold start. Additionally, consider enabling CloudWatch Logs for your API and checking the logs for any errors that may be causing the high latency issues. Moreover, consider enabling detailed CloudWatch metrics to get a view of this metric per route, to help you narrow down the source of the integration latency.

Intent: This alarm can detect when the API Gateway requests in a stage have a high integration latency. We recommend this alarm for WebSocket APIs, and it is considered optional for HTTP APIs because they already have separate alarm recommendations for the Latency metric. If you have detailed CloudWatch metrics enabled and you have different integration latency performance requirements per route, we recommend that you create alternative alarms in order to have more fine-grained monitoring of the integration latency for each route.

Statistic: p90

Recommended threshold: 2000.0

Threshold justification: The suggested threshold value does not work for all the API workloads. However, you can use it as a starting point for the threshold. You can then choose different threshold values based on the workload and acceptable latency, performance, and SLA requirements for the API. If is acceptable for the API to have a higher latency in general, set a higher threshold value to make the alarm less sensitive. However, if the API is expected to provide near real-time responses, set a lower threshold value. You can also analyze historical data to determine the expected baseline latency for the application workload, and then used to tune the threshold value accordingly.

Period: 60

Evaluation periods: 5

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

IntegrationLatency

Dimensions: ApiId, Stage, Route

Alarm description: This alarm helps to detect if there is high integration latency for the WebSocket API requests for a route in a stage. You can correlate the `IntegrationLatency` metric value with the corresponding latency metric of your backend such as the `Duration` metric for Lambda integrations. This helps you determine whether the API backend is taking more time to process requests from clients due to performance issues or if there is some other overhead from initialization or cold start. Additionally, consider enabling CloudWatch Logs for your API and checking the logs for any errors that may be causing the high latency issues.

Intent: This alarm can detect when the API Gateway requests for a route in a stage have high integration latency.

Statistic: p90

Recommended threshold: 2000.0

Threshold justification: The suggested threshold value does not work for all the API workloads. However, you can use it as a starting point for the threshold. You can then choose different threshold values based on the workload and acceptable latency, performance, and SLA requirements for the API. If it is acceptable for the API to have a higher latency in general, you can set a higher threshold value to make the alarm less sensitive. However, if the API is

expected to provide near real-time responses, set a lower threshold value. You can also analyze historical data to determine the expected baseline latency for the application workload, and then used to tune the threshold value accordingly.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

Latency

Dimensions: ApiName, Stage

Alarm description: This alarm detects high latency in a stage. Find the `IntegrationLatency` metric value to check the API backend latency. If the two metrics are mostly aligned, the API backend is the source of higher latency and you should investigate there for issues. Consider also enabling CloudWatch Logs and checking for errors that might be causing the high latency. Moreover, consider enabling detailed CloudWatch metrics to view this metric per resource and method and narrow down the source of the latency. If applicable, refer to the troubleshooting with Lambda or troubleshooting for edge-optimized API endpoints guides.

Intent: This alarm can detect when the API Gateway requests in a stage have high latency. If you have detailed CloudWatch metrics enabled and you have different latency performance requirements for each method and resource, we recommend that you create alternative alarms to have more fine-grained monitoring of the latency for each resource and method.

Statistic: p90

Recommended threshold: 2500.0

Threshold justification: The suggested threshold value does not work for all API workloads. However, you can use it as a starting point for the threshold. You can then choose different threshold values based on the workload and acceptable latency, performance, and SLA requirements for the API. If it is acceptable for the API to have a higher latency in general, you can set a higher threshold value to make the alarm less sensitive. However, if the API is expected to provide near real-time responses, set a lower threshold value. Amazon EC2 Auto Scaling

GroupInServiceCapacity

Dimensions: AutoScalingGroupName

Alarm description: This alarm helps to detect when the capacity in the group is below the desired capacity required for your workload. To troubleshoot, check your scaling activities for launch failures and confirm that your desired capacity configuration is correct.

Intent: This alarm can detect a low availability in your auto scaling group because of launch failures or suspended launches.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The threshold value should be the minimum capacity required to run your workload. In most cases, you can set this to match the GroupDesiredCapacity metric.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

AWS Certificate Manager (ACM)

DaysToExpiry

Dimensions: CertificateArn

Alarm description: This alarm helps you detect when a certificate managed by or imported into ACM is approaching its expiration date. It helps to prevent unexpected certificate expirations that could lead to service disruptions. When the alarm transitions into ALARM state, you should take immediate action to renew or re-import the certificate. For ACM-managed certificates, see the instructions at certificate renewal process. For imported certificates, see the instructions at re-import process.

Intent: This alarm can proactively alert you about upcoming certificate expirations. It provides sufficient advance notice to allow for manual intervention, enabling you to renew or replace certificates before they expire. This helps you maintain the security and availability of TLS-enabled services. When this goes into ALARM, immediately investigate the certificate status and initiate the renewal process if necessary.

Statistic: Minimum

Recommended threshold: 44.0

Threshold justification: The 44-day threshold provides a balance between early warning and avoiding false alarms. It allows sufficient time for manual intervention if automatic renewal fails. Adjust this value based on your certificate renewal process and operational response times.

Period: 86400

Datapoints to alarm: 1

Evaluation periods: 1

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

Amazon CloudFront

5xxErrorRate

Dimensions: DistributionId, Region=Global

Alarm description: This alarm monitors the percentage of 5xx error responses from your origin server, to help you detect if the CloudFront service is having issues. See Troubleshooting error responses from your origin for information to help you understand the problems with your server. Also, turn on additional metrics to get detailed error metrics.

Intent: This alarm is used to detect problems with serving requests from the origin server, or problems with communication between CloudFront and your origin server.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the tolerance for 5xx responses. You can analyze historical data and trends, and then set the threshold accordingly. Because 5xx errors can be caused by transient issues, we recommend that you set the threshold to a value greater than 0 so that the alarm is not too sensitive.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

OriginLatency

Dimensions: DistributionId, Region=Global

Alarm description: The alarm helps to monitor if the origin server is taking too long to respond. If the server takes too long to respond, it might lead to a timeout. Refer to find and fix delayed responses from applications on your origin server if you experience consistently high `OriginLatency` values.

Intent: This alarm is used to detect problems with the origin server taking too long to respond.

Statistic: p90

Recommended threshold: Depends on your situation

Threshold justification: You should calculate the value of about 80% of the origin response timeout, and use the result as the threshold value. If this metric is consistently close to the origin response timeout value, you might start experiencing 504 errors.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

FunctionValidationErrors

Dimensions: DistributionId, FunctionName, Region=Global

Alarm description: This alarm helps you monitor validation errors from CloudFront functions so that you can take steps to resolve them. Analyze the CloudWatch function logs and look at the function code to find and resolve the root cause of the problem. See Restrictions on edge functions to understand the common misconfigurations for CloudFront Functions.

Intent: This alarm is used to detect validation errors from CloudFront functions.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: A value greater than 0 indicates a validation error. We recommend setting the threshold to 0 because validation errors imply a problem when CloudFront functions hand off back to CloudFront. For example, CloudFront needs the HTTP Host header to process a request. There is nothing stopping a user from deleting the Host header in their CloudFront functions code. But when CloudFront gets the response back and the Host header is missing, CloudFront throws a validation error.

Period: 60

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: GREATER_THAN_THRESHOLD

FunctionExecutionErrors

Dimensions: DistributionId, FunctionName, Region=Global

Alarm description: This alarm helps you monitor execution errors from CloudFront functions so that you can take steps to resolve them. Analyze the CloudWatch function logs and look at the function code to find and resolve the root cause of the problem.

Intent: This alarm is used to detect execution errors from CloudFront functions.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: We recommend to set the threshold to 0 because an execution error indicates a problem with the code that occurs at runtime.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

FunctionThrottles

Dimensions: DistributionId, FunctionName, Region=Global

Alarm description: This alarm helps you to monitor if your CloudFront function is throttled. If your function is throttled, it means that it is taking too long to execute. To avoid function throttles, consider optimizing the function code.

Intent: This alarm can detect when your CloudFront function is throttled so that you can react and resolve the issue for a smooth customer experience.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: We recommend setting the threshold to 0, to allow quicker resolution of the function throttles.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon Cognito

SignUpThrottles

Dimensions: UserPool, UserPoolClient

Alarm description: This alarm monitors the count of throttled requests. If users are consistently getting throttled, you should increase the limit by requesting a service quota increase. Refer to Quotas in Amazon Cognito to learn how to request a quota increase. To take actions proactively, consider tracking the usage quota.

Intent: This alarm helps to monitor the occurrence of throttled sign-up requests. This can help you know when to take actions to mitigate any degradation in sign-up experience. Sustained throttling of requests is a negative user sign-up experience.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: A well-provisioned user pool should not encounter any throttling which spans across multiple data points. So, a typical threshold for an expected workload should be zero. For an irregular workload with frequent bursts, you can analyze historical data to determine the acceptable throttling for the application workload, and then you can tune the threshold accordingly. A throttled request should be retried to minimize the impact on the application.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

SignInThrottles

Dimensions: UserPool, UserPoolClient

Alarm description: This alarm monitors the count of throttled user authentication requests. If users are consistently getting throttled, you might need to increase the limit by requesting a service quota increase. Refer to Quotas in Amazon Cognito to learn how to request a quota increase. To take actions proactively, consider tracking the usage quota.

Intent: This alarm helps to monitor the occurrence of throttled sign-in requests. This can help you know when to take actions to mitigate any degradation in sign-in experience. Sustained throttling of requests is a bad user authentication experience.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: A well-provisioned user pool should not encounter any throttling which spans across multiple data points. So, a typical threshold for an expected workload should be zero. For an irregular workload with frequent bursts, you can analyze historical data to determine the acceptable throttling for the application workload, and then you can tune the threshold accordingly. A throttled request should be retried to minimize the impact on the application.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TokenRefreshThrottles

Dimensions: UserPool, UserPoolClient

Alarm description: You can set the threshold value can to suit the traffic of the request as well as to match acceptable throttling for token refresh requests. Throttling is used to protect your system from too many requests. However, it is important to monitor if you are under provisioned for your normal traffic as well. You can analyze historical data to find the acceptable throttling for the application workload, and then you can tune your alarm threshold to be higher than your acceptable throttling level. Throttled requests should be retried by the

application/service as they are transient. Therefore, a very low value for the threshold can cause alarm to be sensitive.

Intent: This alarm helps to monitor the occurrence of throttled token refresh requests. This can help you know when to take actions to mitigate any potential problems, to make sure a smooth user experience and the health and reliability of your authentication system. Sustained throttling of requests is a bad user authentication experience.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Threshold value can also be set/tuned to suit the traffic of the request as well as acceptable throttling for token refresh requests. Throttling are there for protecting your system from too many requests, however it is important to monitor if you are under provisioned for your normal traffic as well and see if it is causing the impact. Historical data can also be analyzed to see what is the acceptable throttling for the application workload and threshold can be tuned higher than your usual acceptable throttling level. Throttled requests should be retried by the application/service as they are transient. Therefore, a very low value for the threshold can cause alarm to be sensitive.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

FederationThrottles

Dimensions: UserPool, UserPoolClient, IdentityProvider

Alarm description: This alarm monitors the count of throttled identity federation requests. If you consistently see throttling, it might indicate that you need to increase the limit by requesting a service quota increase. Refer to Quotas in Amazon Cognito to learn how to request a quota increase.

Intent: This alarm helps to monitor the occurrence of throttled identity federation requests. This can help you take proactive responses to performance bottlenecks or misconfigurations, and make sure a smooth authentication experience for your users. Sustained throttling of requests is a bad user authentication experience.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: You can set the threshold to suit the traffic of the request as well as to match the acceptable throttling for identity federation requests. Throttling is used for protecting your system from too many requests. However, it is important to monitor if you are under provisioned for your normal traffic as well. You can analyze historical data to find the acceptable throttling for the application workload, and then set the threshold to a value above your acceptable throttling level. Throttled requests should be retried by the application/service as they are transient. Therefore, a very low value for the threshold can cause alarm to be sensitive.

Amazon DynamoDB

AccountProvisionedReadCapacityUtilization

Dimensions: None

Alarm description: This alarm detects if the account's read capacity is reaching its provisioned limit. You can raise the account quota for read capacity utilization if this occurs. You can view your current quotas for read capacity units and request increases using Service Quotas.

Intent: The alarm can detect if the account's read capacity utilization is approaching its provisioned read capacity utilization. If the utilization reaches its maximum limit, DynamoDB starts to throttle read requests.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: Set the threshold to 80%, so that action (such as raising the account limits) can be taken before it reaches full capacity to avoid throttling.

Period: 300

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: GREATER_THAN_THRESHOLD

AccountProvisionedWriteCapacityUtilization

Dimensions: None

Alarm description: This alarm detects if the account's write capacity is reaching its provisioned limit. You can raise the account quota for write capacity utilization if this occurs. You can view your current quotas for write capacity units and request increases using Service Quotas.

Intent: This alarm can detect if the account's write capacity utilization is approaching its provisioned write capacity utilization. If the utilization reaches its maximum limit, DynamoDB starts to throttle write requests.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: Set the threshold to 80%, so that the action (such as raising the account limits) can be taken before it reaches full capacity to avoid throttling.

Period: 300

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: GREATER_THAN_THRESHOLD

AgeOfOldestUnreplicatedRecord

Dimensions: TableName, DelegatedOperation

Alarm description: This alarm detects the delay in replication to a Kinesis data stream. Under normal operation, `AgeOfOldestUnreplicatedRecord` should be only milliseconds. This number grows based on unsuccessful replication attempts caused by customer-controlled configuration choices. Customer-controlled configuration examples that lead to unsuccessful replication attempts are an under-provisioned Kinesis data stream capacity that leads to

excessive throttling. or a manual update to the Kinesis data stream's access policies that prevents DynamoDB from adding data to the data stream. To keep this metric as low as possible, you need to make sure the right provisioning of Kinesis data stream capacity and make sure that DynamoDB's permissions are unchanged.

Intent: This alarm can monitor unsuccessful replication attempts and the resulting delay in replication to the Kinesis data stream.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the desired replication delay measured in milliseconds. This value depends on your workload's requirements and expected performance.

Period: 300

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: GREATER_THAN_THRESHOLD

FailedToReplicateRecordCount

Dimensions: TableName, DelegatedOperation

Alarm description: This alarm detects the number of records that DynamoDB failed to replicate to your Kinesis data stream. Certain items larger than 34 KB might expand in size to change data records that are larger than the 1 MB item size limit of Kinesis Data Streams. This size expansion occurs when these larger than 34 KB items include a large number of Boolean or empty attribute values. Boolean and empty attribute values are stored as 1 byte in DynamoDB, but expand up to 5 bytes when they're serialized using standard JSON for Kinesis Data Streams replication. DynamoDB can't replicate such change records to your Kinesis data stream. DynamoDB skips these change data records, and automatically continues replicating subsequent records.

Intent: This alarm can monitor the number of records that DynamoDB failed to replicate to your Kinesis data stream because of the item size limit of Kinesis Data Streams.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Set the threshold to 0 to detect any records that DynamoDB failed to replicate.

Period: 60

Datapoints to alarm: 1

Evaluation periods: 1

Comparison Operator: GREATER_THAN_THRESHOLD

ReadThrottleEvents

Dimensions: TableName

Alarm description: This alarm detects if there are high number of read requests getting throttled for the DynamoDB table. To troubleshoot the issue, see Troubleshooting throttling issues in Amazon DynamoDB.

Intent: This alarm can detect sustained throttling for read requests to the DynamoDB table. Sustained throttling of read requests can negatively impact your workload read operations and reduce the overall efficiency of the system.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected read traffic for the DynamoDB table, accounting for an acceptable level of throttling. It is important to monitor whether you are under provisioned and not causing consistent throttling. You can also analyze historical data to find the acceptable throttling level for the application workload, and then tune the threshold to be higher than your usual throttling level. Throttled requests should be retried by the application or service as they are transient. Therefore, a very low threshold may cause the alarm to be too sensitive, causing unwanted state transitions.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReadThrottleEvents

Dimensions: TableName, GlobalSecondaryIndexName

Alarm description: This alarm detects if there are a high number of read requests getting throttled for the Global Secondary Index of the DynamoDB table. To troubleshoot the issue, see Troubleshooting throttling issues in Amazon DynamoDB.

Intent: The alarm can detect sustained throttling for read requests for the Global Secondary Index of the DynamoDB Table. Sustained throttling of read requests can negatively impact your workload read operations and reduce the overall efficiency of the system.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected read traffic for the DynamoDB table, accounting for an acceptable level of throttling. It is important to monitor if you are under provisioned and not causing consistent throttling. You can also analyze historical data to find an acceptable throttling level for the application workload, and then tune the threshold to be higher than your usual acceptable throttling level. Throttled requests should be retried by the application or service as they are transient. Therefore, a very low threshold may cause the alarm to be too sensitive, causing unwanted state transitions.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReplicationLatency

Dimensions: TableName, ReceivingRegion

Alarm description: The alarm detects if the replica in a Region for the global table is lagging behind the source Region. The latency can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region. If you are using 2017.11.29 (Legacy) of global tables, you should verify that write capacity units (WCUs) are identical for

each of the replica tables. You can also make sure to follow recommendations in Best practices and requirements for managing capacity.

Intent: The alarm can detect if the replica table in a Region is falling behind replicating the changes from another Region. This could cause your replica to diverge from the other replicas. It's useful to know the replication latency of each AWS Region and alert if that replication latency increases continually. The replication of the table applies to global tables only.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on your use case. Replication latencies longer than 3 minutes are generally a cause for investigation. Review the criticality and requirements of replication delay and analyze historical trends, and then select the threshold accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

SuccessfulRequestLatency

Dimensions: TableName, Operation

Alarm description: This alarm detects a high latency for the DynamoDB table operation (indicated by the dimension value of the `Operation` in the alarm). See this troubleshooting document for troubleshooting latency issues in Amazon DynamoDB.

Intent: This alarm can detect a high latency for the DynamoDB table operation. Higher latency for the operations can negatively impact the overall efficiency of the system.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: DynamoDB provides single-digit millisecond latency on average for singleton operations such as GetItem, PutItem, and so on. However, you can set the threshold based on acceptable tolerance for the latency for the type of operation and table involved in

the workload. You can analyze historical data of this metric to find the usual latency for the table operation, and then set the threshold to a number which represents critical delay for the operation.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

SystemErrors

Dimensions: TableName

Alarm description: This alarm detects a sustained high number of system errors for the DynamoDB table requests. If you continue to get 5xx errors, open the AWS Service Health Dashboard to check for operational issues with the service. You can use this alarm to get notified in case there is a prolonged internal service issue from DynamoDB and it helps you correlate with the issue your client application is facing. Refer Error handling for DynamoDB for more information.

Intent: This alarm can detect sustained system errors for the DynamoDB table requests. System errors indicate internal service errors from DynamoDB and helps correlate to the issue that the client is having.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected traffic, accounting for an acceptable level of system errors. You can also analyze historical data to find the acceptable error count for the application workload, and then tune the threshold accordingly. System errors should be retried by the application/service as they are transient. Therefore, a very low threshold might cause the alarm to be too sensitive, causing unwanted state transitions.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

ThrottledPutRecordCount

Dimensions: TableName, DelegatedOperation

Alarm description: This alarm detects the records getting throttled by your Kinesis data stream during the replication of change data capture to Kinesis. This throttling happens because of insufficient Kinesis data stream capacity. If you experience excessive and regular throttling, you might need to increase the number of Kinesis stream shards proportionally to the observed write throughput of your table. To learn more about determining the size of a Kinesis data stream, see Determining the Initial Size of a Kinesis Data Stream.

Intent: This alarm can monitor the number of records that that were throttled by your Kinesis data stream because of insufficient Kinesis data stream capacity.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: You might experience some throttling during exceptional usage peaks. However, throttled records should remain as low as possible to avoid higher replication latency (DynamoDB retries sending throttled records to the Kinesis data stream). Set the threshold to a number which can help you catch regular excessive throttling. You can also analyze historical data of this metric to find the acceptable throttling rates for the application workload. Tune the threshold to a value that the application can tolerate based on your use case.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

UserErrors

Dimensions: None

Alarm description: This alarm detects a sustained high number of user errors for the DynamoDB table requests. You can check client application logs during the issue time frame to see why the requests are invalid. You can check HTTP status code 400 to see the type of error

you are getting and take action accordingly. You might have to fix the application logic to create valid requests.

Intent: This alarm can detect sustained user errors for the DynamoDB table requests. User errors for requested operations mean that the client is producing invalid requests and it is failing.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to zero to detect any client side errors. Or you can set it to a higher value if you want to avoid the alarm triggering for a very lower number of errors. Decide based on your use case and traffic for the requests.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

WriteThrottleEvents

Dimensions: TableName

Alarm description: This alarm detects if there are a high number of write requests getting throttled for the DynamoDB table. See Troubleshooting throttling issues in Amazon DynamoDB to troubleshoot the issue.

Intent: This alarm can detect sustained throttling for write requests to the DynamoDB table. Sustained throttling of write requests can negatively impact your workload write operations and reduce the overall efficiency of the system.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected write traffic for the DynamoDB table, accounting for an acceptable level of throttling. It is important to monitor if you are under provisioned and not causing consistent throttling. You can also analyze

historical data to find the acceptable level of throttling for the application workload, and then tune the threshold to a value higher than your usual acceptable throttling level. Throttled requests should be retried by the application/service as they are transient. Therefore, a very low threshold might cause the alarm to be too sensitive, causing unwanted state transitions.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

WriteThrottleEvents

Dimensions: TableName, GlobalSecondaryIndexName

Alarm description: This alarm detects if there are a high number of write requests getting throttled for Global Secondary Index of the DynamoDB table. See Troubleshooting throttling issues in Amazon DynamoDB to troubleshoot the issue.

Intent: This alarm can detect sustained throttling for write requests for the Global Secondary Index of DynamoDB Table. Sustained throttling of write requests can negatively impact your workload write operations and reduce the overall efficiency of the system.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected Write traffic for the DynamoDB table, accounting for an acceptable level of throttling. It is important to monitor if you are under provisioned and not causing consistent throttling. You can also analyze historical data to find the acceptable throttling level for the application workload, and then tune the threshold to a value higher than your usual acceptable throttling level. Throttled requests should be retried by the application/service as they are transient. Therefore, a very low value might cause the alarm to be too sensitive, causing unwanted state transitions.

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon EBS

VolumeStalledIOCheck

Dimensions: VolumeId, InstanceId

Alarm description: This alarm helps you monitor the IO performance of your Amazon EBS volumes. This check detects underlying issues with the Amazon EBS infrastructure, such as hardware or software issues on the storage subsystems underlying the Amazon EBS volumes, hardware issues on the physical host that impact the reachability of the Amazon EBS volumes from your Amazon EC2 instance, and can detect connectivity issues between the instance and the Amazon EBS volumes. If the Stalled IO Check fails, you can either wait for AWS to resolve the issue, or you can take action such as replacing the affected volume or stopping and restarting the instance to which the volume is attached. In most cases, when this metric fails, Amazon EBS will automatically diagnose and recover your volume within a few minutes.

Intent: This alarm can detect the status of your Amazon EBS volumes to determine when these volumes are impaired and can not complete I/O operations.

Statistic: Maximum

Recommended threshold: 1.0

Threshold justification: When a status check fails, the value of this metric is 1. The threshold is set so that whenever the status check fails, the alarm is in ALARM state.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

Amazon EC2

CPUUtilization

Dimensions: InstanceId

Alarm description: This alarm helps to monitor the CPU utilization of an EC2 instance. Depending on the application, consistently high utilization levels might be normal. But if performance is degraded, and the application is not constrained by disk I/O, memory, or network resources, then a maxed-out CPU might indicate a resource bottleneck or application performance problems. High CPU utilization might indicate that an upgrade to a more CPU intensive instance is required. If detailed monitoring is enabled, you can change the period to 60 seconds instead of 300 seconds. For more information, see Enable or turn off detailed monitoring for your instances.

Intent: This alarm is used to detect high CPU utilization.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Typically, you can set the threshold for CPU utilization to 70-80%. However, you can adjust this value based on your acceptable performance level and workload characteristics. For some systems, consistently high CPU utilization may be normal and not indicate a problem, while for others, it may be cause of concern. Analyze historical CPU utilization data to identify the usage, find what CPU utilization is acceptable for your system, and set the threshold accordingly.

Period: 300

Evaluation periods: 3

Comparison Operator: GREATER_THAN_THRESHOLD

StatusCheckFailed

Dimensions: InstanceId

Alarm description: This alarm helps to monitor both system status checks and instance status checks. If either type of status check fails, then this alarm should be in ALARM state.

Intent: This alarm is used to detect the underlying problems with instances, including both system status check failures and instance status check failures.

Statistic: Maximum

Recommended threshold: 1.0

Threshold justification: When a status check fails, the value of this metric is 1. The threshold is set so that whenever the status check fails, the alarm is in ALARM state.

Period: 300

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

StatusCheckFailed_AttachedEBS

Dimensions: InstanceId

Alarm description: This alarm helps you monitor whether the Amazon EBS volumes attached to an instance are reachable and able to complete I/O operations. This status check detects underlying issues with the compute or Amazon EBS infrastructure such as the following:

- Hardware or software issues on the storage subsystems underlying the Amazon EBS volumes
- Hardware issues on the physical host that impact reachability of the Amazon EBS volumes
- Connectivity issues between the instance and Amazon EBS volumes

When the attached EBS status check fails, you can either wait for Amazon to resolve the issue, or you can take an action such as replacing the affected volumes or stopping and restarting the instance.

Intent: This alarm is used to detect unreachable Amazon EBS volumes attached to an instance. These can cause failures in I/O operations.

Statistic: Maximum

Recommended threshold: 1.0

Threshold justification: When a status check fails, the value of this metric is 1. The threshold is set so that whenever the status check fails, the alarm is in ALARM state.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

Amazon ElastiCache

CPUUtilization

Dimensions: CacheClusterId, CacheNodeId

Alarm description: This alarm helps to monitor the CPU utilization for the entire ElastiCache instance, including the database engine processes and other processes running on the instance. AWS Elasticache supports two engine types: Memcached and Redis OSS. When you reach high CPU utilization on a Memcached node, you should consider scaling up your instance type or adding new cache nodes. For Redis OSS, if your main workload is from read requests, you should consider adding more read replicas to your cache cluster. If your main workload is from write requests, you should consider adding more shards to distribute the workload across more primary nodes if you're running in clustered mode, or scaling up your instance type if you're running Redis OSS in non-clustered mode.

Intent: This alarm is used to detect high CPU utilization of ElastiCache hosts. It is useful to get a broad view of the CPU usage across the entire instance, including non-engine processes.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to the percentage that reflects a critical CPU utilization level for your application. For Memcached, the engine can use up to num_threads cores. For Redis OSS, the engine is largely single-threaded, but might use additional cores if available to accelerate I/O. In most cases, you can set the threshold to about 90% of your available CPU. Because Redis OSS is single-threaded, the actual threshold value should be calculated as a fraction of the node's total capacity.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

CurrConnections

Dimensions: CacheClusterId, CacheNodeId

Alarm description: This alarm detects high connection count, which might indicate heavy load or performance issues. A constant increase of `CurrConnections` might lead to exhaustion of the 65,000 available connections. It may indicate that connections improperly closed on the application side and were left established on the server side. You should consider using connection pooling or idle connection timeouts to limit the number of connections made to the cluster, or for Redis OSS, consider tuning tcp-keepalive on your cluster to detect and terminate potential dead peers.

Intent: The alarm helps you identify high connection counts that could impact the performance and stability of your ElastiCache cluster.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the acceptable range of connections for your cluster. Review the capacity and the expected workload of your ElastiCache cluster and analyze the historical connection counts during regular usage to establish a baseline, and then select a threshold accordingly. Remember that each node can support up to 65,000 concurrent connections.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

DatabaseMemoryUsagePercentage

Dimensions: CacheClusterId

Alarm description: This alarm helps you monitor the memory utilization of your cluster. When your `DatabaseMemoryUsagePercentage` reaches 100%, the Redis OSS maxmemory policy is triggered and evictions might occur based on the policy selected. If no object in the cache matches the eviction policy, write operations fail. Some workloads expect or rely on evictions,

but if not, you will need to increase the memory capacity of your cluster. You can scale your cluster out by adding more primary nodes, or scale it up by using a larger node type. Refer to Scaling ElastiCache for Redis OSS clusters for details.

Intent: This alarm is used to detect high memory utilization of your cluster so that you can avoid failures when writing to your cluster. It is useful to know when you'll need to scale up your cluster if your application does not expect to experience evictions.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Depending on your application's memory requirements and the memory capacity of your ElastiCache cluster, you should set the threshold to the percentage that reflects the critical level of memory usage of the cluster. You can use historical memory usage data as reference for acceptable memory usage threshold.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

EngineCPUUtilization

Dimensions: CacheClusterId

Alarm description: This alarm helps to monitor the CPU utilization of a Redis OSS engine thread within the ElastiCache instance. Common reasons for high engine CPU are long-running commands that consume high CPU, a high number of requests, an increase of new client connection requests in a short time period, and high evictions when the cache doesn't have enough memory to hold new data. You should consider Scaling ElastiCache for Redis OSS clusters by adding more nodes or scaling up your instance type.

Intent: This alarm is used to detect high CPU utilization of the Redis OSS engine thread. It is useful if you want to monitor the CPU usage of the database engine itself.

Statistic: Average

Recommended threshold: 90.0

Threshold justification: Set the threshold to a percentage that reflects the critical engine CPU utilization level for your application. You can benchmark your cluster using your application and expected workload to correlate EngineCPUUtilization and performance as a reference, and then set the threshold accordingly. In most cases, you can set the threshold to about 90% of your available CPU.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReplicationLag

Dimensions: CacheClusterId

Alarm description: This alarm helps to monitor the replication health of your ElastiCache cluster. A high replication lag means that the primary node or the replica can't keep up the pace of the replication. If your write activity is too high, consider scaling your cluster out by adding more primary nodes, or scaling it up by using a larger node type. Refer to Scaling ElastiCache for Redis OSS clusters for details. If your read replicas are overloaded by the amount of read requests, consider adding more read replicas.

Intent: This alarm is used to detect a delay between data updates on the primary node and their synchronization to replica node. It helps to make sure data consistency of a read replica cluster node.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to your application's requirements and the potential impact of replication lag. You should consider your application's expected write rates and network conditions for the acceptable replication lag.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon ECS

The following are the recommended alarms for Amazon ECS.

CPUReservation

Dimensions: ClusterName

Alarm description: This alarm helps you detect a high CPU reservation of the ECS cluster. High CPU reservation might indicate that the cluster is running out of registered CPUs for the task. To troubleshoot, you can add more capacity, you can scale the cluster, or you can set up auto scaling.

Intent: The alarm is used to detect whether the total number of CPU units reserved by tasks on the cluster is reaching the total CPU units registered for the cluster. This helps you know when to scale up the cluster. Reaching the total CPU units for the cluster can result in running out of CPU for tasks. If you have EC2 capacity providers managed scaling turned on, or you have associated Fargate to capacity providers, then this alarm is not recommended.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold for CPU reservation to 80%. Alternatively, you can choose a lower value based on cluster characteristics.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

CPUUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a high CPU utilization of the ECS service. If there is no ongoing ECS deployment, a maxed-out CPU utilization might indicate a resource

bottleneck or application performance problems. To troubleshoot, you can increase the CPU limit.

Intent: This alarm is used to detect high CPU utilization for the Amazon ECS service. Consistent high CPU utilization can indicate a resource bottleneck or application performance problems.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: The service metrics for CPU utilization might exceed 100% utilization. However, we recommend that you monitor the metric for high CPU utilization to avoid impacting other services. Set the threshold to about 80-85%. We recommend that you update your task definitions to reflect actual usage to prevent future issues with other services.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

EBSFilesystemUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect high storage utilization of the Amazon EBS volume attached to Amazon ECS tasks. If the utilization of the Amazon EBS volume is consistently high, you can check the usage and increase the volume size for new tasks.

Intent: This alarm is used to detect high storage utilization of the Amazon EBS volumes attached to Amazon ECS tasks. Consistently high storage utilization can indicate that the Amazon EBS volume is full and it might lead to failure of the container.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: You can set the threshold for Amazon EBS file system utilization to about 80%. You can adjust this value based on the acceptable storage utilization. For a read-only snapshot volume, a high utilization might indicate that the volume is right sized. For an

active data volume, high storage utilization might indicate that the application is writing a large amount of data which may cause the container to fail if there is not enough capacity.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

MemoryReservation

Dimensions: ClusterName

Alarm description: This alarm helps you detect a high memory reservation of the Amazon ECS cluster. High memory reservation might indicate a resource bottleneck for the cluster. To troubleshoot, analyze the service task for performance to see if memory utilization of the task can be optimized. Also, you can register more memory or set up auto scaling.

Intent: The alarm is used to detect whether the total memory units reserved by tasks on the cluster is reaching the total memory units registered for the cluster. This can help you know when to scale up the cluster. Reaching the total memory units for the cluster can cause the cluster to be unable to launch new tasks. If you have EC2 capacity providers managed scaling turned on or you have associated Fargate to capacity providers, this alarm is not recommended.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold for memory reservation to 80%. You can adjust this to a lower value based on cluster characteristics.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

MemoryUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a high memory utilization of the Amazon ECS service. If there is no ongoing Amazon ECS deployment, a maxed-out memory utilization might indicate a resource bottleneck or application performance problems. To troubleshoot, you can increase the memory limit.

Intent: This alarm is used to detect high memory utilization for the Amazon ECS service. Consistent high memory utilization can indicate a resource bottleneck or application performance problems.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: The service metrics for memory utilization might exceed 100% utilization. However, we recommend that you monitor the metric for high memory utilization to avoid impacting other services. Set the threshold to about 80%. We recommend that you update your task definitions to reflect actual usage to prevent future issues with other services.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

HTTPCode_Target_5XX_Count

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a high server-side error count for the ECS service. This can indicate that there are errors that cause the server to be unable to serve requests. To troubleshoot, check your application logs.

Intent: This alarm is used to detect a high server-side error count for the ECS service.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Calculate the value of about 5% of the your average traffic and use this value as a starting point for the threshold. You can find the average traffic by using the `RequestCount` metric. You can also analyze historical data to determine the acceptable error

rate for the application workload, and then tune the threshold accordingly. Frequently occurring 5XX errors need to be alarmed on. However, setting a very low value for the threshold can cause the alarm to be too sensitive.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TargetResponseTime

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a high target response time for ECS service requests. This can indicate that there are problems that cause the service to be unable to serve requests in time. To troubleshoot, check the CPUUtilization metric to see if the service is running out of CPU, or check the CPU utilization of other downstream services that your service depends on.

Intent: This alarm is used to detect a high target response time for ECS service requests.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on your use case. Review the criticality and requirements of the target response time of the service and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon ECS with Container Insights

The following are the recommended alarms for Amazon ECS with Container Insights.

EphemeralStorageUtilized

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect high ephemeral storage utilized of the Fargate cluster. If ephemeral storage is consistently high, you can check ephemeral storage usage and increase the ephemeral storage.

Intent: This alarm is used to detect high ephemeral storage usage for the Fargate cluster. Consistent high ephemeral storage utilized can indicate that the disk is full and it might lead to failure of the container.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to about 90% of the ephemeral storage size. You can adjust this value based on your acceptable ephemeral storage utilization of the Fargate cluster. For some systems, a consistently high ephemeral storage utilized might be normal, while for others, it might lead to failure of the container.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

RunningTaskCount

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a low running task count of the Amazon ECS service. If the running task count is too low, it can can indicate that the application can't handle the service load and it might lead to performance issues. If there is no running task, the Amazon ECS service might be unavailable or there might be deployment issues.

Intent: This alarm is used to detect whether the number of running tasks are too low. A consistent low running task count can indicate Amazon ECS service deployment or performance issues.

Statistic: Average

Recommended threshold: 0.0

Threshold justification: You can adjust the threshold based on the minimum running task count of the Amazon ECS service. If the running task count is 0, the Amazon ECS service will be unavailable.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

instance_filesystem_utilization

Dimensions: InstanceId, ContainerInstanceId, ClusterName

Alarm description: This alarm helps you detect a high file system utilization of the Amazon ECS cluster. If the file system utilization is consistently high, check the disk usage.

Intent: This alarm is used to detect high file system utilization for the Amazon ECS cluster. A consistent high file system utilization can indicate a resource bottleneck or application performance problems, and it might prevent running new tasks.

Statistic: Average

Recommended threshold: 90.0

Threshold justification: You can set the threshold for file system utilization to about 90-95%. You can adjust this value based on the acceptable file system capacity level of the Amazon ECS cluster. For some systems, a consistently high file system utilization might be normal and not indicate a problem, while for others, it might be a cause of concern and might lead to performance issues and prevent running new tasks.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon ECS with Container Insights with enhanced observability

The following are the recommended alarms for Amazon ECS with Container Insights with enhanced observability.

TaskCpuUtilization

Dimensions: ClusterName

Alarm description: This alarm helps you detect high CPU utilization of tasks in your Amazon ECS cluster. If task CPU utilization is consistently high, you might need to optimize your tasks or increase their CPU reservation.

Intent: This alarm is used to detect high CPU utilization for tasks in the Amazon ECS cluster. Consistent high CPU utilization can indicate that the tasks are under stress and might need more CPU resources or optimization to maintain performance.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the task's CPU reservation.
You can adjust this value based on your acceptable CPU utilization for the tasks. For some workloads, consistently high CPU utilization might be normal, while for others, it might indicate performance issues or the need for more resources.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskCpuUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of CPU units being used by a task.

Intent: This alarm is used to detect high task CPU utilization.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Typically, you can set the threshold for CPU utilization to 80%. However, you can adjust this value based on your acceptable performance level and workload characteristics. For some tasks, consistently high CPU utilization may be normal and not indicate a problem, while for others, it may be cause of concern. Analyze historical CPU utilization data to identify the usage, find what CPU utilization is acceptable for your tasks, and set the threshold accordingly.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskMemoryUtilization

Dimensions: ClusterName

Alarm description: This alarm helps you detect high memory utilization of tasks in your Amazon ECS cluster. If memory utilization is consistently high, you might need to optimize your tasks or increase the memory reservation.

Intent: This alarm is used to detect high memory utilization for tasks in the Amazon ECS cluster. Consistent high memory utilization can indicate that the task is under memory pressure and might need more memory resources or optimization to maintain stability.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the task's memory reservation. You can adjust this value based on your acceptable memory utilization for the tasks. For some workloads, consistently high memory utilization might be normal, while for others, it might indicate memory pressure or the need for more resources.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskMemoryUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of memory being used by a task.

Intent: This alarm is used to detect high memory utilization.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Typically, you can set the threshold for memory utilization to 80%. However, you can adjust this value based on your acceptable performance level and workload characteristics. For some tasks, consistently high memory utilization may be normal and not indicate a problem, while for others, it may be cause of concern. Analyze historical memory utilization data to identify the usage, find what memory utilization is acceptable for your tasks, and set the threshold accordingly.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

ContainerCpuUtilization

Dimensions: ClusterName

Alarm description: This alarm monitors the percentage of CPU units used by containers in your Amazon ECS cluster relative to their reserved CPU. It helps detect when containers are approaching their CPU limits based on the ContainerCpuUtilized/ContainerCpuReserved ratio.

Intent: This alarm detects when containers in the Amazon ECS cluster are using a high percentage of their reserved CPU capacity, calculated as `ContainerCpuUtilized/ContainerCpuReserved`. Sustained high values indicate containers are operating near their CPU limits and might need capacity adjustments.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the container's CPU utilization ratio. This provides an early warning when containers are approaching their CPU capacity limits while allowing for normal fluctuations in CPU usage. The threshold can be adjusted based on your workload characteristics and performance requirements.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ContainerCPUUtilization

Dimensions: ContainerName, ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of CPU units being used by a container.

Intent: This alarm is used to detect high task CPU utilization.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Typically, you can set the threshold for CPU utilization to 80%. However, you can adjust this value based on your acceptable performance level and workload characteristics. For some containers, consistently high CPU utilization may be normal and not indicate a problem, while for others, it may be cause of concern. Analyze historical CPU utilization data to identify the usage, find what CPU utilization is acceptable for your containers, and set the threshold accordingly.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskEBSfilesystemUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of ephemeral storage being used by a task. .

Intent: This alarm is used to detect high Amazon EBS file system usage for a task.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the Amazon EBS file system size.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskEphemeralStorageUtilization

Dimensions: ClusterName

Alarm description: This alarm helps you detect high ephemeral storage utilization of tasks in your Amazon ECS cluster. If storage utilization is consistently high, you might need to optimize your storage usage or increase the storage reservation.

Intent: This alarm is used to detect high ephemeral storage utilization for tasks in the Amazon ECS cluster. Consistent high storage utilization can indicate that the task is running out of disk space and might need more storage resources or optimization to maintain proper operation.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the task's ephemeral storage reservation. You can adjust this value based on your acceptable storage utilization for the tasks. For some workloads, consistently high storage utilization might be normal, while for others, it might indicate potential disk space issues or the need for more storage.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskEphemeralStorageUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of ephemeral storage being used by a task.

Intent: This alarm is used to detect high ephemeral storage usage for a task. Consistent high ephemeral storage utilized can indicate that the disk is full and it might lead to failure of the task.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the ephemeral storage size.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon EFS

PercentIOLimit

Dimensions: FileSystemId

Alarm description: This alarm helps in ensuring that the workload stays within the I/O limit available to the file system. If the metric reaches its I/O limit consistently, consider moving the application to a file system that uses Max I/O performance as mode. For troubleshooting, check clients that are connected to the file system and applications of the clients that throttles the file system.

Intent: This alarm is used to detect how close the file system is to reach the I/O limit of the General Purpose performance mode. Consistent high I/O percentage can be an indicator of the file system cannot scale with respect to I/O requests enough and the file system can be a resource bottleneck for the applications that use the file system.

Statistic: Average

Recommended threshold: 100.0

Threshold justification: When the file system reaches its I/O limit, it may respond to read and write requests slower. Therefore, it is recommended that the metric is monitored to avoid impacting applications that use the file system. The threshold can be set around 100%. However, this value can be adjusted to a lower value based on file system characteristics.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

BurstCreditBalance

Dimensions: FileSystemId

Alarm description: This alarm helps in ensuring that there is available burst credit balance for the file system usage. When there is no available burst credit, applications access to the the file system will be limited due to low throughput. If the metric drops to 0 consistently, consider changing the throughput mode to Elastic or Provisioned throughput mode.

Intent: This alarm is used to detect low burst credit balance of the file system. Consistent low burst credit balance can be an indicator of the slowing down in throughput and increase in I/O latency.

Statistic: Average

Recommended threshold: 0.0

Threshold justification: When the file system run out of burst credits and even if the baseline throughput rate is lower, EFS continues to provide a metered throughput of 1 MiBps to all file systems. However, it is recommended that the metric is monitored for low burst credit balance to avoid the file system acting as resource bottleneck for the applications. The threshold can be set around 0 bytes.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

Amazon EKS with Container Insights

node_cpu_utilization

Dimensions: ClusterName

Alarm description: This alarm helps to detect high CPU utilization in worker nodes of the EKS cluster. If the utilization is consistently high, it might indicate a need for replacing your worker nodes with instances that have greater CPU or a need to scale the system horizontally.

Intent: This alarm helps to monitor the CPU utilization of the worker nodes in the EKS cluster so that the system performance doesn't degrade.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: It is recommended to set the threshold at less than or equal to 80% to allow enough time to debug the issue before the system starts seeing impact.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

node_filesystem_utilization

Dimensions: ClusterName

Alarm description: This alarm helps to detect high file system utilization in the worker nodes of the EKS cluster. If the utilization is consistently high, you might need to update your worker nodes to have larger disk volume, or you might need to scale horizontally.

Intent: This alarm helps to monitor the filesystem utilization of the worker nodes in the EKS cluster. If the utilization reaches 100%, it can lead to application failure, disk I/O bottlenecks, pod eviction, or the node to become unresponsive entirely.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: If there's sufficient disk pressure (meaning that the disk is getting full), nodes are marked as not healthy, and the pods are evicted from the node. Pods on a node with disk pressure are evicted when the available file system is lower than the eviction thresholds set on the kubelet. Set the alarm threshold so that you have enough time to react before the node is evicted from the cluster.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

node_memory_utilization

Dimensions: ClusterName

Alarm description: This alarm helps in detecting high memory utilization in worker nodes of the EKS cluster. If the utilization is consistently high, it might indicate a need to scale the number of pod replicas, or optimize your application.

Intent: This alarm helps to monitor the memory utilization of the worker nodes in the EKS cluster so that the system performance doesn't degrade.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: It is recommended to set the threshold at less than or equal to 80% to allow having enough time to debug the issue before the system starts seeing impact.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

pod_cpu_utilization_over_pod_limit

Dimensions: ClusterName, Namespace, Service

Alarm description: This alarm helps in detecting high CPU utilization in pods of the EKS cluster. If the utilization is consistently high, it might indicate a need to increase the CPU limit for the affected pod.

Intent: This alarm helps to monitor the CPU utilization of the pods belonging to a Kubernetes Service in the EKS cluster, so that you can quickly identify if a service's pod is consuming higher CPU than expected.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: It is recommended to set the threshold at less than or equal to 80% to allow having enough time to debug the issue before the system starts seeing impact.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

pod_memory_utilization_over_pod_limit

Dimensions: ClusterName, Namespace, Service

Alarm description: This alarm helps in detecting high memory utilization in pods of the EKS cluster. If the utilization is consistently high, it might indicate a need to increase the memory limit for the affected pod.

Intent: This alarm helps to monitor the memory utilization of the pods in the EKS cluster so that the system performance doesn't degrade.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: It is recommended to set the threshold at less than or equal to 80% to allow having enough time to debug the issue before the system starts seeing impact.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon EventBridge Scheduler

TargetErrorThrottledCount

Dimensions: None

Alarm description: This alarm helps you identify target throttling. To avoid target throttling error, consider configuring flexible time windows to spread your invocation load or increasing limits with the target service.

Intent: This alarm is used to detect target throttling errors, which can cause schedule delays.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: If the target throttling error is consistently greater than 0, schedule delivery is delayed. For some systems, target throttling errors for a brief period of time might be normal, while for others, it might be a cause of concern. Set this alarm's threshold, `datapointsToAlarm`, and `evaluationPeriods` accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

InvocationThrottleCount

Dimensions: None

Alarm description: This alarm helps you identify invocation throttling by Amazon EventBridge Scheduler. To avoid invocation throttling errors, consider configuring flexible time windows to spread your invocation load or increasing invocations throttle limit.

Intent: This alarm is used to detect Amazon EventBridge Scheduler invocation throttling errors, which can cause schedule delays.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: If the invocation throttling is consistently greater than 0, schedule delivery is delayed. For some systems, invocation throttling errors for a brief period of time might be normal, while for others, it might be a cause of concern. Set this alarm's threshold, `datapointsToAlarm`, and `evaluationPeriods` accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

InvocationDroppedCount

Dimensions: None

Alarm description: This alarm helps you identify invocations dropped by Amazon EventBridge Scheduler. Consider investigating by configuring a DLQ for the schedule.

Intent: This alarm is used to detect dropped invocations by Amazon EventBridge Scheduler. If you have configured a DLQ correctly on all of your schedules, dropped invocations will appear in the DLQ and you can skip setting up this alarm.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Set the threshold to 0 to detect dropped invocations.

Period: 60

Datapoints to alarm: 1

Evaluation periods: 1

Comparison Operator: GREATER_THAN_THRESHOLD

InvocationsFailedToBeSentToDeadLetterCount

Dimensions: None

Alarm description: This alarm helps you identify invocations that were failed to be sent to the configured DLQ by Amazon EventBridge Scheduler. If the metric is consistently greater than 0, modify your DLQ configuration to resolve the issue. Use `InvocationsFailedToBeSentToDeadLetterCount`_metrics to determine the issue.

Intent: This alarm is used to detect invocations failed to be sent to the configured DLQ by Amazon EventBridge Scheduler.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Set the threshold to 0 to detect any invocations that were failed to be sent to the configured DLQ. Retryable errors also show up in this metric, so `datapointsToAlarm` for this alarm has been set to 15.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon Kinesis Data Streams

GetRecords.IteratorAgeMilliseconds

Dimensions: StreamName

Alarm description: This alarm can detect if iterator maximum age is too high. For real-time data processing applications, configure data retention according to tolerance of the delay. This is usually within minutes. For applications that process historic data, use this metric to monitor catchup speed. A quick solution to stop data loss is to increase the retention period while you troubleshoot the issue. You can also increase the number of workers processing records in your consumer application. The most common causes for gradual iterator age increase are insufficient physical resources or record processing logic that has not scaled with an increase in stream throughput. See link for more details.

Intent: This alarm is used to detect if data in your stream is going to expire because of being preserved too long or because record processing is too slow. It helps you avoid data loss after reaching 100% of the stream retention time.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the stream retention period and tolerance of processing delay for the records. Review

your requirements and analyze historical trends, and then set the threshold to the number of milliseconds that represents a critical processing delay. If an iterator's age passes 50% of the retention period (by default, 24 hours, configurable up to 365 days), there is a risk for data loss because of record expiration. You can monitor the metric to make sure that none of your shards ever approach this limit.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

GetRecords.Success

Dimensions: StreamName

Alarm description: This metric increments whenever your consumers successfully read data from your stream. `GetRecords` doesn't return any data when it throws an exception. The most common exception is `ProvisionedThroughputExceededException` because request rate for the stream is too high, or because available throughput is already served for the given second. Reduce the frequency or size of your requests. For more information, see Streams Limits in the Amazon Kinesis Data Streams Developer Guide, and Error Retries and Exponential Backoff in AWS.

Intent: This alarm can detect if the retrieval of records from the stream by consumers is failing. By setting an alarm on this metric, you can proactively detect any issues with data consumption, such as increased error rates or a decline in successful retrievals. This allows you to take timely actions to resolve potential problems and maintain a smooth data processing pipeline.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Depending on the importance of retrieving records from the stream, set the threshold based on your application’s tolerance for failed records. The threshold should be the corresponding percentage of successful operations. You can use historical GetRecords metric data as reference for the acceptable failure rate. You should also consider retries when setting the threshold because failed records can be retried. This helps to prevent transient spikes from triggering unnecessary alerts.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

PutRecord.Success

Dimensions: StreamName

Alarm description: This alarm detects when the number of failed `PutRecord` operations breaches the threshold. Investigate the data producer logs to find the root causes of the failures. The most common reason is insufficient provisioned throughput on the shard that caused the `ProvisionedThroughputExceededException`. It happens because the request rate for the stream is too high, or the throughput attempted to be ingested into the shard is too high. Reduce the frequency or size of your requests. For more information, see Streams Limits and Error Retries and Exponential Backoff in AWS.

Intent: This alarm can detect if ingestion of records into the stream is failing. It helps you identify issues in writing data to the stream. By setting an alarm on this metric, you can proactively detect any issues of producers in publishing data to the stream, such as increased error rates or a decrease in successful records being published. This enables you to take timely actions to address potential problems and maintain a reliable data ingestion process.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Depending on the importance of data ingestion and processing to your service, set the threshold based on your application's tolerance for failed records. The threshold should be the corresponding percentage of successful operations. You can use historical PutRecord metric data as reference for the acceptable failure rate. You should also consider retries when setting the threshold because failed records can be retried.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

PutRecords.FailedRecords

Dimensions: StreamName

Alarm description: This alarm detects when the number of failed `PutRecords` exceeds the threshold. Kinesis Data Streams attempts to process all records in each `PutRecords` request, but a single record failure does not stop the processing of subsequent records. The main reason for these failures is exceeding the throughput of a stream or an individual shard. Common causes are traffic spikes and network latencies that cause records to arrive to the stream unevenly. You should detect unsuccessfully processed records and retry them in a subsequent call. Refer to Handling Failures When Using PutRecords for more details.

Intent: This alarm can detect consistent failures when using batch operation to put records to your stream. By setting an alarm on this metric, you can proactively detect an increase in failed records, enabling you to take timely actions to address the underlying problems and make sure a smooth and reliable data ingestion process.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to the number of failed records reflecting the tolerance of the the application for failed records. You can use historical data as reference for the acceptable failure value. You should also consider retries when setting the threshold because failed records can be retried in subsequent PutRecords calls.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReadProvisionedThroughputExceeded

Dimensions: StreamName

Alarm description: The alarm tracks the number of records that result in read throughput capacity throttling. If you find that you are being consistently throttled, you should consider

adding more shards to your stream to increase your provisioned read throughput. If there is more than one consumer application running on the stream, and they share the `GetRecords` limit, we recommend that you register new consumer applications through Enhanced Fan-Out. If adding more shards does not lower the number of throttles, you may have a “hot” shard that is being read from more than other shards are. Enable enhanced monitoring, find the “hot” shard, and split it.

Intent: This alarm can detect if consumers are throttled when they exceed your provisioned read throughput (determined by the number of shards you have). In that case, you won’t be able to read from the stream, and the stream can start backing up.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Usually throttled requests can be retried and hence setting the threshold to zero makes the alarm too sensitive. However, consistent throttling can impact reading from the stream and should trigger the alarm. Set the threshold to a percentage according to the throttled requests for the application and retry configurations.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

SubscribeToShardEvent.MillisBehindLatest

Dimensions: StreamName, ConsumerName

Alarm description: This alarm detects when the delay of record processing in the application breaches the threshold. Transient problems such as API operation failures to a downstream application can cause a sudden increase in the metric. You should investigate if they consistently happen. A common cause is the consumer is not processing records fast enough because of insufficient physical resources or record processing logic that has not scaled with an increase in stream throughput. Blocking calls in critical path is often the cause of slowdowns in record processing. You can increase your parallelism by increasing the number of shards. You should also confirm underlying processing nodes have sufficient physical resources during peak demand.

Intent: This alarm can detect delay in the subscription to shard event of the stream. This indicates a processing lag and can help identify potential issues with the consumer application's performance or the overall stream's health. When the processing lag becomes significant, you should investigate and address any bottlenecks or consumer application inefficiencies to make sure real-time data processing and minimize data backlog.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the delay that your application can tolerate. Review your application's requirements and analyze historical trends, and then select a threshold accordingly. When the SubscribeToShard call succeeds, your consumer starts receiving SubscribeToShardEvent events over the persistent connection for up to 5 minutes, after which time you need to call SubscribeToShard again to renew the subscription if you want to continue to receive records.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

WriteProvisionedThroughputExceeded

Dimensions: StreamName

Alarm description: This alarm detects when the number of records resulting in write throughput capacity throttling reached the threshold. When your producers exceed your provisioned write throughput (determined by the number of shards you have), they are throttled and you won’t be able to put records to the stream. To address consistent throttling, you should consider adding shards to your stream. This raises your provisioned write throughput and prevents future throttling. You should also consider partition key choice when ingesting records. Random partition key is preferred because it spreads records evenly across the shards of the stream, whenever possible.

Intent: This alarm can detect if your producers are being rejected for writing records because of throttling of the stream or shard. If your stream is in Provisioned mode, then setting this alarm helps you proactively take actions when the data stream reaches its limits, allowing you

to optimize the provisioned capacity or take appropriate scaling actions to avoid data loss and maintain smooth data processing.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Usually throttled requests can be retried, so setting the threshold to zero makes the alarm too sensitive. However, consistent throttling can impact writing to the stream, and you should set the alarm threshold to detect this. Set the threshold to a percentage according to the throttled requests for the application and retry configurations.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Lambda

ClaimedAccountConcurrency

Dimensions: None

Alarm description: This alarm helps to monitor if the concurrency of your Lambda functions is approaching the Region-level concurrency limit of your account. A function starts to be throttled if it reaches the concurrency limit. You can take the following actions to avoid throttling.

1. Request a concurrency increase in this Region.
2. Identify and reduce any unused reserved concurrency or provisioned concurrency.
3. Identify performance issues in the functions to improve the speed of processing and therefore improve throughput.
4. Increase the batch size of the functions, so that more messages are processed by each function invocation.

Intent: This alarm can proactively detect if the concurrency of your Lambda functions is approaching the Region-level concurrency quota of your account, so that you can act on it. Functions are throttled if `ClaimedAccountConcurrency` reaches the Region-level

concurrency quota of the account. If you are using Reserved Concurrency (RC) or Provisioned Concurrency (PC), this alarm gives you more visibility on concurrency utilization than an alarm on `ConcurrentExecutions` would.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: You should calculate the value of about 90% of the concurrency quota set for the account in the Region, and use the result as the threshold value. By default, your account has a concurrency quota of 1,000 across all functions in a Region. However, you should check the quota of your account from the Service Quotas dashboard.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

Errors

Dimensions: FunctionName

Alarm description: This alarm detects high error counts. Errors includes the exceptions thrown by the code as well as exceptions thrown by the Lambda runtime. You can check the logs related to the function to diagnose the issue.

Intent: The alarm helps detect high error counts in function invocations.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to a number greater than zero. The exact value can depend on the tolerance for errors in your application. Understand the criticality of the invocations that the function is handling. For some applications, any error might be unacceptable, while other applications might allow for a certain margin of error.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: GREATER_THAN_THRESHOLD

Throttles

Dimensions: FunctionName

Alarm description: This alarm detects a high number of throttled invocation requests. Throttling occurs when there is no concurrency is available for scale up. There are several approaches to resolve this issue. 1) Request a concurrency increase from AWS Support in this Region. 2) Identify performance issues in the function to improve the speed of processing and therefore improve throughput. 3) Increase the batch size of the function, so that more messages are processed by each function invocation.

Intent: The alarm helps detect a high number of throttled invocation requests for a Lambda function. It is important to know if requests are constantly getting rejected due to throttling and if you need to improve Lambda function performance or increase concurrency capacity to avoid constant throttling.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to a number greater than zero. The exact value of the threshold can depend on the tolerance of the application. Set the threshold according to its usage and scaling requirements of the function.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

Duration

Dimensions: FunctionName

Alarm description: This alarm detects long duration times for processing an event by a Lambda function. Long durations might be because of changes in function code making the function take longer to execute, or the function's dependencies taking longer.

Intent: This alarm can detect a long running duration of a Lambda function. High runtime duration indicates that a function is taking a longer time for invocation, and can also impact the concurrency capacity of invocation if Lambda is handling a higher number of events. It is critical to know if the Lambda function is constantly taking longer execution time than expected.

Statistic: p90

Recommended threshold: Depends on your situation

Threshold justification: The threshold for the duration depends on your application and workloads and your performance requirements. For high-performance requirements, set the threshold to a shorter time to see if the function is meeting expectations. You can also analyze historical data for duration metrics to see the if the time taken matches the performance expectation of the function, and then set the threshold to a longer time than the historical average. Make sure to set the threshold lower than the configured function timeout.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

ConcurrentExecutions

Dimensions: FunctionName

Alarm description: This alarm helps to monitor if the concurrency of the function is approaching the Region-level concurrency limit of your account. A function starts to be throttled if it reaches the concurrency limit. You can take the following actions to avoid throttling.

1. Request a concurrency increase in this Region.
2. Identify performance issues in the functions to improve the speed of processing and therefore improve throughput.
3. Increase the batch size of the functions, so that more messages are processed by each function invocation.

To get better visibility on reserved concurrency and provisioned concurrency utilization, set an alarm on the new metric `ClaimedAccountConcurrency` instead.

Intent: This alarm can proactively detect if the concurrency of the function is approaching the Region-level concurrency quota of your account, so that you can act on it. A function is throttled if it reaches the Region-level concurrency quota of the account.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to about 90% of the concurrency quota set for the account in the Region. By default, your account has a concurrency quota of 1,000 across all functions in a Region. However, you can check the quota of your account, as it can be increased by contacting AWS support.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

Lambda Insights

We recommend setting best-practice alarms for the following Lambda Insights metrics.

memory_utilization

Dimensions: function_name

Alarm description: This alarm is used to detect if the memory utilization of a lambda function is approaching the configured limit. For troubleshooting, you can try to 1) Optimize your code. 2) Rightly size your memory allocation by accurately estimating the memory requirements. You can refer to Lambda Power Tuning for the same. 3) Use connection pooling. Refer to Using Amazon RDS Proxy with Lambda for the connection pooling for RDS database. 4) You can also consider designing your functions to avoid storing large amounts of data in memory between invocations.

Intent: This alarm is used to detect if the memory utilization for the Lambda function is approaching the configured limit.

Statistic: Average

Threshold Suggestion: 90.0

Threshold Justification: Set the threshold to 90% to get an alert when memory utilization exceeds 90% of the allocated memory. You can adjust this to a lower value if you have a concern for the workload for memory utilization. You can also check the historical data for this metric and set the threshold accordingly.

Period: 60

Datapoints to alarm: 10

Evaluation Periods: 10

ComparisonOperator: GREATER_THAN_THRESHOLD

Amazon VPC (`AWS/NATGateway`)

ErrorPortAllocation

Dimensions: NatGatewayId

Alarm description: This alarm helps to detect when the NAT Gateway is unable to allocate ports to new connections. To resolve this issue, see Resolve port allocation errors on NAT Gateway.

Intent: This alarm is used to detect if the NAT gateway could not allocate a source port.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: If the value of ErrorPortAllocation is greater than zero, that means too many concurrent connections to a single popular destination are open through NATGateway.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

PacketsDropCount

Dimensions: NatGatewayId

Alarm description: This alarm helps to detect when packets are dropped by NAT Gateway. This might happen because of an issue with NAT Gateway, so check AWS service health dashboard for the status of AWS NAT Gateway in your Region. This can help you correlate the network issue related to traffic using NAT gateway.

Intent: This alarm is used to detect if packets are being dropped by NAT Gateway.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: You should calculate the value of 0.01 percent of the total traffic on the NAT Gateway and use that result as the threshold value. Use historical data of the traffic on NAT Gateway to determine the threshold.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

AWS Private Link (`AWS/PrivateLinkEndpoints`)

PacketsDropped

Dimensions: VPC Id, VPC Endpoint Id, Endpoint Type, Subnet Id, Service Name

Alarm description: This alarm helps to detect if the endpoint or endpoint service is unhealthy by monitoring the number of packets dropped by the endpoint. Note that packets larger than 8500 bytes that arrive at the VPC endpoint are dropped. For troubleshooting, see connectivity problems between an interface VPC endpoint and an endpoint service.

Intent: This alarm is used to detect if the endpoint or endpoint service is unhealthy.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the use case. If you want to be aware of the unhealthy status of the endpoint or endpoint service, you should set the threshold low so that you get a chance to fix the issue before a huge data loss. You can use historical data to understand the tolerance for dropped packets and set the threshold accordingly.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

AWS Private Link (`AWS/PrivateLinkServices`)

RstPacketsSent

Dimensions: Service Id, Load Balancer Arn, Az

Alarm description: This alarm helps you detect unhealthy targets of an endpoint service based on the number of reset packets that are sent to endpoints. When you debug connection errors with a consumer of your service, you can validate whether the service is resetting connections with the RstPacketsSent metric, or if something else is failing on the network path.

Intent: This alarm is used to detect unhealthy targets of an endpoint service.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: The threshold depends on the use case. If your use case can tolerate targets being unhealthy, you can set the threshold high. If the use case can't tolerate unhealthy targets you can set the threshold very low.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon RDS

CPUUtilization

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor consistent high CPU utilization. CPU utilization measures non-idle time. Consider using Enhanced Monitoring or Performance Insights to review which wait time is consuming the most of the CPU time (`guest`, `irq`, `wait`, `nice`, and so on) for MariaDB, MySQL, Oracle, and PostgreSQL. Then evaluate which queries consume the highest amount of CPU. If you can't tune your workload, consider moving to a larger DB instance class.

Intent: This alarm is used to detect consistent high CPU utilization in order to prevent very high response time and time-outs. If you want to check micro-bursting of CPU utilization you can set a lower alarm evaluation time.

Statistic: Average

Recommended threshold: 90.0

Threshold justification: Random spikes in CPU consumption might not hamper database performance, but sustained high CPU can hinder upcoming database requests. Depending on the overall database workload, high CPU at your RDS/Aurora instance can degrade the overall performance.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

DatabaseConnections

Dimensions: DBInstanceIdentifier

Alarm description: This alarm detects a high number of connections. Review existing connections and terminate any that are in `sleep` state or that are improperly closed. Consider using connection pooling to limit the number of new connections. Alternatively, increase the DB instance size to use a class with more memory and hence a higher default value for

`max_connections` or increase the `max_connections` value in RDS and Aurora MySQL and PostgreSQL for the current class if it can support your workload.

Intent: This alarm is used to help prevent rejected connections when the maximum number of DB connections is reached. This alarm is not recommended if you frequently change DB instance class, because doing so changes the memory and default maximum number of connections.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The number of connections allowed depends on the size of your DB instance class and database engine-specific parameters related to processes/connections. You should calculate a value between 90-95% of the maximum number of connections for your database and use that result as the threshold value.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

EBSByteBalance%

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor a low percentage of throughput credits remaining. For troubleshooting, check latency problems in RDS.

Intent: This alarm is used to detect a low percentage of throughput credits remaining in the burst bucket. Low byte balance percentage can cause throughput bottleneck issues. This alarm is not recommended for Aurora PostgreSQL instances.

Statistic: Average

Recommended threshold: 10.0

Threshold justification: A throughput credit balance below 10% is considered to be poor and you should set the threshold accordingly. You can also set a lower threshold if your application can tolerate a lower throughput for the workload.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

EBSIOBalance%

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor low percentage of IOPS credits remaining. For troubleshooting, see latency problems in RDS.

Intent: This alarm is used to detect a low percentage of I/O credits remaining in the burst bucket. Low IOPS balance percentage can cause IOPS bottleneck issues. This alarm is not recommended for Aurora instances.

Statistic: Average

Recommended threshold: 10.0

Threshold justification: An IOPS credits balance below 10% is considered to be poor and you can set the threshold accordingly. You can also set a lower threshold, if your application can tolerate a lower IOPS for the workload.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

FreeableMemory

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor low freeable memory which can mean that there is a spike in database connections or that your instance may be under high memory pressure. Check for memory pressure by monitoring the CloudWatch metrics for `SwapUsage`in addition to `FreeableMemory`. If the instance memory consumption is frequently too high, this indicates that you should check your workload or upgrade your instance class. For Aurora reader

DB instance, consider adding additional reader DB instances to the cluster. For information about troubleshooting Aurora, see freeable memory issues.

Intent: This alarm is used to help prevent running out of memory which can result in rejected connections.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Depending on the workload and instance class, different values for the threshold can be appropriate. Ideally, available memory should not go below 25% of total memory for prolonged periods. For Aurora, you can set the threshold close to 5%, because the metric approaching 0 means that the DB instance has scaled up as much as it can. You can analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: LESS_THAN_THRESHOLD

FreeLocalStorage

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor low free local storage. Aurora PostgreSQL-Compatible Edition uses local storage for storing error logs and temporary files. Aurora MySQL uses local storage for storing error logs, general logs, slow query logs, audit logs, and non-InnoDB temporary tables. These local storage volumes are backed by Amazon EBS Store and can be extended by using a larger DB instance class. For troubleshooting, check Aurora PostgreSQL-Compatible and MySQL-Compatible.

Intent: This alarm is used to detect how close the Aurora DB instance is to reaching the local storage limit, if you do not use Aurora Serverless v2 or higher. Local storage can reach capacity when you store non-persistent data, such as temporary table and log files, in the local storage. This alarm can prevent an out-of-space error that occurs when your DB instance runs out of local storage.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: You should calculate about 10%-20% of the amount of storage available based on velocity and trend of volume usage, and then use that result as the threshold value to proactively take action before the volume reaches its limit.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

FreeStorageSpace

Dimensions: DBInstanceIdentifier

Alarm description: This alarm watches for a low amount of available storage space. Consider scaling up your database storage if you frequently approach storage capacity limits. Include some buffer to accommodate unforeseen increases in demand from your applications. Alternatively, consider enabling RDS storage auto scaling. Additionally, consider freeing up more space by deleting unused or outdated data and logs. For further information, check RDS run out of storage document and PostgreSQL storage issues document.

Intent: This alarm helps prevent storage full issues. This can prevent downtime that occurs when your database instance runs out of storage. We do not recommend using this alarm if you have storage auto scaling enabled, or if you frequently change the storage capacity of the database instance.

Statistic: Minimum

Recommended threshold: Depends on your situation

Threshold justification: The threshold value will depend on the currently allocated storage space. Typically, you should calculate the value of 10 percent of the allocated storage space and use that result as the threshold value.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

MaximumUsedTransactionIDs

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps prevent transaction ID wraparound for PostgreSQL. Refer to the troubleshooting steps in this blog to investigate and resolve the issue. You can also refer to this blog to familiarize yourself further with autovacuum concepts, common issues and best practices.

Intent: This alarm is used to help prevent transaction ID wraparound for PostgreSQL.

Statistic: Average

Recommended threshold: 1.0E9

Threshold justification: Setting this threshold to 1 billion should give you time to investigate the problem. The default autovacuum_freeze_max_age value is 200 million. If the age of the oldest transaction is 1 billion, autovacuum is having a problem keeping this threshold below the target of 200 million transaction IDs.

Period: 60

Datapoints to alarm: 1

Evaluation periods: 1

Comparison Operator: GREATER_THAN_THRESHOLD

ReadLatency

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor high read latency. If storage latency is high, it's because the workload is exceeding resource limits. You can review I/O utilization relative to instance and allocated storage configuration. Refer to troubleshoot the latency of Amazon EBS volumes caused by an IOPS bottleneck. For Aurora, you can switch to an instance class that has I/O-Optimized storage configuration. See Planning I/O in Aurora for guidance.

Intent: This alarm is used to detect high read latency. Database disks normally have a low read/write latency, but they can have issues that can cause high latency operations.

Statistic: p90

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on your use case. Read latencies higher than 20 milliseconds are likely a cause for investigation. You can also set a higher threshold if your application can have higher latency for read operations. Review the criticality and requirements of read latency and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReplicaLag

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps you understand the number of seconds a replica is behind the primary instance. A PostgreSQL Read Replica reports a replication lag of up to five minutes if there are no user transactions occurring on the source database instance. When the ReplicaLag metric reaches 0, the replica has caught up to the primary DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. For guidance related to RDS PostgreSQL, see replication best practices and for troubleshooting `ReplicaLag` and related errors, see troubleshooting ReplicaLag.

Intent: This alarm can detect the replica lag which reflects the data loss that could happen in case of a failure of the primary instance. If the replica gets too far behind the primary and the primary fails, the replica will be missing data that was in the primary instance.

Statistic: Maximum

Recommended threshold: 60.0

Threshold justification: Typically, the acceptable lag depends on the application. We recommend no more than 60 seconds.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

WriteLatency

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor high write latency. If storage latency is high, it's because the workload is exceeding resource limits. You can review I/O utilization relative to instance and allocated storage configuration. Refer to troubleshoot the latency of Amazon EBS volumes caused by an IOPS bottleneck. For Aurora, you can switch to an instance class that has I/O-Optimized storage configuration. See Planning I/O in Aurora for guidance.

Intent: This alarm is used to detect high write latency. Although database disks typically have low read/write latency, they may experience problems that cause high latency operations. Monitoring this will assure you the disk latency is as low as expected.

Statistic: p90

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on your use case. Write latencies higher than 20 milliseconds are likely a cause for investigation. You can also set a higher threshold if your application can have a higher latency for write operations. Review the criticality and requirements of write latency and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

DBLoad

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor high DB load. If the number of processes exceed the number of vCPUs, the processes start queuing. When the queuing increases, the performance is impacted. If the DB load is often above the maximum vCPU, and the primary

wait state is CPU, the CPU is overloaded. In this case, you can monitor `CPUUtilization`, `DBLoadCPU` and queued tasks in Performance Insights/Enhanced Monitoring. You might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve.

Intent: This alarm is used to detect a high DB load. High DB load can cause performance issues in the DB instance. This alarm is not applicable to serverless DB instances.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The maximum vCPU value is determined by the number of vCPU (virtual CPU) cores for your DB instance. Depending on the maximum vCPU, different values for the threshold can be appropriate. Ideally, DB load should not go above vCPU line.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

AuroraVolumeBytesLeftTotal

Dimensions: DBClusterIdentifier

Alarm description: This alarm helps to monitor low remaining total volume. When the total volume left reaches the size limit, the cluster reports an out-of-space error. Aurora storage automatically scales with the data in the cluster volume and expands up to 128 TiB or 64 TiB depending on the DB engine version. Consider reducing storage by dropping tables and databases that you no longer need. For more information, check storage scaling.

Intent: This alarm is used to detect how close the Aurora cluster is to the volume size limit. This alarm can prevent an out-of-space error that occurs when your cluster runs out of space. This alarm is recommended only for Aurora MySQL.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: You should calculate 10%-20% of the actual size limit based on velocity and trend of volume usage increase, and then use that result as the threshold value to proactively take action before the volume reaches its limit.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

AuroraBinlogReplicaLag

Dimensions: DBClusterIdentifier, Role=WRITER

Alarm description: This alarm helps to monitor the error state of Aurora writer instance replication. For more information, see Replicating Aurora MySQL DB clusters across AWS Regions. For troubleshooting, see Aurora MySQL replication issues.

Intent: This alarm is used to detect whether the writer instance is in an error state and can't replicate the source. This alarm is recommended only for Aurora MySQL.

Statistic: Average

Recommended threshold: -1.0

Threshold justification: We recommend that you use -1 as the threshold value because Aurora MySQL publishes this value if the replica is in an error state.

Period: 60

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

BlockedTransactions

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor a high blocked transaction count in an Aurora DB instance. Blocked transactions can end in either a rollback or a commit. High concurrency,

idles in transaction, or long running transactions can lead to blocked transactions. For troubleshooting, see Aurora MySQL documentation.

Intent: This alarm is used to detect a high count of blocked transactions in an Aurora DB instance in order to prevent transaction rollbacks and performance degradation.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: You should calculate 5% of all transactions of your instance using the `ActiveTransactions` metric and use that result as the threshold value. You can also review the criticality and requirements of blocked transactions and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

BufferCacheHitRatio

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps you monitor a consistent low cache hit ratio of the Aurora cluster. A low hit ratio indicates that your queries on this DB instance are frequently going to disk. For troubleshooting, investigate your workload to see which queries are causing this behavior, and see the DB instance RAM recommendations document.

Intent: This alarm is used to detect consistent low cache hit ratio in order to prevent a sustained performance decrease in the Aurora instance.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: You can set the threshold for buffer cache hit ratio to 80%. However, you can adjust this value based on your acceptable performance level and workload characteristics.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

EngineUptime

Dimensions: DBClusterIdentifier, Role=WRITER

Alarm description: This alarm helps to monitor low downtime of the writer DB instance. The writer DB instance can go down due to a reboot, maintenance, upgrade, or failover. When the uptime reaches 0 because of a failover in the cluster, and the cluster has one or more Aurora Replicas, then an Aurora Replica is promoted to the primary writer instance during a failure event. To increase the availability of your DB cluster, consider creating one or more Aurora Replicas in two or more different Availability Zones. For more information check factors that influence Aurora downtime.

Intent: This alarm is used to detect whether the Aurora writer DB instance is in downtime. This can prevent long-running failure in the writer instance that occurs because of a crash or failover.

Statistic: Average

Recommended threshold: 0.0

Threshold justification: A failure event results in a brief interruption, during which read and write operations fail with an exception. However, service is typically restored in less than 60 seconds, and often less than 30 seconds.

Period: 60

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

RollbackSegmentHistoryListLength

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor a consistent high rollback segment history length of an Aurora instance. A high InnoDB history list length indicates that a large number of

old row versions, queries and database shutdowns have become slower. For more information and troubleshooting, see the InnoDB history list length increased significantly documentation.

Intent: This alarm is used to detect consistent high rollback segment history length. This can help you prevent sustained performance degradation and high CPU usage in the Aurora instance. This alarm is recommended only for Aurora MySQL.

Statistic: Average

Recommended threshold: 1000000.0

Threshold justification: Setting this threshold to 1 million should give you time to investigate the problem. However, you can adjust this value based on your acceptable performance level and workload characteristics.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

StorageNetworkThroughput

Dimensions: DBClusterIdentifier, Role=WRITER

Alarm description: This alarm helps to monitor high storage network throughput. If storage network throughput passes the total network bandwidth of the EC2 instance, it can lead to high read and write latency, which can cause degraded performance. You can check your EC2 instance type from AWS Console. For troubleshooting, check any changes on write/read latencies and evaluate if you've also hit an alarm on this metric. If that is the case, evaluate your workload pattern during the times that the alarm was triggered. This can help you identify if you can optimize y our workload to reduce the total amount of network traffic. If this is not possible, you might need to consider scaling your instance.

Intent: This alarm is used to detect high storage network throughput. Detecting high throughput can prevent network packet drops and degraded performance.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: You should calculate about 80%-90% of the total network bandwidth of the EC2 instance type, and then use that result as the threshold value to proactively take action before the network packets are affected. You can also review the criticality and requirements of storage network throughput and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon Route 53 Public Data Plane

HealthCheckStatus

Dimensions: HealthCheckId

Alarm description: This alarm helps to detect unhealthy endpoints as per health checkers. To understand the reason for a failure that results in unhealthy status, use the Health Checkers tab in the Route 53 Health Check Console to view the status from each Region as well as the last failure of the health check. The status tab also displays the reason that the endpoint is reported as unhealthy. Refer to troubleshooting steps.

Intent: This alarm uses Route53 health checkers to detect unhealthy endpoints.

Statistic: Average

Recommended threshold: 1.0

Threshold justification: The status of the endpoint is reported as 1 when it's healthy. Everything less than 1 is unhealthy.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

Amazon S3

4xxErrors

Dimensions: BucketName, FilterId

Alarm description: This alarm helps us report the total number of 4xx error status codes that are made in response to client requests. 403 error codes might indicate an incorrect IAM policy, and 404 error codes might indicate mis-behaving client application, for example. Enabling S3 server access logging on a temporary basis will help you to pinpoint the issue's origin using the fields HTTP status and Error Code. To understand more about the error code, see Error Responses.

Intent: This alarm is used to create a baseline for typical 4xx error rates so that you can look into any abnormalities that might indicate a setup issue.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: The recommended threshold is to detect if more than 5% of total requests are getting 4XX errors. Frequently occurring 4XX errors should be alarmed. However, setting a very low value for the threshold can cause alarm to be too sensitive. You can also tune the threshold to suit to the load of the requests, accounting for an acceptable level of 4XX errors. You can also analyze historical data to find the acceptable error rate for the application workload, and then tune the threshold accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

5xxErrors

Dimensions: BucketName, FilterId

Alarm description: This alarm helps you detect a high number of server-side errors. These errors indicate that a client made a request that the server couldn't complete. This can help you correlate the issue your application is facing because of S3. For more information to help you

efficiently handle or reduce errors, see Optimizing performance design patterns. Errors might also be caused by an the issue with S3, check AWS service health dashboard for the status of Amazon S3 in your Region.

Intent: This alarm can help to detect if the application is experiencing issues due to 5xx errors.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: We recommend setting the threshold to detect if more than 5% of total requests are getting 5XXError. However, you can tune the threshold to suit the traffic of the requests, as well as acceptable error rates. You can also analyze historical data to see what is the acceptable error rate for the application workload, and tune the threshold accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

OperationsFailedReplication

Dimensions: SourceBucket, DestinationBucket, RuleId

Alarm description: This alarm helps in understanding a replication failure. This metric tracks the status of new objects replicated using S3 CRR or S3 SRR, and also tracks existing objects replicated using S3 batch replication. See Replication troubleshooting for more details.

Intent: This alarm is used to detect if there is a failed replication operation.

Statistic: Maximum

Recommended threshold: 0.0

Threshold justification: This metric emits a value of 0 for successful operations, and nothing when there are no replication operations carried out for the minute. When the metric emits a value greater than 0, the replication operation is unsuccessful.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Amazon SNS

NumberOfMessagesPublished

Dimensions: TopicName

Alarm description: This alarm can detect when the number of SNS messages published is too low. For troubleshooting, check why the publishers are sending less traffic.

Intent: This alarm helps you proactively monitor and detect significant drops in notification publishing. This helps you identify potential issues with your application or business processes, so that you can take appropriate actions to maintain the expected flow of notifications. You should create this alarm if you expect your system to have a minimum traffic that it is serving.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: The number of messages published should be in line with the expected number of published messages for your application. You can also analyze the historical data, trends and traffic to find the right threshold.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

NumberOfNotificationsDelivered

Dimensions: TopicName

Alarm description: This alarm can detect when the number of SNS messages delivered is too low. This could be because of unintentional unsubscribing of an endpoint, or because of an SNS event that causes messages to experience delay.

Intent: This alarm helps you detect a drop in the volume of messages delivered. You should create this alarm if you expect your system to have a minimum traffic that it is serving.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: The number of messages delivered should be in line with the expected number of messages produced and the number of consumers. You can also analyze the historical data, trends and traffic to find the right threshold.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

NumberOfNotificationsFailed

Dimensions: TopicName

Alarm description: This alarm can detect when the number of failed SNS messages is too high. To troubleshoot failed notifications, enable logging to CloudWatch Logs. Checking the logs can help you find which subscribers are failing, as well as the status codes they are returning.

Intent: This alarm helps you proactively find issues with the delivery of notifications and take appropriate actions to address them.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the impact of failed notifications. Review the SLAs provided to your end users, fault tolerance and criticality of notifications and analyze historical data, and then select a threshold accordingly. The number of notifications failed should be 0 for topics that have only SQS, Lambda or Firehose subscriptions.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

NumberOfNotificationsFilteredOut-InvalidAttributes

Dimensions: TopicName

Alarm description: This alarm helps to monitor and resolve potential problems with the publisher or subscribers. Check if a publisher is publishing messages with invalid attributes or if an inappropriate filter is applied to a subscriber. You can also analyze CloudWatch Logs to help find the root cause of the issue.

Intent: The alarm is used to detect if the published messages are not valid or if inappropriate filters have been applied to a subscriber.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Invalid attributes are almost always a mistake by the publisher. We recommend to set the threshold to 0 because invalid attributes are not expected in a healthy system.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

NumberOfNotificationsFilteredOut-InvalidMessageBody

Dimensions: TopicName

Alarm description: This alarm helps to monitor and resolve potential problems with the publisher or subscribers. Check if a publisher is publishing messages with invalid message bodies, or if an inappropriate filter is applied to a subscriber. You can also analyze CloudWatch Logs to help find the root cause of the issue.

Intent: The alarm is used to detect if the published messages are not valid or if inappropriate filters have been applied to a subscriber.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Invalid message bodies are almost always a mistake by the publisher. We recommend to set the threshold to 0 because invalid message bodies are not expected in a healthy system.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

NumberOfNotificationsRedrivenToDlq

Dimensions: TopicName

Alarm description: This alarm helps to monitor the number of messages that are moved to a dead-letter queue.

Intent: The alarm is used to detect messages that moved to a dead-letter queue. We recommend that you create this alarm when SNS is coupled with SQS, Lambda or Firehose.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: In a healthy system of any subscriber type, messages should not be moved to the dead-letter queue. We recommend that you be notified if any messages land in the queue, so that you can identify and address the root cause, and potentially redrive the messages in the dead-letter queue to prevent data loss.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

NumberOfNotificationsFailedToRedriveToDlq

Dimensions: TopicName

Alarm description: This alarm helps to monitor messages that couldn't be moved to a dead-letter queue. Check whether your dead-letter queue exists and that it's configured correctly. Also, verify that SNS has permissions to access the dead-letter queue. Refer to the dead-letter queue documentation to learn more.

Intent: The alarm is used to detect messages that couldn't be moved to a dead-letter queue.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: It's almost always a mistake if messages can't be moved to the dead-letter queue. The recommendation for the threshold is 0, meaning all messages that fail processing must be able to reach the dead-letter queue when the queue has been configured.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

SMSMonthToDateSpentUSD

Dimensions: TopicName

Alarm description: The alarm helps to monitor if you have a sufficient quota in your account for SNS to be able to deliver messages. If you reach your quota, SNS won't be able to deliver SMS messages. For information about setting your monthly SMS spend quota, or for information about requesting a spend quota increase with AWS, see Setting SMS messaging preferences.

Intent: This alarm is used to detect if you have a sufficient quota in your account for your SMS messages to be delivered successfully.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold in accordance with the quota (Account spend limit) for the account. Choose a threshold which informs you early enough that you are reaching your quota limit so that you have time to request an increase.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

SMSSuccessRate

Dimensions: TopicName

Alarm description: This alarm helps to monitor the rate of failing SMS message deliveries. You can set up Cloudwatch Logs to understand the nature of the failure and take action based on that.

Intent: This alarm is used to detect failing SMS message deliveries.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold for the alarm in line with your tolerance for failing SMS message deliveries.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon SQS

ApproximateAgeOfOldestMessage

Dimensions: QueueName

Alarm description: This alarm watches the age of the oldest message in the queue. You can use this alarm to monitor if your consumers are processing SQS messages at the desired speed. Consider increasing the consumer count or consumer throughput to reduce message age. This metric can be used in combination with `ApproximateNumberOfMessagesVisible` to determine how big the queue backlog is and how quickly messages are being processed. To prevent messages from being deleted before processed, consider configuring the dead-letter queue to sideline potential poison pill messages.

Intent: This alarm is used to detect whether the age of the oldest message in the QueueName queue is too high. High age can be an indication that messages are not processed quickly enough or that there are some poison-pill messages that are stuck in the queue and can't be processed.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the expected message processing time. You can use historical data to calculate the average message processing time, and then set the threshold to 50% higher than the maximum expected SQS message processing time by queue consumers.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

ApproximateNumberOfMessagesNotVisible

Dimensions: QueueName

Alarm description: This alarm helps to detect a high number of in-flight messages with respect to `QueueName`. For troubleshooting, check message backlog decreasing.

Intent: This alarm is used to detect a high number of in-flight messages in the queue. If consumers do not delete messages within the visibility timeout period, when the queue is polled, messages reappear in the queue. For FIFO queues, there can be a maximum of 20,000 in-flight messages. If you reach this quota, SQS returns no error messages. A FIFO queue looks through the first 20k messages to determine available message groups. This means that if you have a backlog of messages in a single message group, you cannot consume messages from other message groups that were sent to the queue at a later time until you successfully consume the messages from the backlog.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the expected number of messages in flight. You can use historical data to calculate the maximum expected number of messages in flight and set the threshold to 50% over this value. If consumers of the queue are processing but not deleting messages from the queue, this number will suddenly increase.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

ApproximateNumberOfMessagesVisible

Dimensions: QueueName

Alarm description: This alarm watches for the message queue backlog to be bigger than expected, indicating that consumers are too slow or there are not enough consumers. Consider increasing the consumer count or speeding up consumers, if this alarm goes into ALARM state.

Intent: This alarm is used to detect whether the message count of the active queue is too high and consumers are slow to process the messages or there are not enough consumers to process them.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: An unexpectedly high number of messages visible indicates that messages are not being processed by a consumer at the expected rate. You should consider historical data when you set this threshold.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

NumberOfMessagesSent

Dimensions: QueueName

Alarm description: This alarm helps to detect if there are no messages being sent from a producer with respect to `QueueName`. For troubleshooting, check the reason that the producer is not sending messages.

Intent: This alarm is used to detect when a producer stops sending messages.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: If the number of messages sent is 0, the producer is not sending any messages. If this queue has a low TPS, increase the number of EvaluationPeriods accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

Site-to-Site VPN

TunnelState

Dimensions: VpnId

Alarm description: This alarm helps you understand if the state of one or more tunnels is DOWN. For troubleshooting, see VPN tunnel troubleshooting.

Intent: This alarm is used to detect if at least one tunnel is in the DOWN state for this VPN, so that you can troubleshoot the impacted VPN. This alarm will always be in the ALARM state for networks that only have a single tunnel configured.

Statistic: Minimum

Recommended threshold: 1.0

Threshold justification: A value less than 1 indicates that at least one tunnel is in DOWN state.

Period: 300

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

TunnelState

Dimensions: TunnelIpAddress

Alarm description: This alarm helps you understand if the state of this tunnel is DOWN. For troubleshooting, see VPN tunnel troubleshooting.

Intent: This alarm is used to detect if the tunnel is in the DOWN state, so that you can troubleshoot the impacted VPN. This alarm will always be in the ALARM state for networks that only have a single tunnel configured.

Statistic: Minimum

Recommended threshold: 1.0

Threshold justification: A value less than 1 indicates that the tunnel is in DOWN state.

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

Alarm use cases and examples

The following sections provides examples and tutorials for alarms for common use cases.

Topics

- Create a billing alarm to monitor your estimated AWS charges
- Create a CPU usage alarm
- Create a load balancer latency alarm that sends email
- Create a storage throughput alarm that sends email
- Create an alarm on Performance Insights counter metrics from an AWS database
- Create a Log Alarm on error patterns
- Create a Log Alarm on high latency per endpoint
- Create an alarm that triggers an Auto Scaling action

Create a billing alarm to monitor your estimated AWS charges

You can monitor your estimated AWS charges by using Amazon CloudWatch. When you enable the monitoring of estimated charges for your AWS account, the estimated charges are calculated and sent several times daily to CloudWatch as metric data.

Billing metric data is stored in the US East (N. Virginia) Region and represents worldwide charges. This data includes the estimated charges for every service in AWS that you use, in addition to the estimated overall total of your AWS charges.

The alarm triggers when your account billing exceeds the threshold you specify. It triggers only when the current billing exceeds the threshold. It doesn't use projections based on your usage so far in the month.

If you create a billing alarm at a time when your charges have already exceeded the threshold, the alarm goes to the ALARM state immediately.

> **Note**
>
> For information about analyzing CloudWatch charges that you have already been billed for, see Analyzing, optimizing, and reducing CloudWatch costs.

Tasks

- Enabling billing alerts
- Create a billing alarm
- Deleting a billing alarm

Enabling billing alerts

Before you can create an alarm for your estimated charges, you must enable billing alerts, so that you can monitor your estimated AWS charges and create an alarm using billing metric data. After you enable billing alerts, you can't disable data collection, but you can delete any billing alarms that you created.

After you enable billing alerts for the first time, it takes about 15 minutes before you can view billing data and set billing alarms.

Requirements

- You must be signed in using account root user credentials or as an IAM user that has been given permission to view billing information.
- For consolidated billing accounts, billing data for each linked account can be found by logging in as the paying account. You can view billing data for total estimated charges and estimated charges by service for each linked account, in addition to the consolidated account.
- In a consolidated billing account, member linked account metrics are captured only if the payer account enables the **Receive Billing Alerts** preference. If you change which account is your management/payer account, you must enable the billing alerts in the new management/payer account.
- The account must not be part of the Amazon Partner Network (APN) because billing metrics are not published to CloudWatch for APN accounts. For more information, see AWS Partner Network.

To enable the monitoring of estimated charges

1. Open the AWS Billing and Cost Management console at https://console.aws.amazon.com/costmanagement/.
2. In the navigation pane, choose **Billing Preferences**.
3. By **Alert preferences** choose **Edit**.
4. Choose **Receive CloudWatch Billing Alerts**.
5. Choose **Save preferences**.

Create a billing alarm

> **Important**
>
> Before you create a billing alarm, you must set your Region to US East (N. Virginia). Billing metric data is stored in this Region and represents worldwide charges. You also must enable billing alerts for your account or in the management/payer account (if you are using consolidated billing). For more information, see Enabling billing alerts.

In this procedure, you create an alarm that sends a notification when your estimated charges for AWS exceed a defined threshold.

To create a billing alarm using the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**. In **AWS Namespaces**, choose **Billing**, and then choose **Total Estimated Charge**.

   > **Note**
   >
   > If you don't see the **Billing/Total Estimated Charge** metric, enable billing alerts, and change your Region to US East (N. Virginia). For more information, see Enabling billing alerts.

5. Select the box for the **EstimatedCharges** metric, and then choose **Select metric**.

6. For **Statistic**, choose **Maximum**.
7. For **Period**, choose **6 hours**.
8. For **Threshold type**, choose **Static**.
9. For **Whenever EstimatedCharges is . . .**, choose **Greater**.
10. For **than . . .**, define the value that you want to cause your alarm to trigger. For example, **`200`** USD.

    The **EstimatedCharges** metric values are only in US dollars (USD), and the currency conversion is provided by Amazon Services LLC. For more information, see What is AWS Billing?.

    > **Note**
    >
    > After you define a threshold value, the preview graph displays your estimated charges for the current month.

11. Choose **Additional Configuration** and do the following:

    - For **Datapoints to alarm**, specify **1 out of 1**.
    - For **Missing data treatment**, choose **Treat missing data as missing**.

12. Choose **Next**.
13. Under **Notification**, make sure that **In alarm** is selected. Then specify an Amazon SNS topic to be notified when your alarm is in the `ALARM` state. The Amazon SNS topic can include your email address so that you receive email when the billing amount crosses the threshold that you specified.

    You can select an existing Amazon SNS topic, create a new Amazon SNS topic, or use a topic ARN to notify other account. If you want your alarm to send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

14. Choose **Next**.
15. Under **Name and description**, enter a name for your alarm. The name must contain only UTF-8 characters, and can't contain ASCII control characters.

    - (Optional) Enter a description of your alarm. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

16. Choose **Next**.

17. Under **Preview and create**, make sure that your configuration is correct, and then choose **Create alarm**.

Deleting a billing alarm

You can delete your billing alarm when you no longer need it.

To delete a billing alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.
4. Select the check box next to the alarm and choose **Actions**, **Delete**.
5. When prompted for confirmation, choose **Yes, Delete**.

Create a CPU usage alarm

You can create an CloudWatch alarm that sends a notification using Amazon SNS when the alarm changes state from `OK` to `ALARM`.

The alarm changes to the `ALARM` state when the average CPU use of an EC2 instance exceeds a specified threshold for consecutive specified periods.

Setting up a CPU usage alarm using the AWS Management Console

Use these steps to use the AWS Management Console to create a CPU usage alarm.

To create an alarm based on CPU usage

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**.
5. In the **Browse** tab, choose **EC2 metrics**.
6. Choose a metric category (for example, **Per-Instance Metrics**).

7. Find the row with the instance that you want listed in the **InstanceId** column and **CPUUtilization** in the **Metric Name** column. Select the check box next to this row, and choose **Select metric**.
8. Under **Specify metric and conditions**, for **Statistic** choose **Average**, choose one of the predefined percentiles, or specify a custom percentile (for example, **p95.45**).
9. Choose a period (for example, **5 minutes**).
10. Under **Conditions**, specify the following:

    a. For **Threshold type**, choose **Static**.

    b. For **Whenever CPUUtilization is**, specify **Greater**. Under **than...**, specify the threshold that is to trigger the alarm to go to ALARM state if the CPU utilization exceeds this percentage. For example, 70.

    c. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the ALARM state to trigger the alarm. If the two values here match, you create an alarm that goes to ALARM state if that many consecutive periods are breaching.

    To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Alarm evaluation.

    d. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.

    e. If the alarm uses a percentile as the monitored statistic, a **Percentiles with low samples** box appears. Use it to choose whether to evaluate or ignore cases with low sample rates. If you choose **ignore (maintain alarm state)**, the current alarm state is always maintained when the sample size is too low. For more information, see Percentile-based alarms and low data samples.
11. Choose **Next**.
12. Under **Notification**, choose **In alarm** and select an SNS topic to notify when the alarm is in ALARM state

    To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    To have the alarm not send notifications, choose **Remove**.
13. When finished, choose **Next**.

14. Enter a name and description for the alarm. Then choose **Next**.

    The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

15. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

Setting up a CPU usage alarm using the AWS CLI

Use these steps to use the AWS CLI to create a CPU usage alarm.

To create an alarm based on CPU usage

1. Set up an SNS topic. For more information, see Setting up Amazon SNS notifications.
2. Create an alarm using the put-metric-alarm command as follows.

```
aws cloudwatch put-metric-alarm --alarm-name cpu-mon --alarm-description "Alarm
 when CPU exceeds 70%" --metric-name CPUUtilization --namespace AWS/EC2 --statistic
 Average --period 300 --threshold 70 --comparison-operator GreaterThanThreshold --
dimensions  Name=InstanceId,Value=i-12345678 --evaluation-periods 2 --alarm-actions
 arn:aws:sns:us-east-1:111122223333:my-topic --unit Percent
```

3. Test the alarm by forcing an alarm state change using the set-alarm-state command.

    a. Change the alarm state from `INSUFFICIENT_DATA` to `OK`.

    ```
    aws cloudwatch set-alarm-state --alarm-name cpu-mon --state-reason
     "initializing" --state-value OK
    ```

    b. Change the alarm state from `OK` to `ALARM`.

    ```
    aws cloudwatch set-alarm-state --alarm-name cpu-mon --state-reason
     "initializing" --state-value ALARM
    ```

    c. Check that you have received a notification about the alarm.

Create a load balancer latency alarm that sends email

You can set up an Amazon SNS notification and configure an alarm that monitors latency exceeding 100 ms for your Classic Load Balancer.

Setting up a latency alarm using the AWS Management Console

Use these steps to use the AWS Management Console to create a load balancer latency alarm.

To create a load balancer latency alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose **Create alarm**.
4. Under **CloudWatch Metrics by Category**, choose the **ELB Metrics** category.
5. Select the row with the Classic Load Balancer and the **Latency** metric.
6. For the statistic, choose **Average**, choose one of the predefined percentiles, or specify a custom percentile (for example, **p95.45**).
7. For the period, choose **1 Minute**.
8. Choose **Next**.
9. Under **Alarm Threshold**, enter a unique name for the alarm (for example, **myHighCpuAlarm**) and a description of the alarm (for example, **Alarm when Latency exceeds 100s**). Alarm names must contain only UTF-8 characters, and can't contain ASCII control characters

   The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.
10. Under **Whenever**, for **is**, choose **>** and enter **0.1**. For **for**, enter **3**.
11. Under **Additional settings**, for **Treat missing data as**, choose **ignore (maintain alarm state)** so that missing data points don't trigger alarm state changes.

    For **Percentiles with low samples**, choose **ignore (maintain the alarm state)** so that the alarm evaluates only situations with adequate numbers of data samples.
12. Under **Actions**, for **Whenever this alarm**, choose **State is ALARM**. For **Send notification to**, choose an existing SNS topic or create a new one.

To create an SNS topic, choose **New list**. For **Send notification to**, enter a name for the SNS topic (for example, **myHighCpuAlarm**), and for **Email list**, enter a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent.

13. Choose **Create Alarm**.

Setting up a latency alarm using the AWS CLI

Use these steps to use the AWS CLI to create a load balancer latency alarm.

To create a load balancer latency alarm

1. Set up an SNS topic. For more information, see Setting up Amazon SNS notifications.
2. Create the alarm using the put-metric-alarm command as follows:

```
aws cloudwatch put-metric-alarm --alarm-name lb-mon --alarm-description "Alarm
 when Latency exceeds 100s" --metric-name Latency --namespace AWS/ELB --statistic
 Average --period 60 --threshold 100 --comparison-operator GreaterThanThreshold --
dimensions Name=LoadBalancerName,Value=my-server --evaluation-periods 3 --alarm-
actions arn:aws:sns:us-east-1:111122223333:my-topic --unit Seconds
```

3. Test the alarm by forcing an alarm state change using the set-alarm-state command.

   a. Change the alarm state from INSUFFICIENT_DATA to OK.

   ```
   aws cloudwatch set-alarm-state --alarm-name lb-mon --state-reason
    "initializing" --state-value OK
   ```

   b. Change the alarm state from OK to ALARM.

   ```
   aws cloudwatch set-alarm-state --alarm-name lb-mon --state-reason
    "initializing" --state-value ALARM
   ```

   c. Check that you have received an email notification about the alarm.

Create a storage throughput alarm that sends email

You can set up an SNS notification and configure an alarm that is triggered when Amazon EBS exceeds 100 MB throughput.

Setting up a storage throughput alarm using the AWS Management Console

Use these steps to use the AWS Management Console to create an alarm based on Amazon EBS throughput.

To create a storage throughput alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose **Create alarm**.
4. Under **EBS Metrics**, choose a metric category.
5. Select the row with the volume and the **VolumeWriteBytes** metric.
6. For the statistic, choose **Average**. For the period, choose **5 Minutes**. Choose **Next**.
7. Under **Alarm Threshold**, enter a unique name for the alarm (for example, **`myHighWriteAlarm`**) and a description of the alarm (for example, **`VolumeWriteBytes exceeds 100,000 KiB/s`**). The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.
8. Under **Whenever**, for **is**, choose **>** and enter **`100000`**. For **for**, enter **15** consecutive periods.

   A graphical representation of the threshold is shown under **Alarm Preview**.
9. Under **Additional settings**, for **Treat missing data as**, choose **ignore (maintain alarm state)** so that missing data points don't trigger alarm state changes.
10. Under **Actions**, for **Whenever this alarm**, choose **State is ALARM**. For **Send notification to**, choose an existing SNS topic or create one.

    To create an SNS topic, choose **New list**. For **Send notification to**, enter a name for the SNS topic (for example, **`myHighCpuAlarm`**), and for **Email list**, enter a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.

11. Choose **Create Alarm**.

Setting up a storage throughput alarm using the AWS CLI

Use these steps to use the AWS CLI to create an alarm based on Amazon EBS throughput.

To create a storage throughput alarm

1. Create an SNS topic. For more information, see Setting up Amazon SNS notifications.
2. Create the alarm.

```
aws cloudwatch put-metric-alarm --alarm-name ebs-mon --alarm-description "Alarm
 when EBS volume exceeds 100MB throughput" --metric-name VolumeReadBytes --
namespace AWS/EBS --statistic Average --period 300 --threshold 100000000 --
comparison-operator GreaterThanThreshold --dimensions Name=VolumeId,Value=my-
volume-id --evaluation-periods 3 --alarm-actions arn:aws:sns:us-
east-1:111122223333:my-alarm-topic --insufficient-data-actions arn:aws:sns:us-
east-1:111122223333:my-insufficient-data-topic
```

3. Test the alarm by forcing an alarm state change using the set-alarm-state command.

   a. Change the alarm state from `INSUFFICIENT_DATA` to `OK`.

   ```
   aws cloudwatch set-alarm-state --alarm-name ebs-mon --state-reason
    "initializing" --state-value OK
   ```

   b. Change the alarm state from `OK` to `ALARM`.

   ```
   aws cloudwatch set-alarm-state --alarm-name ebs-mon --state-reason
    "initializing" --state-value ALARM
   ```

   c. Change the alarm state from `ALARM` to `INSUFFICIENT_DATA`.

   ```
   aws cloudwatch set-alarm-state --alarm-name ebs-mon --state-reason
    "initializing" --state-value INSUFFICIENT_DATA
   ```

   d. Check that you have received an email notification about the alarm.

Create an alarm on Performance Insights counter metrics from an AWS database

CloudWatch includes a **DB_PERF_INSIGHTS** metric math function which you can use to bring Performance Insights counter metrics into CloudWatch from Amazon Relational Database Service and Amazon DocumentDB (with MongoDB compatibility). **DB_PERF_INSIGHTS** also brings in the DBLoad metric at sub-minute intervals. You can set CloudWatch alarms on these metrics.

For more information about Amazon RDS Performance Insights, see Monitoring DB load with Performance Insights on Amazon RDS.

For more information about Amazon DocumentDB Performance Insights, see Monitoring with Performance Insights.

Anomaly detection is not supported for alarms based on the **DB_PERF_INSIGHTS** function.

> **Note**
>
> High-resolution metrics with sub-minute granularity retrieved by **DB_PERF_INSIGHTS** are only applicable to the **DBLoad** metric, or for operating system metrics if you have enabled Enhanced Monitoring at a higher resolution. For more information about Amazon RDS enhanced monitoring, see Monitoring OS metrics with Enhanced Monitoring..
> You can create a high-resolution alarm using the **DB_PERF_INSIGHTS** function. The maximum evaluation range for a high-resolution alarm is three hours. You can use the CloudWatch console to graph metrics retrieved with the **DB_PERF_INSIGHTS** function for any time range.

To create an alarm that's based on Performance Insights metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select Metric**.
5. Choose the **Add math** dropdown, and then select **All functions**, **DB_PERF_INSIGHTS** from the list.

After you choose **DB_PERF_INSIGHTS**, a math expression box appears where you apply or edit math expressions.

6. In the math expression box, enter your **DB_PERF_INSIGHTS** math expression, and then choose **Apply**.

   For example, **`DB_PERF_INSIGHTS('RDS', 'db-ABCDEFGHIJKLMNOPQRSTUVWXY1', 'os.cpuUtilization.user.avg')`**

   > **Important**
   >
   > When you use the **DB_PERF_INSIGHTS** math expression, you must specify the Unique Database Resource ID of the database. This is different than the database identifier. To find the database resource ID in the Amazon RDS console, choose the DB instance to see its details. Then choose the **Configuration** tab. The **Resource ID** is displayed in the **Configuration** section.

   For information about the **DB_PERF_INSIGHTS** function and other functions that are available for metric math, see Metric math syntax and functions.

7. Choose **Select metric**.

   The **Specify metric and conditions** page appears, showing a graph and other information about the math expression that you have selected.

8. For **Whenever *`expression`* is**, specify whether the expression must be greater than, less than, or equal to the threshold. Under **than...**, specify the threshold value.

9. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the ALARM state to trigger the alarm. If the two values here match, you create an alarm that goes to ALARM state if that many consecutive periods are breaching.

   To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Alarm evaluation.

10. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.

11. Choose **Next**.

12. Under **Notification**, select an SNS topic to notify when the alarm is in ALARM state, OK state, or INSUFFICIENT_DATA state.

    To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    To have the alarm not send notifications, choose **Remove**.

13. To have the alarm perform Auto Scaling, EC2, Lambda, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. If you choose a Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

    Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

    > **Note**
    >
    > To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for AWS Systems Manager Incident Manager.

14. When finished, choose **Next**.
15. Enter a name and description for the alarm. Then choose **Next**.

    The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

16. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

Create a Log Alarm on error patterns

You can create a Log Alarm that monitors your logs for error patterns and sends a notification when the error count exceeds a threshold.

The following example creates a Log Alarm that transitions to ALARM state when more than 10 ERROR messages appear in 3 out of 5 query executions.

```
aws cloudwatch put-log-alarm \
    --alarm-name "LambdaErrors" \
    --alarm-description "Alarm when Lambda error count exceeds 10" \
    --comparison-operator GreaterThanThreshold \
    --threshold 10 \
    --query-results-to-evaluate 5 \
    --query-results-to-alarm 3 \
    --treat-missing-data notBreaching \
    --alarm-actions "arn:aws:sns:region:account-id:topic-name" \
    --scheduled-query-configuration '{
        "QueryString": "fields @timestamp, @message | filter @message like /ERROR/",
        "LogGroupIdentifiers": ["/aws/lambda/my-function"],
        "ScheduledQueryRoleARN": "arn:aws:iam::account-id:role/ScheduledQueryRole",
        "AggregationExpression": "count(*)",
        "ScheduleConfiguration": {
            "ScheduleExpression": "rate(5 minutes)",
            "StartTimeOffset": 300
        }
    }'
```

Create a Log Alarm on high latency per endpoint

You can create a multi-contributor Log Alarm that monitors average latency grouped by endpoint. The alarm transitions to ALARM state if any endpoint exceeds the latency threshold.

The following example creates a Log Alarm that enters ALARM state when any endpoint has average latency greater than 1000 ms in 3 out of 5 query executions.

```
aws cloudwatch put-log-alarm \
    --alarm-name "EndpointLatency" \
    --alarm-description "Alarm when any endpoint latency exceeds 1000ms" \
    --comparison-operator GreaterThanThreshold \
    --threshold 1000 \
    --query-results-to-evaluate 5 \
    --query-results-to-alarm 3 \
    --treat-missing-data missing \
    --alarm-actions "arn:aws:sns:region:account-id:topic-name" \
    --scheduled-query-configuration '{
```

```
        "QueryString": "parse @message /endpoint=(?<endpoint>\\S+).*latency=(?<latency>
\\d+)/",
        "LogGroupIdentifiers": ["/aws/apigateway/my-api"],
        "ScheduledQueryRoleARN": "arn:aws:iam::account-id:role/ScheduledQueryRole",
        "AggregationExpression": "avg(latency) by endpoint",
        "ScheduleConfiguration": {
            "ScheduleExpression": "rate(5 minutes)",
            "StartTimeOffset": 300
        }
    }'
```

In this example, each unique value of `endpoint` becomes a contributor. If any contributor's average latency exceeds 1000 ms, the alarm transitions to `ALARM` state and sends a notification identifying which endpoint is breaching.

Create an alarm that triggers an Auto Scaling action

With a metric alarm, you can trigger an Auto Scaling scaling policy to add or remove capacity when a metric breaches a threshold. This example scales an Auto Scaling group when the average CPU of the group exceeds a threshold.

You first create the scaling policy, and then attach its ARN as the alarm action. This applies to simple and step scaling policies. For target tracking scaling policies, the Auto Scaling service creates and manages the alarms for you.

Composite alarms can't trigger Auto Scaling actions. For more information, see Auto Scaling actions.

Setting up an Auto Scaling action alarm using the AWS Management Console

Use the AWS Management Console to create an alarm that triggers an Auto Scaling action. Because the full workflow has more than seven steps, it is divided into two parts.

Part 1: Select the metric and set the condition

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**.

5. Select the **AWS/EC2** namespace, and then select **By Auto Scaling Group**. Find the row with **CPUUtilization** for the **AutoScalingGroupName** dimension set to your group. Select the check box next to this row, and choose **Select metric**.
6. For **Statistic**, choose **Average**, and choose a period (for example, **`5 minutes`**).
7. Under **Conditions**, for **Threshold type** choose **Static**. For **Whenever CPUUtilization is**, choose **Greater**, and under **than...** enter **`70`**. Then choose **Next**.

Part 2: Configure the action and create the alarm

1. Under **Notification**, configure an Amazon SNS notification, or choose **Remove** if you don't want one.
2. Choose **Add EC2 Auto Scaling action**. Select the alarm state that triggers the action, select the Auto Scaling group, and then select the scaling policy to run. Then choose **Next**.
3. Under **Name and description**, enter a name and description for the alarm, and choose **Next**.
4. Under **Preview and create**, choose **Create alarm**.

It might take a few minutes for the alarm to become active.

Setting up an Auto Scaling action alarm using the AWS CLI

Use the AWS CLI to create an alarm that triggers an Auto Scaling action.

To create an alarm that triggers an Auto Scaling action

1. Create a simple scaling policy using the put-scaling-policy command. Replace *`my-asg`* and *`scale-out`* with your Auto Scaling group name and policy name.

   ```
   aws autoscaling put-scaling-policy --auto-scaling-group-name my-asg --policy-
   name scale-out --policy-type SimpleScaling --adjustment-type ChangeInCapacity --
   scaling-adjustment 1 --cooldown 300
   ```

   After the command runs, copy the `PolicyARN` value from the output to use in the next step. The output looks similar to the following:

   ```
   {
       "PolicyARN": "arn:aws:autoscaling:us-
   east-1:111122223333:scalingPolicy:12345678-1234-1234-1234-123456789012:autoScalingGroupName
   my-asg:policyName/scale-out"
   ```

```
}
```

2. Create the alarm using the put-metric-alarm command. Replace *my-asg* with your Auto Scaling group name, and replace the ARN in `--alarm-actions` with the `PolicyARN` value from the previous step.

```
aws cloudwatch put-metric-alarm --alarm-name asg-cpu-high --alarm-description
 "Scale out when CPU exceeds 70%" --metric-name CPUUtilization --namespace
 AWS/EC2 --statistic Average --period 300 --threshold 70 --comparison-operator
 GreaterThanThreshold --dimensions Name=AutoScalingGroupName,Value=my-
asg --evaluation-periods 2 --alarm-actions arn:aws:autoscaling:us-
east-1:111122223333:scalingPolicy:...:policyName/scale-out
```

If the command succeeds, it returns no output.

Telemetry discovery and enablement

Amazon CloudWatch telemetry configuration provides a centralized experience to discover and audit the state of telemetry across your AWS resources, and to create rules that automatically enable telemetry for popular AWS resource types. You can use telemetry configuration within a single account or across multiple accounts in AWS Organizations using the management account or a CloudWatch delegated administrator account.

Topics

- What is telemetry discovery and enablement?
- Setting up telemetry configuration
- Discovering resource telemetry
- Telemetry enablement rules
- Troubleshooting telemetry configuration
- Disabling telemetry configuration

What is telemetry discovery and enablement?

CloudWatch telemetry configuration gives you two core capabilities:

- **Discovery and auditing** – Discover AWS resources across your account or organization and audit which resources have telemetry enabled. The experience shows the configuration status at the resource-type level and at more granular telemetry-detail levels.
- **Enablement rules** – Create rules that automatically configure telemetry collection for AWS resources that match your criteria. Rules help you standardize telemetry collection across your organization or accounts and make sure consistent monitoring coverage.

Telemetry configuration supports the following resource types for **discovery and auditing** (using the `ListResourceTelemetry` and `ListResourceTelemetryForOrganization` APIs):

- Amazon Amazon EC2 Instance (`AWS::EC2::Instance`) – Detailed Metrics
- Amazon Amazon VPC (`AWS::EC2::VPC`) – Flow Logs, Route 53 Resolver Query Logs
- AWS Lambda Function (`AWS::Lambda::Function`) – Active Tracing
- Amazon EKS Cluster (`AWS::EKS::Cluster`) – Control Plane Logs

- AWS WAFv2 Web ACL (`AWS::WAFv2::WebACL`) – WAF Logs
- Elastic Load Balancing Network Load Balancer (`AWS::ElasticLoadBalancingV2::LoadBalancer`) – NLB Access Logs

> **Note**
>
> The `AWS::ElasticLoadBalancingV2::LoadBalancer` resource type for discovery only includes Network Load Balancers (NLBs). Application Load Balancers (ALBs) are not currently supported for discovery.

In addition to the resource types above, telemetry **enablement rules** (using the `CreateTelemetryRule` and `CreateTelemetryRuleForOrganization` APIs) support the following additional data sources:

- AWS CloudTrail Data Events and Management Events
- Amazon Bedrock AgentCore Logs
- AWS Security Hub
- Amazon Bedrock AgentCore Gateway
- Amazon Bedrock AgentCore Memory
- Amazon CloudFront Distribution
- Amazon S3 Server Access Logs
- Amazon MSK Cluster Metrics
- OpenTelemetry Enrichment Metrics
- Amazon Bedrock AgentCore Workload Identity
- Elastic Load Balancing Application Load Balancer Logs
- Amazon Bedrock Knowledge Base Logs
- Amazon Bedrock AgentCore Payment Manager
- AWS X-Ray Transaction Search
- Amazon EKS Container Insights

When you enable telemetry configuration, CloudWatch creates AWS Config service-linked configuration recorders that discover resources and their associated telemetry configuration metadata. For more information, see Configuration Recorder in the AWS Config Developer Guide.

> **Note**
>
> AWS Config periodically takes inventory of, or discovers, all the resources in your account as an anti-entropy behavior, regardless of the resource types in scope for your configuration recorders. The inventory includes deleted resources and resources that AWS Config is not currently recording. This behavior helps maintain data consistency.
> This means that although the service-linked configuration recorder for the CloudWatch telemetry configuration feature is configured to record specific resource types, you might see describe calls from `ConfigResourceCompositionSession` and `AWSConfig-Describe` in AWS CloudTrail. For more information, see Non-recorded Resources in the AWS Config Developer Guide.

Amazon CloudWatch uses AWS Config Internal service linked recorder. You are not charged for CIs that CloudWatch uses as part of the Internal Service Linked Recorders.

You can manage telemetry configuration across multiple AWS Regions from a single Region. When you enable multi-Region support, the current Region becomes your home Region and telemetry configuration is replicated to the Regions you select. For more information, see Setting up telemetry configuration.

Setting up telemetry configuration

Use the CloudWatch console to set up telemetry configuration for your AWS account or organization. For an organization, as a management account or a CloudWatch delegated administrator account, CloudWatch discovers AWS resources and provides visibility into the telemetry configurations across all the member accounts in the organization.

Telemetry config remains active until you turn it off. For more information, see Disabling telemetry configuration.

Topics

- Prerequisites and permissions

- Enable telemetry configuration for your account
- Enable telemetry configuration for your organization
- Registering a delegated administrator account for your organization

Prerequisites and permissions

Telemetry configuration for your organization requires trusted access between AWS Organizations and CloudWatch. When trusted access is enabled, CloudWatch creates a service-linked role named **AWSServiceRoleForObservabilityAdmin** to support resource and telemetry configuration discovery for the organization.

When you turn on telemetry configuration for your organization from a management account, CloudWatch automatically enables trusted access and creates the service-linked role. You do not need to set up trusted access manually before starting telemetry evaluation.

> **Important**
>
> CloudWatch uses your IAM permissions to perform this setup. It does not use CloudWatch service permissions. In addition to the telemetry configuration permissions, you must be allowed to perform the following actions:
>
> - `iam:CreateServiceLinkedRole`—to create the **AWSServiceRoleForObservabilityAdmin** and **AWSServiceRoleForObservabilityAdmin_TelemetryEnablement** service-linked roles.
> - `organizations:EnableAWSServiceAccess`—to enable trusted access between AWS Organizations and CloudWatch.
>
> If you are not allowed to perform these actions, turning on telemetry configuration fails with an `AccessDeniedException`. CloudWatch does not enable trusted access.

The following example JSON policy grants the additional permissions required to turn on telemetry configuration for an organization:

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Sid": "AllowCreateObservabilityAdminServiceLinkedRoles",
            "Effect": "Allow",
            "Action": "iam:CreateServiceLinkedRole",
            "Resource": [
                "arn:aws:iam::*:role/aws-service-role/observabilityadmin.amazonaws.com/
AWSServiceRoleForObservabilityAdmin",
                "arn:aws:iam::*:role/aws-service-role/telemetry-
enablement.observabilityadmin.amazonaws.com/
AWSServiceRoleForObservabilityAdmin_TelemetryEnablement"
            ],
            "Condition": {
                "StringEquals": {
                    "iam:AWSServiceName": [
                        "observabilityadmin.amazonaws.com",
                        "telemetry-enablement.observabilityadmin.amazonaws.com"
                    ]
                }
            }
        },
        {
            "Sid": "AllowEnableTrustedAccessForObservabilityAdmin",
            "Effect": "Allow",
            "Action": "organizations:EnableAWSServiceAccess",
            "Resource": "*"
        }
    ]
}
```

> **Note**
>
> If you use a delegated administrator account to turn on telemetry configuration, the service-linked role is automatically created in all member accounts but is *not* automatically created in the management account. In this case, you must manually create the **AWSServiceRoleForObservabilityAdmin** service-linked role in the management account.

For more information about the service-linked role, see Service-linked role permissions for CloudWatch telemetry config. For more information about AWS Organizations, see Amazon CloudWatch and AWS Organizations in the AWS Organizations User Guide.

Enable telemetry configuration for your account

Configure telemetry for your AWS account to monitor telemetry for the AWS resources in that account. If you have an organization in AWS Organizations, configure telemetry for your organization instead. For more information, see Configuring telemetry for your organization.

To configure telemetry for your AWS account

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Ingestion**.
3. Choose the **Data Source** tab, and then select **Enable Resource Discovery**. CloudWatch begins discovering AWS resources in your account. As CloudWatch discovers resources, it updates information on the **Overview** page.

> **Note**
>
> The delay before resources appear on the **Overview** page depends on the number of resources in your account.

Enabling across Regions

You can extend telemetry configuration to multiple AWS Regions from a single Region. When you enable multi-Region support, the current Region becomes your *home Region*. Telemetry configuration is replicated to the Regions you select.

To enable telemetry configuration across Regions for your account (initial setup)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**, and then choose the **Account** tab.
3. In the **CloudWatch telemetry config** section on the **Global** tab, the status shows **Off**. When multi-Region is enabled, a **Target regions** selector appears inline below the status.
4. Use the **All regions** toggle to include all Regions, or use the multiselect dropdown to choose individual Regions. The current Region is always included automatically and is not shown in the selector.
5. Choose **Turn on**.

6. After telemetry configuration is turned on, a **Region status** table appears showing the per-Region evaluation status.

To reconfigure Regions (telemetry already running)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**, and then choose the **Account** tab.
3. In the **CloudWatch telemetry config** section, choose **Configure regions**. The **Target regions** selector appears inline, pre-populated with the currently configured Regions.
4. Modify the Region selection as needed, and then choose **Save**.

If you select **All regions**, new Regions are automatically included when you opt in to them. The system periodically reconciles configuration across Regions to correct any drift.

Enable telemetry configuration for your organization

To turn on telemetry configuration for your organization, you must use a AWS Organization management account or a delegated administrator account. CloudWatch uses this account to discover your organization's AWS resources and configure their telemetry.

When you turn on telemetry configuration from a management account, CloudWatch automatically sets up trusted access between AWS Organizations and CloudWatch, including creating the required service-linked role. You do not need to enable trusted access manually as a separate step. CloudWatch uses your own IAM permissions to perform this setup. You must be allowed to perform `iam:CreateServiceLinkedRole` and `organizations:EnableAWSServiceAccess`. For more information about permissions, see Prerequisites and permissions.

To turn on telemetry auditing for your organization

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Organizations** tab.
4. On the **CloudWatch** settings page, in the **Organizational settings management** pane, choose **Turn on**. CloudWatch automatically enables trusted access and creates the **AWSServiceRoleForObservabilityAdmin** service-linked role in your organization.

To review the role policy, choose **View permission details**.

5. After Telemetry config is turned on for the organization, a notification appears. On the notification, choose Go to Telemetry config. The Telemetry Configuration experience can be accessed in the **Ingestion** page and CloudWatch begins discovering AWS resources in the organization. As CloudWatch discovers resources, it updates information on the **Telemetry config** page.

> **Note**
>
> The time delay before resources appear on the **Telemetry config** page depends on the number of member accounts and resources in your organization or account.

Configuring telemetry for your organization

Configure telemetry for AWS Organizations to monitor the telemetry for the AWS resources across all your member accounts. This also configures the telemetry for individual accounts. You can also configure telemetry for only your account. For more information, see Enable telemetry configuration for your account.

You can disable trusted access across all your member accounts. For more information, see Turning off trusted access for AWS Organizations.

To configure telemetry auditing for your organization

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Ingestion**.
3. Choose **Data sources**, and then choose the **Enable Resources Discovery Button**. CloudWatch begins discovering AWS resources in your organization. As CloudWatch discovers resources, it updates information in the **Overview** page.

> **Note**
>
> The delay before resources appear on the **Overview** page depends on the number of member accounts and resources in your organization.

Enabling across Regions

You can extend telemetry configuration to multiple AWS Regions from a single Region for your entire organization. When you enable multi-Region support, the current Region becomes your *home Region*. Telemetry configuration is replicated to the Regions you select for all member accounts.

To enable telemetry configuration across Regions for your organization (initial setup)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**, and then choose the **Organizations** tab.
3. In the **CloudWatch telemetry config** section on the **Global** tab, the status shows **Off**. When multi-Region is enabled, a **Target regions** selector appears inline below the status.
4. Use the **All regions** toggle to include all Regions, or use the multiselect dropdown to choose individual Regions. The current Region is always included automatically and is not shown in the selector.
5. Choose **Turn on**.
6. After telemetry configuration is turned on, a **Region status** table appears showing the per-Region evaluation status.

To reconfigure Regions for your organization (telemetry already running)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**, and then choose the **Organizations** tab.
3. In the **CloudWatch telemetry config** section, choose **Configure regions**. The **Target regions** selector appears inline, pre-populated with the currently configured Regions.
4. Modify the Region selection as needed, and then choose **Save**.

If you select **All regions**, new Regions are automatically included when you opt in to them. The system periodically reconciles configuration across Regions to correct any drift.

Registering a delegated administrator account for your organization

A delegated administrator account is a member account that shares administrator access for service-managed permissions. The account that you register as a delegated administrator must be in your organization. A delegated administrator account for your organization can be used

outside of CloudWatch, so make sure that you understand this account type before you follow this procedure. For more information, see Amazon CloudWatch and AWS Organizations in the AWS Organizations User Guide.

To remove or change the delegated administrator account, deregister the account first. For more information, see Deregistering a delegated administrator account.

To register a delegated administrator account

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Organization** tab.
4. In the **Organizational settings management** pane, choose **Register delegated administrator**.
5. In the **Register delegated administrator** dialog, for **Delegated administrator account ID**, enter the 12-digit account ID for an organization member account.
6. Choose **Register delegated administrator**. At the top of the **CloudWatch settings** page, a message appears indicating the account was registered successfully. To see information about the delegated administrator account, select the number below **Delegated administrators**.

Deregistering a delegated administrator account

Deregister the delegated administrator account before turning off trusted access for AWS Organizations. You can also deregister a delegated administrator account if it no longer has access to the appropriate AWS resources for telemetry configuration or to choose a different member account to be the delegated administrator. This account will not be able to perform account management tasks for AWS Organizations. For more information, see Amazon CloudWatch and AWS Organizations in the AWS Organizations User Guide.

To deregister the delegated administrator account

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. On the **Organization** tab, choose **Deregister**.
4. On the **Deregister delegated administrator** page, choose **Deregister**.

To register an account as a delegated administrator, see Registering a delegated administrator account for your organization.

Turning off trusted access for AWS Organizations

Trusted access extends the functionality of the management account in AWS Organizations to other AWS services. When you turn off trusted access, trusted access between your organization and all AWS services—not just CloudWatch—will stop.

If you no longer want trusted access turned on for your organization, you can turn it off. For more information, see Amazon CloudWatch and AWS Organizations in the AWS Organizations User Guide.

> **Note**
>
> Before turning off trusted access for an organization, deregister the delegated administrator account. For more information, see Deregistering a delegated administrator account.

To turn off trusted access for AWS Organizations

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Organization** tab.
4. In the **Organizational Management Settings** section, select **Turn off**.

Discovering resource telemetry

The telemetry configuration experience displays AWS resources in two places: as an overview on the **Ingestion – Data sources** and in detail on the **Discovered resources** page.

Topics

- Viewing data sources
- Viewing discovered resources
- Filtering and preferences

Viewing data sources

The **Ingestion – Data sources** shows the AWS resources that you can send to CloudWatch. For specific resource types, it shows the percentage of resources with telemetry configured and the total number of resources detected. You can filter the display of resources in the **Data source** tab by account ID or by the tags applied to your resources.

To view resources on the Ingestion page

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Ingestion**.
3. The **Ingestion** page shows the total number of each resource that was discovered by CloudWatch, the number of resources providing telemetry, and the percentage of discovered resources that are providing telemetry.
4. To see recent changes to resources, choose **Refresh**.

Viewing discovered resources

The **Discovered resources** page shows details about each AWS resource that has been discovered by telemetry configuration, including the resource ID, the type of telemetry each resource is providing, and the time when information about the resource was last refreshed.

For each AWS resource tracked by CloudWatch, the **Discovered resources** page shows the status of its telemetry by providing the following information:

- For telemetry types that CloudWatch detects that the resource is sending to CloudWatch, the **Discovered resources** page shows **On**.
- For telemetry types that CloudWatch detects the resource is not providing, the **Discovered resources** page shows **Off**.
- For telemetry types that are not supported for a resource, the **Discovered resources** page shows **NS**, that is, not supported.

To view resources on the Discovered resources page

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Ingestion**.

3. Do one of the following to view all resource types discovered by telemetry configuration or to view one resource type:

   a. To view all resources that have been discovered by CloudWatch, click **View data sources**. The **Discovered resources** page appears and shows all resources discovered.

   b. To view one resource type, click the name of the AWS resource type in the **Ingestion > Data sources**. The **Discovered resources** page appears. The **Discovered resources** page shows that a filter has been applied for that data source and now displays all discovered resources for that resource type.

4. On the **Discovered resources** page, to view information about the resource or to change its telemetry settings, click the resource ID. The console page for the AWS resource will open, navigate to the configuration setting and turn on or off the configuration.

> **Note**
>
> You can only view a resource on its console page if the resource belongs to your account. To determine if the resource belongs to your account, check the **AWS account** column. If the **AWS account** column does not appear, change your **Discovered resources** page preferences. For more information, see Changing preferences for the Discovered resources page.

Viewing resources across Regions

When multi-Region support is active, the **Discovered resources** page includes a **Region** column. You can filter resources by Region to focus on specific Regions.

CloudWatch uses a AWS Config aggregator to collect resource data across Regions. Because of this, there may be a short delay before resources from spoke Regions appear in the home Region view.

Filtering and preferences

You can use one or more filters on the **Ingestion > Data Sources** page and the **Discovered resources** page to change your view of the resources. Your filter settings persist across both pages.

To filter resources on the Data Sources page

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Ingestion**, and then choose **Data sources**.

3. You can filter the discovered resources that are displayed on the page by specifying an account ID or tag value.

   a. Choose **Find resource**.

   b. Choose **Account ID** or **Tag value**, and then choose additional options for the filter. Statistics about telemetry coverage for each resource change based on your filter options.

4. To remove a filter, in the filter text box, choose **X**.

To filter resources on the Discovered Data sources page

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Ingestion**.
3. To view all resource types discovered by telemetry configuration or to view one resource type, do one of the following:

   a. To view all resources discovered by CloudWatch, choose **View data sources**. The **Discovered resources** page appears and shows all resources discovered.

   b. To view one resource type, at the bottom of the page, choose a type of AWS resource. The **Discovered resources** page appears. The **Discovered resources** page filters all discovered resources for that resource type.

4. You can filter the resources displayed in the page based on any of the columns in the page. You can change the columns in the page by changing your preferences for the **Discovered resources** page. For more information, see the preferences procedure below.

   a. Choose **Find resource**. Filters for each column in the page appear. Choose one, then choose additional options to define the filter. Resources appear in the page that match the filter settings.

   b. To further filter the resources displayed in the page, choose **Find resources** again, choose another filter, and choose additional options. Resources appear in the page that match all of the filter settings.

5. To remove one of the filters, in the filter text box, choose **X**.
6. To remove all of the filters and see all resource types discovered, choose **Clear filters**.

Changing preferences for the Discovered resources page

You can change your preferences for the **Discovered resources** page to control how many resources appear per page and which detailed metrics appear in the page. Only detailed metrics in view can be used to filter the resources displayed in the discovered resources page. For more information, see Filtering and preferences.

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Ingestion** and **Data sources tab**.
3. Choose **Discovered resources**. The **Discovered resources** page appears.
4. Choose the gear icon.
5. In the **Preferences** dialog box, choose the number of resources per page and the visible content to show as columns.
6. Choose **Confirm**.

Telemetry enablement rules

You can create telemetry enablement rules to automatically configure telemetry collection for your AWS resources. Rules help you standardize telemetry collection across your organization or accounts and make sure consistent monitoring coverage.

Topics

- How rules work
- Creating a telemetry enablement rule
- Managing telemetry rules
- Encrypting log groups with customer managed keys
- Supported data sources

How rules work

Telemetry configuration follows specific patterns when evaluating and applying rules.

Rule evaluation hierarchy

Enablement rules are evaluated according to a hierarchical pattern. Organizational rules are evaluated first, then rules that apply to organizational units (OUs), and finally rules that apply to

individual accounts. Rules at the organizational level provide the baseline required telemetry for your organization. Rules at the OU and account level can collect additional telemetry data, but they cannot collect less telemetry data. If such a rule is created, it will create a rule conflict.

Within each scope (organization, OU, or account), rules must maintain uniqueness based on their resource type, telemetry type, and destination configuration. Duplicate rules trigger a conflict exception. If the same rule exists in different scopes, such as an organization level rule for Amazon VPC Flow logs to CloudWatch and an OU level rule for Amazon VPC Flow logs, the rule higher in the hierarchy is applied. However, if there are multiple conflicting rules, none of the rules are applied.

When multiple rules apply to the same resource, telemetry configuration resolves conflicts using these priorities:

1. Organizational-level rules take precedence over account-level rules
2. More specific tag matches take precedence over general rules
3. If there are multiple conflicting rules, none of the rules are applied. You must resolve the conflicts first.

Rule behavior on updates

If you update an enablement rule, only new resources that match the rule adopt the updated configuration. The existing telemetry settings remain unchanged for existing resources. If a resource becomes non-compliant with an existing rule due to manual deletion of telemetry data, the new enablement rule is adopted after the resource is brought back into compliance.

For Amazon VPC Flow logs, telemetry config only creates new flow logs for resources that match the rule scope. It does not delete or impact previously established Amazon VPC Flow logs, even if they differ from current rule parameters. For CloudWatch Logs, existing log groups are maintained provided they match the resource pattern.

Integration with AWS Config

CloudWatch telemetry auditing and configuration integrates with AWS Config to automatically discover resources that match your enablement rule and apply it to your telemetry data collection. When you create an enablement rule, the telemetry configuration creates a corresponding AWS Config recorder. This recorder includes configuration items for the specific resource types you define in the enablement rule.

Amazon CloudWatch uses AWS Config Internal service linked recorder. You are not charged for CIs that CloudWatch uses as part of the Internal Service Linked Recorders.

> **Note**
>
> When you create an enablement rule, we discover non-compliant resources (those without telemetry enabled) through AWS Config Configuration Items (CIs) before turning them on based on your enablement rule scope. The initial discovery of the resources may take up to 24 hours to complete in some cases.

Telemetry config uses AWS Config to:

- Discover resources across your organization or accounts
- Track telemetry configuration changes

Rules across Regions

When you create a rule with target Regions, the current Region becomes the *home Region* for that rule. The rule is automatically replicated to the spoke Regions you select.

Key concepts for multi-Region rules:

- Replicated rules cannot be edited or deleted in spoke Regions. You must navigate to the home Region to modify or remove them.
- If you select **All regions**, new Regions are automatically included when you opt in to them.
- The system periodically reconciles rules across Regions to correct any drift between the home Region and spoke Regions.
- Tags applied to rules in the home Region are replicated to spoke Regions.

When a replicated rule is created, updated, or deleted in a spoke Region, AWS CloudTrail records an `AwsServiceEvent` in the spoke Region. These events are logged with `observabilityadmin.amazonaws.com` as the invoking service and include the rule ARN in the spoke Region. You can use these events to audit multi-Region rule replication activity.

The following is an example AWS CloudTrail event recorded when a replicated rule is created in a spoke Region:

```
{
    "eventVersion": "1.11",
    "userIdentity": {
        "accountId": "123456789012",
        "invokedBy": "observabilityadmin.amazonaws.com"
    },
    "eventTime": "2026-04-06T19:50:37Z",
    "eventSource": "observabilityadmin.amazonaws.com",
    "eventName": "CreateTelemetryRule",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "observabilityadmin.amazonaws.com",
    "userAgent": "observabilityadmin.amazonaws.com",
    "requestParameters": null,
    "responseElements": null,
    "eventID": "435d6da2-d099-4775-8944-1e039418de6f",
    "readOnly": false,
    "resources": [
        {
            "accountId": "123456789012",
            "type": "AWS::ObservabilityAdmin::TelemetryRule",
            "ARN": "arn:aws:observabilityadmin:us-east-1:123456789012:telemetry-
rule/my-multi-region-rule"
        }
    ],
    "eventType": "AwsServiceEvent",
    "managementEvent": true,
    "recipientAccountId": "123456789012",
    "eventCategory": "Management"
}
```

The `eventName` field reflects the operation performed on the replicated rule: `CreateTelemetryRule`, `UpdateTelemetryRule`, or `DeleteTelemetryRule`. The `eventType` is always `AwsServiceEvent` because the operation is performed by the ObservabilityAdmin service on behalf of the customer, not by a direct customer API call.

Creating a telemetry enablement rule

When you create a telemetry enablement rule, you specify:

- The scope of the rule (organization, organizational unit, or account)
- The resource types the rule applies to

- The telemetry types to enable (metrics, logs, or traces)
- Optional tags to filter which resources the rule affects
- Optional target Regions to replicate the rule across multiple Regions
- Optional AWS KMS key ARN to encrypt log groups created by the rule with a customer managed key

To create a telemetry enablement rule

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Ingestion**.
3. Choose the **Enablement rules** tab.
4. Choose **Add rule**.
5. For **Rule name**, enter a name for your rule.
6. For **Rule scope**, choose one of the following:
   - **Organization** – Rule applies across your entire AWS Organizations
   - **Organizational unit** – Rule applies to a specific OU
   - **Account** – Rule applies to a single account
7. For **Data source**, select the AWS service to configure.
8. For **Telemetry type**, select the types of telemetry to enable.
9. (Optional) Add tags to filter which resources the rule affects.
10. (Optional) For **Target regions**, select the Regions where you want this rule to apply. The current Region is automatically designated as the home Region for the rule. If you select **All regions**, new Regions are automatically included when you opt in to them.
11. (Optional) For **KMS key ARN**, enter the ARN of an AWS KMS key to encrypt log groups created by this rule. For cross-Region rules, you must use a multi-Region key (key ID starts with `mrk-`). For more information, see Encrypting log groups with customer managed keys.
12. Choose **Create rule**.

Managing telemetry rules

After creating rules, you can edit or delete them. You can also view which resources each rule affects and monitor rule compliance.

To manage an existing rule

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Ingestion**.
3. Choose the **Enablement rules** tab.
4. Select a rule to view its details or choose one of these actions:

   - **Edit rule** – Modify rule settings
   - **Delete** – Remove the rule

Managing replicated rules

When you view a replicated rule in a spoke Region, the console displays an informational alert indicating that the rule was replicated from another Region. The **Edit rule** and **Delete** actions are disabled for replicated rules in spoke Regions.

To edit or delete a replicated rule, navigate to the home Region where the rule was originally created. The home Region is displayed in the informational alert.

You can add or modify tags on replicated rules in spoke Regions. Tag changes made in spoke Regions apply only to the local copy of the rule and are not replicated back to the home Region.

Encrypting log groups with customer managed keys

You can encrypt log groups created by telemetry enablement rules using a customer managed AWS KMS key. Encrypting log groups with a customer managed key gives you control over key rotation and helps meet compliance requirements. When you specify a AWS KMS key ARN in your rule's destination configuration, CloudWatch automatically associates the key with each log group created during remediation.

Requirements for KMS keys

- For cross-Region rules, you must use a multi-Region AWS KMS key. Multi-Region keys have a key ID that starts with `mrk-`. This ensures consistent encryption across all Regions where the rule is applied.
- For rules that target a single Region, both single-Region and multi-Region keys are accepted.
- The AWS KMS key must be enabled and accessible to the service-linked role used by telemetry rules.

- When you create or update a rule with a AWS KMS key ARN, the service validates that the key exists and is enabled by calling `kms:DescribeKey`.

Required KMS key policy

Your AWS KMS key policy must allow the CloudWatch Logs service to use the key for encryption. Add the following statement to your key policy:

```
{
    "Sid": "AllowCloudWatchLogsToUseKey",
    "Effect": "Allow",
    "Principal": { "Service": "logs.amazonaws.com" },
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:SourceOrgID": "your-organization-id"
        },
        "ArnLike": {
            "kms:EncryptionContext:aws:logs:arn": "arn:aws:logs:*:*:log-group:*"
        }
    }
}
```

Replace *your-organization-id* with your AWS Organizations organization ID. The `aws:SourceOrgID` condition ensures that only accounts in your organization can use the key for log group encryption.

> **Note**
>
> For organization-scope rules that remediate across member accounts, this key policy grants the CloudWatch Logs service in member accounts permission to encrypt and decrypt log data using your key. The telemetry rules service-linked role does not directly perform encryption or decryption—it only associates the key with the log group.

Service-linked role permissions for encryption

The telemetry rules service-linked role requires additional permissions to support AWS KMS key encryption. The following permissions are automatically added to the service-linked role when you use AWS KMS encryption with telemetry rules:

- `kms:DescribeKey` – Allows the service to validate that the AWS KMS key exists, is enabled, and is a multi-Region key (for cross-Region rules). This permission is used during rule creation and update validation. The call is always same-account (the service-linked role describes the key in the rule creator's own account).
- `logs:AssociateKmsKey` – Allows the service to associate the AWS KMS key with log groups created during remediation. This permission is scoped to log groups that are tagged with `CloudWatchTelemetryRuleManaged: true`, which limits the association to log groups managed by telemetry rules.

> **Note**
>
> The service-linked role does not perform encryption or decryption of log data directly. After the service associates the AWS KMS key with a log group, CloudWatch Logs uses the key for all subsequent encrypt and decrypt operations on that log group. Cross-account AWS KMS access during remediation is handled by the AWS KMS key policy (granting the `logs.amazonaws.com` service principal access), not by the service-linked role.

How multi-Region keys work with telemetry rules

Multi-Region AWS KMS keys share the same key ID across Regions. When a telemetry rule with a AWS KMS key is applied in multiple Regions, the service automatically resolves the key ARN to the target Region. For example, if you provide the key ARN `arn:aws:kms:us-east-1:123456789012:key/mrk-1234abcd` and the rule creates a log group in `eu-west-1`, the service uses `arn:aws:kms:eu-west-1:123456789012:key/mrk-1234abcd` for encryption in that Region.

You must make sure that the multi-Region key is replicated to all Regions where the rule applies. If the key has not been replicated to a target Region, remediation for resources in that Region fails, and the service retries the operation.

Updating encryption settings

When you update a rule to add a AWS KMS key, the service applies the key only to log groups that the rule creates after the update. The service does not retroactively encrypt log groups that the rule created before you added the key.

When you remove the AWS KMS key ARN from a rule, the service changes the encryption configuration that it previously applied to the rule's managed log groups.

Supported data sources

The following data sources are supported by telemetry enablement rules. Each data source has specific behavior and configuration considerations.

Amazon VPC Flow Logs

When creating flow logs:

- Uses default pattern /aws/vpc/vpc-id if none specified
- Existing customer-created flow logs are preserved
- Rule updates only affect new flow logs
- You can use <vpc-id>, <account-id> macros to split log groups.
- CloudWatch does not create flow logs for VPCs that already are ingesting logs to CloudWatch Logs
- When you enable automatic configuration updates on a rule, CloudWatch monitors the flow logs it created and remediates configuration drift. Drift occurs when the log format, traffic type, maximum aggregation interval, or destination log group name pattern of a rule-managed flow log no longer matches the rule. To remediate, CloudWatch creates a new flow log with the correct configuration and then deletes the outdated one.
- Automatic configuration updates apply only to Amazon VPC Flow Logs. CloudWatch never modifies or deletes flow logs that you created.

Amazon EKS Control Plane Logs

When enabling control plane logging:

- Uses default CloudWatch log group pattern /aws/eks/<cluster-name>/cluster. Amazon EKS creates Log Group per Cluster automatically.

- Rule updates only affect new clusters or only clusters that do not have the scoped log types enabled
- Can enable specific log types: api, audit, authenticator, controllerManager, scheduler

Amazon EKS Container Insights

When enabling Container Insights:

- Supports the INSIGHTS telemetry type on the `AWS::EKS::Cluster` resource type. The rule enables Container Insights as a whole and ignores any telemetry source types that you specify.
- Does not support a destination configuration. CloudWatch installs the Amazon CloudWatch Observability EKS add-on on each matching cluster, and the add-on sends metrics and logs to CloudWatch. For more information, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart.
- CloudWatch creates one service role named **CloudWatchTelemetryRuleEKSAddonRole** that every matching cluster in the account shares. CloudWatch always creates this role from an AWS managed IAM role template, so you cannot direct CloudWatch to use a different role or a different configuration.
- CloudWatch identifies the role it created by the `CloudWatchTelemetryRuleManaged` tag. If your account already has a role with this name that does not have that tag, CloudWatch does not install the add-on on any cluster in the account, and does not report an error. Rename or delete the conflicting role, and CloudWatch installs the add-on on the next evaluation.
- You can create only one Container Insights rule per account or organization in each Region. This limit does not apply to Amazon EKS control plane logs rules.
- Deleting the rule does not stop telemetry collection or the associated charges. To stop collection, uninstall the add-on from each cluster, which also removes the add-on-managed Amazon EKS Pod Identity association, and then delete the IAM role if no cluster still needs it.
- Available only in the commercial AWS Regions where CloudWatch telemetry configuration is available. Not available in the AWS GovCloud (US) Regions or in the European Sovereign Cloud. In other Regions, `CreateTelemetryRule` returns a validation error and the option does not appear in the console.

AWS WAF Web ACL Logs

When creating WAF logs:

- Uses default CloudWatch log group pattern and always prefixes with aws-waf-logs-
- Rule updates only affect new Web ACLs or existing Web ACLs that do not have logging enabled to CloudWatch Logs
- CloudWatch does not enable logs for Web ACLs that already are ingesting logs to CloudWatch Logs

Amazon Route 53 Resolver Logs

When enabling resolver query logging:

- Uses default CloudWatch log group pattern /aws/route53resolver if none specified
- You can use <account-id> macros to split log groups.
- CloudWatch does not create resolver query logs for VPCs that already are ingesting logs to CloudWatch Logs
- Enablement rules configure Route 53 query logging for your VPCs based on rule scope. CloudWatch does not discover Route 53 profiles and related configurations.

NLB Access Logs

When enabling access logs:

- Uses default CloudWatch log group pattern with prefix /aws/nlb/access-logs if none specified
- CloudWatch does not enable log deliveries for NLBs that already are ingesting logs to CloudWatch Logs

CloudTrail Logs using service-linked channel

When enabling CloudTrail logs using the SLC path:

- Uses managed CloudWatch log groups aws/cloudtrail/<event-types>
- Existing customer-created CloudTrail Trail forwarding configurations are preserved
- CloudWatch Enablement Rules only uses service-linked channel to ingest logs
- Events use the retention period configured for the log group
- For CloudTrail events, as part of the enablement wizard, you can choose at least one event type to ingest to CloudWatch.
- If events are delivered with delay (indicated by addendum reason DELIVERY_DELAY) and you previously configured a shorter retention period, delayed events might only be available for the duration of the shorter retention period.

> **Tip**
>
> To configure CloudTrail logs across multiple Regions, use the **Target regions** selector when creating your enablement rule. This replicates the rule to your selected Regions automatically from the home Region.

Amazon Amazon EC2 Detailed Metrics

When enabling detailed monitoring:

- Instance state changes may affect metric collection

AWS Security Hub

When enabling Security Hub logging:

- Uses managed CloudWatch log group pattern aws/securityhub_cspm/findings
- CloudWatch does not enable log deliveries for Security Hub that already are ingesting logs to managed CloudWatch Logs

Amazon Bedrock AgentCore

- Enable both logs and traces emitted from all available Bedrock AgentCore primitives such as Runtime, Browser Tools, Code Interpreter Tools, and so on. Follow the Telemetry Configure console experience for creating a logs delivery rule then followed by creating a traces delivery rule.
- When creating a trace delivery rule, Transaction Search will be enabled and additional permission policy will be created to allow for CloudWatch X-Ray to send correlated trace to managed log group in your account. In addition, X-Ray resource policy will be created to allow for current and new Bedrock AgentCore primitives to deliver traces to your account.

Amazon Bedrock Agentcore Gateway

When enabling Bedrock Agentcore Gateway logging:

- Uses default CloudWatch log group pattern /aws/bedrock/agentcore if none specified
- CloudWatch does not enable log deliveries for Bedrock Agentcore Gateway that already are ingesting logs to CloudWatch Logs

Amazon Bedrock Agentcore Memory

When enabling Bedrock Agentcore Memory logging:

- Uses default CloudWatch log group pattern /aws/bedrock/agentcore if none specified

- CloudWatch does not enable log deliveries for Bedrock Agentcore Memory that already are ingesting logs to CloudWatch Logs

Amazon CloudFront Distribution

When enabling CloudFront Distribution logging:

- CloudWatch does not enable log deliveries for CloudFront distributions that already are ingesting logs to CloudWatch Logs

Amazon S3 Server Access Logs

S3 server access logging has the following constraints:

- Supports the LOGS telemetry type with log type S3_SERVER_ACCESS_LOGS only.
- Supports only CloudWatch Logs as the destination type.
- Supports only tag-based selection criteria to target specific S3 buckets.

Amazon MSK Cluster Metrics

When enabling MSK Cluster metrics:

- Only supports METRICS telemetry type
- You can configure enhanced monitoring levels (PER_BROKER, PER_TOPIC_PER_BROKER, and so on) to control the granularity of metrics collected
- Rules with different enhanced monitoring levels can coexist for the same MSK cluster

OpenTelemetry Enrichment Metrics

When enabling OpenTelemetry Enrichment metrics:

- Only supports METRICS telemetry type
- This is an account-level enablement with no user-configurable destination
- Resource-level selection criteria is not supported

Amazon Bedrock Agentcore Workload Identity

When enabling Bedrock Agentcore Workload Identity logging:

- Uses default CloudWatch log group pattern /aws/bedrock/agentcore if none specified
- CloudWatch does not enable log deliveries for Bedrock Agentcore Workload Identity that already are ingesting logs to CloudWatch Logs

Elastic Load Balancing Application Load Balancer Logs

When enabling Application Load Balancer logging:

- Supports the LOGS telemetry type with log types `ALB_ACCESS_LOGS`, `ALB_CONNECTION_LOGS`, and `ALB_HEALTH_CHECK_LOGS`.
- Supports only CloudWatch Logs as the destination type.
- CloudWatch does not enable log deliveries for Application Load Balancers that already are ingesting the specified log types to CloudWatch Logs

Amazon Bedrock Knowledge Base

When enabling Bedrock Knowledge Base telemetry:

- Supports the LOGS telemetry type with log type `APPLICATION_LOGS`.
- Supports the TRACES telemetry type.
- For LOGS, supports only CloudWatch Logs as the destination type.
- CloudWatch does not enable log deliveries for Bedrock Knowledge Bases that already are ingesting the specified log types to CloudWatch Logs

Amazon Bedrock AgentCore Payment Manager

When enabling Bedrock AgentCore Payment Manager telemetry:

- Supports the LOGS telemetry type with log type `APPLICATION_LOGS`. Payment Manager does not support `USAGE_LOGS`.
- Supports the TRACES telemetry type.
- For LOGS, supports only CloudWatch Logs as the destination type.
- CloudWatch does not enable log deliveries for payment managers that already are ingesting the specified log types to CloudWatch Logs

AWS X-Ray Transaction Search

When enabling Transaction Search:

- Supports the TRACES telemetry type on the `AWS::XRay::TransactionSearchConfig` resource type. This resource type is the mechanism that enables Transaction Search, so telemetry source types do not apply and the rule ignores any that you specify. For more information, see Transaction Search.
- Transaction Search is an account-wide setting. Enabling it switches all span ingestion for the account through X-Ray into CloudWatch Logs, which changes how that span data is billed.
- Does not support a destination configuration. Transaction Search always sends spans to the service-managed `aws/spans` log group.

- CloudWatch creates the `aws/spans` and `/aws/application-signals/data` log groups if they do not already exist, and attaches a resource policy to each one that allows X-Ray to call `logs:PutLogEvents` on it.
- If either log group already exists and CloudWatch telemetry rules did not create it, CloudWatch does not modify the log group or its resource policy.
- CloudWatch does not change your span indexing configuration. Transaction Search uses whatever indexing rate the account already has.
- CloudWatch does not change accounts that already have Transaction Search enabled.
- You can create only one Transaction Search rule per scope. An account-level rule and an organization-level rule are tracked separately, so both can exist at the same time and both act on the same account-wide setting.
- Deleting the rule does not turn Transaction Search off, and does not delete the log groups or their resource policies. To turn Transaction Search off, set the X-Ray trace segment destination back to X-Ray yourself.

Troubleshooting telemetry configuration

This section describes common issues you might encounter when using telemetry configuration and how to resolve them.

Resources not appearing

If resources are not appearing in discovery, verify the following:

- The resource type is supported by telemetry configuration. For a list of supported data sources, see Supported data sources.
- The AWS Config recorder is enabled in your account. Telemetry configuration requires AWS Config service-linked recorders to discover resources.
- You have appropriate IAM permissions to view the resources.
- Sufficient time has elapsed since enabling telemetry configuration. The initial discovery of resources may take up to 24 hours to complete in some cases.

Rules not applying

If enablement rules are not applying to your resources, check the following:

- Verify the rule scope configuration. Make sure the rule targets the correct organization, OU, or account.
- Check tag filters. If the rule uses tag-based filtering, verify that the target resources have the expected tags.
- Check for rule conflicts. If multiple conflicting rules exist, none of the conflicting rules are applied. For more information, see Rule evaluation hierarchy.
- For Amazon EKS Container Insights, check the cluster state. A rule does not apply to a cluster until the cluster reaches the `ACTIVE` state. CloudWatch retries on a later evaluation cycle.
- For Amazon EKS Container Insights, check the add-on state. The Amazon CloudWatch Observability EKS add-on deploys the CloudWatch agent as a DaemonSet, so on a cluster that has no nodes the add-on installs but reports `DEGRADED` in the Amazon EKS `DescribeAddon` response and sends no telemetry. CloudWatch treats the rule as satisfied and does not retry. The add-on starts sending telemetry when a node becomes available.

> **Note**
>
> When you create an enablement rule, we discover non-compliant resources (those without telemetry enabled) through AWS Config Configuration Items (CIs) before turning them on based on your enablement rule scope. The initial discovery of the resources may take up to 24 hours to complete in some cases.

Multi-Region issues

When using multi-Region telemetry configuration, you might encounter the following issues:

- **Spoke Region failures** – If a rule fails to replicate to a spoke Region, the failure is visible in the rule status dashboard. The system automatically retries failed replications. Check the per-Region status in the console or by using the API to identify which Regions are affected.
- **Delayed resource discovery** – Resources from spoke Regions may take longer to appear in the home Region view because CloudWatch uses a AWS Config aggregator to collect resource data across Regions.
- **Reconciliation drift** – The system periodically reconciles rules across Regions to correct drift. If you notice inconsistencies between the home Region and spoke Regions, allow time for the reconciliation process to complete.

Home Region conflicts

You might encounter errors when attempting to edit or delete a rule from a Region that is not the home Region for that rule. Replicated rules can only be modified in the home Region where they were originally created.

To resolve home Region conflicts:

- Check the informational alert displayed on the rule in the console. The alert identifies the home Region for the rule.
- Navigate to the home Region in the CloudWatch console to edit or delete the rule.
- If you need to create a different rule in the spoke Region, create a new rule with a different name and scope that does not conflict with the replicated rule.

Disabling telemetry configuration

When you no longer need telemetry configuration, you can turn it off. When telemetry configuration is turned off, it no longer shows the status of telemetry for resources in your account or organization. You can turn on telemetry configuration again at any time. For more information, see Setting up telemetry configuration.

To turn off telemetry configuration

1. Open the CloudWatch console.
2. In the navigation pane, choose **Ingestion**.
3. Choose **Turn off**.

> **Note**
>
> Turning off telemetry configuration does not delete or modify any existing telemetry settings for your resources. It only stops the centralized management and visibility of these settings.

Infrastructure monitoring

The topics in this section explain CloudWatch features that can help you gain operational visibility into your AWS resources.

Topics

- Container Insights
- Lambda Insights
- CloudWatch Database Insights
- SageMaker AI Insights
- ElastiCache Insights
- Use Contributor Insights to analyze high-cardinality data
- Detect common application problems with CloudWatch Application Insights
- Using the resource health view in the CloudWatch console

Container Insights

Use CloudWatch Container Insights to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. Container Insights is available for Amazon Elastic Container Service (Amazon ECS), Amazon Elastic Kubernetes Service (Amazon EKS), RedHat OpenShift on AWS (ROSA), and Kubernetes platforms on Amazon EC2. Container Insights supports collecting metrics from clusters deployed on AWS Fargate for both Amazon ECS and Amazon EKS.

CloudWatch automatically collects metrics for many resources, such as CPU, memory, disk, and network. Container Insights also provides diagnostic information, such as container restart failures, to help you isolate issues and resolve them quickly. You can also set CloudWatch alarms on metrics that Container Insights collects.

Container Insights collects data as *performance log events* using embedded metric format. These performance log events are entries that use a structured JSON schema that enables high-cardinality data to be ingested and stored at scale. From this data, CloudWatch creates aggregated metrics at the cluster, node, pod, task, and service level as CloudWatch metrics. The metrics that Container Insights collects are available in CloudWatch automatic dashboards, and are also viewable in the **Metrics** section of the CloudWatch console. Metrics are not visible until the container tasks have been running for some time.

When you deploy Container Insights, it automatically creates a log group for the performance log events. You don't need to create this log group yourself.

To help you manage your Container Insights costs, CloudWatch does not automatically create all possible metrics from the log data. However, you can view additional metrics and additional levels of granularity by using CloudWatch Logs Insights to analyze the raw performance log events.

With the original version of Container Insights, metrics collected and logs ingested are charged as custom metrics. With Container Insights with enhanced observability for Amazon EKS, Container Insights metrics and logs are charged per observation instead of being charged per metric stored or log ingested. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

For Amazon EKS, OTel Container Insights collects metrics using the OpenTelemetry Protocol (OTLP) and supports PromQL queries. Each metric is enriched with up to 150 labels, including OpenTelemetry semantic convention attributes and Kubernetes pod and node labels. For more information, see OTel Container Insights (Recommended).

In Amazon EKS, RedHatOpenshift on AWS, and Kubernetes, Container Insights uses a containerized version of the CloudWatch agent to discover all of the running containers in a cluster. It then collects performance data at every layer of the performance stack.

Container Insights supports encryption with the AWS KMS key for the logs and metrics that it collects. To enable this encryption, you must manually enable AWS KMS encryption for the log group that receives Container Insights data. This causes Container Insights to encrypt this data using the provided KMS key. Only symmetric keys are supported. Do not use asymmetric KMS keys to encrypt your log groups.

For more information, see Encrypt Log Data in CloudWatch Logs Using AWS KMS.

Topics

- Amazon EKS
- Amazon ECS
- Setting up Container Insights on Red Hat OpenShift on AWS (ROSA)
- Viewing Container Insights metrics
- Metrics collected by Container Insights

Amazon EKS

Container Insights on Amazon EKS provides comprehensive observability for your Kubernetes workloads. Two approaches are available: OTel Container Insights (recommended) and Enhanced Container Insights (Classic). Both use the `amazon-cloudwatch-observability` EKS add-on with different configurations.

Topics

- OTel Container Insights (Recommended)
- Enhanced Container Insights (Classic)
- Compare Container Insights approaches
- Migration guides
- Troubleshooting Container Insights on Amazon EKS

OTel Container Insights (Recommended)

OTel Container Insights is the recommended approach for enabling Container Insights on Amazon EKS clusters. Built on OpenTelemetry, it provides comprehensive observability across metrics and logs with a simplified deployment model and active ongoing development.

Both OTel Container Insights and Enhanced Container Insights (Classic) use the same `amazon-cloudwatch-observability` Amazon EKS add-on. The difference is the add-on version and configuration, not a different product. OTel Container Insights is the newer, actively developed configuration of that add-on.

This approach is designed for the following use cases:

- New Amazon EKS customers who want the best-supported path to cluster observability
- Existing customers looking to consolidate on a single, modern telemetry pipeline
- Teams adopting OpenTelemetry who want native integration with CloudWatch

Key benefits

OTel Container Insights provides the following benefits:

- **Simplified setup** — Enable full observability in minutes through the console, AWS CLI, or CloudFormation

- **Comprehensive signals** — Collect metrics and logs from a single agent deployment
- **Enhanced observability** — Access detailed Kubernetes metrics, pod-level insights, and correlated signals
- **Active development** — Receives new features, performance improvements, and expanded signal coverage on an ongoing basis
- **OpenTelemetry-native** — Built on the OpenTelemetry Collector, aligning with the industry-standard observability framework

Why this approach is recommended

OTel Container Insights is recommended over other Container Insights approaches because it provides the broadest signal coverage (metrics and logs) with the simplest deployment model. Other approaches are in maintenance-only mode or require more complex manual configuration.

The following table compares OTel Container Insights with Enhanced Container Insights (Classic).

Consideration	OTel Container Insights	Enhanced Container Insights (Classic)
Signals	Metrics, Logs	Metrics, Logs
Enhanced observability	Yes	Yes
Maintenance status	Active development	Maintenance
Deployment complexity	Low	Low

Metric sources and receivers

OTel Container Insights collects metrics from open-source receivers and automatically enriches them with OpenTelemetry semantic conventions. Unlike Enhanced Container Insights (Classic), which uses proprietary metric names, OTel Container Insights preserves the original metric names from each source. This makes them compatible with existing PromQL dashboards and community documentation.

OTel Container Insights collects open-source metrics from multiple receivers using the OpenTelemetry Protocol (OTLP) at 30-second granularity. Metrics use their original source names (for example, `container_cpu_usage_seconds_total` from cAdvisor) rather than CloudWatch-format names, and you can query them with PromQL.

The following table lists the available receivers and their prerequisites.

Receiver	What it collects	Prerequisites
cAdvisor	Container CPU, memory, network, disk/filesystem metrics	Built into kubelet — no additional setup
Prometheus Node Exporter	Node-level CPU, memory, disk, filesystem, network, system, VMStat, netstat/socket metrics	Included in the add-on
Kube State Metrics	Pod, node, Deployment, DaemonSet, StatefulSet, ReplicaSet, Job, CronJob, Service, Namespace, PV, PVC metrics	Included in the add-on
Kubernetes API Server	API server and etcd metrics	Available on control plane
NVIDIA DCGM	GPU utilization, memory, power/thermal, throttling, error/reliability, NVLink metrics	NVIDIA device plugin and container toolkit required
AWS Neuron Monitor	NeuronCore, NeuronDevice, and Neuron system metrics	Neuron driver and device plugin required
AWS Elastic Fabric Adapter	EFA networking metrics	EFA device plugin required
NVMe	NVMe SMART health metrics	No additional setup

Each metric is enriched with up to 150 labels from the following three sources:

1. **Telemetry source native labels** — From the original receiver (for example, pod, `namespace`, `container` from cAdvisor)
2. **OpenTelemetry resource attributes** — Following OTel semantic conventions for Kubernetes, Host, and Cloud
3. **Kubernetes pod and node labels** — All labels from the Kubernetes API, prefixed with `k8s.pod.label.*` and `k8s.node.label.*`

Dual publishing and migration

OTel Container Insights is disabled by default. To enable it, set `otelContainerInsights.enabled` to `true` in the add-on configuration.

Starting with add-on version v6.2.0, the add-on supports publishing metrics through both Enhanced Container Insights (Classic) and OTel Container Insights simultaneously. This allows you to validate the new metrics pipeline before fully migrating.

To enable OTel Container Insights alongside Enhanced Container Insights (Classic), run the following command.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{"containerInsights":
{"enabled":true},"otelContainerInsights":{"enabled":true}}'
```

To disable OTel Container Insights and keep only Enhanced Container Insights (Classic), run the following command.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{"otelContainerInsights":{"enabled":false}}'
```

To disable Enhanced Container Insights (Classic) and keep only OTel Container Insights, run the following command.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
```

```
  --configuration-values '{"containerInsights":
{"enabled":false},"otelContainerInsights":{"enabled":true}}'
```

Getting started

Use the following topics to set up and configure OTel Container Insights on your Amazon EKS clusters.

- Quick start: OTel Container Insights on Amazon EKS — Get started with OTel Container Insights using the fastest setup path.
- Enable OTel Container Insights from the console — Enable OTel Container Insights through the AWS Management Console.
- Deploy OTel Container Insights with Helm — Deploy OTel Container Insights using the Helm chart for flexible, GitOps-friendly management.
- Deploy OTel Container Insights with CloudFormation — Deploy OTel Container Insights using a CloudFormation template.
- Sending logs to Amazon CloudWatch — Configure log collection for your Amazon EKS clusters.
- Advanced configuration for OTel Container Insights on Amazon EKS — Customize and fine-tune OTel Container Insights for your environment.

Quick start: OTel Container Insights on Amazon EKS

This guide walks you through enabling OTel Container Insights on an existing Amazon EKS cluster. By the end of this procedure, your cluster sends infrastructure metrics and container logs to Amazon CloudWatch with Enhanced Observability enabled.

You can enable OTel Container Insights in two ways: by using the AWS Management Console (fastest) or by using the AWS CLI. Both approaches install the same `amazon-cloudwatch-observability` EKS add-on with the OTel Container Insights configuration. You don't need manual agent deployment, Helm charts, or custom collector pipelines. The entire process takes under 5 minutes.

Prerequisites

Before you enable OTel Container Insights, verify that you meet the following requirements.

- An existing Amazon EKS cluster running Kubernetes version 1.28 or later
- Platform version `eks.1` or later

- Version 6.2.0 or later of the `amazon-cloudwatch-observability` add-on
- AWS CLI version 2.15.0 or later (for CLI-based setup)
- `kubectl` configured to communicate with your target cluster
- IAM permissions: `eks:CreateAddon`, `eks:DescribeAddon`, and `iam:CreateServiceLinkedRole`
- The EKS Pod Identity Agent add-on installed on your cluster, or IAM Roles for Service Accounts (IRSA) configured
- Outbound internet access from the cluster to CloudWatch endpoints

Enable OTel Container Insights (console)

The AWS Management Console provides the fastest path to enable OTel Container Insights.

To enable OTel Container Insights by using the console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/.
2. Choose **Clusters**, and then choose your cluster name.
3. Choose the **Observability** tab.
4. Choose **Enable Container Insights** and follow the on-screen instructions.

For a detailed console walkthrough, see Enable OTel Container Insights from the console.

Enable OTel Container Insights (AWS CLI)

Use the following steps to enable OTel Container Insights by using the AWS CLI.

Step 1: Create the IAM role

Create an IAM role that allows the CloudWatch Observability add-on to send data to CloudWatch.

To create the CloudWatch Observability add-on IAM role

1. Run the following command to create the role with a trust policy for EKS Pod Identity.

```
aws iam create-role \
  --role-name EKS-CloudWatch-Observability-Role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [{
```

```
      "Effect": "Allow",
      "Principal": { "Service": "pods.eks.amazonaws.com" },
      "Action": ["sts:AssumeRole", "sts:TagSession"]
    }]
  }'
```

2. Attach the `CloudWatchAgentServerPolicy` managed policy to the role.

```
aws iam attach-role-policy \
  --role-name EKS-CloudWatch-Observability-Role \
  --policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Step 2: Create the Pod Identity association

Associate the IAM role with the CloudWatch agent service account in your cluster.

To create the Pod Identity association

- Run the following command. Replace *`cluster-name`* with the name of your Amazon EKS cluster and *`account-id`* with your AWS account ID.

```
aws eks create-pod-identity-association \
  --cluster-name cluster-name \
  --namespace amazon-cloudwatch \
  --service-account cloudwatch-agent \
  --role-arn arn:aws:iam::account-id:role/EKS-CloudWatch-Observability-Role
```

Step 3: Install the Amazon CloudWatch Observability add-on

Install the `amazon-cloudwatch-observability` add-on with OTel Container Insights enabled.

To install the add-on

- Run the following command. Replace *`cluster-name`* with the name of your Amazon EKS cluster.

```
aws eks create-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{"otelContainerInsights":{"enabled":true}}'
```

> **Important**
>
> The `otelContainerInsights.enabled` configuration is required. OTel Container Insights is not enabled by default.

Step 4: Verify the add-on status

Confirm that the add-on installed successfully.

To verify the add-on status

- Run the following command. Replace *`cluster-name`* with the name of your Amazon EKS cluster.

  ```
  aws eks describe-addon \
    --cluster-name cluster-name \
    --addon-name amazon-cloudwatch-observability \
    --query "addon.status" \
    --output text
  ```

  The expected output is `ACTIVE`.

Step 5: Confirm agent pods are running

Verify that the CloudWatch agent pods are running in the `amazon-cloudwatch` namespace.

To confirm agent pods are running

- Run the following command.

  ```
  kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent
  ```

  All agent pods must show `Running` status.

Verify data in CloudWatch

After you complete the setup, Container Insights data appears in CloudWatch within 3 to 5 minutes.

Check metrics

To check metrics in CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Query Studio**.
3. Search for metrics such as `container_cpu_usage_seconds_total` by using PromQL.

Check logs

To verify that log groups exist for your cluster, run the following command. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws logs describe-log-groups \
  --log-group-name-prefix "/aws/containerinsights/cluster-name" \
  --query "logGroups[].logGroupName" \
  --output table
```

Expected time-to-data

The following table shows the expected latency for each signal type after you enable OTel Container Insights.

Signal	Expected latency
Infrastructure metrics	2–3 minutes
Container logs	2–3 minutes
Performance log events	3–5 minutes

Troubleshooting

Use the following guidance to resolve common issues when you enable OTel Container Insights on Amazon EKS.

Add-on status shows CREATE_FAILED or DEGRADED

Symptom: When you run `aws eks describe-addon`, the status shows `CREATE_FAILED` or `DEGRADED`.

Cause: The add-on installation failed, typically because of insufficient IAM permissions or a missing Pod Identity association.

Solution: Complete the following steps to resolve this issue.

1. Run the following command to check for detailed error information. Replace *cluster-name* with the name of your cluster.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --query "addon.health"
```

2. Verify that the IAM role exists and has the `CloudWatchAgentServerPolicy` attached.
3. Verify that the Pod Identity association targets the correct namespace (`amazon-cloudwatch`) and service account (`cloudwatch-agent`).
4. Delete the failed add-on and reinstall it after you resolve the issue.

```
aws eks delete-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability
```

Agent pods are in CrashLoopBackOff or Pending state

Symptom: When you run `kubectl get pods -n amazon-cloudwatch`, one or more pods show `CrashLoopBackOff` or `Pending` status.

Cause: The agent pods can't start because of insufficient node resources, missing permissions, or network connectivity issues.

Solution: Complete the following steps to resolve this issue.

1. Check the pod events for detailed error messages.

```
kubectl describe pod -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent
```

2. Check the agent container logs for startup errors.

```
kubectl logs -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent --
tail=50
```

3. Verify that your nodes have sufficient CPU and memory available for the agent pods.
4. Verify that the EKS Pod Identity Agent add-on is installed and running.

```
kubectl get pods -n kube-system -l app.kubernetes.io/name=eks-pod-identity-agent
```

Metrics not appearing in CloudWatch after 5 minutes

Symptom: The agent pods show `Running` status, but no metrics appear in CloudWatch after 5 minutes.

Cause: The agent can't send data to CloudWatch, typically because of network restrictions or incorrect IAM permissions.

Solution: Complete the following steps to resolve this issue.

1. Verify that the agent pods can reach CloudWatch endpoints. Check that your VPC security groups and network ACLs allow outbound HTTPS traffic (port 443) to CloudWatch endpoints.
2. Check the agent logs for permission errors or connection timeouts.

```
kubectl logs -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent --
tail=100 | grep -i "error\|timeout\|denied"
```

3. Verify that the IAM role has the `CloudWatchAgentServerPolicy` policy attached and that the trust policy allows `pods.eks.amazonaws.com`.
4. If you use a VPC endpoint for CloudWatch, confirm that the endpoint policy allows the required actions.

Enable OTel Container Insights from the console

You can enable OTel Container Insights directly from the AWS Management Console with a minimal-click workflow. This approach is ideal if you prefer a UI-driven experience and want to enable full observability on an existing Amazon EKS cluster without writing infrastructure code or running CLI commands.

Prerequisites

Before you enable OTel Container Insights from the console, verify that you meet the following requirements.

- You are signed in to the Amazon EKS console.
- An existing Amazon EKS cluster running Kubernetes version 1.28 or later.
- Version 6.2.0 or later of the `amazon-cloudwatch-observability` add-on.
- IAM permissions: `eks:DescribeCluster`, `eks:UpdateClusterConfig`, `eks:ListAddons`, `eks:CreateAddon`, `eks:DescribeAddon`, `iam:AttachRolePolicy`, and `iam:CreateServiceLinkedRole`.
- The node IAM role must have the `CloudWatchAgentServerPolicy` managed policy attached.
- The cluster is in `ACTIVE` state.

Enable OTel Container Insights

Use the following procedure to enable OTel Container Insights from the Amazon EKS console.

To enable OTel Container Insights by using the console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/.
2. Choose **Clusters**, and then choose your cluster name.
3. Choose the **Observability** tab.
4. Next to **Container Insights** status, choose **Manage**.
5. Select the **OTel Container Insights** configuration.
6. Confirm the IAM role for the add-on. The console auto-creates the role if one doesn't already exist.
7. Choose **Enable**.

What the console configures

When you enable OTel Container Insights from the console, the console performs the following actions on your behalf.

- Creates and configures the Pod Identity association for the `amazon-cloudwatch` namespace
- Installs the `amazon-cloudwatch-observability` Amazon EKS add-on with version 6.2.0 or later and `otelContainerInsights.enabled=true`
- Attaches the `CloudWatchAgentServerPolicy` to the designated IAM role

Verify that data appears in CloudWatch

After you enable OTel Container Insights, data appears in CloudWatch within 5 minutes.

To verify Container Insights data

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Insights**, and then choose **Container Insights**.
3. Choose your cluster from the cluster list.

The Container Insights dashboards populate with metrics data from your cluster.

Troubleshooting

Use the following guidance to resolve common issues when you enable OTel Container Insights from the console.

The Enable button is unavailable

Symptom: The **Enable** button is greyed out and you can't choose it.

Cause: The cluster might be in an updating state, or you don't have sufficient IAM permissions.

Solution: Complete the following steps to resolve this issue.

1. Verify that the cluster status is `ACTIVE` on the cluster details page.
2. Verify that your IAM user or role has the required permissions listed in the prerequisites.
3. If the cluster is updating, wait for the update to complete and try again.

Status shows DEGRADED after you enable

Symptom: After you enable OTel Container Insights, the add-on status shows `DEGRADED`.

Cause: The add-on installed but can't function correctly, typically because of IAM role permission issues or node connectivity problems.

Solution: Complete the following steps to resolve this issue.

1. Verify that the IAM role has the `CloudWatchAgentServerPolicy` managed policy attached.
2. Verify that the cluster nodes have outbound connectivity to CloudWatch endpoints.

3. Check the add-on health details in the Amazon EKS console by choosing the **Add-ons** tab on the cluster details page.

Deploy OTel Container Insights with Helm

The Amazon CloudWatch Observability Helm chart provides a flexible deployment option for OTel Container Insights. It installs the CloudWatch agent (OTel-based) with the OpenTelemetry filelog receiver for log collection. The Helm chart is maintained at https://github.com/aws-observability/helm-charts.

Use the Helm chart when you need one or more of the following capabilities:

- Fine-grained control over agent configuration
- OTel-native log collection using the filelog receiver (no Fluent Bit dependency)
- Custom TLS certificate management through cert-manager
- Non-EKS Kubernetes clusters (ROSA, self-managed Kubernetes)
- GitOps workflows with ArgoCD or Flux

Prerequisites

Before you deploy OTel Container Insights with Helm, verify that you meet the following requirements.

- An existing Amazon EKS cluster running Kubernetes version 1.28 or later
- Helm version 3.9 or later
- `kubectl` configured to communicate with your target cluster
- IAM permissions: `CloudWatchAgentServerPolicy` managed policy attached to the agent role
- An OpenID Connect (OIDC) provider configured for IAM Roles for Service Accounts (IRSA)
- Outbound internet access from the cluster to CloudWatch endpoints

Install the Helm chart

Complete the following steps to deploy OTel Container Insights by using the Helm chart.

Step 1: Add the Helm repository

Add the AWS Observability Helm chart repository to your local Helm configuration.

To add the Helm repository

1. Run the following command to add the repository.

```
helm repo add aws-observability \
  https://aws-observability.github.io/helm-charts
```

2. Update the repository to get the latest chart versions.

```
helm repo update
```

Step 2: Create the IAM role

Create an IAM role that allows the CloudWatch agent to send data to CloudWatch. This role uses IRSA to associate IAM permissions with a Kubernetes service account.

To create the IAM role for the CloudWatch agent

1. Retrieve the OIDC issuer URL for your cluster. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws eks describe-cluster \
  --name cluster-name \
  --query "cluster.identity.oidc.issuer" \
  --output text
```

2. Create the IAM role with a trust policy for IRSA. Replace the example account ID (111122223333) with your AWS account ID, and replace *oidc-id* with the OIDC provider ID from the preceding step (the portion after `https://oidc.eks.region.amazonaws.com/id/`).

```
aws iam create-role \
  --role-name EKS-CW-Observability-Role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [{
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::111122223333:oidc-provider/oidc.eks.us-
east-1.amazonaws.com/id/oidc-id"
      },
```

```
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "oidc.eks.us-east-1.amazonaws.com/id/oidc-id:sub":
 "system:serviceaccount:amazon-cloudwatch:cloudwatch-agent"
        }
      }
    }]
  }'
```

3. Attach the `CloudWatchAgentServerPolicy` managed policy to the role.

```
aws iam attach-role-policy \
  --role-name EKS-CW-Observability-Role \
  --policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Step 3: Install the chart

Install the Amazon CloudWatch Observability Helm chart with OTel Container Insights enabled.

To install the Helm chart

- Run the following command. Replace *cluster-name* with the name of your Amazon EKS cluster, the example AWS Region (`us-east-1`) with your own Region, and the example account ID (111122223333) with your AWS account ID.

```
helm install amazon-cloudwatch-observability \
  aws-observability/amazon-cloudwatch-observability \
  --namespace amazon-cloudwatch \
  --create-namespace \
  --set clusterName=cluster-name \
  --set region=us-east-1 \
  --set agent.serviceAccount.name=cloudwatch-agent \
  --set "agent.serviceAccount.annotations.eks\\.amazonaws\\.com/role-
arn=arn:aws:iam::111122223333:role/EKS-CW-Observability-Role" \
  --set otelContainerInsights.enabled=true
```

> **Important**
>
> The `otelContainerInsights.enabled` parameter is required. OTel Container Insights is not enabled by default.

Step 4: Verify the installation

Confirm that the Helm release and agent pods deployed successfully.

To verify the Helm installation

1. Verify that the Helm release status shows `deployed`.

```
helm list -n amazon-cloudwatch
```

2. Confirm that the operator pod is running.

```
kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=amazon-cloudwatch-observability
```

3. Confirm that the CloudWatch agent pods are running on all nodes.

```
kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent
```

   All agent pods must show `Running` status.

Key configuration options

The following tables describe the key Helm chart values that you can configure. Pass these values by using the `--set` flag or a custom `values.yaml` file.

Cluster settings

Parameter	Default	Description
`clusterName`	—	The name of the Amazon EKS cluster. Required.

Parameter	Default	Description
region	—	The AWS Region where the cluster runs. Required.
otelContainerInsights.enabled	false	Enables OTel Container Insights with the filelog receiver.

Container logs (OTel filelog receiver)

Parameter	Default	Description
containerLogs.enabled	true	Enables container log collection by using the OTel filelog receiver.
containerLogs.logGroupName	/aws/containerinsights/ *clustername* /application	The CloudWatch Logs log group name for container logs.
containerLogs.logRetentionDays	7	The number of days to retain container logs in CloudWatch Logs.

Agent (metrics)

Parameter	Default	Description
agent.enabled	true	Enables the CloudWatch agent DaemonSet for metric collection.
agent.serviceAccount.name	cloudwatch-agent	The name of the Kubernetes service account for the agent.

Parameter	Default	Description
`agent.resources.requests.cpu`	`100m`	The CPU request for the agent container.
`agent.resources.requests.memory`	`128Mi`	The memory request for the agent container.
`agent.resources.limits.cpu`	`200m`	The CPU limit for the agent container.
`agent.resources.limits.memory`	`256Mi`	The memory limit for the agent container.

GPU monitoring

Parameter	Default	Description
`agent.config.logs.metrics_collected.kubernetes.enhanced_container_insights`	`true`	Enables Enhanced Container Insights metrics, including GPU metrics.
`dcgmExporter.enabled`	`false`	Enables the DCGM exporter for NVIDIA GPU metrics. Requires NVIDIA GPU nodes.
`neuronMonitor.enabled`	`false`	Enables the Neuron monitor for AWS Inferentia and Trainium metrics.

TLS certificate management

The CloudWatch Observability operator requires TLS certificates for webhook communication. By default, the chart generates self-signed certificates. You can use cert-manager to manage certificates automatically.

Self-signed certificates (default)

By default, the Helm chart generates a self-signed CA and issues certificates from that CA. No additional configuration is required. The chart automatically rotates these certificates during upgrades.

cert-manager integration

You can use cert-manager to automate certificate issuance and renewal. This approach is useful when your organization requires externally signed certificates or centralized certificate management.

To configure cert-manager integration

1. Verify that cert-manager is installed in your cluster.

```
kubectl get pods -n cert-manager
```

2. Install the Helm chart with cert-manager enabled. Replace *cluster-name* with the name of your Amazon EKS cluster, the example AWS Region (us-east-1) with your own Region, and the example account ID (111122223333) with your AWS account ID.

```
helm install amazon-cloudwatch-observability \
  aws-observability/amazon-cloudwatch-observability \
  --namespace amazon-cloudwatch \
  --create-namespace \
  --set clusterName=cluster-name \
  --set region=us-east-1 \
  --set agent.serviceAccount.name=cloudwatch-agent \
  --set "agent.serviceAccount.annotations.eks\\.amazonaws\\.com/role-
arn=arn:aws:iam::111122223333:role/EKS-CW-Observability-Role" \
  --set otelContainerInsights.enabled=true \
  --set admissionWebhooks.certManager.enabled=true
```

When cert-manager is enabled, the chart creates a `Certificate` resource that cert-manager uses to issue and manage the webhook TLS certificate automatically.

> **Note**
>
> You can also use cert-manager with external issuers such as HashiCorp Vault. To configure an external issuer, set `admissionWebhooks.certManager.issuerRef.name` and

`admissionWebhooks.certManager.issuerRef.kind` to match your cert-manager issuer.

Upgrade the chart

Upgrade the Helm chart to apply new configuration values or to update to a newer chart version.

To upgrade the Helm chart

1. Update the Helm repository to get the latest chart versions.

```
helm repo update
```

2. Run the upgrade command with your desired values. Replace *`cluster-name`* with the name of your Amazon EKS cluster, the example AWS Region (`us-east-1`) with your own Region, and the example account ID (111122223333) with your AWS account ID.

```
helm upgrade amazon-cloudwatch-observability \
  aws-observability/amazon-cloudwatch-observability \
  --namespace amazon-cloudwatch \
  --set clusterName=cluster-name \
  --set region=us-east-1 \
  --set agent.serviceAccount.name=cloudwatch-agent \
  --set "agent.serviceAccount.annotations.eks\\.amazonaws\\.com/role-
arn=arn:aws:iam::111122223333:role/EKS-CW-Observability-Role" \
  --set otelContainerInsights.enabled=true
```

3. Verify that the upgrade completed successfully.

```
helm list -n amazon-cloudwatch
```

The revision number must increment and the status must show `deployed`.

Tip

To avoid losing configuration values during upgrades, store your custom values in a `values.yaml` file and pass it with the `-f values.yaml` flag.

Uninstall the chart

To remove OTel Container Insights from your cluster, uninstall the Helm release.

To uninstall the Helm chart

1. Run the following command to uninstall the release.

```
helm uninstall amazon-cloudwatch-observability \
  --namespace amazon-cloudwatch
```

2. Optionally, delete the namespace if it is no longer needed.

```
kubectl delete namespace amazon-cloudwatch
```

After you uninstall the Helm chart, the IAM role and OIDC provider configuration remain in your AWS account. Delete these resources separately if they are no longer needed.

```
aws iam detach-role-policy \
  --role-name EKS-CW-Observability-Role \
  --policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy

aws iam delete-role \
  --role-name EKS-CW-Observability-Role
```

Verify data in CloudWatch

After you install the Helm chart, Container Insights data appears in CloudWatch within 3 to 5 minutes.

Check metrics

To check metrics in CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Container Insights**.
3. Verify that your cluster appears in the cluster list and that infrastructure metrics are populating.

Check logs

To verify that log groups exist for your cluster, run the following command. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws logs describe-log-groups \
  --log-group-name-prefix "/aws/containerinsights/cluster-name" \
  --query "logGroups[].logGroupName" \
  --output table
```

Troubleshooting

Use the following guidance to resolve common issues when you deploy OTel Container Insights with Helm.

Operator pod in CrashLoopBackOff

Symptom: When you run `kubectl get pods -n amazon-cloudwatch`, the operator pod shows `CrashLoopBackOff` status.

Cause: The operator pod can't start because of TLS certificate issues or insufficient permissions.

Solution: Complete the following steps to resolve this issue.

1. Check the operator pod logs for certificate-related errors.

   ```
   kubectl logs -n amazon-cloudwatch -l app.kubernetes.io/name=amazon-cloudwatch-
   observability --tail=50
   ```

2. Verify that the webhook TLS secret exists in the namespace.

   ```
   kubectl get secrets -n amazon-cloudwatch | grep webhook
   ```

3. If you use cert-manager, verify that the `Certificate` resource status shows `Ready`.

   ```
   kubectl get certificate -n amazon-cloudwatch
   ```

4. If the certificate is missing or invalid, uninstall and reinstall the chart to regenerate certificates.

   ```
   helm uninstall amazon-cloudwatch-observability -n amazon-cloudwatch
   ```

Agent pods not scheduled on all nodes

Symptom: The agent DaemonSet shows fewer pods than the number of nodes in your cluster.

Cause: Node taints, resource constraints, or node selectors prevent the agent pods from scheduling on certain nodes.

Solution: Complete the following steps to resolve this issue.

1. Check the DaemonSet status for scheduling issues.

```
kubectl get daemonset -n amazon-cloudwatch cloudwatch-agent
```

2. Check for unschedulable pods and view their events.

```
kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent --
field-selector=status.phase!=Running
```

3. If nodes have taints, add tolerations to the Helm chart values. For example, to tolerate all taints, upgrade the chart with the following flag.

```
helm upgrade amazon-cloudwatch-observability \
  aws-observability/amazon-cloudwatch-observability \
  --namespace amazon-cloudwatch \
  --reuse-values \
  --set "agent.tolerations[0].operator=Exists"
```

4. Verify that the agent pods now run on all nodes.

```
kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent -o
 wide
```

Deploy OTel Container Insights with CloudFormation

You can deploy OTel Container Insights as infrastructure as code by using a CloudFormation template. This approach is best for teams that manage clusters through IaC pipelines and want repeatable, version-controlled deployments.

The template installs the `amazon-cloudwatch-observability` EKS add-on with OTel Container Insights enabled. If you prefer Kubernetes-native package management, see Deploy OTel Container Insights with Helm.

Prerequisites

Before you deploy OTel Container Insights with CloudFormation, verify that you meet the following requirements.

- An existing Amazon EKS cluster running Kubernetes version 1.28 or later
- AWS CLI version 2.15.0 or later
- `kubectl` configured to communicate with your target cluster
- IAM permissions for CloudFormation stack creation
- Outbound internet access from the cluster to CloudWatch endpoints

Deploy with CloudFormation

Use a CloudFormation template to deploy the CloudWatch Observability add-on, the required IAM role, and the Pod Identity association in a single stack. This template uses the `AWS::EKS::Addon` resource to install the add-on with OTel Container Insights enabled.

CloudFormation template

The following template creates the complete set of resources that you need to enable OTel Container Insights on your Amazon EKS cluster.

```
AWSTemplateFormatVersion: '2010-09-09'
Description: Deploy OTel Container Insights on an EKS cluster

Parameters:
  ClusterName:
    Type: String
    Description: The name of your EKS cluster

Resources:
  CloudWatchAgentRole:
    Type: AWS::IAM::Role
    Properties:
      RoleName: EKS-CloudWatch-Observability-Role
      AssumeRolePolicyDocument:
        Version: '2012-10-17'
        Statement:
          - Effect: Allow
            Principal:
```

```
            Service: pods.eks.amazonaws.com
          Action:
            - sts:AssumeRole
            - sts:TagSession
    ManagedPolicyArns:
      - arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy

PodIdentityAssociation:
  Type: AWS::EKS::PodIdentityAssociation
  Properties:
    ClusterName: !Ref ClusterName
    Namespace: amazon-cloudwatch
    ServiceAccount: cloudwatch-agent
    RoleArn: !GetAtt CloudWatchAgentRole.Arn

CloudWatchObservabilityAddon:
  Type: AWS::EKS::Addon
  DependsOn: PodIdentityAssociation
  Properties:
    ClusterName: !Ref ClusterName
    AddonName: amazon-cloudwatch-observability
    AddonVersion: v6.2.0-eksbuild.1
    ConfigurationValues: '{"otelContainerInsights":{"enabled":true}}'
    ServiceAccountRoleArn: !GetAtt CloudWatchAgentRole.Arn
    ResolveConflicts: OVERWRITE
```

This template creates the following resources:

- An IAM role with the `CloudWatchAgentServerPolicy` managed policy attached
- An EKS Pod Identity association that maps the role to the CloudWatch agent service account
- The `amazon-cloudwatch-observability` EKS add-on with OTel Container Insights enabled

To deploy the CloudFormation stack

Use the AWS CLI to create the CloudFormation stack from the template.

To deploy the stack

1. Save the preceding template to a file named `otel-container-insights.yaml`.
2. Run the following command. Replace *`cluster-name`* with the name of your Amazon EKS cluster.

```
aws cloudformation create-stack \
  --stack-name otel-container-insights \
  --template-body file://otel-container-insights.yaml \
  --parameters ParameterKey=ClusterName,ParameterValue=cluster-name \
  --capabilities CAPABILITY_NAMED_IAM
```

3. Wait for the stack creation to complete.

```
aws cloudformation wait stack-create-complete \
  --stack-name otel-container-insights
```

4. Verify that the stack status is `CREATE_COMPLETE`.

```
aws cloudformation describe-stacks \
  --stack-name otel-container-insights \
  --query "Stacks[0].StackStatus" \
  --output text
```

Verify the deployment

After the CloudFormation stack creation completes, verify that the add-on is running and sending data to CloudWatch.

To verify the deployment

1. Confirm that the CloudWatch agent pods are running.

```
kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent
```

   All pods must show `Running` status.

2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the navigation pane, choose **Container Insights**.
4. Verify that your cluster appears in the cluster list and that metrics are populating.

Metrics typically appear in CloudWatch within 3 to 5 minutes after the deployment completes.

Remove the deployment

To remove all resources that the CloudFormation template created, delete the stack.

```
aws cloudformation delete-stack \
  --stack-name otel-container-insights
```

Sending logs to Amazon CloudWatch

OTel Container Insights collects and sends container logs to Amazon CloudWatch Logs by using the OpenTelemetry Collector's log pipeline. The Amazon CloudWatch Observability EKS add-on deploys an OpenTelemetry Collector as a DaemonSet that uses the filelog receiver to tail container log files, enrich them with Kubernetes metadata, and export them to CloudWatch Logs through the CloudWatch Logs exporter.

No additional setup is required for basic log collection. Log collection is enabled by default when you follow the Quick start: OTel Container Insights on Amazon EKS.

Log collection costs

Enabling log collection ingests all container stdout and stderr from every pod in the cluster, which can significantly increase CloudWatch Logs costs. To control cost, filter logs before ingestion and set a retention policy on the log groups. For information about filtering, see Log filtering. For information about retention policies, see Set log retention.

Correlating logs with traces

Collecting container logs does not by itself correlate them with traces in CloudWatch Application Signals. To correlate traces with logs, instrument your application for Application Signals by using the enablement guide for your architecture, such as Enable your applications on Amazon EKS clusters, and then configure your logging output as described in Enable trace to log correlation.

Prerequisites

Before you configure log collection, verify that you meet the following requirements.

- OTel Container Insights installed and the `amazon-cloudwatch-observability` add-on active on your cluster
- IAM permissions: `logs:CreateLogGroup`, `logs:CreateLogStream`, `logs:PutLogEvents`, `logs:DescribeLogGroups`, and `logs:DescribeLogStreams` (included in the `CloudWatchAgentServerPolicy` managed policy)
- Node access: the collector requires access to `/var/log/pods` on each node

Log groups and sources

The following table describes the log group that OTel Container Insights creates and the source it collects from.

Log group	Source	Contents
`/aws/containerinsights/` *`cluster-name`* `/application`	`/var/log/pods/**/*.log`	All container stdout and stderr logs

> **Note**
>
> Host and dataplane logs will be available in a future release.

How the OTel log pipeline works

The add-on's OpenTelemetry Collector runs a log pipeline with the following components.

- **Receivers** – The `filelog` receiver tails container log files from `/var/log/pods/`.
- **Processors** – The `k8sattributes` processor enriches logs with Kubernetes metadata. The `batch` processor batches log records before export. The `resource` processor appends resource attributes.
- **Exporters** – The `awscloudwatchlogs` exporter sends log records to CloudWatch Logs.

Log enrichment

The pipeline enriches every log record with the following attributes.

- **Kubernetes resource attributes** – `k8s.pod.name`, `k8s.namespace.name`, `k8s.container.name`, `k8s.node.name`, and `k8s.deployment.name`
- **Pod labels** – All pod labels as `k8s.pod.label.*` attributes
- **Cloud attributes** – `cloud.region`, `cloud.account.id`, and `cloud.platform`
- **Cluster attributes** – `k8s.cluster.name`

Customizing log collection

You can customize log collection by updating the add-on configuration values. The following sections describe common customization options.

Disable log collection

To disable log collection entirely, update the add-on configuration with container logs disabled.

To disable log collection

- Run the following command. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{"containerLogs":{"enabled":false}}' \
  --resolve-conflicts OVERWRITE
```

Set log retention

By default, CloudWatch Logs retains log data indefinitely. To control storage costs, you can set a retention policy on the log group.

To set log retention

- Run the following command. Replace *cluster-name* with the name of your Amazon EKS cluster. Replace *30* with the number of days to retain logs.

```
aws logs put-retention-policy \
  --log-group-name "/aws/containerinsights/cluster-name/application" \
  --retention-in-days 30
```

Verification

To verify that log collection is working, check that the expected log groups exist and contain data.

To verify log collection

- Run the following command. Replace *cluster-name* with the name of your Amazon EKS cluster.

  ```
  aws logs describe-log-groups \
    --log-group-name-prefix "/aws/containerinsights/cluster-name" \
    --query "logGroups[].{Name:logGroupName,StoredBytes:storedBytes}" \
    --output table
  ```

  The output displays the log group names and the number of stored bytes. A non-zero value for `StoredBytes` confirms that the pipeline is delivering logs.

Troubleshooting

Use the following guidance to resolve common log collection issues.

Log groups not created after 5 minutes

Symptom: The `/aws/containerinsights/cluster-name/application` log group does not appear in CloudWatch Logs after 5 minutes.

Cause: The collector does not have the required IAM permissions to create log groups and log streams.

Solution: Verify that the IAM role associated with the collector has the `CloudWatchAgentServerPolicy` managed policy attached. This policy includes the `logs:CreateLogGroup` and `logs:CreateLogStream` permissions.

Application log group exists but is empty

Symptom: The application log group exists in CloudWatch Logs, but it contains no log streams or log events.

Cause: This issue occurs when containers are not writing to stdout or stderr, or the filelog receiver cannot access `/var/log/pods/` on the node.

Solution: Complete the following steps to resolve this issue.

1. Verify that your application containers write logs to stdout or stderr.
2. Check that the collector DaemonSet pod has a volume mount for `/var/log/pods`.

```
kubectl get daemonset -n amazon-cloudwatch -o yaml | grep -A 5 "var/log/pods"
```

3. Check the collector logs for file access errors.

```
kubectl logs -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent --
tail=50 | grep -i "error\|permission"
```

High CloudWatch Logs costs

Symptom: CloudWatch Logs ingestion or storage costs are higher than expected.

Cause: High-volume namespaces (such as load testing or monitoring namespaces) generate large volumes of logs.

Solution: Set a retention policy on the log group to automatically delete older logs. For instructions, see Set log retention.

Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart

You can use either the Amazon CloudWatch Observability EKS add-on or the Amazon CloudWatch Observability Helm chart to install the CloudWatch Agent and the Fluent-bit agent on an Amazon EKS cluster. You can also use the Helm chart to install the CloudWatch Agent and the Fluent-bit agent on a Kubernetes cluster that is not hosted on Amazon EKS.

Using either method on an Amazon EKS cluster enables both Container Insights for Amazon EKS and CloudWatch Application Signals by default. Both features help you to collect infrastructure metrics, application performance telemetry, and container logs from the cluster.

From version `v6.2.0-eksbuild.1` or later of the add-on, Container Insights with OpenTelemetry metrics can be enabled, which collects metrics using the OpenTelemetry Protocol (OTLP) and supports PromQL queries. For more information, see OTel Container Insights (Recommended).

With Container Insights with OpenTelemetry for Amazon EKS, Container Insights metrics are charged per GB ingested or per observation if you are using Enhanced Container Insights (Classic). For Application Signals, billing is based on inbound requests to your applications, outbound

requests from your applications, and each configured service level objective (SLO). Each inbound request received generates one application signal, and each outbound request made generates one application signal. Every SLO creates two application signals per measurement period. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

Both methods enable Container Insights on both Linux and Windows worker nodes in the Amazon EKS cluster. To enable Container Insights on Windows, you must use version 1.5.0 or later of the Amazon EKS add-on or the Helm chart. Application Signals is not supported on Windows in Amazon EKS clusters.

The Amazon CloudWatch Observability EKS add-on is supported on Amazon EKS clusters running with Kubernetes version 1.23 or later.

When you install the add-on or the Helm chart, you must also grant IAM permissions to enable the CloudWatch agent to send metrics, logs, and traces to CloudWatch. There are two ways to do this:

- Attach a policy to the IAM role of your worker nodes. This option grants permissions to worker nodes to send telemetry to CloudWatch.
- Use an IAM role for service accounts for the agent pods, and attach the policy to this role. This works only for Amazon EKS clusters. This option gives CloudWatch access only to the appropriate agent pods.

Topics

- Option 1: Install using EKS Pod Identity
- Option 2: Install with IAM permissions on worker nodes
- Option 3: Install using IAM service account role (applies only to using the add-on)
- (Optional) Additional configuration
- Collect Java Management Extensions (JMX) metrics
- Enable Kueue metrics
- Appending OpenTelemetry collector configuration files
- Enabling APM through Application Signals for your Amazon EKS cluster
- Considerations for large Kubernetes clusters
- Considerations for Amazon EKS Hybrid Nodes
- Troubleshooting the Amazon CloudWatch Observability EKS add-on or the Helm chart
- Opt out of Application Signals

Option 1: Install using EKS Pod Identity

If you use version 3.1.0 or later of the add-on, you can use EKS Pod Identity to grant the required permissions to the add-on. EKS Pod Identity is the recommended option and provides benefits such as least privilege, credential rotation, and auditability. Additionally, using EKS Pod Identity allows you to install the EKS add-on as part of the cluster creation itself.

To use this method, first follow the EKS Pod Identity association steps to create the IAM role and set up the EKS Pod Identity agent.

Then install the Amazon CloudWatch Observability EKS add-on. To install the add-on, you can use the AWS CLI, the Amazon EKS console, CloudFormation, or Terraform.

AWS CLI

To use the AWS CLI to install the Amazon CloudWatch Observability EKS add-on

Enter the following commands. Replace *my-cluster-name* with the name of your cluster and replace *111122223333* with your account ID. Replace *my-role* with the IAM role that you created in the EKS Pod Identity association step.

```
aws iam attach-role-policy \
--role-name my-role \
--policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy

aws eks create-addon \
--addon-name amazon-cloudwatch-observability \
--cluster-name my-cluster-name \
--pod-identity-associations serviceAccount=cloudwatch-
agent,roleArn=arn:aws:iam::111122223333:role/my-role
```

Amazon EKS console

To use the Amazon EKS console to add the Amazon CloudWatch Observability EKS add-on

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**.
3. Choose the name of the cluster that you want to configure the Amazon CloudWatch Observability EKS add-on for.
4. Choose the **Add-ons** tab.

5. Choose **Get more add-ons**.
6. On the **Select add-ons** page, do the following:
   a. In the **Amazon EKS-addons** section, select the **Amazon CloudWatch Observability** check box.
   b. Choose **Next**.
7. On the **Configure selected add-ons settings** page, do the following:
   a. Select the **Version** you'd like to use.
   b. For **Add-on access**, select **EKS Pod Identity**
   c. If you don't have an IAM role configured, choose **Create recommended role**, then choose **Next** until you are at **Step 3 Name, review, and create**. You can change your role name if desired, otherwise, choose **Create Role**, and then return to the Add-on page and select the IAM role that you just created.
   d. (Optional) You can expand the **Optional configuration settings**. If you select **Override** for the **Conflict resolution method**, one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings, the operation fails. You can use the resulting error message to troubleshoot the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage.
   e. Choose **Next**.
8. On the **Review and add** page, choose **Create**. After the add-on installation is complete, you see your installed add-on.

CloudFormation

To use CloudFormation to install the Amazon CloudWatch Observability EKS add-on

1. First, run the following AWS CLI command to attach the necessary IAM policy to your IAM role. Replace *my-role* with the role that you created in the EKS Pod Identity association step.

```
aws iam attach-role-policy \
--role-name my-role \
--policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

2. Then create the following resource. Replace *my-cluster-name* with the name of your cluster, replace *111122223333* with your account ID, and replace *my-role* with the IAM role created in EKS Pod Identity association step. For more information, see AWS::EKS::Addon.

```
{
"Resources": {
    "EKSAddOn": {
        "Type": "AWS::EKS::Addon",
        "Properties": {
            "AddonName": "amazon-cloudwatch-observability",
            "ClusterName": "my-cluster-name",
            "PodIdentityAssociations": [
                {
                    "ServiceAccount": "cloudwatch-agent",
                    "RoleArn": "arn:aws:iam::111122223333:role/my-role"
                }
            ]
        }
    }
}
}
```

Terraform

To use Terraform to install the Amazon CloudWatch Observability EKS add-on

1. Use the following. Replace *my-cluster-name* with the name of your cluster, replace *111122223333* with your account ID, and replace *my-service-account-role* with the IAM role created in EKS Pod Identity association step.

   For more information, see Resource: aws_eks_addon in the Terraform documentation.

2.
```
resource "aws_iam_role_policy_attachment" "CloudWatchAgentServerPolicy" {
  policy_arn = "arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy"
  role       = "my-role"
}

resource "aws_eks_addon" "example" {
  cluster_name = "my-cluster-name"
  addon_name   = "amazon-cloudwatch-observability"
```

```
  pod_identity_associations {
  roleArn = "arn:aws:iam::111122223333:role/my-role"
  serviceAccount = "cloudwatch-agent"
  }
}
```

Option 2: Install with IAM permissions on worker nodes

To use this method, first attach the **CloudWatchAgentServerPolicy** IAM policy to your worker nodes by entering the following command. In this command, replace *my-worker-node-role* with the IAM role used by your Kubernetes worker nodes.

```
aws iam attach-role-policy \
--role-name my-worker-node-role \
--policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Then install the Amazon CloudWatch Observability EKS add-on. To install the add-on, you can use the AWS CLI, the console, CloudFormation, or Terraform.

AWS CLI

To use the AWS CLI to install the Amazon CloudWatch Observability EKS add-on

Enter the following command. Replace *my-cluster-name* with the name of your cluster.

```
aws eks create-addon --addon-name amazon-cloudwatch-observability --cluster-name my-cluster-name
```

Amazon EKS console

To use the Amazon EKS console to add the Amazon CloudWatch Observability EKS add-on

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**.
3. Choose the name of the cluster that you want to configure the Amazon CloudWatch Observability EKS add-on for.
4. Choose the **Add-ons** tab.
5. Choose **Get more add-ons**.

6. On the **Select add-ons** page, do the following:

   a. In the **Amazon EKS-addons** section, select the **Amazon CloudWatch Observability** check box.

   b. Choose **Next**.

7. On the **Configure selected add-ons settings** page, do the following:

   a. Select the **Version** you'd like to use.

   b. (Optional) You can expand the **Optional configuration settings**. If you select **Override** for the **Conflict resolution method**, one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings, the operation fails. You can use the resulting error message to troubleshoot the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage.

   c. Choose **Next**.

8. On the **Review and add** page, choose **Create**. After the add-on installation is complete, you see your installed add-on.

CloudFormation

To use CloudFormation to install the Amazon CloudWatch Observability EKS add-on

Replace *my-cluster-name* with the name of your cluster. For more information, see AWS::EKS::Addon.

```
{
"Resources": {
    "EKSAddOn": {
        "Type": "AWS::EKS::Addon",
        "Properties": {
            "AddonName": "amazon-cloudwatch-observability",
            "ClusterName": "my-cluster-name"
        }
    }
}
}
```

Helm chart

To use the `amazon-cloudwatch-observability` Helm chart

1. You must have Helm installed to use this chart. For more information about installing Helm, see the Helm documentation.
2. After you have installed Helm, enter the following commands. Replace *my-cluster-name* with the name of your cluster, and replace *my-cluster-region* with the Region that the cluster runs in.

```
helm repo add aws-observability https://aws-observability.github.io/helm-charts
helm repo update aws-observability
helm install --wait --create-namespace --namespace amazon-cloudwatch amazon-
cloudwatch-observability aws-observability/amazon-cloudwatch-observability --set
 clusterName=my-cluster-name --set region=my-cluster-region
```

Terraform

To use Terraform to install the Amazon CloudWatch Observability EKS add-on

Replace *my-cluster-name* with the name of your cluster. For more information, see Resource: aws_eks_addon.

```
resource "aws_eks_addon" "example" {
  addon_name   = "amazon-cloudwatch-observability"
  cluster_name = "my-cluster-name"
}
```

Option 3: Install using IAM service account role (applies only to using the add-on)

This method is valid only if you are using the Amazon CloudWatch Observability EKS add-on. Before using this method, verify the following prerequisites:

- You have a functional Amazon EKS cluster with nodes attached in one of the AWS Regions that supports Container Insights. For the list of supported Regions, see Container Insights.
- You have `kubectl` installed and configured for the cluster. For more information, see Installing `kubectl` in the *Amazon EKS User Guide*.

- You have `eksctl` installed. For more information, see Installing or updating `eksctl` in the *Amazon EKS User Guide*.

AWS CLI

To use the AWS CLI to install the Amazon CloudWatch Observability EKS add-on using the IAM service account role

1. Enter the following command to create an OpenID Connect (OIDC) provider, if the cluster doesn't have one already. For more information, see Configuring a Kubernetes service account to assume an IAM role in the *Amazon EKS User Guide*.

```
eksctl utils associate-iam-oidc-provider --cluster my-cluster-name --approve
```

2. Enter the following command to create the IAM role with the **CloudWatchAgentServerPolicy** policy attached, and configure the agent service account to assume that role using OIDC. Replace *my-cluster-name* with the name of your cluster, and replace *my-service-account-role* with the name of the role that you want to associate the service account with. If the role doesn't already exist, `eksctl` creates it for you.

```
eksctl create iamserviceaccount \
  --name cloudwatch-agent \
  --namespace amazon-cloudwatch --cluster my-cluster-name \
  --role-name my-service-account-role \
  --attach-policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy \
  --role-only \
  --approve
```

3. Install the add-on by entering the following command. Replace *my-cluster-name* with the name of your cluster, replace *111122223333* with your account ID, and replace *my-service-account-role* with the IAM role created in the previous step.

```
aws eks create-addon --addon-name amazon-cloudwatch-observability
 --cluster-name my-cluster-name --service-account-role-arn
 arn:aws:iam::111122223333:role/my-service-account-role
```

Amazon EKS console

To use the console to install the Amazon CloudWatch Observability EKS add-on using the IAM service account role

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**.
3. Choose the name of the cluster that you want to configure the Amazon CloudWatch Observability EKS add-on for.
4. Choose the **Add-ons** tab.
5. Choose **Get more add-ons**.
6. On the **Select add-ons** page, do the following:
   a. In the **Amazon EKS-addons** section, select the **Amazon CloudWatch Observability** check box.
   b. Choose **Next**.
7. On the **Configure selected add-ons settings** page, do the following:
   a. Select the **Version** you'd like to use.
   b. For **Add-on access**, select **IAM roles for service accounts (IRSA)**
   c. Select the IAM role in the **Add-on access** box.
   d. (Optional) You can expand the **Optional configuration settings**. If you select **Override** for the **Conflict resolution method**, one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings, the operation fails. You can use the resulting error message to troubleshoot the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage.
   e. Choose **Next**.
8. On the **Review and add** page, choose **Create**. After the add-on installation is complete, you see your installed add-on.

(Optional) Additional configuration

Topics

- Opt out of collecting container logs
- Use a custom Fluent Bit configuration
- Manage Kubernetes tolerations for the installed pod workloads
- Opt out of accelerated compute metrics collection
- Use a custom CloudWatch agent configuration
- Manage admission webhook TLS certificates
- Collect Amazon EBS volume IDs

Opt out of collecting container logs

By default, the add-on uses Fluent Bit to collect container logs from all pods and then sends the logs to CloudWatch Logs. For information about which logs are collected, see Send logs to CloudWatch Logs.

> **Note**
>
> Neither the add-on or the Helm chart manage existing Fluentd or Fluent Bit resources in a cluster. You can delete the existing Fluentd or Fluent Bit resources before installing the add-on or Helm chart. Alternatively, to keep your existing setup and avoid having the add-on or the Helm chart from also installing Fluent Bit, you can disable it by following the instructions in this section.

To opt out of the collection of container logs if you are using the Amazon CloudWatch Observability EKS add-on, pass the following option when you create or update the add-on:

```
--configuration-values '{ "containerLogs": { "enabled": false } }'
```

To opt out of the collection of container logs if you are using the Helm chart, pass the following option when you create or update the add-on:

```
--set containerLogs.enabled=false
```

Use a custom Fluent Bit configuration

Starting with version 1.7.0 of the Amazon CloudWatch Observability EKS add-on, you can modify the Fluent Bit configuration when you create or update the add-on or Helm chart. You supply

the custom Fluent Bit configuration in the `containerLogs` root level section of the advanced configuration of the add-on or the value overrides in the Helm chart. Within this section, you supply the custom Fluent Bit configuration in the `config` section (for Linux) or `configWindows` section (for Windows). The `config` is further broken down into the following sub-sections:

- `service`– This section represents the `SERVICE` config to define the global behavior of the Fluent Bit engine.
- `customParsers`– This section represents any global `PARSER`s that you want to include that are capable of taking unstructured log entries and giving them a structure to make it easier for processing and further filtering.
- `extraFiles`– This section can be used to provide additional Fluent Bit `conf` files to be included. By default, the following 3 `conf` files are included:.
  - `application-log.conf`– A `conf` file for sending application logs from your cluster to the log group `/aws/containerinsights/`*`my-cluster-name`*`/application` in CloudWatch Logs.
  - `dataplane-log.conf`– A `conf` file for sending logs corresponding to your cluster's data plane components including the CRI logs, kubelet logs, kube-proxy logs and Amazon VPC CNI logs to the log group `/aws/containerinsights/`*`my-cluster-name`*`/dataplane` in CloudWatch Logs.
  - `host-log.conf`– A `conf` for sending logs from `/var/log/dmesg`, `/var/log/messages`, and `/var/log/secure` on Linux, and System `winlogs` on Windows, to the log group `/aws/containerinsights/`*`my-cluster-name`*`/host` in CloudWatch.

> **Note**
>
> Provide the full configuration for each of these individual sections even if you are modifying only one field within a sub-section. We recommend that you use the default configuration provided below as a baseline and then modify it accordingly so that you don't disable functionality that is enabled by default. You can use the following YAML configuration when modifying the advanced config for the Amazon EKS add-on or when you supply value overrides for the Helm chart.

To find the `config` section for your cluster, see aws-observability / helm-charts on GitHub and find the release corresponding to the version of the add-on or Helm chart that you are installing.

Then navigate to `/charts/amazon-cloudwatch-observability/values.yaml` to find the `config` section (for Linux) and `configWindows` section (for Windows) within the `fluentBit` section under `containerLogs`.

As an example, the default Fluent Bit configuration for version 1.7.0 can be found here.

We recommend that you provide the `config` as YAML when you supply it using the Amazon EKS add-on's advanced config or when you supply it as value overrides for your Helm installation. Be sure that the YAML conforms to the following structure.

```
containerLogs:
  fluentBit:
config:
  service: |
    ...
  customParsers: |
    ...
  extraFiles:
    application-log.conf: |
      ...
    dataplane-log.conf: |
      ...
    host-log.conf: |
      ...
```

The following example `config` changes the global setting for the flush interval to be 45 seconds. Even though the only modification is to the `Flush` field, you must still provide the full `SERVICE` definition for the service sub-section. Because this example didn't specify overrides for the other sub-sections, the defaults are used for them.

```
containerLogs:
  fluentBit:
config:
  service: |
    [SERVICE]
      Flush                     45
      Grace                     30
      Log_Level                 error
      Daemon                    off
      Parsers_File              parsers.conf
      storage.path              /var/fluent-bit/state/flb-storage/
      storage.sync              normal
```

```
      storage.checksum          off
      storage.backlog.mem_limit 5M
```

The following example configuration includes an extra Fluent bit `conf` file. In this example, you are adding a custom `my-service.conf` under `extraFiles` and it will be included in addition to the three default `extraFiles`.

```
containerLogs:
  fluentBit:
config:
  extraFiles:
    my-service.conf: |
      [INPUT]
        Name              tail
        Tag               myservice.*
        Path              /var/log/containers/*myservice*.log
        DB                /var/fluent-bit/state/flb_myservice.db
        Mem_Buf_Limit     5MB
        Skip_Long_Lines   On
        Ignore_Older      1d
        Refresh_Interval  10

      [OUTPUT]
        Name                cloudwatch_logs
        Match               myservice.*
        region              ${AWS_REGION}
        log_group_name      /aws/containerinsights/${CLUSTER_NAME}/myservice
        log_stream_prefix   ${HOST_NAME}-
        auto_create_group   true
```

The next example removes an existing `conf` file entirely from `extraFiles`. This excludes the `application-log.conf` entirely by overriding it with an empty string. Simply omitting `application-log.conf` from `extraFiles` would instead imply to use the default, which is not what you are trying to achieve in this example. The same applies to removing any custom `conf` file that you might have previously added to `extraFiles`.

```
containerLogs:
  fluentBit:
config:
  extraFiles:
    application-log.conf: ""
```

Manage Kubernetes tolerations for the installed pod workloads

Starting with version 1.7.0 of the Amazon CloudWatch Observability EKS add-on, the add-on and the Helm chart by default set Kubernetes *tolerations* to tolerate all taints on the pod workloads that are installed by the add-on or the Helm chart. This ensures that daemonsets such as the CloudWatch agent and Fluent Bit can schedule pods on all nodes in your cluster by default. For more information about tolerations and taints, see Taints and Tolerations in the Kubernetes documentation.

The default tolerations set by the add-on or the Helm chart are as follows:

```
tolerations:
- operator: Exists
```

You can override the default tolerations by setting the `tolerations` field at the root level when using the add-on advanced config or when you install or upgrade the Helm chart with value overrides. An example would look like the following:

```
tolerations:
- key: "key1"
  operator: "Exists"
  effect: "NoSchedule"
```

To omit tolerations completely, you can use a config that looks like the following:

```
tolerations: []
```

Any changes to tolerations apply to all pod workloads that are installed by the add-on or the Helm chart.

Opt out of accelerated compute metrics collection

By default, Container Insights with enhanced observability collects metrics for Accelerated Compute monitoring, including NVIDIA GPU metrics, AWS Neuron metrics for AWS Trainium and AWS Inferentia, and AWS Elastic Fabric Adapter (EFA) metrics.

NVIDIA GPU metrics from Amazon EKS workloads are collected by default beginning with version `v1.3.0-eksbuild.1` of the EKS add-on or the Helm chart and version `1.300034.0` of the CloudWatch agent. For a list of metrics collected and prerequisites, see NVIDIA GPU metrics.

AWS Neuron metrics for AWS Trainium and AWS Inferentia accelerators are collected by default beginning with version `v1.5.0-eksbuild.1` of the EKS add-on or the Helm chart, and version `1.300036.0` of the CloudWatch agent. For a list of metrics collected and prerequisites, see AWS Neuron metrics for AWS Trainium and AWS Inferentia.

AWS Elastic Fabric Adapter (EFA) metrics from Linux nodes on Amazon EKS clusters are collected by default beginning with version `v1.5.2-eksbuild.1` of the EKS add-on or the Helm chart and version `1.300037.0` of the CloudWatch agent. For a list of metrics collected and prerequisites, see AWS Elastic Fabric Adapter (EFA) metrics.

You can opt out of collecting these metrics by setting the `accelerated_compute_metrics` field in the CloudWatch agent configuration file to `false`. This field is in the `kubernetes` section of the `metrics_collected` section in the CloudWatch configuration file. The following is an example of an opt-out configuration. For more information about how to use custom CloudWatch agent configurations, see the following section, Use a custom CloudWatch agent configuration.

```
{
  "logs": {
"metrics_collected": {
  "kubernetes": {
    "enhanced_container_insights": true,
    "accelerated_compute_metrics": false
  }
}
  }
}
```

Use a custom CloudWatch agent configuration

To collect other metrics, logs or traces using the CloudWatch agent, you can specify a custom configuration while also keeping Container Insights and CloudWatch Application Signals enabled. To do so, embed the CloudWatch agent configuration file within the config key under the agent key of the advanced configuration that you can use when creating or updating the EKS add-on or the Helm chart. The following represents the default agent configuration when you do not provide any additional configuration.

> **Important**
>
> Any custom configuration that you provide using additional configuration settings overrides the default configuration used by the agent. Be cautious not to unintentionally

disable functionality that is enabled by default, such as Container Insights with enhanced observability and CloudWatch Application Signals. In the scenario that you are required to provide a custom agent configuration, we recommend using the following default configuration as a baseline and then modifying it accordingly.

- For using the Amazon CloudWatch observability EKS add-on

```
--configuration-values '{
  "agent": {
"config": {
  "logs": {
    "metrics_collected": {
      "application_signals": {},
      "kubernetes": {
        "enhanced_container_insights": true
      }
    }
  },
  "traces": {
    "traces_collected": {
      "application_signals": {}
    }
  }
}
  }
}'
```

- For using the Helm chart

```
--set agent.config='{
  "logs": {
"metrics_collected": {
  "application_signals": {},
  "kubernetes": {
    "enhanced_container_insights": true
  }
}
  },
  "traces": {
"traces_collected": {
  "application_signals": {}
```

```
}
  }
}'
```

The following example shows the default agent configuration for the CloudWatch agent on Windows. The CloudWatch agent on Windows does not support custom configuration.

```
{
  "logs": {
"metrics_collected": {
  "kubernetes": {
    "enhanced_container_insights": true
  },
}
  }
}
```

Manage admission webhook TLS certificates

The Amazon CloudWatch Observability EKS add-on and the Helm chart use Kubernetes admission webhooks to validate and mutate `AmazonCloudWatchAgent` and `Instrumentation` custom resource (CR) requests, and optionally Kubernetes pod requests on the cluster if CloudWatch Application Signals is enabled. In Kubernetes, webhooks require a TLS certificate that the API server is configured to trust to make sure secure communication.

By default, the Amazon CloudWatch Observability EKS add-on and the Helm chart auto-generate a self-signed CA and a TLS certificate signed by this CA for securing the communication between the API server and the webhook server. This auto-generated certificate has a default expiry of 10 years and is not auto-renewed upon expiry. In addition, the CA bundle and the certificate are re-generated every time the add-on or Helm chart is upgraded or re-installed, thus resetting the expiry. If you want to change the default expiry of the auto-generated certificate, you can use the following additional configurations when creating or updating the add-on. Replace *`expiry-in-days`* with your desired expiry duration in days.

- Use this for the Amazon CloudWatch Observability EKS add-on

```
--configuration-values '{ "admissionWebhooks": { "autoGenerateCert":
 { "expiryDays": expiry-in-days } } }'
```

- Use this for the Helm chart

```
--set admissionWebhooks.autoGenerateCert.expiryDays=expiry-in-days
```

For a more secure and feature-rich certificate authority solution, the add-on has opt-in support for cert-manager, a widely-adopted solution for TLS certificate management in Kubernetes that simplifies the process of obtaining, renewing, managing and using those certificates. It ensures that certificates are valid and up to date, and attempts to renew certificates at a configured time before expiry. cert-manager also simplifies issuing certificates from a variety of supported sources, including AWS Certificate Manager Private Certificate Authority.

We recommend that you review best practices for management of TLS certificates on your clusters and advise you to opt in to cert-manager for production environments. Note that if you opt-in to enabling cert-manager for managing the admission webhook TLS certificates, you are required to pre-install cert-manager on your Amazon EKS cluster before you install the Amazon CloudWatch Observability EKS add-on or the Helm chart. For more information about available installation options, see cert-manager documentation. After you install it, you can opt in to using cert-manager for managing the admission webhook TLS certificates using the following additional configuration.

- If you are using the Amazon CloudWatch Observability EKS add-on

```
--configuration-values '{ "admissionWebhooks": { "certManager": { "enabled":
 true } } }'
```

- If you are using the Helm chart

```
--set admissionWebhooks.certManager.enabled=true
```

```
--configuration-values '{ "admissionWebhooks": { "certManager": { "enabled":
 true } } }'
```

The advanced configuration discussed in this section will by default use a SelfSigned issuer.

Collect Amazon EBS volume IDs

If you want to collect Amazon EBS volume IDs in the performance logs, you must add another policy to the IAM role that is attached to the worker nodes or to the service account. Add the

following as an inline policy. For more information, see Adding and Removing IAM Identity Permissions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "ec2:DescribeVolumes"
            ],
            "Resource": "*",
            "Effect": "Allow"
        }
    ]
}
```

Collect Java Management Extensions (JMX) metrics

The CloudWatch agent supports Java Management Extensions (JMX) metrics collection on Amazon EKS. This allows you to collect additional metrics from Java applications running on Amazon EKS clusters enabling insight into performance, memory usage, traffic, and other critical metrics. For more information, see Collect Java Management Extensions (JMX) metrics.

Enable Kueue metrics

Beginning with version `v2.4.0-eksbuild.1` of the the CloudWatch Observability EKS add-on, Container Insights for Amazon EKS supports collecting Kueue metrics from Amazon EKS clusters. For more information about these metrics, see Kueue metrics.

If you are using the Amazon SageMaker AI Hyperpod Task Governance EKS add-on, you can skip the steps in the **Prerequisites** section and just follow the steps in Enable the configuration flag.

Prerequisites

Before you install Kueue in your Amazon EKS cluster, make the following updates in the manifest file:

1. Enable the optional cluster queue resource metrics for Kueue. To do this, modify the in-line `controller_manager_config.yaml` in the `kueue-system` ConfigMap. In the `metrics` section, add or uncomment the line `enableClusterQueueResources: true`.

```
apiVersion: v1
data:
  controller_manager_config.yaml: |
apiVersion: config.kueue.x-k8s.io/v1beta1
kind: Configuration
health:
  healthProbeBindAddress: :8081
metrics:
  bindAddress: :8080
  enableClusterQueueResources: true  <-- ADD/UNCOMMENT THIS LINE
```

2. By default, all `k8s` services are available cluster-wide. Kueue creates a service `kueue-controller-manager-metrics-service` for exposing metrics. To prevent duplicate observations for metrics, modify this service to allow access only to the metrics service from the same node. To do this, add the line `internalTrafficPolicy: Local` to the `kueue-controller-manager-metrics-service` definition.

```
apiVersion: v1
kind: Service
metadata:
  labels:
...
  name: kueue-controller-manager-metrics-service
  namespace: kueue-system
spec:
  ports:
  - name: https
port: 8443
protocol: TCP
targetPort: https
  internalTrafficPolicy: Local   <-- ADD THIS LINE
  selector:
control-plane: controller-manager
```

3. Lastly, the `kueue-controller-manager` pod creates a `kube-rbac-proxy` container. This container currently has a high level of logging verbosity, which causes the cluster's bearer token to be logged by that container when the metrics scraper accesses the `kueue-controller-`

`manager-metrics-service`. We recommend that you decrease this logging verbosity. The default value in the manifest distributed by Kueue is 10, we recommend to change it to 0.

```
apiVersion: apps/v1
kind: Deployment
metadata:

```

Enable the configuration flag

To enable the Kueue metrics, you must enable `kueue_container_insights` in the add-on additional configuration. You can do this either by using the AWS CLI to set up the EKS Observability add-on, or by using the Amazon EKS console.

After you have successfully installed the EKS Observability add-on with one of the following methods, you can view your Amazon EKS cluster metrics under the HyperPod console **Dashboard** tab.

AWS CLI

To enable Kueue metrics using the AWS CLI

- Enter the following AWS CLI command to install the add-on.

```
aws eks create-addon --cluster-name cluster-name --addon-name amazon-cloudwatch-
observability --configuration-values "configuration_json_file"
```

The following is an example of the JSON file with the configuration values.

```
{
"agent": {
    "config": {
        "logs": {
            "metrics_collected": {
                "kubernetes": {
                    "kueue_container_insights": true,
                    "enhanced_container_insights": true
                },
                "application_signals": { }
            }
        },
        "traces": {
            "traces_collected": {
                "application_signals": { }
            }
        }
    },
},
}
```

Amazon EKS console

To enable Kueue metrics using the Amazon EKS console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the name of your cluster.
3. Choose **Add-ons**.
4. Find the **Amazon CloudWatch Observability** add-on in the list, and install it. When you do so, choose **Optional configuration** and include the following JSON configuration values.

```
{
"agent": {
    "config": {
```

```
        "logs": {
            "metrics_collected": {
                "kubernetes": {
                    "kueue_container_insights": true,
                    "enhanced_container_insights": true
                },
                "application_signals": { }
            }
        },
        "traces": {
            "traces_collected": {
                "application_signals": { }
            }
        }
    },
},
}
```

Appending OpenTelemetry collector configuration files

The CloudWatch agent supports supplemental OpenTelemetry collector configuration files alongside its own configuration files. This feature allows you to use CloudWatch agent features such as CloudWatch Application Signals or Container Insights through the CloudWatch agent configuration and bring in your existing OpenTelemetry collector configuration with a single agent.

To prevent merge conflicts with pipelines automatically created by CloudWatch agent, add a custom suffix to each of the components and pipelines in your OpenTelemetry collector configuration. This will prevent clashing and merge conflicts.

- If you are using the Amazon CloudWatch Observability EKS add-on

```
--configuration-values file://values.yaml
```

or

```
--configuration-values '
  agent:
otelConfig:
  receivers:
    otlp/custom-suffix:
      protocols:
```

```
        http: {}
  exporters:
    awscloudwatchlogs/custom-suffix:
      log_group_name: "test-group"
      log_stream_name: "test-stream"
  service:
    pipelines:
      logs/custom-suffix:
        receivers: [otlp/custom-suffix]
        exporters: [awscloudwatchlogs/custom-suffix]
'
```

- If you are using the Helm chart

```
--set agent.otelConfig='
  receivers:
otlp/custom-suffix:
  protocols:
    http: {}
  exporters:
awscloudwatchlogs/custom-suffix:
  log_group_name: "test-group"
  log_stream_name: "test-stream"
  service:
pipelines:
  logs/custom-suffix:
    receivers: [otlp/custom-suffix]
    exporters: [awscloudwatchlogs/custom-suffix]
'
```

Enabling APM through Application Signals for your Amazon EKS cluster

By default, OpenTelemetry (OTEL) based Application Performance Monitoring (APM) is enabled through Application Signals when installing either the CloudWatch Observability EKS add-on (V5.0.0 or greater) or the Helm chart. You can further customize specific settings using the advanced configuration for the Amazon EKS add-on or by overriding values with the Helm chart.

> **Note**
>
> If you use any OpenTelemetry (OTEL) based APM solution, enabling Application Signals affects your existing observability setup. Review your current implementation before

proceeding. To maintain your existing APM setup after upgrading to V5.0.0 or later, see Opt out of Application Signals.

Application Signals Auto monitor

Version 5.0.0 of the CloudWatch Observability Amazon EKS add-on and Helm chart introduces new functionality. You can now automatically enable Application Signals for all or specific service workloads in your EKS cluster through the Auto monitor configuration. The following `autoMonitor` settings can be specified within the `applicationSignals` section under the `manager` section of the advanced configuration.

- *monitorAllServices* – A boolean flag to enable (true) or disable (false) monitoring of all service workloads by Auto monitor. Defaults to true. Enabling this flag will make sure that all Kubernetes workloads (Deployments, DaemonSets, and StatefulSets) in the cluster that are mapped to a Kubernetes Service will be in scope for automatic enablement of Application Signals when they are brought up for the first time (or when restarted for existing workloads). The system excludes workloads in the `kube-system` and `amazon-cloudwatch` namespaces by default.
- *languages* – A list of strings specifying the set of languages that Application Signals will try to automatically instrument your services with, when `monitorAllServices` is enabled. Defaults to all the supported languages.
- *restartPods* – A boolean flag controls whether workloads restart after configuration changes. Defaults to false. Enabling this flag to `true` controls whether Kubernetes workloads within Auto monitor scope restart automatically when saving configuration changes. Any settings on your Kubernetes workloads that influence the restart of the pods such as `updateStrategy` will be considered. Consider that restarting may cause service downtime.
- *customSelector* – Settings to select specific Kubernetes namespaces or workloads for Auto monitor.
  - *java* – Specify workloads to automatically instrument with Java
  - *python* – Specify workloads to automatically instrument with Python
  - *nodejs* – Specify workloads to automatically instrument with Node.js
  - *dotnet* – Specify workloads to automatically instrument with .NET

  For each of the languages above, the following fields can be configured.

- *namespaces* – A list of strings specifying the namespaces to be selected. Defaults to an empty list, that is []
- *deployments* – A list of strings specifying the deployments to be selected. Specify in `namespace/deployment`format. Defaults to an empty list, that is []
- *daemonsets* – A list of strings specifying the daemonsets to be selected. Specify in `namespace/daemonset` format. Defaults to an empty list, that is []
- *statefulsets* – A list of strings specifying the statefulsets to be selected. Specify in `namespace/statefulset` format. Defaults to an empty list, that is []

- *exclude* – Settings to exclude specific Kubernetes namespaces or workloads from Auto monitor. Excluding a workload takes precedence when the same workload is also within scope of `monitorAllServices` or `customSelector`.
  - *java* – Specify workloads to exclude from being automatically instrumented with Java
  - *python* – Specify workloads to exclude from being automatically instrumented with Python
  - *nodejs* – Specify workloads to exclude from being automatically instrumented with Node.js
  - *dotnet* – Specify workloads to exclude from being automatically instrumented with .NET

  For each of the languages above, the following fields can be configured.
  - *namespaces* – A list of strings specifying the namespaces to be excluded. Defaults to an empty list, that is []
  - *deployments* – A list of strings specifying the deployments to be excluded. Specify in `namespace/deployment`format. Defaults to an empty list, that is []
  - *daemonsets* – A list of strings specifying the daemonsets to be excluded. Specify in `namespace/daemonset` format. Defaults to an empty list, that is []
  - *statefulsets* – A list of strings specifying the statefulsets to be excluded. Specify in `namespace/statefulset` format. Defaults to an empty list, that is []

The following is an example configuration that automatically enables Application Signals for all existing and new service workloads on the cluster.

```
manager:
  applicationSignals:
autoMonitor:
  monitorAllServices: true
  restartPods: true
```

The following is an example configuration that automatically enables Application Signals for any new service workload that is brought up and for any existing service workload that is explicitly restarted on the cluster.

```
manager:
  applicationSignals:
autoMonitor:
  monitorAllServices: true
```

The following is an example configuration that automatically enables Application Signals with Java for all existing and new pods corresponding to a workload in the `pet-warehouse` namespace.

```
manager:
  applicationSignals:
autoMonitor:
  restartPods: true
  customSelector:
    java:
      namespaces: ["pet-warehouse"]
```

The following is an example configuration that automatically enables Application Signals with Python for all existing and new service workloads in the cluster excluding the `pet-clinic` deployment.

```
manager:
  applicationSignals:
autoMonitor:
  monitorAllServices: true
  languages: ["python"]
  restartPods: true
  exclude:
    python:
      deployments: ["pet-warehouse/pet-clinic"]
```

The following is an example configuration that automatically enables Application Signals with Java for all service workloads in the cluster except for the ones in the `python-apps` namespace and further enables Application Signals with Python specifically for the `sample-python-app` deployment in the `python-apps` namespace.

```
manager:
```

```
  applicationSignals:
autoMonitor:
  monitorAllServices: true
  languages: ["java"]
  restartPods: true
  customSelector:
    python:
      deployments: ["python-apps/sample-python-app"]
  exclude:
    java:
      namespaces: ["python-apps"]
```

Considerations for large Kubernetes clusters

If you run large Kubernetes clusters, you might need additional configuration to make sure the CloudWatch agent runs reliably. The following sections describe common issues and recommended configurations for large clusters.

Separate agent installations for cluster-level and node-level metrics

> **Note**
>
> This section applies only if you have Container Insights with enhanced observability enabled. If you use Container Insights with OpenTelemetry metrics exclusively, the default installation already deploys separate agent installations.

By default, the CloudWatch agent runs as a daemonset on each node in your cluster. One agent Pod is elected as a leader to collect cluster-level metrics. These metrics include control plane metrics and workload status metrics. On large clusters, this leader Pod may be terminated with an out-of-memory (OOM) error because it performs additional work while sharing the same resource limits as all other agent Pods.

To determine if you are experiencing this issue, check for agent Pods in a failed state with exit code `137` and reason `OOMKilled`. A common symptom is that one agent Pod (the leader) crashes, a new leader is elected, and that Pod also crashes, creating a recurring cycle. To confirm this behavior, inspect the leader election ConfigMap by running the following command.

```
kubectl describe configmap cwagent-clusterleader -n amazon-cloudwatch
```

If the ConfigMap shows frequent changes to the leader entry, this indicates that a new leader is being elected repeatedly, which confirms the issue.

To avoid this issue, you can separate the agent into two installations:

- A daemonset for node-level metrics and Application Signals
- A deployment for cluster-level metrics

This separation lets you manage and scale each installation independently.

To enable this configuration, use the advanced configuration to define two entries in the `agents` section:

1. Set the `CWAGENT_ROLE` environment variable to `NODE` on the daemonset agent.
2. Set the `CWAGENT_ROLE` environment variable to `LEADER` on the deployment agent.

> **Important**
>
> The deployment agent configuration must enable only Container Insights. Don't enable Application Signals on the deployment agent. Both installations run with `hostNetwork` by default, and enabling Application Signals on both causes port binding conflicts.

The following example shows an advanced configuration that separates the agent into two installations.

```
agents:
  - name: cloudwatch-agent
env:
  - name: CWAGENT_ROLE
    value: NODE
  - name: cloudwatch-agent-ci-leader
mode: deployment
config:
  {
    "logs": {
      "metrics_collected": {
        "kubernetes": {
          "enhanced_container_insights": true
```

```
        }
      }
    }
  }
env:
  - name: CWAGENT_ROLE
    value: LEADER
resources:
  limits:
    memory: 10Gi
    cpu: 2000m
```

In this example, besides setting the `CWAGENT_ROLE` environment variable on each agent installation, it overrides the default mode, configuration, and resource limits for the deployment agent only. The base `cloudwatch-agent` installation uses the defaults.

You can further customize each agent installation by adding `nodeSelector`, `tolerations`, or `nodeAffinity` fields to schedule the leader Pod on a specific node. The resource limits shown in the preceding example are illustrative. Adjust these values based on your cluster size and the number of metrics that the leader Pod collects.

Considerations for Amazon EKS Hybrid Nodes

Node-level metrics aren't available for hybrid nodes because Container Insights depends on the availability of the EC2 Instance Metadata Service (IMDS) for node-level metrics. Cluster, workload, Pod, and container-level metrics are available for hybrid nodes.

After you install the add-on, patch the `amazoncloudwatchagents` resource to add the `RUN_WITH_IRSA` environment variable so the agent runs successfully on hybrid nodes:

```
kubectl patch amazoncloudwatchagents cloudwatch-agent -n amazon-
cloudwatch --type=json -p '[{"op":"add","path":"/spec/env/-","value":
{"name":"RUN_WITH_IRSA","value":"True"}}]'
```

Troubleshooting the Amazon CloudWatch Observability EKS add-on or the Helm chart

Use the following information to help troubleshoot problems with the Amazon CloudWatch Observability EKS add-on or the Helm chart

Topics

- Updating and deleting the Amazon CloudWatch Observability EKS add-on or the Helm chart

- Verify the version of the CloudWatch agent used by the Amazon CloudWatch Observability EKS add-on or the Helm chart
- Handling a ConfigurationConflict when managing the add-on or the Helm chart

Updating and deleting the Amazon CloudWatch Observability EKS add-on or the Helm chart

For instructions about updating or deleting the Amazon CloudWatch Observability EKS add-on, see Managing Amazon EKS add-ons. Use `amazon-cloudwatch-observability` as the name of the add-on.

To delete the Helm chart in a cluster, enter the following command.

```
helm delete amazon-cloudwatch-observability -n amazon-cloudwatch --wait
```

Verify the version of the CloudWatch agent used by the Amazon CloudWatch Observability EKS add-on or the Helm chart

The Amazon CloudWatch Observability EKS add-on and the Helm chart installs a custom resource of kind `AmazonCloudWatchAgent` that controls the behavior of the CloudWatch agent daemonset on the cluster, including the version of the CloudWatch agent being used. You can get a list of all the `AmazonCloudWatchAgent` custom resources installed on your cluster u by entering the following command:

```
kubectl get amazoncloudwatchagent -A
```

In the output of this command, you should be able to check the version of the CloudWatch agent. Alternatively, you can also describe the `amazoncloudwatchagent` resource or one of the `cloudwatch-agent-*` pods running on your cluster to inspect the image being used.

Handling a ConfigurationConflict when managing the add-on or the Helm chart

When you install or update the Amazon CloudWatch Observability EKS add-on or the Helm chart, if you notice a failure caused by existing resources, it is likely because you already have the CloudWatch agent and its associated components such as the ServiceAccount, the ClusterRole and the ClusterRoleBinding installed on the cluster.

The error displayed by the add-on will include `Conflicts found when trying to apply. Will not continue due to resolve conflicts mode`,

The error displayed by the Helm chart will be similar to `Error: INSTALLATION FAILED: Unable to continue with install and invalid ownership metadata.`.

When the add-on or the Helm chart tries to install the CloudWatch agent and its associated components, if it detects any change in the contents, it by default fails the installation or update to avoid overwriting the state of the resources on the cluster.

If you are trying to onboard to the Amazon CloudWatch Observability EKS add-on and you see this failure, we recommend deleting an existing CloudWatch agent setup that you had previously installed on the cluster and then installing the EKS add-on or Helm chart. Be sure to back up any customizations you might have made to the original CloudWatch agent setup such as a custom agent configuration, and provide these to the add-on or Helm chart when you next install or update it. If you had previously installed the CloudWatch agent for onboarding to Container Insights, see Setup guide (AWS CLI) for more information.

Alternatively, the add-on supports a conflict resolution configuration option that has the capability to specify `OVERWRITE`. You can use this option to proceed with installing or updating the add-on by overwriting the conflicts on the cluster. If you are using the Amazon EKS console, you'll find the **Conflict resolution method** when you choose the **Optional configuration settings** when you create or update the add-on. If you are using the AWS CLI, you can supply the `--resolve-conflicts OVERWRITE` to your command to create or update the add-on.

Opt out of Application Signals

Fine-tune your service monitoring preferences in the CloudWatch console or with the SDK.

To disable Application Signals auto-monitoring, follow the procedure below:

Using CLI or SDK

The following configuration can be applied either as an advanced configuration to the EKS add-on or as a values override when using the helm chart.

```
{
  "manager": {
"applicationSignals": {
  "autoMonitor": {
    "monitorAllServices": false
  }
}
  }
```

```
}
```

Restart your services for the changes to take effect.

Using the console

Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

1. In the navigation pane, under **Application Signals (APM)**, choose **Services**.
2. Choose **Enable Application Signals** to view the enablement page.
3. Clear the **Auto-Monitor** checkbox for each service you don't want to monitor.
4. Restart your services for the changes to take effect.

Advanced configuration for OTel Container Insights on Amazon EKS

This topic covers advanced configuration scenarios for OTel Container Insights on Amazon EKS. Use these configurations to customize metric collection, filter logs, collect telemetry across accounts, add custom dimensions, and tune resource allocation for large clusters.

Prerequisites

Before you configure advanced settings, verify that you meet the following requirements.

- OTel Container Insights installed and in `ACTIVE` status on your Amazon EKS cluster
- Amazon EKS cluster running Kubernetes version 1.28 or later
- AWS CLI version 2.15.0 or later
- `kubectl` configured to communicate with your target cluster
- IAM permissions: `eks:UpdateAddon`, `eks:DescribeAddon`, and `iam:AttachRolePolicy` (required for cross-account configuration)

General configuration pattern

All advanced configurations follow the same pattern. You pass a JSON configuration to the `amazon-cloudwatch-observability` add-on by using the `aws eks update-addon` command.

```
aws eks update-addon \
  --cluster-name cluster-name \
```

```
  --addon-name amazon-cloudwatch-observability \
  --configuration-values 'JSON-configuration' \
  --resolve-conflicts OVERWRITE
```

> **Important**
>
> The `--resolve-conflicts OVERWRITE` flag replaces any existing add-on configuration. To preserve existing settings, merge them with your new configuration before you run the command.

Log filtering

You can reduce CloudWatch Logs costs by excluding logs that match specific criteria. Use log filtering to drop debug-level or verbose logs before the agent sends them to CloudWatch.

To configure log filtering

1. Run the following command to update the add-on with a log filter configuration. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{
    "otelContainerInsights": {
      "enabled": true
    },
    "agent": {
      "config": {
        "logs": {
          "metrics_collected": {
            "kubernetes": {
              "enhanced_container_insights": true
            }
          },
          "exclude_filters": [
            {
              "type": "log_level_filter",
              "log_level": "DEBUG"
            }
          ]
```

```
        }
      }
    }
  }' \
  --resolve-conflicts OVERWRITE
```

2. Verify that the add-on status is ACTIVE after the update.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --query "addon.status" \
  --output text
```

The exclude_filters configuration removes log entries that match the specified log level before the agent sends them to CloudWatch Logs. This reduces your log ingestion volume and associated costs.

For additional cost control, set a log retention policy on your log groups to automatically delete older logs. For more information, see Set log retention. Also consider using the CloudWatch Logs Infrequent Access log class for log groups that you query infrequently. For more information, see CloudWatch Logs log classes.

Multi-account collection

You can send telemetry from workload accounts to a central monitoring account by configuring cross-account IAM role assumption. This approach gives you a single view of metrics and logs from multiple Amazon EKS clusters across different AWS accounts.

To set up multi-account collection

To create the cross-account role in the monitoring account

1. In the central monitoring account, create an IAM role with a trust policy that allows the workload account to assume it. Replace the example account ID (111122223333) with the AWS account ID of the workload account.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Attach the `CloudWatchAgentServerPolicy` managed policy to the cross-account role.

To configure the add-on for cross-account delivery

1. In the workload account, update the add-on to assume the cross-account role. Replace *`cluster-name`* with the name of your Amazon EKS cluster and *`monitoring-account-id`* with the AWS account ID of the central monitoring account.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{
    "otelContainerInsights": {
      "enabled": true
    },
    "agent": {
      "config": {
        "credentials": {
          "role_arn": "arn:aws:iam::monitoring-account-id:role/
CrossAccountCWObservabilityRole"
        }
      }
    }
  }' \
  --resolve-conflicts OVERWRITE
```

2. Verify that the add-on status is `ACTIVE` after the update.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --query "addon.status" \
  --output text
```

Custom metric dimensions

You can add custom dimensions derived from Kubernetes labels to your Container Insights metrics. Custom dimensions allow you to filter and group metrics at a finer granularity, such as by team, environment, or application tier.

To add custom dimensions from Kubernetes labels

1. Run the following command to configure custom dimensions. Replace *cluster-name* with the name of your Amazon EKS cluster and *label-key* with the Kubernetes label to use as a dimension.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{
    "otelContainerInsights": {
      "enabled": true
    },
    "agent": {
      "config": {
        "logs": {
          "metrics_collected": {
            "kubernetes": {
              "enhanced_container_insights": true,
              "metric_dimensions": {
                "custom_dimensions": ["label-key"]
              }
            }
          }
        }
      }
    }
  }' \
  --resolve-conflicts OVERWRITE
```

2. Verify that the add-on status is `ACTIVE` after the update.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --query "addon.status" \
```

```
  --output text
```

After the configuration takes effect, the specified Kubernetes labels appear as dimensions on your Container Insights metrics in CloudWatch.

Resource tuning for large clusters

For large clusters, you might need to increase the CPU and memory limits for the CloudWatch agent DaemonSet. The default resource allocation works well for small clusters, but larger clusters generate more telemetry data and require additional agent resources.

The following table provides sizing guidelines based on cluster size.

Cluster size	CPU request	CPU limit	Memory request	Memory limit
Small (20 nodes or fewer)	100m	200m	128Mi	256Mi
Medium (21–100 nodes)	200m	400m	256Mi	512Mi
Large (100+ nodes)	300m	500m	384Mi	768Mi
Extra-large (500+ nodes)	500m	1000m	512Mi	1Gi

To configure resource limits for the agent DaemonSet

1. Run the following command to set resource requests and limits. Replace *cluster-name* with the name of your Amazon EKS cluster and the resource values with values from the preceding table.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{
    "otelContainerInsights": {
      "enabled": true
    },
```

```
    "agent": {
      "resources": {
        "requests": {
          "cpu": "cpu-request",
          "memory": "memory-request"
        },
        "limits": {
          "cpu": "cpu-limit",
          "memory": "memory-limit"
        }
      }
    }
  }' \
  --resolve-conflicts OVERWRITE
```

2. Verify that the add-on status is ACTIVE and that agent pods restart with the new resource allocation.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --query "addon.status" \
  --output text
```

3. Confirm that the agent pods are running with the new resource limits.

```
kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent -o
 jsonpath='{.items[0].spec.containers[0].resources}'
```

Verify configuration changes

After you apply any advanced configuration, verify that the add-on is healthy and that agent pods restarted successfully.

To verify configuration changes

1. Check that the add-on status is ACTIVE. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws eks describe-addon \
  --cluster-name cluster-name \
```

```
  --addon-name amazon-cloudwatch-observability \
  --query "addon.{Status:status,ConfigValues:configurationValues}" \
  --output table
```

2. Verify that agent pods restarted and are in Running status.

```
kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent
```

All agent pods must show Running status with a recent restart time.

Troubleshooting

Use the following guidance to resolve common issues with advanced configurations.

Add-on update fails with ConfigurationConflict

Symptom: The `aws eks update-addon` command returns a `ConfigurationConflict` error.

Cause: The JSON configuration that you provided is malformed or contains invalid keys.

Solution: Complete the following steps to resolve this issue.

1. Validate your JSON configuration by using a JSON linter or by running the following command.

```
echo 'your-json-configuration' | python3 -m json.tool
```

2. Verify that all configuration keys are valid for the `amazon-cloudwatch-observability` add-on.
3. Retry the update with the corrected JSON.

Cross-account metrics not appearing in the monitoring account

Symptom: After you configure multi-account collection, metrics don't appear in the central monitoring account.

Cause: The cross-account IAM role trust policy or permissions are incorrect.

Solution: Complete the following steps to resolve this issue.

1. Verify that the trust policy in the monitoring account allows the workload account to assume the role.

2. Verify that the cross-account role has the `CloudWatchAgentServerPolicy` managed policy attached.
3. Check the agent logs for `AssumeRole` errors.

```
kubectl logs -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent --
tail=100 | grep -i "AssumeRole\|AccessDenied"
```

4. Verify that the agent IAM role in the workload account has `sts:AssumeRole` permission for the cross-account role ARN.

Solutions

With Solutions, you can get pre-built observability for third-party Kubernetes tools that run on your Amazon EKS clusters. Each solution collects metrics from a specific tool and surfaces them in a dedicated dashboard within Container Insights.

Topics

- Collecting Karpenter metrics with OTel Container Insights
- Collecting KEDA metrics with OTel Container Insights

Collecting Karpenter metrics with OTel Container Insights

Karpenter is the recommended node autoscaler for Amazon EKS. Container Insights collects Karpenter metrics through Prometheus scraping. With Container Insights, you gain built-in visibility into node provisioning, scaling speed, and resource use. You do not need to set up Prometheus or Grafana manually.

Karpenter metrics help you answer operational questions such as:

- Why is my pod pending?
- How fast is Karpenter provisioning nodes?
- Is consolidation working effectively?

Prerequisites

Karpenter metrics collection is enabled by default when the following requirements are met.

- Amazon EKS cluster running Kubernetes 1.28 or later

- Karpenter installed and running in the cluster (default namespace: `kube-system`)
- OTel Container Insights enabled on the cluster (see Quick start: OTel Container Insights on Amazon EKS)
- The `amazon-cloudwatch-observability` add-on in `ACTIVE` status

Configuring Karpenter metrics collection

Karpenter metrics collection is enabled by default. If you already have OTel Container Insights enabled (`otelContainerInsights.enabled: true`) and Karpenter is running in your cluster, metrics start flowing automatically with no additional configuration.

If the Karpenter scrape target is not present in the cluster, the pipeline finds no pods and does nothing.

To disable Karpenter metrics collection, set `otelContainerInsights.solutions.karpenter.enabled` to `false`. To disable all solutions at once, set `otelContainerInsights.solutions.enabled` to `false`. The global toggle overrides individual solution settings. If `solutions.enabled` is `false`, no solutions collect metrics, even if their individual `enabled` flag is `true`.

The following Helm values show the default configuration.

```
otelContainerInsights:
  solutions:
    enabled: true
    karpenter:
      enabled: true
```

To disable Karpenter metrics using the Amazon EKS add-on, run the following AWS CLI command. Replace *`cluster-name`* with the name of your Amazon EKS cluster.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{"otelContainerInsights":{"solutions":{"karpenter":
{"enabled":false}}}}' \
  --resolve-conflicts OVERWRITE
```

To disable Karpenter metrics using the Helm chart, run the following command.

```
helm upgrade amazon-cloudwatch-observability \
  aws-observability/amazon-cloudwatch-observability \
  -n amazon-cloudwatch \
  --reuse-values \
  --set otelContainerInsights.solutions.karpenter.enabled=false
```

After you enable Karpenter metrics, the CloudWatch agent finds Karpenter pods by the label `app.kubernetes.io/name=karpenter`. It scrapes the `/metrics` endpoint on the port named `http-metrics` (default 8080) every 30 seconds.

Karpenter metrics pipeline architecture

The Karpenter metrics pipeline uses the following data flow:

1. The Prometheus receiver discovers Karpenter pods using Kubernetes service discovery.
2. The receiver scrapes the `/metrics` endpoint on each Karpenter pod.
3. The OpenTelemetry processor chain adds Kubernetes and cloud resource labels to each metric.
4. The exporter sends the enriched metrics to CloudWatch through OTLP.

The Karpenter pipeline runs independently from other metric pipelines (API server, Kube State Metrics, cAdvisor). This means a failure in one pipeline does not affect the others. If the Karpenter scrape target goes down, other pipelines keep working.

> **Note**
>
> Karpenter metrics are cluster-scoped.

Viewing the Karpenter dashboard

After you turn on Karpenter metrics, you can view the dashboard in the CloudWatch console.

To view the Karpenter dashboard

1. Open the CloudWatch console at CloudWatch console.
2. In the navigation pane, choose **Container Insights**, then choose **Performance monitoring**.
3. For **Service**, choose **EKS OTEL**.
4. In the navigation pane, expand **Solutions** and choose **Karpenter**.

The dashboard displays 30 metrics organized into 8 categories: Pod Scheduling, Node Resources, Cluster State, NodePool, Cloud Provider, Disruption, Interruption, and Controller Health.

Available metrics

The following table lists the 30 Karpenter metrics that Container Insights collects.

Metric name	Category	Description
karpenter_pods_state	Pod Scheduling	Number of pods by state (phase label)
karpenter_pods_bound_duration_seconds	Pod Scheduling	Time for pods to reach bound state
karpenter_nodes_allocatable	Node Resources	Allocatable resources per node by resource type
karpenter_nodes_total_daemon_requests	Node Resources	Total resource requests from DaemonSet pods
karpenter_nodes_total_daemon_limits	Node Resources	Total resource limits from DaemonSet pods
karpenter_nodes_total_pod_requests	Node Resources	Total resource requests from all pods
karpenter_nodes_total_pod_limits	Node Resources	Total resource limits from all pods
karpenter_nodes_system_overhead	Node Resources	Resources reserved for system daemons
karpenter_nodes_current_lifetime_seconds	Node Resources	Current age of each node in seconds
karpenter_cluster_state_node_count	Cluster State	Number of nodes tracked in Karpenter cluster state

Metric name	Category	Description
karpenter_cluster_state_synced	Cluster State	Whether cluster state is synced (1=synced, 0=unsynced)
karpenter_cluster_state_unsynced_time_seconds	Cluster State	Duration cluster state has been unsynced
karpenter_cluster_utilization_percent	Cluster State	Percentage of allocatable resources used by pod requests
karpenter_nodepools_limit	NodePool	Configured resource limits per NodePool
karpenter_nodepools_usage	NodePool	Current resource usage per NodePool
karpenter_cloudprovider_duration_seconds	Cloud Provider	Cloud provider API call latency by method
karpenter_cloudprovider_instance_type_cpu_cores	Cloud Provider	Available vCPU cores per instance type
karpenter_cloudprovider_instance_type_memory_bytes	Cloud Provider	Available memory per instance type
karpenter_cloudprovider_instance_type_offering_available	Cloud Provider	Whether an instance type offering is available
karpenter_cloudprovider_instance_type_offering_price_estimate	Cloud Provider	Estimated hourly price per instance type offering

Metric name	Category	Description
karpenter_voluntary_disruption_eligible_nodes	Disruption	Nodes eligible for voluntary disruption by reason
karpenter_voluntary_disruption_consolidation_timeouts_total	Disruption	Number of consolidation evaluation timeouts
karpenter_voluntary_disruption_decision_evaluation_duration_seconds	Disruption	Time to evaluate disruption decisions
karpenter_nodes_created_total	Node Resources	Total nodes created by Karpenter
karpenter_nodes_terminated_total	Node Resources	Total nodes terminated by Karpenter (by reason)
karpenter_interruption_received_messages_total	Interruption	SQS interruption messages received (spot, rebalance, etc.)
karpenter_interruption_deleted_messages_total	Interruption	SQS interruption messages deleted/processed
controller_runtime_reconcile_errors_total	Controller Health	Total reconciliation errors across controllers
workqueue_depth	Controller Health	Current depth of the controller work queue
leader_election_master_status	Controller Health	Whether this instance is the elected leader (1=leader, 0=standby)

Collecting KEDA metrics with OTel Container Insights

KEDA (Kubernetes Event-Driven Autoscaling) is an open-source project that allows you to scale Kubernetes workloads based on external metrics from sources like Amazon SQS, Amazon CloudWatch, or custom Prometheus queries. Container Insights collects KEDA metrics through Prometheus scraping. With Container Insights, you gain built-in visibility into ScaledObject status, scaler health, and scale loop performance. You do not need to set up Prometheus or Grafana manually.

KEDA metrics help you answer operational questions such as:

- Are my ScaledObjects scaling correctly?
- Which scalers are experiencing errors?
- What is the current scale loop latency?

Prerequisites

KEDA metrics collection is enabled by default when the following requirements are met.

- Amazon EKS cluster running Kubernetes 1.28 or later
- KEDA installed and running in the cluster (default namespace: `keda`)
- OTel Container Insights enabled on the cluster (see Quick start: OTel Container Insights on Amazon EKS)
- The `amazon-cloudwatch-observability` add-on in `ACTIVE` status

Configuring KEDA metrics collection

KEDA metrics collection is enabled by default. If you already have OTel Container Insights enabled (`otelContainerInsights.enabled: true`) and KEDA is running in your cluster, metrics start flowing automatically with no additional configuration.

If the KEDA scrape target is not present in the cluster, the pipeline finds no pods and does nothing.

To disable KEDA metrics collection, set `otelContainerInsights.solutions.keda.enabled` to `false`. To disable all solutions at once, set `otelContainerInsights.solutions.enabled` to `false`. The global toggle overrides individual solution settings. If `solutions.enabled` is `false`, no solutions collect metrics, even if their individual `enabled` flag is `true`.

The following Helm values show the default configuration.

```
otelContainerInsights:
  solutions:
    enabled: true
    keda:
      enabled: true
```

To disable KEDA metrics using the Amazon EKS add-on, run the following AWS CLI command. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{"otelContainerInsights":{"solutions":{"keda":
{"enabled":false}}}}' \
  --resolve-conflicts OVERWRITE
```

To disable KEDA metrics using the Helm chart, run the following command.

```
helm upgrade amazon-cloudwatch-observability \
  aws-observability/amazon-cloudwatch-observability \
  -n amazon-cloudwatch \
  --reuse-values \
  --set otelContainerInsights.solutions.keda.enabled=false
```

After you enable KEDA metrics, the CloudWatch agent finds KEDA operator pods by the label `app.kubernetes.io/name=keda-operator`. It scrapes the `/metrics` endpoint on the port named `metrics` every 30 seconds.

KEDA metrics pipeline architecture

The KEDA metrics pipeline uses the following data flow:

1. The Prometheus receiver discovers KEDA operator pods using Kubernetes service discovery.
2. The receiver scrapes the `/metrics` endpoint on each KEDA operator pod.
3. The OpenTelemetry processor chain adds Kubernetes and cloud resource labels to each metric.
4. The exporter sends the enriched metrics to CloudWatch through OTLP.

The KEDA pipeline runs independently from other metric pipelines (API server, Kube State Metrics, cAdvisor). This means a failure in one pipeline does not affect the others. If the KEDA scrape target goes down, other pipelines keep working.

> **Note**
>
> KEDA metrics are cluster-scoped.

Viewing the KEDA dashboard

After you turn on KEDA metrics, you can view the dashboard in the CloudWatch console.

To view the KEDA dashboard

1. Open the CloudWatch console at CloudWatch console.
2. In the navigation pane, choose **Container Insights**, then choose **Performance monitoring**.
3. For **Service**, choose **EKS OTEL**.
4. In the navigation pane, expand **Solutions** and choose **KEDA**.

The dashboard displays 10 metrics organized into 5 categories: Scaled Objects, Scalers, Triggers, Scaling, and Controller Health.

Available metrics

The following table lists the 10 KEDA metrics that Container Insights collects.

Metric name	Category	Description
`keda_scaled_object_paused`	Scaled Objects	1 if ScaledObject is paused, 0 otherwise
`keda_scaled_object_errors_total`	Scaled Objects	Total errors per ScaledObject
`keda_scaler_active`	Scalers	1 if scaler is active, 0 otherwise
`keda_scaler_metrics_value`	Scalers	Current value returned by the scaler

Metric name	Category	Description
keda_scaler_metrics_latency_seconds	Scalers	Latency of scaler metric retrieval
keda_scaler_detail_errors_total	Scalers	Total errors per scaler
keda_trigger_registered_total	Triggers	Total registered triggers by type
keda_internal_scale_loop_latency_seconds	Scaling	Scale loop latency per ScaledObject
keda_resource_registered_total	Scaling	Total KEDA custom resources registered by type
keda_build_info	Controller Health	KEDA build information (version, git commit)

Enhanced Container Insights (Classic)

Enhanced Container Insights (Classic) is a managed Amazon EKS add-on configuration that deploys the CloudWatch agent and Fluent Bit as a DaemonSet on your cluster. It provides Container Insights with Enhanced Observability, collecting infrastructure metrics, application logs, and performance data from your Amazon EKS workloads.

Both Enhanced Container Insights (Classic) and OTel Container Insights use the same `amazon-cloudwatch-observability` Amazon EKS add-on. The difference is the add-on version and configuration. Enhanced Container Insights (Classic) refers to the legacy configuration of that add-on.

Maintenance mode

Enhanced Container Insights (Classic) is in maintenance mode. It continues to receive security patches and critical bug fixes, but no new features are being developed for this approach.

For new deployments, we recommend OTel Container Insights (Recommended), which provides broader signal coverage, simpler deployment, and active ongoing development.

This approach is designed for the following use cases:

- Existing customers who already have the add-on deployed and operational
- Teams that require a managed add-on model with Amazon EKS add-on lifecycle management

What Enhanced Container Insights (Classic) provides

Enhanced Container Insights (Classic) includes the following capabilities:

- **Enhanced Observability** — Detailed Kubernetes metrics at the pod, node, and cluster level
- **Metrics and logs** — Collects infrastructure metrics and container logs through the CloudWatch agent and Fluent Bit
- **Managed lifecycle** — Install, update, and remove through the Amazon EKS add-on API or console
- **Automatic updates** — Security patches delivered through the Amazon EKS add-on update mechanism

Comparison with OTel Container Insights

The following table summarizes the differences between Enhanced Container Insights (Classic) and OTel Container Insights.

Consideration	Enhanced Container Insights (Classic)	OTel Container Insights (Recommended)
Signals	Metrics, Logs	Metrics, Logs
Enhanced Observability	Yes	Yes
Maintenance status	Maintenance mode	Active development
Deployment model	Amazon EKS managed add-on	Amazon EKS add-on (OTel-based)

Installation methods

You can install Enhanced Container Insights (Classic) using any of the following methods:

- **Amazon EKS console** — Enable from the **Observability** tab on your cluster. For more information, see Enable Enhanced Container Insights (Classic) from the console.
- **AWS CLI** — Use the `aws eks create-addon` command with the `amazon-cloudwatch-observability` add-on name and a v5.x version. For more information, see Setup guide (AWS CLI).
- **Helm chart** — Use `helm install` with a Classic-compatible version of the chart.
- **CloudFormation or AWS CDK** — Use `AWS::EKS::Addon` with the version pinned to a v5.x release. For more information, see Deploy Enhanced Container Insights (Classic) with CloudFormation or Helm.

Metrics reference

For the complete list of Enhanced Container Insights (Classic) metric names and dimensions, see Enhanced Container Insights (Classic) metric reference.

Upgrade to OTel Container Insights

For step-by-step instructions to move from Enhanced Container Insights (Classic) to OTel Container Insights with zero monitoring gaps, see Migrate from Enhanced Container Insights (Classic) to OTel Container Insights.

Topics

- Setup guide (AWS CLI)
- Enable Enhanced Container Insights (Classic) from the console
- Deploy Enhanced Container Insights (Classic) with CloudFormation or Helm
- Enhanced Container Insights (Classic) metric reference
- Send logs to CloudWatch Logs

Setup guide (AWS CLI)

This guide walks you through installing Enhanced Container Insights (Classic) on an existing Amazon EKS cluster by using the AWS CLI. The add-on deploys a CloudWatch agent as a DaemonSet that collects infrastructure metrics, container logs, and performance data.

Maintenance mode

Enhanced Container Insights (Classic) is in maintenance mode. For new deployments, you should recommend OTel Container Insights (Recommended).

Prerequisites

Before you begin, verify that you meet the following requirements.

- An existing Amazon EKS cluster running Kubernetes version 1.25 or later
- Platform version `eks.1` or later
- AWS CLI version 2.12.0 or later
- `kubectl` configured to communicate with your target cluster
- IAM permissions: `eks:CreateAddon`, `eks:DescribeAddon`, `iam:CreateServiceLinkedRole`, `iam:CreateRole`, and `iam:AttachRolePolicy`
- The EKS Pod Identity Agent add-on installed on your cluster, or IAM Roles for Service Accounts (IRSA) configured
- Outbound internet access from the cluster to CloudWatch endpoints

Step 1: Create the IAM role

Create an IAM role that allows the CloudWatch agent to send data to CloudWatch.

To create the CloudWatch agent IAM role

1. Run the following command to create the role with a trust policy for EKS Pod Identity.

```
aws iam create-role \
  --role-name EKS-CloudWatch-Agent-Role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [{
      "Effect": "Allow",
      "Principal": { "Service": "pods.eks.amazonaws.com" },
      "Action": ["sts:AssumeRole", "sts:TagSession"]
    }]
  }'
```

2. Attach the `CloudWatchAgentServerPolicy` managed policy to the role.

```
aws iam attach-role-policy \
  --role-name EKS-CloudWatch-Agent-Role \
  --policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Step 2: Create the Pod Identity association

Associate the IAM role with the CloudWatch agent service account in your cluster.

To create the Pod Identity association

- Run the following command. Replace *`cluster-name`* with the name of your Amazon EKS cluster and *`account-id`* with your AWS account ID.

```
aws eks create-pod-identity-association \
  --cluster-name cluster-name \
  --namespace amazon-cloudwatch \
  --service-account cloudwatch-agent \
  --role-arn arn:aws:iam::account-id:role/EKS-CloudWatch-Agent-Role
```

Step 3: Install the Amazon CloudWatch Observability add-on

Install the `amazon-cloudwatch-observability` add-on on your cluster.

To install the add-on

- Run the following command. Replace *`cluster-name`* with the name of your Amazon EKS cluster.

```
aws eks create-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --addon-version v5.x.x-eksbuild.x
```

  Replace *`v5.x.x-eksbuild.x`* with the latest available v5.x version. Installing without `--addon-version` installs the latest version (v6.2.0+), which activates the OTel pipeline instead of Classic.

Step 4: Verify the add-on status

Confirm that the add-on installed successfully.

To verify the add-on status

- Run the following command. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --query "addon.status" \
  --output text
```

  The expected output is `ACTIVE`.

Step 5: Confirm agent pods are running

Verify that the CloudWatch agent pods are running in the `amazon-cloudwatch` namespace.

To confirm agent pods are running

- Run the following command.

```
kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent
```

  All agent pods must show `Running` status.

Verify data in CloudWatch

After you complete the setup, Container Insights data appears in CloudWatch within 3 to 5 minutes.

To verify Container Insights data

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Container Insights**.

3. Verify that metrics such as `node_cpu_utilization` and `pod_memory_utilization` appear for your cluster.

Troubleshooting

Use the following guidance to resolve common issues when you install Enhanced Container Insights (Classic) on Amazon EKS.

Add-on status shows CREATE_FAILED or DEGRADED

Symptom: When you run `aws eks describe-addon`, the status shows `CREATE_FAILED` or `DEGRADED`.

Cause: The add-on installation failed because of insufficient IAM permissions or a missing Pod Identity association.

Solution: Complete the following steps to resolve this issue.

1. Run the following command to check for detailed error information. Replace *`cluster-name`* with the name of your cluster.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --query "addon.health"
```

2. Verify that the IAM role exists and has the `CloudWatchAgentServerPolicy` attached.
3. Verify that the Pod Identity association targets the correct namespace (`amazon-cloudwatch`) and service account (`cloudwatch-agent`).
4. Delete the failed add-on and reinstall it after you resolve the issue.

```
aws eks delete-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability
```

Metrics not appearing in CloudWatch after 5 minutes

Symptom: The agent pods show `Running` status, but no metrics appear in CloudWatch after 5 minutes.

Cause: The agent can't send data to CloudWatch because of network restrictions or incorrect IAM permissions.

Solution: Complete the following steps to resolve this issue.

1. Verify that your VPC security groups and network ACLs allow outbound HTTPS traffic (port 443) to CloudWatch endpoints.
2. Check the agent logs for permission errors or connection timeouts.

```
kubectl logs -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent --
tail=100 | grep -i "error\|timeout\|denied"
```

3. Verify that the IAM role has the `CloudWatchAgentServerPolicy` policy attached and that the trust policy allows `pods.eks.amazonaws.com`.

Agent pods stuck in Pending or CrashLoopBackOff

Symptom: When you run `kubectl get pods -n amazon-cloudwatch`, one or more pods show `Pending` or `CrashLoopBackOff` status.

Cause: The agent pods can't start because of insufficient node resources, image pull failures, or missing permissions.

Solution: Complete the following steps to resolve this issue.

1. Check the pod events for detailed error messages.

```
kubectl describe pod -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent
```

2. Verify that your nodes have sufficient CPU and memory available for the agent pods.
3. Verify that the EKS Pod Identity Agent add-on is installed and running.

```
kubectl get pods -n kube-system -l app.kubernetes.io/name=eks-pod-identity-agent
```

Next steps

Ready to upgrade? For step-by-step instructions to move from Enhanced Container Insights (Classic) to OTel Container Insights, see Migrate from Enhanced Container Insights (Classic) to OTel Container Insights.

Enable Enhanced Container Insights (Classic) from the console

You can enable Enhanced Container Insights (Classic) directly from the Amazon EKS console. This approach installs the Amazon CloudWatch Observability add-on (version prior to v6.2.0) with the Classic metric pipeline. This is ideal if you prefer a UI-driven experience and want to enable observability without writing infrastructure code or running CLI commands.

> **Recommendation**
>
> For new deployments, we recommend OTel Container Insights (Recommended), which uses add-on version 6.2.0 or later with the OTel-based pipeline.

Prerequisites

Before you enable Enhanced Container Insights (Classic) from the console, verify that you meet the following requirements.

- You are signed in to the Amazon EKS console.
- An existing Amazon EKS cluster running Kubernetes version 1.25 or later.
- The `amazon-cloudwatch-observability` add-on version must be prior to v6.2.0 (for example, v5.4.0).
- IAM permissions: `eks:DescribeCluster`, `eks:UpdateClusterConfig`, `eks:ListAddons`, `eks:CreateAddon`, `eks:DescribeAddon`, `iam:AttachRolePolicy`, and `iam:CreateServiceLinkedRole`.
- The node IAM role must have the `CloudWatchAgentServerPolicy` managed policy attached.
- The cluster is in `ACTIVE` state.

Enable Enhanced Container Insights (Classic)

Use the following procedure to enable Enhanced Container Insights (Classic) from the Amazon EKS console.

To enable Enhanced Container Insights (Classic) by using the console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/.
2. Choose **Clusters**, and then choose your cluster name.

3. Choose the **Observability** tab.
4. Next to **Container Insights** status, choose **Manage**.
5. Select **Enhanced Container Insights**, and then choose **Enable**.

The console installs the add-on with the Classic configuration. Metrics appear in the `ContainerInsights` namespace within 3 to 5 minutes.

Verify that data appears in CloudWatch

After you enable Enhanced Container Insights (Classic), data appears in CloudWatch within 3 to 5 minutes.

To verify Container Insights data

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**.
3. Choose the **ContainerInsights** namespace.
4. Verify that metrics such as `pod_cpu_utilization` and `node_memory_utilization` appear for your cluster.

Next steps

After you enable Enhanced Container Insights (Classic), you can explore the following topics.

- For AWS CLI and advanced setup options, see Setup guide (AWS CLI).
- For information about the metrics that Enhanced Container Insights (Classic) collects, see Enhanced Container Insights (Classic) metric reference.
- To migrate to OTel Container Insights, see Migrate from Enhanced Container Insights (Classic) to OTel Container Insights.
- For more information about OTel Container Insights, see OTel Container Insights (Recommended).

Deploy Enhanced Container Insights (Classic) with CloudFormation or Helm

You can deploy Enhanced Container Insights (Classic) as infrastructure as code by using CloudFormation templates or Helm charts. This approach installs the `amazon-cloudwatch-`

`observability` add-on with a version prior to v6.2.0 to enable the Classic metric pipeline. Choose this approach if you manage clusters through IaC pipelines and want repeatable, version-controlled deployments.

> **Recommendation**
>
> For new deployments, we recommend OTel Container Insights (Recommended), which uses add-on version 6.2.0 or later with the OTel-based pipeline.

Prerequisites

Before you deploy Enhanced Container Insights (Classic) with CloudFormation or Helm, verify that you meet the following requirements.

- An existing Amazon EKS cluster running Kubernetes version 1.25 or later
- AWS CLI version 2.12.0 or later
- `kubectl` configured to communicate with your target cluster
- IAM permissions for CloudFormation stack creation (for the CloudFormation method)
- Helm v3.8 or later (for the Helm method)
- Outbound internet access from the cluster to CloudWatch endpoints

Deploy with CloudFormation

Use a CloudFormation template to deploy the CloudWatch Observability add-on with the Classic configuration. This template uses the `AWS::EKS::Addon` resource to install the add-on with a version prior to v6.2.0.

CloudFormation template

The following template creates the resources that you need to enable Enhanced Container Insights (Classic) on your Amazon EKS cluster.

```
AWSTemplateFormatVersion: '2010-09-09'
Description: Deploy Enhanced Container Insights (Classic) on an EKS cluster

Parameters:
  ClusterName:
```

```
    Type: String
    Description: The name of your EKS cluster

Resources:
  CloudWatchAgentRole:
    Type: AWS::IAM::Role
    Properties:
      RoleName: EKS-CloudWatch-Agent-Role
      AssumeRolePolicyDocument:
        Version: '2012-10-17'
        Statement:
          - Effect: Allow
            Principal:
              Service: pods.eks.amazonaws.com
            Action:
              - sts:AssumeRole
              - sts:TagSession
      ManagedPolicyArns:
        - arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy

  PodIdentityAssociation:
    Type: AWS::EKS::PodIdentityAssociation
    Properties:
      ClusterName: !Ref ClusterName
      Namespace: amazon-cloudwatch
      ServiceAccount: cloudwatch-agent
      RoleArn: !GetAtt CloudWatchAgentRole.Arn

  CloudWatchObservabilityAddon:
    Type: AWS::EKS::Addon
    DependsOn: PodIdentityAssociation
    Properties:
      ClusterName: !Ref ClusterName
      AddonName: amazon-cloudwatch-observability
      AddonVersion: v5.4.0-eksbuild.1
      ServiceAccountRoleArn: !GetAtt CloudWatchAgentRole.Arn
      ResolveConflicts: OVERWRITE
```

This template creates the following resources:

- An IAM role with the `CloudWatchAgentServerPolicy` managed policy attached
- An EKS Pod Identity association that maps the role to the CloudWatch agent service account
- The `amazon-cloudwatch-observability` EKS add-on with a Classic version (prior to v6.2.0)

To deploy the CloudFormation stack

Use the AWS CLI to create the CloudFormation stack from the template.

To deploy the stack

1. Save the preceding template to a file named `classic-container-insights.yaml`.
2. Run the following command. Replace *`cluster-name`* with the name of your Amazon EKS cluster.

```
aws cloudformation create-stack \
  --stack-name classic-container-insights \
  --template-body file://classic-container-insights.yaml \
  --parameters ParameterKey=ClusterName,ParameterValue=cluster-name \
  --capabilities CAPABILITY_NAMED_IAM
```

3. Wait for the stack creation to complete.

```
aws cloudformation wait stack-create-complete \
  --stack-name classic-container-insights
```

4. Verify that the stack status is `CREATE_COMPLETE`.

```
aws cloudformation describe-stacks \
  --stack-name classic-container-insights \
  --query "Stacks[0].StackStatus" \
  --output text
```

Deploy with Helm

Use the Helm chart to deploy Enhanced Container Insights (Classic) if you manage Kubernetes workloads with Helm. The chart installs the CloudWatch Observability operator with the Classic metric pipeline.

> **Note**
>
> When you use Helm, you must create the IAM role and Pod Identity association separately. The Helm chart installs only the Kubernetes resources.

Step 1: Create the IAM role

Create an IAM role for the CloudWatch agent before you install the Helm chart.

To create the IAM role and Pod Identity association

1. Run the following command to create the role with a trust policy for EKS Pod Identity.

```
aws iam create-role \
  --role-name EKS-CloudWatch-Agent-Role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [{
      "Effect": "Allow",
      "Principal": { "Service": "pods.eks.amazonaws.com" },
      "Action": ["sts:AssumeRole", "sts:TagSession"]
    }]
  }'
```

2. Attach the `CloudWatchAgentServerPolicy` managed policy to the role.

```
aws iam attach-role-policy \
  --role-name EKS-CloudWatch-Agent-Role \
  --policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

3. Create the Pod Identity association. Replace *`cluster-name`* with the name of your Amazon EKS cluster and *`account-id`* with your AWS account ID.

```
aws eks create-pod-identity-association \
  --cluster-name cluster-name \
  --namespace amazon-cloudwatch \
  --service-account cloudwatch-agent \
  --role-arn arn:aws:iam::account-id:role/EKS-CloudWatch-Agent-Role
```

Step 2: Install the Helm chart

Install the CloudWatch Observability Helm chart with a Classic version (prior to v6.2.0).

To install the Helm chart

1. Run the following command. Replace *`cluster-name`* with the name of your Amazon EKS cluster and *`region`* with your AWS Region.

```
helm install amazon-cloudwatch-observability \
  oci://public.ecr.aws/cloudwatch-agent/amazon-cloudwatch-observability-helm-chart
 \
  --namespace amazon-cloudwatch \
  --create-namespace \
  --set clusterName=cluster-name \
  --set region=region \
  --version 5.4.0
```

2. Verify that the Helm release deployed successfully.

```
helm list -n amazon-cloudwatch
```

The status must show `deployed`.

Verify the deployment

After the CloudFormation stack creation or Helm installation completes, verify that the add-on is running and sending data to CloudWatch.

To verify the deployment

1. Confirm that the CloudWatch agent pods are running.

```
kubectl get pods -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent
```

All pods must show `Running` status.

2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**.
4. Verify that metrics appear in the `ContainerInsights` namespace for your cluster.

Metrics typically appear in CloudWatch within 3 to 5 minutes after the deployment completes.

Next steps

After you deploy Enhanced Container Insights (Classic), you can explore the following topics.

- For console-based setup, see Enable Enhanced Container Insights (Classic) from the console.

- For AWS CLI-based setup, see Setup guide (AWS CLI).
- For information about the metrics that Enhanced Container Insights (Classic) collects, see Enhanced Container Insights (Classic) metric reference.
- To migrate to OTel Container Insights, see Migrate from Enhanced Container Insights (Classic) to OTel Container Insights.
- For more information about OTel Container Insights, see OTel Container Insights (Recommended).

Enhanced Container Insights (Classic) metric reference

Enhanced Container Insights (Classic) publishes metrics to the `ContainerInsights` namespace in CloudWatch. The following tables list all metrics by category, along with their dimensions and descriptions.

> **Note**
>
> For OTel Container Insights metrics, see OTel Container Insights (Recommended), which lists open-source metric names.

Cluster metrics

The following metrics measure the overall health and capacity of your Amazon EKS cluster.

Metric Name	Dimensions	Description
`cluster_failed_node_count`	`ClusterName`	The number of failed worker nodes in the cluster.
`cluster_node_count`	`ClusterName`	The total number of worker nodes in the cluster.

Node metrics

The following metrics measure resource usage and capacity at the node level.

Metric Name	Dimensions	Description
node_cpu_limit	ClusterName , InstanceId , NodeName	The maximum number of CPU units that can be assigned to the node.
node_cpu_reserved_capacity	ClusterName , InstanceId , NodeName	The percentage of CPU units reserved on the node.
node_cpu_usage_total	ClusterName , InstanceId , NodeName	The number of CPU units used on the node.
node_cpu_utilization	ClusterName , InstanceId , NodeName	The percentage of CPU units used on the node.
node_filesystem_utilization	ClusterName , InstanceId , NodeName	The percentage of filesystem capacity used on the node.
node_memory_limit	ClusterName , InstanceId , NodeName	The maximum amount of memory, in bytes, that can be assigned to the node.
node_memory_reserved_capacity	ClusterName , InstanceId , NodeName	The percentage of memory reserved on the node.
node_memory_utilization	ClusterName , InstanceId , NodeName	The percentage of memory used on the node.
node_memory_working_set	ClusterName , InstanceId , NodeName	The amount of memory, in bytes, in the working set of the node.
node_network_total_bytes	ClusterName , InstanceId , NodeName	The total number of bytes per second transmitted and received over the network on the node.
node_number_of_running_containers	ClusterName , InstanceId , NodeName	The number of running containers on the node.

Metric Name	Dimensions	Description
node_number_of_running_pods	ClusterName , InstanceId , NodeName	The number of running pods on the node.

Pod metrics

The following metrics measure resource usage at the pod level.

Metric Name	Dimensions	Description
pod_cpu_utilization	ClusterName , Namespace , PodName	The percentage of CPU units used by the pod.
pod_cpu_utilization_over_pod_limit	ClusterName , Namespace , PodName	The percentage of CPU units used relative to the pod limit.
pod_cpu_usage_total	ClusterName , Namespace , PodName	The number of CPU units used by the pod.
pod_memory_utilization	ClusterName , Namespace , PodName	The percentage of memory used by the pod.
pod_memory_utilization_over_pod_limit	ClusterName , Namespace , PodName	The percentage of memory used relative to the pod limit.
pod_memory_working_set	ClusterName , Namespace , PodName	The amount of memory, in bytes, in the working set of the pod.
pod_network_rx_bytes	ClusterName , Namespace , PodName	The number of bytes received per second over the network by the pod.
pod_network_tx_bytes	ClusterName , Namespace , PodName	The number of bytes transmitted per second over the network by the pod.

Metric Name	Dimensions	Description
pod_number_of_container_restarts	ClusterName , Namespace , PodName	The total number of container restarts in the pod.

Container metrics

The following metrics measure resource usage at the container level.

Metric Name	Dimensions	Description
container_cpu_utilization	ClusterName , Namespace , PodName, ContainerName	The percentage of CPU units used by the container.
container_memory_utilization	ClusterName , Namespace , PodName, ContainerName	The percentage of memory used by the container.

Service and namespace metrics

The following metrics measure pod counts at the service and namespace level.

Metric Name	Dimensions	Description
service_number_of_running_pods	ClusterName , Namespace , Service	The number of running pods for the service.
namespace_number_of_running_pods	ClusterName , Namespace	The number of running pods in the namespace.

NVIDIA GPU metrics

The following metrics are collected when your cluster has NVIDIA GPU-equipped nodes. These metrics help you monitor GPU compute and memory utilization across nodes, pods, and containers.

Metric Name	Dimensions	Description
node_gpu_utilization	ClusterName , InstanceId , NodeName	The percentage of GPU compute capacity used on the node.
node_gpu_memory_utilization	ClusterName , InstanceId , NodeName	The percentage of GPU memory used on the node.
node_gpu_temperature	ClusterName , InstanceId , NodeName	The GPU temperature in degrees Celsius on the node.
pod_gpu_utilization	ClusterName , Namespace , PodName	The percentage of GPU compute capacity used by the pod.
container_gpu_utilization	ClusterName , Namespace , PodName, ContainerName	The percentage of GPU compute capacity used by the container.

AWS Neuron metrics

The following metrics are collected when your cluster has AWS Neuron-equipped instances, such as Inf1 or Inf2. These metrics help you monitor NeuronCore utilization at the node and pod level.

Metric Name	Dimensions	Description
node_neuroncore_utilization	ClusterName , InstanceId , NodeName	The percentage of NeuronCore compute capacity used on the node.
pod_neuroncore_utilization	ClusterName , Namespace , PodName	The percentage of NeuronCore compute capacity used by the pod.

Kubernetes API server metrics

The following metrics are collected from the Kubernetes API server. These metrics help you monitor the health and performance of the control plane.

Metric Name	Dimensions	Description
`apiserver_storage_objects`	`ClusterName`	The number of objects stored in etcd by the API server.
`apiserver_request_total`	`ClusterName`	The total number of requests received by the API server.
`apiserver_request_duration_seconds`	`ClusterName`	The latency of API server requests, in seconds.

Send logs to CloudWatch Logs

To send logs from your containers to Amazon CloudWatch Logs, you can use Fluent Bit. For more information, see Fluent Bit.

> **Note**
>
> As of February 10 2025, AWS has deprecated support for FluentD as a log forwarder to CloudWatch Logs. We recommend that you use Fluent Bit, which is a lightweight and resource-efficient alternative. Existing FluentD deployments will continue to function. Migrate your logging pipeline to Fluent Bit to make sure continued support and optimal performance.
> Container Insights previously also supported using FluentD to send logs from your containers. FluentD has been deprecated and is now not supported for Container Insights. Use Fluent Bit instead.

Topics

- Set up Fluent Bit as a DaemonSet to send logs to CloudWatch Logs
- (Optional) Set up Amazon EKS control plane logging
- (Optional) Enable the Use_Kubelet feature for large clusters

Set up Fluent Bit as a DaemonSet to send logs to CloudWatch Logs

The following sections help you deploy Fluent Bit to send logs from containers to CloudWatch Logs.

Topics

- Setting up Fluent Bit
- Multi-line log support
- (Optional) Reducing the log volume from Fluent Bit
- Troubleshooting
- Dashboard

Setting up Fluent Bit

To set up Fluent Bit to collect logs from your containers, you can follow the steps in Setup guide (AWS CLI) or you can follow the steps in this section.

With either method, the IAM role that is attached to the cluster nodes must have sufficient permissions. For more information about the permissions required to run an Amazon EKS cluster, see Amazon EKS IAM Policies, Roles, and Permissions in the *Amazon EKS User Guide*.

In the following steps, you set up Fluent Bit as a daemonSet to send logs to CloudWatch Logs. When you complete this step, Fluent Bit creates the following log groups if they don't already exist.

> **Important**
>
> If you already have FluentD configured in Container Insights and the FluentD DaemonSet is not running as expected (this can happen if you use the `containerd` runtime), you must uninstall it before installing Fluent Bit to prevent Fluent Bit from processing the FluentD error log messages. Otherwise, you must uninstall FluentD immediately after you have successfully installed Fluent Bit. Uninstalling Fluentd after installing Fluent Bit ensures continuity in logging during this migration process. Only one of Fluent Bit or FluentD is needed to send logs to CloudWatch Logs.

Log group name	Log source
/aws/containerinsights/ *Cluster_Name* /application	All log files in /var/log/containers
/aws/containerinsights/ *Cluster_Name* /host	Logs from /var/log/dmesg , /var/log/secure , and /var/log/messages
/aws/containerinsights/ *Cluster_Name* /dataplane	The logs in /var/log/journal for kubelet.service , kubeproxy.service , and docker.service .

To install Fluent Bit to send logs from containers to CloudWatch Logs

1. If you don't already have a namespace called amazon-cloudwatch, create one by entering the following command:

```
kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-
container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/
daemonset/container-insights-monitoring/cloudwatch-namespace.yaml
```

2. Run the following command to create a ConfigMap named cluster-info with the cluster name and the Region to send logs to. Replace *cluster-name* and *cluster-region* with your cluster's name and Region.

```
ClusterName=cluster-name
RegionName=cluster-region
FluentBitHttpPort='2020'
FluentBitReadFromHead='Off'
[[ ${FluentBitReadFromHead} = 'On' ]] && FluentBitReadFromTail='Off'||
 FluentBitReadFromTail='On'
[[ -z ${FluentBitHttpPort} ]] && FluentBitHttpServer='Off' ||
 FluentBitHttpServer='On'
kubectl create configmap fluent-bit-cluster-info \
--from-literal=cluster.name=${ClusterName} \
--from-literal=http.server=${FluentBitHttpServer} \
--from-literal=http.port=${FluentBitHttpPort} \
--from-literal=read.head=${FluentBitReadFromHead} \
--from-literal=read.tail=${FluentBitReadFromTail} \
```

```
--from-literal=logs.region=${RegionName} -n amazon-cloudwatch
```

In this command, the `FluentBitHttpServer` for monitoring plugin metrics is on by default. To turn it off, change the third line in the command to `FluentBitHttpPort=''` (empty string) in the command.

Also by default, Fluent Bit reads log files from the tail, and will capture only new logs after it is deployed. If you want the opposite, set `FluentBitReadFromHead='On'` and it will collect all logs in the file system.

3. Download and deploy the Fluent Bit daemonset to the cluster by running one of the following commands.

   - If you want the Fluent Bit optimized configuration for Linux computers, run this command.

     ```
     kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-
     cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/
     deployment-mode/daemonset/container-insights-monitoring/fluent-bit/fluent-
     bit.yaml
     ```

   - If you want the Fluent Bit optimized configuration for Windows computers, run this command.

     ```
     kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-
     cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/
     deployment-mode/daemonset/container-insights-monitoring/fluent-bit/fluent-bit-
     windows.yaml
     ```

   - If you are using Linux computers and want the Fluent Bit configuration that is more similar to Fluentd, run this command.

     ```
     kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-
     cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/
     deployment-mode/daemonset/container-insights-monitoring/fluent-bit/fluent-bit-
     compatible.yaml
     ```

> **Important**
>
> The Fluent Bit daemonset configuration by default sets the log level to INFO, which can result in higher CloudWatch Logs ingestion costs. If you want to reduce log ingestion volume and costs, you can change the log level to ERROR.
> For more information about how to reduce the log volume, see (Optional) Reducing the log volume from Fluent Bit

4. Validate the deployment by entering the following command. Each node should have one pod named **fluent-bit-***.

```
kubectl get pods -n amazon-cloudwatch
```

The above steps create the following resources in the cluster:

- A service account named `Fluent-Bit` in the `amazon-cloudwatch` namespace. This service account is used to run the Fluent Bit daemonSet. For more information, see Managing Service Accounts in the Kubernetes Reference.
- A cluster role named `Fluent-Bit-role` in the `amazon-cloudwatch` namespace. This cluster role grants `get`, `list`, and `watch` permissions on pod logs to the `Fluent-Bit` service account. For more information, see API Overview in the Kubernetes Reference.
- A ConfigMap named `Fluent-Bit-config` in the `amazon-cloudwatch` namespace. This ConfigMap contains the configuration to be used by Fluent Bit. For more information, see Configure a Pod to Use a ConfigMap in the Kubernetes Tasks documentation.

If you want to verify your Fluent Bit setup, follow these steps.

Verify the Fluent Bit setup

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Log groups**.
3. Make sure that you're in the Region where you deployed Fluent Bit.
4. Check the list of log groups in the Region. You should see the following:
   - `/aws/containerinsights/`*`Cluster_Name`*`/application`

- `/aws/containerinsights/Cluster_Name/host`
- `/aws/containerinsights/Cluster_Name/dataplane`

5. Navigate to one of these log groups and check the **Last Event Time** for the log streams. If it is recent relative to when you deployed Fluent Bit, the setup is verified.

   There might be a slight delay in creating the `/dataplane` log group. This is normal as these log groups only get created when Fluent Bit starts sending logs for that log group.

Multi-line log support

For information on how to use Fluent Bit with multi-line logs, see the following sections of the Fluent Bit documentation:

- Multiline Parsing
- Multiline and Containers (v1.8)
- Multiline Core (v1.8)
- Always use multiline in the tail input

(Optional) Reducing the log volume from Fluent Bit

By default, we send Fluent Bit application logs and Kubernetes metadata to CloudWatch. If you want to reduce the volume of data being sent to CloudWatch, you can stop one or both of these data sources from being sent to CloudWatch. If you have followed the steps on this page to set up Fluent Bit, download the Kubernetes manifest YAML file from the kubectl `apply` command that you previously ran and modify it with your changes, which you can then re-apply to your cluster. Alternatively, if you are using the Amazon CloudWatch Observability EKS add-on or Helm chart, see (Optional) Additional configuration for information about managing the Fluent Bit configuration by using the add-on's advanced config or the Helm chart.

To stop Fluent Bit application logs, remove the following section from the `Fluent Bit configuration` file.

```
[INPUT]
  Name                tail
  Tag                 application.*
  Path                /var/log/containers/fluent-bit*
  Parser              docker
```

```
  DB                  /fluent-bit/state/flb_log.db
  Mem_Buf_Limit       5MB
  Skip_Long_Lines     On
  Refresh_Interval    10
```

To remove Kubernetes metadata from being appended to log events that are sent to CloudWatch, add the following filters to the `application-log.conf` section in the Fluent Bit configuration. Replace *<Metadata_1>* and the similar fields with with the actual metadata identifiers.

```
application-log.conf: |
    [FILTER]
  Name                nest
  Match               application.*
  Operation           lift
  Nested_under        kubernetes
  Add_prefix          Kube.

    [FILTER]
  Name                modify
  Match               application.*
  Remove              Kube.<Metadata_1>
  Remove              Kube.<Metadata_2>
  Remove              Kube.<Metadata_3>

    [FILTER]
  Name                nest
  Match               application.*
  Operation           nest
  Wildcard            Kube.*
  Nested_under        kubernetes
  Remove_prefix       Kube.
```

Troubleshooting

If you don't see these log groups and are looking in the correct Region, check the logs for the Fluent Bit daemonSet pods to look for the error.

Run the following command and make sure that the status is `Running`.

```
kubectl get pods -n amazon-cloudwatch
```

If the logs have errors related to IAM permissions, check the IAM role that is attached to the cluster nodes. For more information about the permissions required to run an Amazon EKS cluster, see Amazon EKS IAM Policies, Roles, and Permissions in the *Amazon EKS User Guide*.

If the pod status is `CreateContainerConfigError`, get the exact error by running the following command.

```
kubectl describe pod pod_name -n amazon-cloudwatch
```

Dashboard

You can create a dashboard to monitor metrics of each running plugin. You can see data for input and output bytes and for record processing rates as well as output errors and retry/failed rates. To view these metrics, you will need to install the CloudWatch agent with Prometheus metrics collection for Amazon EKS and Kubernetes clusters. For more information about how to set up the dashboard, see Install the CloudWatch agent with Prometheus metrics collection on Amazon EKS and Kubernetes clusters.

> **Note**
>
> Before you can set up this dashboard, you must set up Container Insights for Prometheus metrics. For more information, see Container Insights Prometheus metrics monitoring.

To create a dashboard for the Fluent Bit Prometheus metrics

1. Create environment variables, replacing the values on the right in the following lines to match your deployment.

   ```
   DASHBOARD_NAME=your_cw_dashboard_name
   REGION_NAME=your_metric_region_such_as_us-west-1
   CLUSTER_NAME=your_kubernetes_cluster_name
   ```

2. Create the dashboard by running the following command.

   ```
   curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
   insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
   prometheus/sample_cloudwatch_dashboards/fluent-bit/cw_dashboard_fluent_bit.json \
   | sed "s/{{YOUR_AWS_REGION}}/${REGION_NAME}/g" \
   | sed "s/{{YOUR_CLUSTER_NAME}}/${CLUSTER_NAME}/g" \
   ```

```
| xargs -0 aws cloudwatch put-dashboard --dashboard-name ${DASHBOARD_NAME} --
dashboard-body
```

(Optional) Set up Amazon EKS control plane logging

If you're using Amazon EKS, you can optionally enable Amazon EKS control plane logging, to provide audit and diagnostic logs directly from the Amazon EKS control plane to CloudWatch Logs. For more information, see Amazon EKS Control Plane Logging.

(Optional) Enable the Use_Kubelet feature for large clusters

By default, the Use_Kubelet feature is disabled in the FluentBit Kubernetes plugin. Enabling this feature can reduce traffic to the API server and mitigate the issue of the API Server being a bottleneck. We recommend that you enable this feature for large clusters.

To enable Use_Kubelet, first add the nodes and nodes/proxy permissions to the clusterRole config.

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: fluent-bit-role
rules:
  - nonResourceURLs:
- /metrics
    verbs:
- get
  - apiGroups: [""]
    resources:
- namespaces
- pods
- pods/logs
- nodes
- nodes/proxy
    verbs: ["get", "list", "watch"]
```

In the DaemonSet configuration, this feature needs host network access. The image version for `amazon/aws-for-fluent-bit` should 2.12.0 or later, or the fluent bit image version should be 1.7.2 or later.

```
apiVersion: apps/v1
kind: DaemonSet
```

```
metadata:
  name: fluent-bit

```

The Kubernetes Plugin configuration should be similar to the following:

```
[FILTER]
  Name                kubernetes
  Match               application.*
  Kube_URL            https://kubernetes.default.svc:443
  Kube_Tag_Prefix     application.var.log.containers.
  Merge_Log           On
  Merge_Log_Key       log_processed
  K8S-Logging.Parser  On
  K8S-Logging.Exclude Off
```

```
  Labels              Off
  Annotations         Off
  Use_Kubelet         On
  Kubelet_Port        10250
  Buffer_Size         0
```

Compare Container Insights approaches

Two Container Insights approaches are available for Amazon EKS clusters, each with different capabilities, deployment models, and support levels. Both use the same `amazon-cloudwatch-observability` Amazon EKS add-on — the difference is the add-on version and configuration.

Use this page to understand the differences between the two approaches and determine which one is right for your environment. For detailed setup instructions, see OTel Container Insights (Recommended) or Enhanced Container Insights (Classic).

Feature comparison

The following table compares the two Container Insights approaches across key attributes.

Attribute	OTel Container Insights	Enhanced Container Insights (Classic)
Supported signals	Metrics, logs	Metrics, logs
Enhanced Observability	Yes	Yes
Maintenance status	Active development	Maintenance mode
Deployment complexity	Low	Low
Setup method	Amazon EKS add-on (OTel-based)	Amazon EKS add-on (managed)
Minimum Amazon EKS version	1.28	1.25
Minimum add-on version	v6.2.0	Prior to v6.2.0
Configuration model	Add-on configuration	Add-on configuration

Attribute	OTel Container Insights	Enhanced Container Insights (Classic)
Metric format	Prometheus/PromQL-native	CloudWatch-format (EMF)

Capabilities and limitations

Each approach has specific strengths and constraints. Review the following sections to understand what each approach provides and where it has limitations.

OTel Container Insights (Recommended)

OTel Container Insights provides the following capabilities:

- Full-signal observability through a single OpenTelemetry-based agent
- Active development with new features delivered regularly
- Simplified deployment as a managed Amazon EKS add-on
- PromQL-queryable metrics with up to 150 labels per metric

OTel Container Insights has the following limitations:

- Requires Amazon EKS 1.28 or later
- Requires add-on version v6.2.0 or later
- Newer offering with a smaller ecosystem of community examples

For setup instructions, see Quick start: OTel Container Insights on Amazon EKS.

Enhanced Container Insights (Classic)

Enhanced Container Insights (Classic) provides the following capabilities:

- Managed Amazon EKS add-on with automated lifecycle management
- Supports Enhanced Observability

Enhanced Container Insights (Classic) has the following limitations:

- In maintenance mode — receives security patches only

- Limited configuration flexibility
- Metrics use proprietary CloudWatch-format names, not compatible with standard PromQL dashboards

For setup instructions, see Setup guide (AWS CLI).

Decision guide

Use the following table to determine which approach is right for your situation.

Selection criteria	Recommended approach	Rationale
New Amazon EKS deployment	OTel Container Insights	Actively developed, full signal coverage, lowest complexity
Need full Enhanced Observability	OTel Container Insights	Only actively developed option
Already running Classic in production	Classic (short-term), OTel (migration target)	Continue for stability, then plan migration
Prefer managed add-on with minimal overhead	OTel Container Insights	Low configuration burden
Need PromQL-compatible metrics	OTel Container Insights	Preserves original Prometheus metric names

If you are currently running Enhanced Container Insights (Classic) and want to migrate, see Migration guides for step-by-step instructions.

Prerequisites summary

The following table lists the prerequisites for each approach.

Prerequisite	OTel Container Insights	Enhanced Container Insights (Classic)
Minimum Amazon EKS version	1.28	1.25
Minimum add-on version	v6.2.0	Prior to v6.2.0
IAM permissions	CloudWatchAgentServerPolicy	CloudWatchAgentServerPolicy
Required tools	kubectl, AWS CLI	kubectl, AWS CLI
OIDC provider required	Yes (for IRSA)	Yes (for IRSA)

Next steps

After you choose an approach, use the following links to get started:

- Quick start: OTel Container Insights on Amazon EKS — Set up OTel Container Insights with the fastest path.
- Setup guide (AWS CLI) — Set up Enhanced Container Insights (Classic).
- Migration guides — Migrate from Classic to OTel Container Insights.

Migration guides

This section provides step-by-step migration guides for moving from your current Container Insights setup to OTel Container Insights — the recommended, actively developed approach.

Why migrate?

OTel Container Insights is the recommended approach for Amazon EKS observability. Migrating provides the following benefits:

- **Active development** — OTel Container Insights receives new features, performance improvements, and expanded signal coverage on an ongoing basis.
- **Enhanced Observability** — Access detailed Kubernetes metrics at the pod, node, and cluster level with comprehensive log collection.

- **OpenTelemetry standard** — Built on the industry-standard observability framework, compatible with existing PromQL dashboards and community documentation.

What's covered

Each migration guide covers the following areas:

- **Parallel run** — Run both metrics streams simultaneously to validate data equivalence before switching over.
- **Breaking changes** — Removed features and changed defaults that might affect your workflows.
- **Migration steps** — A phased procedure for cutover with minimal monitoring gaps.
- **Verification** — Confirm that equivalent data flows through the new pipeline.
- **Rollback** — Restore your previous approach if needed.

Available migration guides

Choose the guide that matches your current Container Insights setup.

- Migrate from Enhanced Container Insights (Classic) to OTel Container Insights — Migrate from Enhanced Container Insights (Classic) to OTel Container Insights through an in-place add-on version update.

Migrate from Enhanced Container Insights (Classic) to OTel Container Insights

Both Enhanced Container Insights (Classic) and OTel Container Insights use the same `amazon-cloudwatch-observability` Amazon EKS add-on. The migration is an in-place add-on version update that you can complete in 15–30 minutes.

> **Warning**
>
> CloudWatch alarms configured with Classic metric names do not automatically work with OTel metrics. You must recreate alarms using PromQL-based alarm rules.

Prerequisites

Before you begin the migration, verify that you meet the following requirements.

- An Amazon EKS cluster running Kubernetes version 1.28 or later
- The `amazon-cloudwatch-observability` add-on installed and in `ACTIVE` status
- AWS CLI version 2.15.0 or later
- `kubectl` configured to communicate with your target cluster
- An IAM role with the `CloudWatchAgentServerPolicy` managed policy attached

Breaking changes

Review the following breaking changes before you begin the migration.

Removed features

The following features are not available in OTel Container Insights:

- **StatsD custom metrics** — Use the OTel StatsD receiver instead.
- **collectd plugin** — Migrate to OTel-native instrumentation.

Changed defaults

The following table shows default values that change between Classic and OTel Container Insights.

Setting	Classic default	OTel CI default
Collection interval	60 seconds	60 seconds
Enhanced Observability	Enabled	Enabled
Agent CPU request	200m	100m
Agent memory request	200Mi	128Mi

Migration steps

This migration uses a phased approach to minimize monitoring gaps. You run both Classic and OTel metrics streams in parallel, validate the data, and then disable the Classic stream.

Phase 1: Confirm current state (Classic only)

Before you make changes, confirm your current add-on state and record the version for rollback.

To confirm your current add-on configuration

1. Run the following command to check the current add-on status.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability
```

2. Verify that the `status` field is `ACTIVE`.
3. Record the `addonVersion` value. You need this value if you must roll back.

Phase 2: Enable dual publishing (Classic + OTel)

Enable OTel Container Insights alongside Enhanced Container Insights (Classic). This publishes both metric streams simultaneously so that you can validate data equivalence.

> **Important**
>
> Both metric streams incur charges during this phase. We recommend keeping the dual publishing window as short as possible to minimize costs.

To enable dual publishing

1. Run the following command to update the add-on with both streams enabled.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --addon-version latest-version \
  --configuration-values '{"containerInsights":
{"enabled":true},"otelContainerInsights":{"enabled":true}}' \
  --resolve-conflicts OVERWRITE
```

2. Wait for the add-on status to return to `ACTIVE`.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --query "addon.status"
```

3. Verify that OTel metrics appear in CloudWatch by querying a known metric with PromQL.

Phase 3: Recreate alarms and update dashboards

Build OTel replacements for your existing Classic alarms and dashboards. Keep Classic alarms active as a safety net during this phase.

To recreate alarms for OTel metrics

1. Identify all CloudWatch alarms that reference Classic Container Insights metric names.
2. Create equivalent alarms using PromQL-based metric math expressions that reference OTel metric names.
3. Verify that the new alarms enter OK state and produce equivalent threshold evaluations.
4. Update any CloudWatch dashboards to include widgets based on OTel metrics alongside the existing Classic widgets.

Phase 4: Disable Classic (switch to OTel only)

After you validate that OTel metrics, alarms, and dashboards work correctly, disable the Classic stream.

To disable Classic and keep OTel only

1. Run the following command to disable Classic metrics publishing.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --configuration-values '{"containerInsights":
{"enabled":false},"otelContainerInsights":{"enabled":true}}' \
  --resolve-conflicts OVERWRITE
```

2. Wait for the add-on status to return to `ACTIVE`.
3. Remove the Classic alarms that you replaced in Phase 3.

Verification

After you complete the migration, verify that your observability stack is working correctly.

- **Check metrics in Query Studio** — Use PromQL queries to confirm that metrics flow from the OTel pipeline.
- **Compare with baseline values** — Verify that metric values are consistent with the Classic metrics you recorded during Phase 2.
- **Verify Container Insights dashboards** — Confirm that the Container Insights console displays data for your cluster.
- **Verify log delivery** — Check that container logs continue to appear in CloudWatch Logs.
- **Verify alarms** — Confirm that no alarms are in `INSUFFICIENT_DATA` state.

Rollback

If you encounter issues after migration, you can restore the previous Classic configuration.

To roll back to Enhanced Container Insights (Classic)

1. Identify the previous add-on version that you recorded in Phase 1.
2. Run the following command to downgrade the add-on.

```
aws eks update-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --addon-version previous-version \
  --resolve-conflicts OVERWRITE
```

3. Wait for the add-on status to return to `ACTIVE`.

```
aws eks describe-addon \
  --cluster-name cluster-name \
  --addon-name amazon-cloudwatch-observability \
  --query "addon.status"
```

4. Re-apply any custom configuration values that you used with the previous version.

Troubleshooting Container Insights on Amazon EKS

This section covers common issues that you might encounter when you set up or operate Container Insights on Amazon EKS. Use the following tables and diagnostic commands to identify and resolve problems regardless of whether you use the OTel or Classic approach.

For approach-specific setup guidance, see Quick start: OTel Container Insights on Amazon EKS or Setup guide (AWS CLI). To compare approaches, see Compare Container Insights approaches.

Metrics not appearing in CloudWatch

If you don't see metrics in the `ContainerInsights` namespace, use the following table to identify the cause.

Symptom	Cause	Resolution
No metrics in the `ContainerInsights` namespace	IAM role lacks `cloudwatch:PutMetricData` permission	Attach the `CloudWatchAgentServerPolicy` managed policy to the agent IAM role.
Metrics appear for some nodes but not others	Agent DaemonSet not scheduled on all nodes because of taints	Add tolerations to the agent DaemonSet to allow scheduling on tainted nodes.
Metrics stop appearing	Agent pod is OOMKilled or restarting	Increase the memory limits in the agent pod resource specification.
Metrics are stale or zero	Network connectivity is blocked	Check VPC security groups and verify that a CloudWatch VPC endpoint exists.
Enhanced metrics are missing	Agent not configured for Enhanced Observability	Set `enhancedObservability: true` in the agent configuration.

Agent pods not starting

If agent pods fail to start or remain in a non-running state, use the following table to diagnose the issue.

Symptom	Cause	Resolution
`ImagePullBackOff`	Amazon ECR is unreachable or the image tag is incorrect	Verify the image URI and confirm that your nodes can access Amazon ECR.

Symptom	Cause	Resolution
`Pending`	Insufficient CPU or memory on the node	Scale the node group or reduce resource requests in the agent pod specification.
`CrashLoopBackOff`	Invalid configuration or missing volume mount	Check pod logs for configuration errors by running `kubectl logs` on the affected pod.
`FailedScheduling`	Node affinity or taints prevent scheduling	Review the `nodeSelector` and tolerations in the DaemonSet spec.
Exit code 1	Service account lacks IRSA annotation	Verify that the service account has the `eks.amazonaws.com/role-arn` annotation.

Add-on installation failures

If the `amazon-cloudwatch-observability` add-on fails to install or reports an unhealthy status, use the following table to troubleshoot.

Symptom	Cause	Resolution
`CREATE_FAILED`	Conflicting resources from a previous installation	Delete conflicting resources and use `--resolve-conflicts OVERWRITE` when you create the add-on.
OIDC provider not found	No IAM OIDC identity provider exists for the cluster	Create the provider by running `eksctl utils associate-iam-oidc-provider .`
Version conflict	Add-on version is incompatible with the Kubernetes version	List compatible versions by running `aws eks describe-addon-versions .`

Symptom	Cause	Resolution
DEGRADED status	Health checks are failing because of missing permissions	Check pod logs and verify that the IRSA role has the required policies attached.

Log delivery issues

If container logs don't appear in Amazon CloudWatch Logs, use the following table to identify the cause.

Symptom	Cause	Resolution
Log group doesn't exist	Missing `logs:CreateLogGroup` permission	Add Amazon CloudWatch Logs permissions to the agent IAM role.
Log group exists but is empty	Agent not configured for logs, or Region mismatch	Verify that the agent configuration includes log collection and that the Region matches your cluster Region.
Logs are delayed more than 5 minutes	Flush interval is too high or the node is under heavy load	Reduce the `force_flush_interval` value in the agent configuration.
Performance logs are missing	Agent is configured for application logs only	Verify that the Container Insights performance log section is present in the agent configuration.

Migration-specific issues

If you experience issues while migrating between Container Insights approaches, use the following table. For the full migration workflow, see Migration guides.

Symptom	Cause	Resolution
Duplicate metrics during parallel run	Both approaches are publishing metrics simultaneously	This behavior is expected during a parallel run. Disable the legacy

Symptom	Cause	Resolution
		approach after you validate the new approach.
Different metric values between approaches	Different calculation methods	Small differences (less than 5%) are expected. Large differences indicate a configuration mismatch between approaches.
Rollback fails	Custom configuration was not reapplied	Re-apply your complete configuration values when you roll back.
Alarms fire during migration	Metric gaps during the switchover period	Temporarily set the missing data treatment to `notBreaching` on affected alarms.

OTel Container Insights issues

The following issues are specific to the OTel Container Insights approach. For general setup guidance, see Quick start: OTel Container Insights on Amazon EKS.

Symptom	Cause	Resolution
403 Forbidden exporter error	IAM role is missing CloudWatch permissions	Verify that the `CloudWatchAgentServerPolicy` is attached to the agent role.
Connection refused on metrics endpoint	Collector cannot reach the kubelet	Verify that `hostNetwork: true` is set in the pod spec, or confirm that the service account has the required permissions.
High memory usage	Batch processor queue is too large	Reduce the `batch/timeout` and `batch/send_batch_size` values in the collector configuration.

Symptom	Cause	Resolution
Custom metrics not appearing	Receiver not configured for the application endpoint	Add a Prometheus receiver that targets your application metrics port in the collector configuration.

General diagnostic commands

Use the following commands to gather information about your Container Insights deployment.

To check agent pod status, run the following command.

```
kubectl get pods -n amazon-cloudwatch
```

To view agent pod logs, run the following command.

```
kubectl logs -n amazon-cloudwatch -l app.kubernetes.io/name=cloudwatch-agent --tail=50
```

To check the agent DaemonSet status, run the following command.

```
kubectl get daemonset -n amazon-cloudwatch
```

To verify the IAM role on a service account, run the following command.

```
kubectl get serviceaccount -n amazon-cloudwatch -o yaml
```

To check the cluster add-on status, run the following command. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws eks describe-addon --cluster-name cluster-name --addon-name amazon-cloudwatch-
observability
```

To list Container Insights log groups, run the following command. Replace *cluster-name* with the name of your Amazon EKS cluster.

```
aws logs describe-log-groups --log-group-name-prefix "/aws/containerinsights/cluster-
name"
```

Related resources

For more information about setting up and operating Container Insights on Amazon EKS, see the following topics.

- Quick start: OTel Container Insights on Amazon EKS – Set up OTel Container Insights
- Setup guide (AWS CLI) – Set up Classic Container Insights

- Compare Container Insights approaches – Compare Container Insights approaches

Amazon ECS

You can use one or both of the following options to enable Container Insights on Amazon ECS clusters:

- Use the AWS Management Console or the AWS CLI to start collecting cluster-level, task-level, and service-level metrics.
- Deploy the CloudWatch agent as a daemon service to start collecting of instance-level metrics on clusters that are hosted on Amazon EC2 instances.

Topics

- Setting up Container Insights on Amazon ECS
- Setting up Container Insights on Amazon ECS using AWS Distro for OpenTelemetry
- Deploying the CloudWatch agent to collect EC2 instance-level metrics on Amazon ECS
- Deploying the AWS Distro for OpenTelemetry to collect EC2 instance-level metrics on Amazon ECS clusters
- Set up FireLens to send logs to CloudWatch Logs

Setting up Container Insights on Amazon ECS

You can set up Container Insights with enhanced observability or Container Insights on new and existing Amazon ECS clusters using either the Amazon ECS console or the AWS CLI. Container Insights collects metrics at the cluster, task, and service levels. Container Insights with enhanced observability provides additional dimensions and metrics, allowing you to deep dive down to container level visibility.

If you're using Amazon ECS on an Amazon EC2 instance, launch that instance using an AMI that includes Amazon ECS agent version 1.29 or later. For information about updating your agent version, see Updating the Amazon ECS Container Agent.

> **Note**
>
> If the customer managed AWS KMS key that you use for your Amazon ECS Container Insights metrics is not already configured to work with CloudWatch, you must update the key policy to allow for encrypted logs in CloudWatch Logs. You must also associate your own AWS KMS key with the log group in `/aws/ecs/containerinsights/ClusterName/performance`. For more information, see Encrypt log data in CloudWatch Logs using AWS Key Management Service.

We recommend that you use Container Insights with enhanced observability instead of Container Insights as it provides detailed visibility in your container environment, reducing the mean time to resolution.

Set up Container Insights with enhanced observability

You can turn on Container Insights with enhanced observability using the Amazon ECS console or AWS CLI.

AWS CLI

Use the following command to turn on Container Insights with enhanced observability.

Set the `containerInsights` account setting to `enhanced`

```
aws ecs put-account-setting --name containerInsights --value enhanced
```

Example output

```
{
  "setting": {
      "name": "containerInsights",
      "value": "enhanced",
      "principalArn": "arn:aws:iam::123456789012:johndoe",
       "type": user
  }
```

```
}
```

> **Note**
>
> By default, the `put-account-setting` applies only to the currently authenticated user. To enable the setting account-wide for all users and roles, use the root user as in the following example.
>
> ```
> aws ecs put-account-setting --name containerInsights --value enhanced --
> principal-arn arn:aws:iam::accountID:root
> ```

After you set this account setting, all new clusters automatically use Container Insights with enhanced observability. Use the `update-cluster-settings` command to add Container Insights with enhanced observability to existing cluster, or to upgrade clusters that currently use Container Insights to Container Insights with enhanced observability.

```
aws ecs update-cluster-settings --cluster cluster-name --settings
 name=containerInsights,value=enhanced
```

Amazon ECS console

1. Open the console at https://console.aws.amazon.com/ecs/v2.
2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose **Account Settings**.
4. Choose **Update**.
5. To use Container Insights with enhanced observability, choose **Container Insights with enhanced observability**.
6. Choose **Save changes**.
7. On the confirmation screen, choose **Confirm** to save the selection.

After you set this, all new clusters automatically use Container Insights with enhanced observability. You can add Container Insights with enhanced observability to existing clusters, or update clusters that currently use Container Insights to Container Insights with enhanced observability. For more information, see Updating an Amazon ECS cluster in the *Amazon Elastic Container Service Developer Guide*.

Set up Container Insights

You can turn on Container Insights using the Amazon ECS console or AWS CLI.

AWS CLI

To use Container Insights, set the `container Insights` account setting to `enabled`. Use the following command to turn on Container Insights.

```
aws ecs put-account-setting --name containerInsights --value enabled
```

Example output

```
{
  "setting": {
      "name": "container Insights",
      "value": "enabled",
      "principalArn": "arn:aws:iam::123456789012:johndoe",
       "type": user
  }
}
```

When you set the `container Insights` account setting to `enabled`, all new clusters have Container Insights enabled by default. Use the `update-cluster-settings` command to add Container Insights to an existing cluster.

```
aws ecs update-cluster-settings --cluster cluster-name --settings
 name=containerInsights,value=enabled
```

Amazon ECS console

1. Open the console at https://console.aws.amazon.com/ecs/v2.
2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose **Account Settings**.
4. Choose **Update**.
5. To use Container Insights, choose **Container Insights**.
6. Choose **Save changes**.
7. On the confirmation screen, choose **Confirm** to save the selection.

After you set this, all new clusters automatically use Container Insights. Update existing clusters to add Container Insights. For more information, see Updating an Amazon ECS cluster in the *Amazon Elastic Container Service Developer Guide*.

Setting up Container Insights on Amazon ECS using AWS Distro for OpenTelemetry

Use this section if you want to use AWS Distro for OpenTelemetry to set up CloudWatch Container Insights on an Amazon ECS cluster. For more information about AWS Distro for Open Telemetry, see AWS Distro for OpenTelemetry.

These steps assume that you already have a cluster running Amazon ECS. For more information about using AWS Distro for Open Telemetry with Amazon ECS and setting up an Amazon ECS cluster for this purpose, see Setting up AWS Distro for OpenTelemetry Collector in Amazon Elastic Container Service.

Step 1: Create a task role

The first step is creating a task role in the cluster that the AWS OpenTelemetry Collector will use.

To create a task role for AWS Distro for OpenTelemetry

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies** and then choose **Create policy**.
3. Choose the **JSON** tab and copy in the following policy:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "logs:PutLogEvents",
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:DescribeLogStreams",
                "logs:DescribeLogGroups",
```

```
                "ssm:GetParameters"
            ],
            "Resource": "*"
        }
    ]
}
```

4. Choose **Review policy**.
5. For name, enter **`AWSDistroOpenTelemetryPolicy`**, and then choose **Create policy**.
6. In the left navigation pane, choose **Roles** and then choose **Create role**.
7. In the list of services, choose **Elastic Container Service**.
8. Lower on the page, choose **Elastic Container Service Task** and then choose **Next: Permissions**.
9. In the list of policies, search for **AWSDistroOpenTelemetryPolicy**.
10. Select the check box next to **AWSDistroOpenTelemetryPolicy**.
11. Choose **Next: Tags** and then choose **Next: Review.**
12. For **Role name** enter **`AWSOpenTelemetryTaskRole`** and then choose **Create role**.

Step 2: Create a task execution role

The next step is creating a task execution role for the AWS OpenTelemetry Collector.

To create a task execution role for AWS Distro for OpenTelemetry

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Roles** and then choose **Create role**.
3. In the list of services, choose **Elastic Container Service**.
4. Lower on the page, choose **Elastic Container Service Task** and then choose **Next: Permissions**.
5. In the list of policies, search for **AmazonECSTaskExecutionRolePolicy** and then select the check box next to **AmazonECSTaskExecutionRolePolicy**.
6. In the list of policies, search for **CloudWatchLogsFullAccess** and then select the check box next to **CloudWatchLogsFullAccess**.
7. In the list of policies, search for **AmazonSSMReadOnlyAccess** and then select the check box next to **AmazonSSMReadOnlyAccess**.
8. Choose **Next: Tags** and then choose **Next: Review.**

9. For **Role name** enter **`AWSOpenTelemetryTaskExecutionRole`** and then choose **Create role**.

Step 3: Create a task definition

The next step is creating a task definition.

To create a task definition for AWS Distro for OpenTelemetry

1. Open the console at https://console.aws.amazon.com/ecs/v2.
2. In the navigation pane, choose **Task definitions**
3. Choose **Create new task definition**, **Create new task definition**.
4. For **Task definition family**, specify a unique name for the task definition.
5. Configure your containers, and then choose **Next**.
6. Under **Metrics and logging**, select **Use metric collection**.
7. Choose **Next**.
8. Choose **Create**.

For more information about using the AWS OpenTelemetry collector with Amazon ECS, see Setting up AWS Distro for OpenTelemetry Collector in Amazon Elastic Container Service.

Step 4: Run the task

The final step is running the task that you've created.

To run the task for AWS Distro for OpenTelemetry

1. Open the console at https://console.aws.amazon.com/ecs/v2.
2. In the left navigation pane, choose **Task Definitions** and then select the task that you just created.
3. Choose **Actions**, **Deploy**, **Run task**.
4. Choose **Deploy**, **Run task**.
5. In the **Compute options** section, from **Existing cluster**, choose the cluster.
6. Choose **Create**.
7. Next, you can check for the new metrics in the CloudWatch console.
8. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

9. In the left navigation pane, choose **Metrics**.

   You should see a **ECS/ContainerInsights** namespace. Choose that namespace and you should see eight metrics.

Deploying the CloudWatch agent to collect EC2 instance-level metrics on Amazon ECS

To deploy the CloudWatch agent to collect instance-level metrics from Amazon ECS clusters that are hosted on EC2 instance, use a quick start setup with a default configuration, or install the agent manually to be able to customize it.

Both methods require that you already have at least one Amazon ECS cluster deployed with an EC2 launch type and that the CloudWatch agent continer has access to the Amazon EC2 Instance Metadata Service (IMDS). For more information about IMDS, see Instance metadata and user data.

These methods also assume that you have the AWS CLI installed. Additionally, to run the commands in the following procedures, you must be logged on to an account or role that has the **IAMFullAccess** and **AmazonECS_FullAccess** policies.

> **Important**
>
> When defining the CloudWatch Agent container in your task definition, set `essential: false`. This prevents the entire Amazon ECS service from stopping if the CloudWatch Agent container fails. Other critical application containers will continue running even if the agent is temporarily unavailable.

Topics

- Quick setup using CloudFormation
- Manual and custom setup

Quick setup using CloudFormation

To use the quick setup, enter the following command to use CloudFormation to install the agent. Replace *`cluster-name`* and *`cluster-region`* with the name and Region of your Amazon ECS cluster.

This command creates the IAM roles **CWAgentECSTaskRole** and **CWAgentECSExecutionRole**. If these roles already exist in your account, use `ParameterKey=CreateIAMRoles,ParameterValue=False` instead of `ParameterKey=CreateIAMRoles,ParameterValue=True` when you enter the command. Otherwise, the command will fail.

```
ClusterName=cluster-name
Region=cluster-region
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/daemon-service/cwagent-
ecs-instance-metric/cloudformation-quickstart/cwagent-ecs-instance-metric-cfn.json
aws cloudformation create-stack --stack-name CWAgentECS-${ClusterName}-${Region} \
  --template-body file://cwagent-ecs-instance-metric-cfn.json \
  --parameters ParameterKey=ClusterName,ParameterValue=${ClusterName} \
               ParameterKey=CreateIAMRoles,ParameterValue=True \
  --capabilities CAPABILITY_NAMED_IAM \
  --region ${Region}
```

(Alternative) Using your own IAM roles

If you want to use your own custom ECS task role and ECS task execution role instead of the **CWAgentECSTaskRole** and **CWAgentECSExecutionRole** roles, first make sure that the role to be used as the ECS task role has **CloudWatchAgentServerPolicy** attached. Also, make sure that the role to be used as the ECS task execution role has both the **CloudWatchAgentServerPolicy** and **AmazonECSTaskExecutionRolePolicy** policies attached. Then enter the following command. In the command, replace *task-role-arn* with the ARN of your custom ECS task role, and replace *execution-role-arn* with the ARN of your custom ECS task execution role.

```
ClusterName=cluster-name
Region=cluster-region
TaskRoleArn=task-role-arn
ExecutionRoleArn=execution-role-arn
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/daemon-service/cwagent-
ecs-instance-metric/cloudformation-quickstart/cwagent-ecs-instance-metric-cfn.json
aws cloudformation create-stack --stack-name CWAgentECS-${ClusterName}-${Region} \
  --template-body file://cwagent-ecs-instance-metric-cfn.json \
  --parameters ParameterKey=ClusterName,ParameterValue=${ClusterName} \
               ParameterKey=TaskRoleArn,ParameterValue=${TaskRoleArn} \
               ParameterKey=ExecutionRoleArn,ParameterValue=${ExecutionRoleArn} \
  --capabilities CAPABILITY_NAMED_IAM \
```

```
  --region ${Region}
```

Troubleshooting the quick setup

To check the status of the CloudFormation stack, enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation describe-stacks --stack-name CWAgentECS-$ClusterName-$Region --
region $Region
```

If you see the `StackStatus` is other than `CREATE_COMPLETE` or `CREATE_IN_PROGRESS`, check the stack events to find the error. Enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation describe-stack-events --stack-name CWAgentECS-$ClusterName-$Region
 --region $Region
```

To check the status of the `cwagent` daemon service, enter the following command. In the output, you should see that the `runningCount` is equal to the `desiredCount` in the `deployment` section. If it isn't equal, check the `failures` section in the output.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs describe-services --services cwagent-daemon-service --cluster $ClusterName --
region $Region
```

You can also use the CloudWatch Logs console to check the agent log. Look for the **/ecs/ecs-cwagent-daemon-service** log group.

Deleting the CloudFormation stack for the CloudWatch agent

If you need to delete the CloudFormation stack, enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation delete-stack --stack-name CWAgentECS-${ClusterName}-${Region} --
region ${Region}
```

Manual and custom setup

Follow the steps in this section to manually deploy the CloudWatch agent to collect instance-level metrics from your Amazon ECS clusters that are hosted on EC2 instances.

Necessary IAM roles and policies

Two IAM roles are required. You must create them if they don't already exist. For more information about these roles, see IAM roles for Tasks and Amazon ECS Task Execution Role.

- An *ECS task role*, which is used by the CloudWatch agent to publish metrics. If this role already exists, you must make sure it has the `CloudWatchAgentServerPolicy` policy attached.
- An *ECS task execution role*, which is used by Amazon ECS agent to launch the CloudWatch agent. If this role already exists, you must make sure it has the `AmazonECSTaskExecutionRolePolicy` and `CloudWatchAgentServerPolicy` policies attached.

If you do not already have these roles, you can use the following commands to create them and attach the necessary policies. This first command creates the ECS task role.

```
aws iam create-role --role-name CWAgentECSTaskRole \
  --assume-role-policy-document "{\"Version\": \"2012-10-17\",       \"Statement
\": [{\"Sid\": \"\",\"Effect\": \"Allow\",\"Principal\": {\"Service\": \"ecs-
tasks.amazonaws.com\"},\"Action\": \"sts:AssumeRole\"}]}"
```

After you enter the previous command, note the value of `Arn` from the command output as "TaskRoleArn". You'll need to use it later when you create the task definition. Then enter the following command to attach the necessary policies.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
CloudWatchAgentServerPolicy \
  --role-name CWAgentECSTaskRole
```

This next command creates the ECS task execution role.

```
aws iam create-role --role-name CWAgentECSExecutionRole \
  --assume-role-policy-document "{\"Version\": \"2012-10-17\",       \"Statement
\": [{\"Sid\": \"\",\"Effect\": \"Allow\",\"Principal\": {\"Service\": \"ecs-
tasks.amazonaws.com\"},\"Action\": \"sts:AssumeRole\"}]}"
```

After you enter the previous command, note the value of `Arn` from the command output as "ExecutionRoleArn". You'll need to use it later when you create the task definition. Then enter the following commands to attach the necessary policies.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
CloudWatchAgentServerPolicy \
  --role-name CWAgentECSExecutionRole

aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/service-role/
AmazonECSTaskExecutionRolePolicy \
  --role-name CWAgentECSExecutionRole
```

Create the task definition and launch the daemon service

Create a task definition and use it to launch the CloudWatch agent as a daemon service. To create the task definition, enter the following command. In the first lines, replace the placeholders with the actual values for your deployment. *`logs-region`* is the Region where CloudWatch Logs is located, and *`cluster-region`* is the Region where your cluster is located. *`task-role-arn`* is the Arn of the ECS task role that you are using, and *`execution-role-arn`* is the Arn of the ECS task execution role.

```
TaskRoleArn=task-role-arn
ExecutionRoleArn=execution-role-arn
AWSLogsRegion=logs-region
Region=cluster-region
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/daemon-service/cwagent-
ecs-instance-metric/cwagent-ecs-instance-metric.json \
  | sed "s|{{task-role-arn}}|${TaskRoleArn}|;s|{{execution-role-arn}}|
${ExecutionRoleArn}|;s|{{awslogs-region}}|${AWSLogsRegion}|" \
  | xargs -0 aws ecs register-task-definition --region ${Region} --cli-input-json
```

Then run the following command to launch the daemon service. Replace *`cluster-name`* and *`cluster-region`* with the name and Region of your Amazon ECS cluster.

> **Important**
>
> Remove all capacity provider strategies before you run this command. Otherwise, the command won't work.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs create-service \
  --cluster ${ClusterName} \
  --service-name cwagent-daemon-service \
  --task-definition ecs-cwagent-daemon-service \
  --scheduling-strategy DAEMON \
  --region ${Region}
```

If you see this error message, `An error occurred (InvalidParameterException) when calling the CreateService operation: Creation of service was not idempotent`, you have already created a daemon service named `cwagent-daemon-service`. You must delete that service first, using the following command as an example.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs delete-service \
  --cluster ${ClusterName} \
  --service cwagent-daemon-service \
  --region ${Region} \
  --force
```

(Optional) Advanced configuration

Optionally, you can use SSM to specify other configuration options for the CloudWatch agent in your Amazon ECS clusters that are hosted on EC2 instances. These options are as follows:

- `metrics_collection_interval` – How often in seconds that the CloudWatch agent collects metrics. The default is 60. The range is 1–172,000.
- `endpoint_override` – (Optional) Specifies a different endpoint to send logs to. You might want to do this if you're publishing from a cluster in a VPC and you want the logs data to go to a VPC endpoint.

  The value of `endpoint_override` must be a string that is a URL.
- `force_flush_interval` – Specifies in seconds the maximum amount of time that logs remain in the memory buffer before being sent to the server. No matter the setting for this field, if the size of the logs in the buffer reaches 1 MB, the logs are immediately sent to the server. The default value is 5 seconds.

- `region` – By default, the agent publishes metrics to the same Region where the Amazon ECS container instance is located. To override this, you can specify a different Region here. For example, `"region" : "us-east-1"`

The following is an example of a customized configuration:

```
{
  "agent": {
      "region": "us-east-1"
  },
  "logs": {
      "metrics_collected": {
          "ecs": {
              "metrics_collection_interval": 30
          }
      },
      "force_flush_interval": 5
  }
}
```

To customize your CloudWatch agent configuration in your Amazon ECS containers

1. Make sure that the **AmazonSSMReadOnlyAccess** policy is attached to your Amazon ECS Task Execution role. You can enter the following command to do so. This example assumes that your Amazon ECS Task Execution role is CWAgentECSExecutionRole. If you are using a different role, substitute that role name in the following command.

   ```
   aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
   AmazonSSMReadOnlyAccess \
         --role-name CWAgentECSExecutionRole
   ```

2. Create the customized configuration file similar to the preceding example. Name this file `/tmp/ecs-cwagent-daemon-config.json`.
3. Run the following command to put this configuration into the Parameter Store. Replace *`cluster-region`* with the Region of your Amazon ECS cluster. To run this command, you must be logged on to a user or role that has the **AmazonSSMFullAccess** policy.

   ```
   Region=cluster-region
   aws ssm put-parameter \
     --name "ecs-cwagent-daemon-service" \
   ```

```
  --type "String" \
  --value "`cat /tmp/ecs-cwagent-daemon-config.json`" \
  --region $Region
```

4. Download the task definition file to a local file, such as `/tmp/cwagent-ecs-instance-metric.json`

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/daemon-service/cwagent-ecs-instance-metric/cwagent-ecs-instance-metric.json -o /tmp/cwagent-ecs-instance-metric.json
```

5. Modify the task definition file. Remove the following section:

```
"environment": [
              {
                  "name": "USE_DEFAULT_CONFIG",
                  "value": "True"
              }
          ],
```

Replace that section with the following:

```
"secrets": [
              {
                  "name": "CW_CONFIG_CONTENT",
                  "valueFrom": "ecs-cwagent-daemon-service"
              }
          ],
```

6. Restart the agent as a daemon service by following these steps:

   a. Run the following command.

```
TaskRoleArn=task-role-arn
ExecutionRoleArn=execution-role-arn
AWSLogsRegion=logs-region
Region=cluster-region
cat /tmp/cwagent-ecs-instance-metric.json \
  | sed "s|{{task-role-arn}}|${TaskRoleArn}|;s|{{execution-role-arn}}|
${ExecutionRoleArn}|;s|{{awslogs-region}}|${AWSLogsRegion}|" \
```

```
  | xargs -0 aws ecs register-task-definition --region ${Region} --cli-input-
json
```

b. Run the following command to launch the daemon service. Replace *cluster-name* and *cluster-region* with the name and Region of your Amazon ECS cluster.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs create-service \
  --cluster ${ClusterName} \
  --service-name cwagent-daemon-service \
  --task-definition ecs-cwagent-daemon-service \
  --scheduling-strategy DAEMON \
  --region ${Region}
```

If you see this error message, `An error occurred (InvalidParameterException) when calling the CreateService operation: Creation of service was not idempotent`, you have already created a daemon service named `cwagent-daemon-service`. You must delete that service first, using the following command as an example.

```
ClusterName=cluster-name
Region=Region
aws ecs delete-service \
  --cluster ${ClusterName} \
  --service cwagent-daemon-service \
  --region ${Region} \
  --force
```

Deploying the AWS Distro for OpenTelemetry to collect EC2 instance-level metrics on Amazon ECS clusters

Use the steps in this section to use AWS Distro for OpenTelemetry to collect EC2 instance-level metrics on an Amazon ECS cluster. For more information about the AWS Distro for OpenTelemetry, see AWS Distro for OpenTelemetry.

These steps assume that you already have a cluster running Amazon ECS. This cluster must be deployed with the EC2 launch type. For more information about using AWS Distro for Open Telemetry with Amazon ECS and setting up an Amazon ECS cluster for this purpose, see Setting up

AWS Distro for OpenTelemetry Collector in Amazon Elastic Container Service for ECS EC2 instance level metrics.

Topics

- Quick setup using CloudFormation
- Manual and custom setup

Quick setup using CloudFormation

Download the CloudFormation template file for installing the AWS Distro for OpenTelemetry collector for Amazon ECS on EC2. Run the following curl command.

```
curl -O https://raw.githubusercontent.com/aws-observability/aws-otel-collector/main/
deployment-template/ecs/aws-otel-ec2-instance-metrics-daemon-deployment-cfn.yaml
```

After you download the template file, open it and replace *PATH_TO_CloudFormation_TEMPLATE* with the path where you saved the template file. Then export the following parameters and run the CloudFormation command, as shown in the following command.

- **Cluster_Name**– The Amazon ECS cluster name
- **AWS_Region**– The Region where the data will be sent
- **PATH_TO_CloudFormation_TEMPLATE**– The path where you saved the CloudFormation template file.
- **command**– To enable the AWS Distro for OpenTelemetry collector to collect the instance-level metrics for Amazon ECS on Amazon EC2, you must specify `--config=/etc/ecs/otel-instance-metrics-config.yaml` for this parameter.

```
ClusterName=Cluster_Name
Region=AWS_Region
command=--config=/etc/ecs/otel-instance-metrics-config.yaml
aws cloudformation create-stack --stack-name AOCECS-${ClusterName}-${Region} \
--template-body file://PATH_TO_CloudFormation_TEMPLATE \
--parameters ParameterKey=ClusterName,ParameterValue=${ClusterName} \
ParameterKey=CreateIAMRoles,ParameterValue=True \
ParameterKey=command,ParameterValue=${command} \
--capabilities CAPABILITY_NAMED_IAM \
--region ${Region}
```

After running this command, use the Amazon ECS console to see if the task is running.

Troubleshooting the quick setup

To check the status of the CloudFormation stack, enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation describe-stack --stack-name AOCECS-$ClusterName-$Region --region
 $Region
```

If the value of `StackStatus` is anything other than `CREATE_COMPLETE` or `CREATE_IN_PROGRESS`, check the stack events to find the error. Enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation describe-stack-events --stack-name AOCECS-$ClusterName-$Region --
region $Region
```

To check the status of the `AOCECS` daemon service, enter the following command. In the output, you should see that `runningCount` is equal to the `desiredCount` in the deployment section. If it isn't equal, check the failures section in the output.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs describe-services --services AOCECS-daemon-service --cluster $ClusterName --
region $Region
```

You can also use the CloudWatch Logs console to check the agent log. Look for the **/aws/ecs/containerinsights/{ClusterName}/performance** log group.

Manual and custom setup

Follow the steps in this section to manually deploy the AWS Distro for OpenTelemetry to collect instance-level metrics from your Amazon ECS clusters that are hosted on Amazon EC2 instances.

Step 1: Necessary roles and policies

Two IAM roles are required. You must create them if they don't already exist. For more information about these roles, see Create IAM policy and Create IAM role.

Step 2: Create the task definition

Create a task definition and use it to launch the AWS Distro for OpenTelemetry as a daemon service.

To use the task definition template to create the task definition, follow the instructions in Create ECS EC2 Task Definition for EC2 instance with AWS OTel Collector.

To use the Amazon ECS console to create the task definition, follow the instructions in Install AWS OTel Collector by creating Task Definition through AWS console for Amazon ECS EC2 instance metrics.

Step 3: Launch the daemon service

To launch the AWS Distro for OpenTelemetry as a daemon service, follow the instructions in Run your task on the Amazon Elastic Container Service (Amazon ECS) using daemon service.

(Optional) Advanced configuration

Optionally, you can use SSM to specify other configuration options for the AWS Distro for OpenTelemetry in your Amazon ECS clusters that are hosted on Amazon EC2 instances. For more information, about creating a configuration file, see Custom OpenTelemetry Configuration. For more information about the options that you can use in the configuration file, see AWS Container Insights Receiver.

Set up FireLens to send logs to CloudWatch Logs

FireLens for Amazon ECS enables you to use task definition parameters to route logs to Amazon CloudWatch Logs for log storage and analytics. FireLens works with Fluent Bit and Fluentd. We provide an AWS for Fluent Bit image, or you can use your own Fluent Bit or Fluentd image. Creating Amazon ECS task definitions with a FireLens configuration is supported using the AWS SDKs, AWS CLI, and AWS Management Console. For more information about CloudWatch Logs, see What is CloudWatch Logs?.

There are key considerations when using FireLens for Amazon ECS. For more information, see Considerations.

To find the AWS for Fluent Bit images, see Using the AWS for Fluent Bit image.

To create a task definition that uses a FireLens configuration, see Creating a task definition that uses a FireLens configuration.

Example

The following task definition example demonstrates how to specify a log configuration that forwards logs to a CloudWatch Logs log group. For more information, see What Is Amazon CloudWatch Logs? in the *Amazon CloudWatch Logs User Guide*.

In the log configuration options, specify the log group name and the Region it exists in. To have Fluent Bit create the log group on your behalf, specify `"auto_create_group":"true"`. You can also specify the task ID as the log stream prefix, which assists in filtering. For more information, see Fluent Bit Plugin for CloudWatch Logs.

```
{
 "family": "firelens-example-cloudwatch",
 "taskRoleArn": "arn:aws:iam::123456789012:role/ecs_task_iam_role",
 "containerDefinitions": [
  {
   "essential": true,
   "image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:latest",
   "name": "log_router",
   "firelensConfiguration": {
    "type": "fluentbit"
   },
   "logConfiguration": {
    "logDriver": "awslogs",
    "options": {
     "awslogs-group": "firelens-container",
     "awslogs-region": "us-west-2",
     "awslogs-create-group": "true",
     "awslogs-stream-prefix": "firelens"
    }
   },
   "memoryReservation": 50
   },
   {
    "essential": true,
    "image": "nginx",
    "name": "app",
    "logConfiguration": {
     "logDriver":"awsfirelens",
     "options": {
     "Name": "cloudwatch_logs",
     "region": "us-west-2",
     "log_key": "log",
```

```
                                "log_group_name": "/aws/ecs/containerinsights/my-
cluster/application",
     "auto_create_group": "true",
     "log_stream_name": "my-task-id"
    }
   },
   "memoryReservation": 100
  }
 ]
}
```

Setting up Container Insights on Red Hat OpenShift on AWS (ROSA)

CloudWatch Container Insights with enhanced observability supports Red Hat OpenShift on AWS (ROSA). This version supports enhanced observability for ROSA clusters. After you install the CloudWatch agent operator Helm chart, Container Insights auto-collects detailed infrastructure telemetry from the cluster level down to the container level in your environment. It then displays this performance data in curated dashboards removing the heavy lifting in observability setup.

> **Note**
>
> For Red Hat OpenShift on AWS (ROSA), when you install the CloudWatch agent operator using helm charts, the CloudWatch agent is by default also enabled to receive both metrics and traces from your applications that are instrumented for Application Signals. If you would like to optionally pass in custom configuration rules, you can do so by passing in a custom agent configuration by using the Helm chart, as outlined in (Optional) [Additional configuration], as outlined in (Optional) Additional configuration.

To install Container Insights with enhanced observability on a Red Hat OpenShift on AWS (ROSA) cluster

1. If necessary, install Helm. For more information, see Quickstart Guide in the Helm documentation.
2. Install the CloudWatch agent operator by entering the following commands. Replace *my-cluster-name* with the name of your cluster, and replace *my-cluster-region* with the Region that the cluster runs in.

```
helm repo add aws-observability https://aws-observability.github.io/helm-charts
```

```
helm repo update aws-observability
helm install --wait --create-namespace \
  --namespace amazon-cloudwatch amazon-cloudwatch-observability \
  aws-observability/amazon-cloudwatch-observability \
  --set clusterName=my-cluster-name \
  --set region=my-cluster-region \
  --set k8sMode=ROSA
```

3. Set up authorization for the agent operator by following the steps in Option 1, Option 2, or Option 3 in Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart.

Viewing Container Insights metrics

After you have Container Insights set up and it is collecting metrics, you can view those metrics in the CloudWatch console.

For Container Insights metrics to appear on your dashboard, you must complete the Container Insights setup. For more information, see Container Insights.

This procedure explains how to view the metrics that Container Insights automatically generates from the collected log data. The rest of this section explains how to further dive into your data and use CloudWatch Logs Insights to see more metrics at more levels of granularity.

To view Container Insights metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Insights**, **Container Insights**.
3. Use the drop-down boxes near the top to select the type of resource to view, as well as the specific resource.

You can set a CloudWatch alarm on any metric that Container Insights collects. For more information, see Using Amazon CloudWatch alarms

> **Note**
>
> If you have already set up CloudWatch Application Insights to monitor your containerized applications, the Application Insights dashboard appears below the Container Insights dashboard. If you have not already enabled Application Insights, you can do so by choosing

Auto-configure Application Insights below the performance view in the Container Insights dashboard.
For more information about Application Insights and containerized applications, see Enable Application Insights for Amazon ECS and Amazon EKS resource monitoring.

Viewing the top contributors

For some of the views in Container Insights performance monitoring, you can also see the top contributors by memory or CPU, or the most recently active resources. This is available when you select any of the following dashboards in the drop-down box near the top of the page:

- ECS Services
- ECS Tasks
- EKS Namespaces
- EKS Services
- EKS Pods

When you are viewing one of these types of resources, the bottom of the page displays a table sorted initially by CPU usage. You can change it to sort by memory usage or recent activity. To see more about one of the rows in the table, you can select the checkbox next to that row and then choose **Actions** and choose one of the options in the **Actions** menu.

Using CloudWatch Logs Insights to view Container Insights data

Container Insights collects metrics by using performance log events with using embedded metric format. The logs are stored in CloudWatch Logs. CloudWatch generates several metrics automatically from the logs which you can view in the CloudWatch console. You can also do a deeper analysis of the performance data that is collected by using CloudWatch Logs Insights queries.

For more information about CloudWatch Logs Insights, see Analyze Log Data with CloudWatch Logs Insights. For more information about the log fields you can use in queries, see Container Insights performance log events for Amazon EKS and Kubernetes.

To use CloudWatch Logs Insights to query your container metric data

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Logs**, **Logs Insights**.

   Near the top of the screen is the query editor. When you first open CloudWatch Logs Insights, this box contains a default query that returns the 20 most recent log events.

3. In the box above the query editor, select one of the Container Insights log groups to query. For the following example queries to work, the log group name must end with **performance**.

   When you select a log group, CloudWatch Logs Insights automatically detects fields in the data in the log group and displays them in **Discovered fields** in the right pane. It also displays a bar graph of log events in this log group over time. This bar graph shows the distribution of events in the log group that matches your query and time range, not only the events displayed in the table.

4. In the query editor, replace the default query with the following query and choose **Run query**.

   ```
   STATS avg(node_cpu_utilization) as avg_node_cpu_utilization by NodeName
   | SORT avg_node_cpu_utilization DESC
   ```

   This query shows a list of nodes, sorted by average node CPU utilization.

5. To try another example, replace that query with another query and choose **Run query**. More sample queries are listed later on this page.

   ```
   STATS avg(number_of_container_restarts) as avg_number_of_container_restarts by
    PodName
   | SORT avg_number_of_container_restarts DESC
   ```

   This query displays a list of your pods, sorted by average number of container restarts.

6. If you want to try another query, you can use include fields in the list at the right of the screen. For more information about query syntax, see CloudWatch Logs Insights Query Syntax.

To see lists of your resources

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Resources**.
3. The default view is a list of your resources being monitored by Container Insights, and alarms that you have set on these resources. To see a visual map of the resources, choose **Map view**.

4. From the map view, you can pause your pointer over any resource in the map to see basic metrics about that resource. You can choose any resource to see more detailed graphs about the resource.

Use case: Seeing task-level metrics in Amazon ECS containers

The following example illustrates how to use CloudWatch Logs Insights to dive deeper into your Container Insights logs. For more examples, see the blog Introducing Amazon CloudWatch Container Insights for Amazon ECS.

Container Insights does not automatically generate metrics at the Task level of granularity. The following query displays task-level metrics for CPU and memory usage.

```
stats avg(CpuUtilized) as CPU, avg(MemoryUtilized) as Mem by TaskId, ContainerName
| sort Mem, CPU desc
```

Other sample queries for Container Insights

List of your pods, sorted by average number of container restarts

```
STATS avg(number_of_container_restarts) as avg_number_of_container_restarts by PodName
| SORT avg_number_of_container_restarts DESC
```

Pods requested versus pods running

```
fields @timestamp, @message
| sort @timestamp desc
| filter Type="Pod"
| stats min(pod_number_of_containers) as requested,
 min(pod_number_of_running_containers) as running, ceil(avg(pod_number_of_containers-
pod_number_of_running_containers)) as pods_missing by kubernetes.pod_name
| sort pods_missing desc
```

Count of cluster node failures

```
stats avg(cluster_failed_node_count) as CountOfNodeFailures
| filter Type="Cluster"
| sort @timestamp desc
```

Application log errors by container name

```
stats count() as countoferrors by kubernetes.container_name
| filter stream="stderr"
| sort countoferrors desc
```

Metrics collected by Container Insights

Container Insights collects one set of metrics for Amazon ECS and AWS Fargate on Amazon ECS, and a different set for Amazon EKS, AWS Fargate on Amazon EKS, RedHat OpenShift on AWS (ROSA), and Kubernetes.

Metrics are not visible until the container tasks have been running for some time.

Topics

- Amazon ECS Container Insights with enhanced observability metrics
- Amazon ECS Container Insights metrics
- Amazon EKS and Kubernetes Container Insights with enhanced observability metrics
- Amazon EKS and Kubernetes Container Insights metrics
- Container Insights performance log reference

- Building your own CloudWatch agent Docker image
- Deploying other CloudWatch agent features in your containers

Amazon ECS Container Insights with enhanced observability metrics

Container Insights with enhanced observability provides deeper visibility into containerized workloads by offering:

- Higher metrics granularity at both task and container levels
- Improved monitoring and troubleshooting capabilities
- Integration with CloudWatch Logs for:
  - Correlating metrics anomalies with log entries

- Performing faster root cause analysis
- Reducing resolution time for complex container issues

Use cases

Container Insights with enhanced observability extends the capabilities of standard Container Insights. It enables the following use cases:

- **Task-level troubleshooting** – Identify performance bottlenecks at the task level. Analyze task-level metrics and compare them with reserved resources to determine if tasks have sufficient processing capacity
- **Container-level resource optimization** – Track utilization against reservation levels to identify containers that are either resource-constrained or over-provisioned
- **Container health assessment** – Monitor restart counts and state transitions to detect unstable containers requiring intervention
- **Application performance monitoring** – Track how applications communicate with each other, monitor resource usage patterns, and optimize data storage performance
- **Operational monitoring** – Monitor deployments, track task sets for blue or green deployments, and maintain platform health through service metrics

For more information on Amazon ECS metrics, see Amazon ECS service utilization metrics use cases and for information on container insights with enhanced observability Amazon ECS Container Insights with enhanced observability metrics.

Container Insights also shows cluster, service, and daemon-wide statistics by averaging data across all tasks. This provides a higher-level view of your service and daemon health, assisting in both environment monitoring and capacity planning.

> **Note**
>
> Amazon ECS Managed Daemon metrics use the same `ECS/ContainerInsights` namespace and the same `ServiceName` dimension as service metrics. For daemon metrics, the `ServiceName` dimension value uses the format `daemon:`*`daemon-name`*. For example, a daemon named `my-daemon` has a `ServiceName` dimension value of `daemon:my-daemon`. All metrics in the table below that include the `ServiceName` dimension also apply to Managed Daemons.

The following table lists the metrics and dimensions that Container Insights with enhanced observability collects for Amazon ECS. These metrics are in the `ECS/ContainerInsights` namespace. For more information, see Metrics.

If you do not see any Container Insights metrics in your console, be sure that you have completed the setup of Container Insights with enhanced observability. Metrics do not appear before Container Insights with enhanced observability has been set up completely. For more information, see Set up Container Insights with enhanced observability.

The following metrics are available for all launch types.

Metric name	Dimensions	Description
`ContainerInstanceCount`	`ClusterName`	The number of EC2 instances running the Amazon ECS agent that are registered with a cluster. This metric is collected only for container instances that are running Amazon ECS tasks in the cluster. It is not collected for empty container instances that do not have any Amazon ECS tasks. Unit: Count

`ContainerCpuUtilized`	`ClusterName`
	
	`ContainerName` , `TaskId`, `ServiceName` , `ClusterName`
	
	`ContainerName` , `TaskDefinitionFami`
		The CPU units used by containers in the resource that is specified by the dimension set that you're using.
		
		Also applies to Managed Daemons.

Metric name	Dimensions	Description
	ly ,ClusterName , TaskId TaskDefinitionFamily ,ClusterName , ContainerName ServiceName , ClusterName , ContainerName	Unit: None
ContainerCpuReserved	ClusterName ContainerName , TaskId, ServiceName , ClusterName ContainerName , TaskDefinitionFamily ,ClusterName , TaskId TaskDefinitionFamily ,ClusterName , ContainerName ServiceName , ClusterName , ContainerName	The CPU units reserved by containers in the resource that is specified by the dimension set that you're using. This metric is collected based on the CPU reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance CPU reservation is used. Also applies to Managed Daemons. Unit: None

Metric name	Dimensions	Description
ContainerCpuUtilization	ClusterName ContainerName , TaskId, ServiceName , ClusterName ContainerName , TaskDefinitionFamily ,ClusterName , TaskId TaskDefinitionFamily ,ClusterName , ContainerName ServiceName , ClusterName , ContainerName	The total percentage of CPU units being used by containers in the resource that is specified by the dimension set that you're using. Unit: Percent
ContainerMemoryUtilized	ClusterName ContainerName , TaskId, ServiceName , ClusterName ContainerName , TaskDefinitionFamily ,ClusterName , TaskId TaskDefinitionFamily ,ClusterName , ContainerName ServiceName , ClusterName , ContainerName	The memory being used by containers in the resource that is specified by the dimension set that you're using. Also applies to Managed Daemons. Unit: Megabytes

Metric name	Dimensions	Description
ContainerMemoryReserved	ClusterName ContainerName , TaskId, ServiceName , ClusterName ContainerName , TaskDefinitionFamily ,ClusterName , TaskId TaskDefinitionFamily ,ClusterName , ContainerName ServiceName , ClusterName , ContainerName	The memory that is reserved by container s in the resource that is specified by the dimension set that you're using. This metric is collected based on the memory reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance memory reservation is used. Also applies to Managed Daemons. Unit: Megabytes

Metric name	Dimensions	Description
ContainerMemoryUtilization	ClusterName ContainerName , TaskId, ServiceName , ClusterName ContainerName , TaskDefinitionFamily ,ClusterName , TaskId TaskDefinitionFamily ,ClusterName , ContainerName ServiceName , ClusterName , ContainerName	The total percentage of memory being used by containers in the resource that is specified by the dimension set that you're using. Also applies to Managed Daemons. Unit: Percent
ContainerNetworkRxBytes	ClusterName ContainerName , TaskId, ServiceName , ClusterName ContainerName , TaskDefinitionFamily ,ClusterName , TaskId TaskDefinitionFamily ,ClusterName , ContainerName ServiceName , ClusterName , ContainerName	The number of bytes received by the container that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. This metric is available only for containers in tasks using the awsvpc or bridge network modes. Also applies to Managed Daemons. Unit: Bytes/Second

Metric name	Dimensions	Description
ContainerNetworkTxBytes	ClusterName ContainerName , TaskId, ServiceName , ClusterName ContainerName , TaskDefinitionFamily ,ClusterName , TaskId TaskDefinitionFamily ,ClusterName , ContainerName ServiceName , ClusterName , ContainerName	The number of bytes transmitted by the container that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. This metric is available only for containers in tasks using the awsvpc or bridge network modes. Also applies to Managed Daemons. Unit: Bytes/Second

Metric name	Dimensions	Description
ContainerStorageReadBytes	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName	The number of bytes read from storage on the container in the resource that is specified by the dimensions that you're using. This does not include read bytes for your storage devices. This metric is obtained from the Docker runtime. Also applies to Managed Daemons. Unit: Bytes
ContainerStorageWriteBytes	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName	The number of bytes written to storage in the container that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. Also applies to Managed Daemons. Unit: Bytes

Metric name	Dimensions	Description
CpuUtilized	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The CPU units used by tasks in the resource that is specified by the dimension set that you're using. Also applies to Managed Daemons. Unit: None
CpuReserved	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The CPU units reserved by tasks in the resource that is specified by the dimension set that you're using. This metric is collected based on the CPU reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance CPU reservation is used. Also applies to Managed Daemons. Unit: None

Metric name	Dimensions	Description
DeploymentCount	ServiceName , ClusterName	The number of deployments in an Amazon ECS service. Unit: Count
DesiredTaskCount	ServiceName , ClusterName	The desired number of tasks for an Amazon ECS service. Unit: Count
EBSFilesystemSize	ClusterName ,TaskDefinitionFamily , VolumeName TaskDefinitionFamily ,ClusterName ServiceName , ClusterName	The total amount, in gigabytes (GB), of Amazon EBS filesystem storage that is allocated to the resources specified by the dimensions you're using. This metric is only available for tasks that run on Amazon ECS infrastructure running on Fargate using platform version 1.4.0 or Amazon EC2 instances using container agent version 1.79.0 or later. Also applies to Managed Daemons. Unit: Gigabytes (GB)

Metric name	Dimensions	Description
EBSFilesystemUtilized	ClusterName ,TaskDefinitionFamily , VolumeName TaskDefinitionFamily ,ClusterName ServiceName , ClusterName	The total amount, in gigabytes (GB), of Amazon EBS filesystem storage that is being used by the resources specified by the dimensions that you're using. This metric is only available for tasks that run on Amazon ECS infrastructure running on Fargate using platform version 1.4.0 or Amazon EC2 instances using container agent version 1.79.0 or later. For tasks run on Fargate, Fargate reserves space on the disk that is only used by Fargate. There is no cost associated with the space Fargate uses, but you will see this additional storage using tools like df. Also applies to Managed Daemons. Unit: Gigabytes (GB)

Metric name	Dimensions	Description
TaskEBSFilesystemUtilization	TaskDefinitionFamily ,ClusterName ClusterName , ServiceName ClusterName ClusterName , ServiceName ,TaskId TaskDefinitionFamily ,ClusterName , TaskId	The percentage of Amazon EBS filesystem storage that is being used by the task specified by the dimensions that you're using. This metric is only available for tasks that run on Amazon ECS infrastructure running on Fargate using platform version 1.4.0 or Amazon EC2 instances using container agent version 1.79.0 or later. Also applies to Managed Daemons. Unit: Percent

Metric name	Dimensions	Description
EphemeralStorageReserved [1]	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The number of bytes reserved from ephemeral storage in the resource that is specified by the dimensions that you're using. Ephemeral storage is used for the container root filesystem and any bind mount host volumes defined in the container image and task definition. The amount of ephemeral storage can't be changed in a running task. This metric is only available for tasks that run on Fargate Linux platform version 1.4.0 or later. Also applies to Managed Daemons. Unit: Gigabytes (GB)

Metric name	Dimensions	Description
EphemeralStorageUtilized [1]	ClusterName ClusterName , TaskDefinitionFamily ClusterName , ServiceName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The number of bytes used from ephemeral storage in the resource that is specified by the dimensions that you're using. Ephemeral storage is used for the container root filesystem and any bind mount host volumes defined in the container image and task definition. The amount of ephemeral storage can't be changed in a running task. This metric is only available for tasks that run on Fargate Linux platform version 1.4.0 or later. Also applies to Managed Daemons. Unit: Gigabytes (GB)

Metric name	Dimensions	Description
MemoryUtilized	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The memory being used by tasks in the resource that is specified by the dimension set that you're using. Also applies to Managed Daemons. Unit: Megabytes
MemoryReserved	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The memory that is reserved by tasks in the resource that is specified by the dimension set that you're using. This metric is collected based on the memory reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance memory reservation is used. Also applies to Managed Daemons. Unit: Megabytes

Metric name	Dimensions	Description
NetworkRxBytes	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The number of bytes received by the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. This metric is available only for containers in tasks using the awsvpc or bridge network modes. Also applies to Managed Daemons. Unit: Bytes/Second

Metric name	Dimensions	Description
NetworkTxBytes	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The number of bytes transmitted by the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. This metric is available only for containers in tasks using the awsvpc or bridge network modes. Also applies to Managed Daemons. Unit: Bytes/Second
PendingTaskCount	ServiceName , ClusterName	The number of tasks currently in the PENDING state. Unit: Count
RunningTaskCount	ServiceName , ClusterName	The number of tasks currently in the RUNNING state. Unit: Count

Metric name	Dimensions	Description
RestartCount	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId ClusterName , ServiceName , ContainerName ClusterName , ServiceName , TaskId, ContainerName TaskDefinitionFamily , ClusterName , ContainerName TaskDefinitionFamily , ClusterName , TaskId, ContainerName	The number of times a container in an Amazon ECS task has been restarted. This metric is collected only for containers that have a restart policy enabled. Also applies to Managed Daemons. Unit: Count

Metric name	Dimensions	Description
UnHealthyContainerHealthStatus	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName	The number of unhealthy containers based on container health check status. A container is considered unhealthy when its health check returns an unhealthy status. This metric is collected only for containers that have a health check configured in the task definition. The metric value is 1 when the container health status is UNHEALTHY , and 0 when the health status is HEALTHY. Unit: Count
ServiceCount	ClusterName	The number of services in the cluster. Unit: Count

Metric name	Dimensions	Description
StorageReadBytes	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The number of bytes read from storage on the instance in the resource that is specified by the dimensions that you're using. This does not include read bytes for your storage devices. This metric is obtained from the Docker runtime. Also applies to Managed Daemons. Unit: Bytes
StorageWriteBytes	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The number of bytes written to storage in the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. Also applies to Managed Daemons. Unit: Bytes
TaskCount	ClusterName	The number of tasks running in the cluster. Unit: Count

Metric name	Dimensions	Description
TaskCpuUtilization	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The total percentage of CPU units being used by a task. Also applies to Managed Daemons. Unit: Percent
TaskEphemeralStorageUtilization	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The total percentage of ephemeral storage being used by a task. Also applies to Managed Daemons. Unit: Percent

Metric name	Dimensions	Description
TaskMemoryUtilization	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The total percentage of memory being used by a task. Also applies to Managed Daemons. Unit: Percent
TaskSetCount	ServiceName , ClusterName	The number of task sets in the service. Unit: Count

Metric name	Dimensions	Description
ContainerGPUUtilization	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName ClusterName , ServiceName , TaskId, ContainerName , AcceleratedDevice	The percentage utilization of the GPU(s) allocated to the container. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Percent

Metric name	Dimensions	Description
ContainerGPUMemoryUtilization	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName ClusterName , ServiceName , TaskId, ContainerName , AcceleratedDevice	The percentage of frame buffer memory used on the GPU(s) allocated to the container. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Percent

Metric name	Dimensions	Description
ContainerGPUMemoryTotal	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName ClusterName , ServiceName , TaskId, ContainerName , AcceleratedDevice	The total frame buffer size, in bytes, on the GPU(s) allocated to the container. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Bytes

Metric name	Dimensions	Description
ContainerGPUMemoryUsed	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName ClusterName , ServiceName , TaskId, ContainerName , AcceleratedDevice	The frame buffer memory, in bytes, used on the GPU(s) allocated to the container. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Bytes

Metric name	Dimensions	Description
ContainerGPUPowerDraw	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName ClusterName , ServiceName , TaskId, ContainerName , AcceleratedDevice	The power usage, in watts, of the GPU(s) allocated to the container. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Watts

Metric name	Dimensions	Description
ContainerGPUTemperature	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName ClusterName , ServiceName , TaskId, ContainerName , AcceleratedDevice	The temperature, in degrees Celsius, of the GPU(s) allocated to the container. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Celsius

Metric name	Dimensions	Description
ContainerGPURestartAppXidCount	ClusterName ClusterName , ServiceName , ContainerName ClusterName , TaskDefinitionFamily , ContainerName ClusterName , ServiceName , TaskId, ContainerName ClusterName , TaskDefinitionFamily , TaskId, ContainerName ClusterName , ServiceName , TaskId, ContainerName , AcceleratedDevice	The count of NVIDIA Xid errors whose immediate-action resolution bucket is RESTART_APP , observed on the GPU(s) allocated to the container. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Count

Metric name	Dimensions	Description
TaskGPUUtilization	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId ClusterName , ServiceName ,TaskId, AcceleratedDevice	The percentage utilization of the GPU(s) allocated to the task. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Percent

Metric name	Dimensions	Description
TaskGPUMemoryUtilization	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId ClusterName , ServiceName , TaskId, AcceleratedDevice	The percentage of frame buffer memory used on the GPU(s) allocated to the task. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Percent

Metric name	Dimensions	Description
TaskGPUMemoryTotal	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId ClusterName , ServiceName ,TaskId, AcceleratedDevice	The total frame buffer size, in bytes, on the GPU(s) allocated to the task. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Bytes

Metric name	Dimensions	Description
TaskGPUMemoryUsed	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId ClusterName , ServiceName ,TaskId, AcceleratedDevice	The frame buffer memory, in bytes, used on the GPU(s) allocated to the task. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Bytes

Metric name	Dimensions	Description
TaskGPUPowerDraw	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId ClusterName , ServiceName , TaskId, AcceleratedDevice	The power usage, in watts, of the GPU(s) allocated to the task. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Watts

Metric name	Dimensions	Description
TaskGPUTemperature	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId ClusterName , ServiceName , TaskId, AcceleratedDevice	The temperature, in degrees Celsius, of the GPU(s) allocated to the task. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Celsius

Metric name	Dimensions	Description
TaskGPURestartAppXidCount	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId ClusterName , ServiceName , TaskId, AcceleratedDevice	The count of NVIDIA Xid errors whose immediate-action resolution bucket is RESTART_APP , observed on the GPU(s) allocated to the task. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Count
InstanceGPULimit	ClusterName ClusterName , CapacityProviderName ClusterName , CapacityProviderName , ContainerInstanceId , EC2InstanceId	The total number of GPUs available on the instance. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Count

Metric name	Dimensions	Description
InstanceGPUUsageTotal	ClusterName ClusterName , CapacityProviderName ClusterName , CapacityProviderName , ContainerInstanceId , EC2InstanceId	The number of GPUs currently allocated to running tasks on the instance. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. Unit: Count

Note

The EphemeralStorageReserved and EphemeralStorageUtilized metrics are only available for tasks that run on Fargate Linux platform version 1.4.0 or later.
Fargate reserves space on disk. It is only used by Fargate. You aren't billed for it. It isn't shown in these metrics. However, you can see this additional storage in other tools such as df.

The following metrics are available when you complete the steps in Deploying the CloudWatch agent to collect EC2 instance-level metrics on Amazon ECS and use the EC2 launch type.

Metric name	Dimensions	Description
instance_cpu_limit	ClusterName	The maximum number of CPU units that can be assigned to a single EC2 instance in the cluster. Unit: None

Metric name	Dimensions	Description
instance_cpu_reserved_capacity	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The percentage of CPU currently being reserved on a single EC2 instance in the cluster. Unit: Percent
instance_cpu_usage_total	ClusterName	The number of CPU units being used on a Single EC2 instance in the cluster. Unit: None
instance_cpu_utilization	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The total percentage of CPU units being used on a single EC2 instance in the cluster. Unit: Percent
instance_filesystem_utilization	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The total percentage of file system capacity being used on a single EC2 instance in the cluster. Unit: Percent

Metric name	Dimensions	Description
instance_memory_limit	ClusterName	The maximum amount of memory, in bytes, that can be assigned to a single EC2 instance in this cluster. Unit: Bytes
instance_memory_reserved_capacity	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The percentage of Memory currently being reserved on a single EC2 instance in the cluster. Unit: Percent
instance_memory_utilization	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The total percentage of memory being used on a single EC2 instance in the cluster. **Note** If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate. Unit: Percent

Metric name	Dimensions	Description
instance_memory_working_set	ClusterName	The amount of memory, in bytes, being used on a single EC2 instance in the cluster. **Note** If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate. Unit: Bytes
instance_network_total_bytes	ClusterName	The total number of bytes per second transmitted and received over the network on a single EC2 instance in the cluster. Unit: Bytes/second
instance_number_of_running_tasks	ClusterName	The number of running tasks on a single EC2 instance in the cluster. Unit: Count

Amazon ECS Container Insights metrics

Container Insights metrics provides additional network, storage, and ephemeral storage metrics. These metrics provide more information than standard Amazon ECS metrics. Container Insights integrates with CloudWatch Logs. You can correlate metric changes with log entries for easier troubleshooting. Container Insights also shows cluster, service, and daemon-wide statistics by averaging data across all tasks. This provides a higher-level view of your service and daemon health, assisting in both environment monitoring and capacity planning.

Use cases

- **Problem identification and troubleshooting** – Track failed deployments by analyzing task state transition patterns, enabling rapid identification of failure points. Diagnose configuration issues through comprehensive examination of task startup sequences and initialization behaviors
- **Cluster and Service-Level health assessment** – Shows average task performance across the cluster. This approach moderates outliers to deliver a more stable view of cluster and service health. Use these insights for general service monitoring where extreme values could be misleading
- **Service availability issues** – Detect deployment failures by monitoring running task count metrics. Correlate service event logs with performance metrics to understand infrastructure impacts. Track task restart patterns to identify unstable services or infrastructure issues
- **Capacity planning for average load** – It helps determine resource requirements based on typical task behavior patterns, provides consistent metrics that support effective long-term planning, and reduces the impact of short-lived spikes on capacity decisions
- **Provides additional metrics** – Collects additional network, storage, and ephemeral storage metrics not available in vended metrics

For more information on Amazon ECS metrics, see Amazon ECS service utilization metrics use cases and for information on container insights with enhanced observability Amazon ECS Container Insights with enhanced observability metrics.

> **Note**
>
> Amazon ECS Managed Daemon metrics use the same `ECS/ContainerInsights` namespace and the same `ServiceName` dimension as service metrics. For daemon metrics, the `ServiceName` dimension value uses the format `daemon:`*`daemon-name`*. For example, a daemon named `my-daemon` has a `ServiceName` dimension value of `daemon:my-`

daemon. All metrics in the table below that include the `ServiceName` dimension also apply to Managed Daemons.

The following table lists the metrics and dimensions that Container Insights collects for Amazon ECS. These metrics are in the `ECS/ContainerInsights` namespace. For more information, see Metrics.

If you do not see any Container Insights metrics in your console, be sure that you have completed the setup of Container Insights. Metrics do not appear before Container Insights has been set up completely. For more information, see Container Insights.

The following metrics are available when you complete the steps in Setting up Container Insights on Amazon ECS.

Metric name	Dimensions	Description
`ContainerInstanceCount`	`ClusterName`	The number of EC2 instances running the Amazon ECS agent that are registered with a cluster. This metric is collected only for container instances that are running Amazon ECS tasks in the cluster. It is not collected for empty container instances that do not have any Amazon ECS tasks. Unit: Count
`CpuUtilized`	`TaskDefinitionFamily` , `ClusterName`	The CPU units used by tasks in the resource that is specified by the

Metric name	Dimensions	Description

	`ServiceName` , `ClusterName`
	
	`ClusterName`
		dimension set that you're using.
		
		Also applies to Managed Daemons.
		
		Unit: None

`CpuReserved`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
		The CPU units reserved by tasks in the resource that is specified by the dimension set that you're using.
		
		This metric is collected based on the CPU reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance CPU reservation is used.
		
		Also applies to Managed Daemons.
		
		Unit: None

`DeploymentCount`	`ServiceName` , `ClusterName`	The number of deployments in an Amazon ECS service. Unit: Count

Metric name	Dimensions	Description
DesiredTaskCount	ServiceName , ClusterName	The desired number of tasks for an Amazon ECS service. Unit: Count
EBSFilesystemSize	VolumeName , TaskDefinitionFamily ,ClusterName TaskDefinitionFamily ,ClusterName ServiceName , ClusterName	The total amount, in gigabytes (GB), of Amazon EBS filesystem storage that is allocated to the resources specified by the dimensions you're using. This metric is only available for tasks that run on Amazon ECS infrastructure running on Fargate using platform version 1.4.0 or Amazon EC2 instances using container agent version 1.79.0 or later. Also applies to Managed Daemons. Unit: Gigabytes (GB)

Metric name	Dimensions	Description
EBSFilesystemUtilized	VolumeName , TaskDefinitionFamily ,ClusterName TaskDefinitionFamily ,ClusterName ServiceName , ClusterName	The total amount, in gigabytes (GB), of Amazon EBS filesystem storage that is being used by the resources specified by the dimensions that you're using. This metric is only available for tasks that run on Amazon ECS infrastructure running on Fargate using platform version 1.4.0 or Amazon EC2 instances using container agent version 1.79.0 or later. For tasks run on Fargate, Fargate reserves space on the disk that is only used by Fargate. There is no cost associated with the space Fargate uses, but you will see this additional storage using tools like df. Also applies to Managed Daemons. Unit: Gigabytes (GB)

Metric name	Dimensions	Description
EphemeralStorageReserved [1]	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName	The number of bytes reserved from ephemeral storage in the resource that is specified by the dimensions that you're using. Ephemeral storage is used for the container root filesystem and any bind mount host volumes defined in the container image and task definition. The amount of ephemeral storage can't be changed in a running task. This metric is only available for tasks that run on Fargate Linux platform version 1.4.0 or later. Also applies to Managed Daemons. Unit: Gigabytes (GB)

Metric name	Dimensions	Description
EphemeralStorageUtilized [1]	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName	The number of bytes used from ephemeral storage in the resource that is specified by the dimensions that you're using. Ephemeral storage is used for the container root filesystem and any bind mount host volumes defined in the container image and task definition. The amount of ephemeral storage can't be changed in a running task. This metric is only available for tasks that run on Fargate Linux platform version 1.4.0 or later. Also applies to Managed Daemons. Unit: Gigabytes (GB)
InstanceOSFilesystemUtilization	CapacityProviderName , ClusterName , ContainerInstanceId , EC2InstanceId ClusterName	The percentage of total disk space that is used for OS volume.

Metric name	Dimensions	Description
InstanceDataFilesystemUtilization	CapacityProviderName ,ClusterName , ContainerInstanceId ,EC2InstanceId ClusterName	The percentage of total disk space that is used for data volume.

Metric name	Dimensions	Description
MemoryUtilized	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName	The memory being used by tasks in the resource that is specified by the dimension set that you're using. **Note** If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate. Although MemoryUtilized and MemoryReserved are marked as "Megabytes", the actual units are in MiB (Mebibytes). Also applies to Managed Daemons. Unit: Megabytes

Metric name	Dimensions	Description
MemoryReserved	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName	The memory that is reserved by tasks in the resource that is specified by the dimension set that you're using. This metric is collected based on the memory reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance memory reservation is used. Also applies to Managed Daemons. Unit: Megabytes **Note** Although MemoryUtilized and MemoryReserved are marked as "Megabytes", the actual units are in MiB (Mebibytes).

Metric name	Dimensions	Description
NetworkRxBytes	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName	The number of bytes received by the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. This metric is available only for containers in tasks using the awsvpc or bridge network modes. Also applies to Managed Daemons. Unit: Bytes/Second

Metric name	Dimensions	Description
NetworkTxBytes	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName	The number of bytes transmitted by the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. This metric is available only for containers in tasks using the awsvpc or bridge network modes. Also applies to Managed Daemons. Unit: Bytes/Second
PendingTaskCount	ServiceName , ClusterName	The number of tasks currently in the PENDING state. Unit: Count
RunningTaskCount	ServiceName , ClusterName	The number of tasks currently in the RUNNING state. Unit: Count

Metric name	Dimensions	Description
RestartCount	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily	The number of times a container in an Amazon ECS task has been restarted. This metric is collected only for containers that have a restart policy enabled. Also applies to Managed Daemons. Unit: Count
ServiceCount	ClusterName	The number of services in the cluster. Unit: Count
StorageReadBytes	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName	The number of bytes read from storage on the instance in the resource that is specified by the dimensions that you're using. This does not include read bytes for your storage devices. This metric is obtained from the Docker runtime. Also applies to Managed Daemons. Unit: Bytes

Metric name	Dimensions	Description
StorageWriteBytes	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName	The number of bytes written to storage in the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. Also applies to Managed Daemons. Unit: Bytes
TaskCount	ClusterName	The number of tasks running in the cluster. Unit: Count
TaskSetCount	ServiceName , ClusterName	The number of task sets in the service. Unit: Count

Note

The EphemeralStorageReserved and EphemeralStorageUtilized metrics are only available for tasks that run on Fargate Linux platform version 1.4.0 or later.
Fargate reserves space on disk. It is only used by Fargate. You aren't billed for it. It isn't shown in these metrics. However, you can see this additional storage in other tools such as df.

The following metrics are available when you complete the steps in Deploying the CloudWatch agent to collect EC2 instance-level metrics on Amazon ECS

Metric name	Dimensions	Description
instance_cpu_limit	ClusterName	The maximum number of CPU units that can be assigned to a single EC2 Instance in the cluster. Unit: None
instance_cpu_reserved_capacity	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The percentage of CPU currently being reserved on a single EC2 instance in the cluster. Unit: Percent
instance_cpu_usage_total	ClusterName	The number of CPU units being used on a Single EC2 instance in the cluster. Unit: None
instance_cpu_utilization	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The total percentage of CPU units being used on a single EC2 instance in the cluster. Unit: Percent
instance_filesystem_utilization	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The total percentage of file system capacity being used on a single

Metric name	Dimensions	Description
		EC2 instance in the cluster. Unit: Percent
instance_memory_limit	ClusterName	The maximum amount of memory, in bytes, that can be assigned to a single EC2 Instance in this cluster. Unit: Bytes
instance_memory_reserved_capacity	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The percentage of Memory currently being reserved on a single EC2 Instance in the cluster. Unit: Percent

Metric name	Dimensions	Description
instance_memory_utilization	ClusterName InstanceId ,ContainerInstanceId , ClusterName	The total percentage of memory being used on a single EC2 Instance in the cluster. **Note** If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate. Unit: Percent

Metric name	Dimensions	Description
instance_memory_working_set	ClusterName	The amount of memory, in bytes, being used on a single EC2 Instance in the cluster. **Note** If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate. Unit: Bytes
instance_network_total_bytes	ClusterName	The total number of bytes per second transmitted and received over the network on a single EC2 Instance in the cluster. Unit: Bytes/second
instance_number_of_running_tasks	ClusterName	The number of running tasks on a single EC2 Instance in the cluster. Unit: Count

Amazon EKS and Kubernetes Container Insights with enhanced observability metrics

The following tables list the metrics and dimensions that Container Insights with enhanced observability collects for Amazon EKS and Kubernetes. These metrics are in the `ContainerInsights` namespace. For more information, see Metrics.

If you do not see any Container Insights with enhanced observability metrics in your console, be sure that you have completed the setup of Container Insights with enhanced observability. Metrics do not appear before Container Insights with enhanced observability has been set up completely. For more information, see Container Insights.

If you are using version 1.5.0 or later of the Amazon EKS add-on or version 1.300035.0 of the CloudWatch agent, most metrics listed in the following table are collected for both Linux and Windows nodes. See the **Metric Name** column of the table to see which metrics are not collected for Windows.

With the earlier version of Container Insights which delivers aggregated metrics at Cluster and Service level, the metrics are charged as custom metrics. With Container Insights with enhanced observability for Amazon EKS, Container Insights metrics are charged per observation instead of being charged per metric stored or log ingested. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

> **Note**
>
> On Windows, network metrics such as `pod_network_rx_bytes` and `pod_network_tx_bytes` are not collected for host process containers.
> On RedHat OpenShift on AWS (ROSA) clusters , diskio metrics such as `node_diskio_io_serviced_total` and `node_diskio_io_service_bytes_total` are not collected.

Metric name	Dimensions	Description
`cluster_failed_node_count`	`ClusterName`	The number of failed worker nodes in the cluster. A node is considered failed if it is suffering from any *node*

Metric name	Dimensions	Description
		conditions. For more informati on, see Conditions in the Kubernetes documentation.
cluster_node_count	ClusterName	The total number of worker nodes in the cluster.
namespace_number_o f_running_pods	Namespace ClusterName ClusterName	The number of pods running per namespace in the resource that is specified by the dimensions that you're using.
node_cpu_limit	ClusterName ClusterName ,InstanceI d ,NodeName	The maximum number of CPU units that can be assigned to a single node in this cluster.

Metric name	Dimensions	Description
node_cpu_reserved_capacity	NodeName, ClusterName , InstanceId ClusterName	The percentage of CPU units that are reserved for node components, such as kubelet, kube-proxy, and Docker. Formula: node_cpu_request / node_cpu_limit **Note** node_cpu_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_cpu_usage_total	ClusterName ClusterName , InstanceId , NodeName	The number of CPU units being used on the nodes in the cluster.
node_cpu_utilization	NodeName, ClusterName , InstanceId ClusterName	The total percentage of CPU units being used on the nodes in the cluster. Formula: node_cpu_usage_total / node_cpu_limit

Metric name	Dimensions	Description
node_filesystem_utilization	NodeName, ClusterName , InstanceId ClusterName	The total percentage of file system capacity being used on nodes in the cluster. Formula: node_filesystem_usage / node_filesystem_capacity **Note** node_filesystem_usage and node_filesystem_capacity are not reported directly as metrics, but are fields in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_memory_limit	ClusterName ClusterName , InstanceId , NodeName	The maximum amount of memory, in bytes, that can be assigned to a single node in this cluster.

Metric name	Dimensions	Description
node_filesystem_inodes It is not available on Windows.	ClusterName ClusterName ,InstanceId ,NodeName	The total number of inodes (used and unused) on a node.
node_filesystem_inodes_free It is not available on Windows.	ClusterName ClusterName ,InstanceId ,NodeName	The number of unused inodes on a node.
node_gpu_limit	ClusterName ClusterName ,InstanceId ,NodeName	The total number of GPU(s) available on the node.
node_gpu_usage_total	ClusterName ClusterName ,InstanceId ,NodeName	The number of GPU(s) being used by the running pods on the node.
node_gpu_reserved_capacity	ClusterName ClusterName ,InstanceId ,NodeName	

Metric name	Dimensions	Description
node_memory_reserved_capacity	NodeName, ClusterName , InstanceId ClusterName	The percentage of memory currently being reserved on the nodes in the cluster. Formula: node_memory_request / node_memory_limit **Note** node_memory_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_memory_utilization	NodeName, ClusterName , InstanceId ClusterName	The percentage of memory currently being used by the node or nodes. It is the percentage of node memory usage divided by the node memory limitation. Formula: node_memory_working_set / node_memory_limit .

Metric name	Dimensions	Description
node_memory_working_set	ClusterName ClusterName , InstanceId , NodeName	The amount of memory, in bytes, being used in the working set of the nodes in the cluster.
node_network_total_bytes	NodeName, ClusterName , InstanceId ClusterName	The total number of bytes per second transmitted and received over the network per node in a cluster. Formula: node_network_rx_bytes + node_network_tx_bytes **Note** node_network_rx_bytes and node_network_tx_bytes are not reported directly as metrics, but are fields in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_number_of_running_containers	NodeName, ClusterName , InstanceId ClusterName	The number of running containers per node in a cluster.

Metric name	Dimensions	Description
node_number_of_running_pods	NodeName, ClusterName , InstanceId ClusterName	The number of running pods per node in a cluster.
node_status_allocatable_pods	ClusterName ClusterName ,InstanceId ,NodeName	The number of pods that can be assigned to a node based on its allocatable resources, which is defined as the remainder of a node's capacity after accounting for system daemons reservations and hard eviction thresholds.
node_status_capacity_pods	ClusterName ClusterName ,InstanceId ,NodeName	The number of pods that can be assigned to a node based on its capacity.
node_status_condition_ready	ClusterName ClusterName ,InstanceId ,NodeName	Indicates whether the node status condition Ready is true for Amazon EC2 nodes.
node_status_condition_memory_pressure	ClusterName ClusterName ,InstanceId ,NodeName	Indicates whether the node status condition MemoryPressure is true.
node_status_condition_pid_pressure	ClusterName ClusterName ,InstanceId ,NodeName	Indicates whether the node status condition PIDPressure is true.
node_status_condition_disk_pressure	ClusterName ClusterName ,InstanceId ,NodeName	Indicates whether the node status condition OutOfDisk is true.

Metric name	Dimensions	Description
node_status_condition_unknown	ClusterName ClusterName , InstanceId , NodeName	Indicates whether any of the node status conditions are Unknown.
node_interface_network_rx_dropped	ClusterName ClusterName , InstanceId , NodeName	The number of packets which were received and subsequently dropped by a network interface on the node.
node_interface_network_tx_dropped	ClusterName ClusterName , InstanceId , NodeName	The number of packets which were due to be transmitted but were dropped by a network interface on the node.
node_diskio_io_service_bytes_total It is not available on Windows or on ROSA clusters.	ClusterName ClusterName , InstanceId , NodeName	The total number of bytes transferred by all I/O operations on the node.
node_diskio_io_serviced_total It is not available on Windows or on ROSA clusters.	ClusterName ClusterName , InstanceId , NodeName	The total number of I/O operations on the node.

Metric name	Dimensions	Description
pod_cpu_reserved_capacity	PodName, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , Service	The CPU capacity that is reserved per pod in a cluster. Formula: pod_cpu_request / node_cpu_limit **Note** pod_cpu_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
pod_cpu_utilization	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The percentage of CPU units being used by pods. Formula: pod_cpu_usage_total / node_cpu_limit

Metric name	Dimensions	Description
pod_cpu_utilization_over_pod_limit	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The percentage of CPU units being used by pods relative to the pod limit. Formula: pod_cpu_usage_total / pod_cpu_limit
pod_memory_reserved_capacity	PodName, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , Service	The percentage of memory that is reserved for pods. Formula: pod_memory_request / node_memory_limit **Note** pod_memory_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_memory_utilization	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The percentage of memory currently being used by the pod or pods. Formula: pod_memory_working_set / node_memory_limit
pod_memory_utilization_over_pod_limit	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The percentage of memory that is being used by pods relative to the pod limit. If any containers in the pod don't have a memory limit defined, this metric doesn't appear. Formula: pod_memory_working_set / pod_memory_limit

Metric name	Dimensions	Description
pod_network_rx_bytes	PodName, Namespace , ClusterName Namespace ,ClusterName Service, Namespace , ClusterName ClusterName ClusterName ,Namespace , PodName, FullPodName	The number of bytes per second being received over the network by the pod. Formula: sum(pod_interface_network_rx_bytes) **Note** pod_interface_network_rx_bytes is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_network_tx_bytes	PodName, Namespace , ClusterName Namespace, ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The number of bytes per second being transmitted over the network by the pod. Formula: sum(pod_interface_network_tx_bytes) **Note** pod_interface_network_tx_bytes is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_cpu_request	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	The CPU requests for the pod. Formula: sum(container_cpu_request) **Note** pod_cpu_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_memory_request	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	The memory requests for the pod. Formula: sum(container_memory_request) **Note** pod_memory_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_cpu_limit	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	The CPU limit defined for the containers in the pod. If any containers in the pod don't have a CPU limit defined, this metric doesn't appear. Formula: sum(container_cpu_limit) **Note** pod_cpu_limit is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_memory_limit	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	The memory limit defined for the containers in the pod. If any containers in the pod don't have a memory limit defined, this metric doesn't appear. Formula: sum(container_memory_limit) **Note** pod_cpu_limit is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
pod_status_failed	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Indicates that all containers in the pod have terminated, and at least one container has terminated with a non-zero status or was terminated by the system.

Metric name	Dimensions	Description
pod_status_ready	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Indicates that all containers in the pod are ready, having reached the condition of ContainerReady .
pod_status_running	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Indicates that all containers in the pod are running.
pod_status_scheduled	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Indicates that the pod has been scheduled to a node.

Metric name	Dimensions	Description
pod_status_unknown	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	Indicates that status of the pod can't be obtained.
pod_status_pending	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	Indicates that the pod has been accepted by the cluster but one or more of the containers has not become ready yet.
pod_status_succeeded	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	Indicates that all containers in the pod have successfully terminated and will not be restarted.

Metric name	Dimensions	Description
pod_number_of_containers	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	Reports the number of containers defined in the pod specification.
pod_number_of_running_containers	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	Reports the number of containers in the pod which are currently in the Running state.
pod_container_status_terminated	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	Reports the number of containers in the pod which are in the Terminated state.

Metric name	Dimensions	Description
pod_container_status_running	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	Reports the number of containers in the pod which are in the Running state.
pod_container_status_waiting	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	Reports the number of containers in the pod which are in the Waiting state.
pod_container_status_waiting_reason_crash_loop_back_off	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending because of a CrashLoopBackOff error, where a container repeatedly fails to start.

Metric name	Dimensions	Description
pod_container_status_waiting_reason_create_container_config_error	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending with the reason CreateContainerConfigError . This is because of an error while creating the container configuration.
pod_container_status_waiting_reason_create_container_error	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending with the reason CreateContainerError because of an error while creating the container.
pod_container_status_waiting_reason_image_pull_error	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending because of ErrImagePull , ImagePullBackOff , or InvalidImageName . These situations are because of an error while pulling the container image.

Metric name	Dimensions	Description
pod_container_status_waiting_reason_start_error	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending with the reason being StartError because of an error while starting the container.
pod_container_status_terminated_reason_oom_killed	ContainerName , FullPodName , PodName, Namespace , ClusterName ContainerName , PodName, Namespace , ClusterName ClusterName	Indicates a pod was terminated for exceeding the memory limit. This metric is only displayed when this issue occurs.
pod_interface_network_rx_dropped	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	The number of packets which were received and subsequently dropped a network interface for the pod.

Metric name	Dimensions	Description
pod_interface_network_tx_dropped	ClusterName PodName, Namespace , ClusterName Namespace ,ClusterName ,Service ClusterName ,Namespace ,PodName, FullPodName	The number of packets which were due to be transmitted but were dropped for the pod.
pod_memory_working_set	ClusterName ClusterName ,Namespace ,PodName ClusterName ,Namespace ,Service ClusterName ,Namespace ,PodName, FullPodName	The memory in bytes that is currently being used by a pod.
pod_cpu_usage_total	ClusterName ClusterName ,Namespace ,PodName ClusterName ,Namespace ,Service ClusterName ,Namespace ,PodName, FullPodName	The number of CPU units used by a pod.

Metric name	Dimensions	Description
container_cpu_utilization	ClusterName PodName, Namespace , ClusterName , ContainerName PodName, Namespace , ClusterName , ContainerName , FullPodName	The percentage of CPU units being used by the container. Formula: container_cpu_usage_total / node_cpu_limit **Note** container_cpu_utilization is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
container_cpu_utilization_over_container_limit	ClusterName PodName, Namespace , ClusterName , ContainerName PodName, Namespace , ClusterName , ContainerName , FullPodName	The percentage of CPU units being used by the container relative to the container limit. If the container doesn't have a CPU limit defined, this metric doesn't appear. Formula: container_cpu_usage_total / container_cpu_limit **Note** container_cpu_utilization_over_container_limit is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
container_memory_utilization	ClusterName PodName, Namespace , ClusterName , ContainerName PodName, Namespace , ClusterName , ContainerName , FullPodName	The percentage of memory units being used by the container. Formula: container_memory_working_set / node_memory_limit **Note** container_memory_utilization is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
container_memory_utilization_over_container_limit	ClusterName PodName, Namespace , ClusterName , ContainerName PodName, Namespace , ClusterName , ContainerName , FullPodName	The percentage of memory units being used by the container relative to the container limit. If the container doesn't have a memory limit defined, this metric doesn't appear. Formula: container_memory_working_set / container_memory_limit **Note** container_memory_utilization_over_container_limit is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
container_memory_failures_total It is not available on Windows.	ClusterName PodName, Namespace , ClusterName , ContainerName PodName, Namespace , ClusterName , ContainerName , FullPodName	The number of memory allocation failures experienced by the container.
pod_number_of_container_restarts	PodName, Namespace , ClusterName	The total number of container restarts in a pod.
service_number_of_running_pods	Service, Namespace , ClusterName ClusterName	The number of pods running the service or services in the cluster.
replicas_desired	ClusterName PodName, Namespace , ClusterName	The number of pods desired for a workload as defined in the workload specification.
replicas_ready	ClusterName PodName, Namespace , ClusterName	The number of pods for a workload that have reached the ready status.
status_replicas_available	ClusterName PodName, Namespace , ClusterName	The number of pods for a workload which are available . A pod is available when it has been ready for the minReadySeconds defined in the workload specification.

Metric name	Dimensions	Description
status_replicas_unavailable	ClusterName PodName, Namespace , ClusterName	The number of pods for a workload which are unavailable. A pod is available when it has been ready for the minReadySeconds defined in the workload specification. Pods are unavailable if they have not met this criterion.
apiserver_storage_objects	ClusterName ClusterName , resource	The number of objects stored in etcd at the time of the last check.
apiserver_storage_db_total_size_in_bytes	ClusterName ClusterName , endpoint	Total size of the storage database file physically allocated in bytes. This metric is experimental and might change in future releases of Kubernetes. Unit: Bytes Meaningful statistics: Sum, Average, Minimum, Maximum
apiserver_request_total	ClusterName ClusterName , code, verb	The total number of API requests to the Kubernetes API server.
apiserver_request_duration_seconds	ClusterName ClusterName , verb	Responce latency for API requests to the Kubernetes API server.

Metric name	Dimensions	Description
apiserver_admission_controller_admission_duration_seconds	ClusterName ClusterName ,operation	Admission controller latency in seconds. An admission controller is code which intercepts requests to the Kubernetes API server.
rest_client_request_duration_seconds	ClusterName ClusterName ,operation	Reponse latency experienced by clients calling the Kubernetes API server. This metric is experimental and may change in future releases of Kubernetes.
rest_client_requests_total	ClusterName ClusterName ,code, method	The total number of API requests to the Kubernetes API server made by clients. This metric is experimental and may change in future releases of Kubernetes.
etcd_request_duration_seconds	ClusterName ClusterName ,operation	Response latency of API calls to Etcd. This metric is experimental and may change in future releases of Kubernetes.
apiserver_storage_size_bytes	ClusterName ClusterName ,endpoint	Size of the storage database file physically allocated in bytes. This metric is experimental and may change in future releases of Kubernetes.
apiserver_longrunning_requests	ClusterName ClusterName ,resource	The number of active long-running requests to the Kubernetes API server.

Metric name	Dimensions	Description
apiserver_current_inflight_requests	ClusterName ClusterName , request_kind	The number of requests that are being processed by Kubernetes API server.
apiserver_admission_webhook_admission_duration_seconds	ClusterName ClusterName , name	Admission webhook latency in seconds. Admission webhooks are HTTP callbacks that receive admission requests and do something with them.
apiserver_admission_step_admission_duration_seconds	ClusterName ClusterName , operation	Admission sub-step latency in seconds.
apiserver_requested_deprecated_apis	ClusterName ClusterName , group	Number of requests to deprecated APIs on the Kubernetes API server.
apiserver_request_total_5xx	ClusterName ClusterName , code, verb	Number of requests to the Kubernetes API server which were responded to with a 5XX HTTP response code.
apiserver_storage_list_duration_seconds	ClusterName ClusterName , resource	Response latency of listing objects from Etc. This metric is experimental and may change in future releases of Kubernetes.
apiserver_flowcontrol_request_concurrency_limit	ClusterName ClusterName , priority_level	The number of threads used by the currently executing requests in the API Priority and Fairness subsystem.

Metric name	Dimensions	Description
apiserver_flowcontrol_rejected_requests_total	ClusterName ClusterName ,reason	Number of requests rejected by API Priority and Fairness subsystem. This metric is experimental and may change in future releases of Kubernetes.
apiserver_current_inqueue_requests	ClusterName ClusterName ,request_kind	The number queued requests queued by the Kubernetes API server. This metric is experimental and may change in future releases of Kubernetes.

NVIDIA GPU metrics

Beginning with version `1.300034.0` of the CloudWatch agent, Container Insights with enhanced observability for Amazon EKS collects NVIDIA GPU metrics from EKS workloads by default. The CloudWatch agent must be installed using the CloudWatch Observability EKS add-on version `v1.3.0-eksbuild.1` or later. For more information, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart. These NVIDIA GPU metrics that are collected are listed in the table in this section.

For Container Insights to collect NVIDIA GPU metrics, you must meet the following prerequisites:

- You must be using Container Insights with enhanced observability for Amazon EKS, with the Amazon CloudWatch Observability EKS add-on version `v1.3.0-eksbuild.1` or later.
- The NVIDIA device plugin for Kubernetes must be installed in the cluster.
- The NVIDIA container toolkit must be installed on the nodes of the cluster. For example, the Amazon EKS optimized accelerated AMIs are built with the necessary components.

You can opt out of collecting NVIDIA GPU metrics by setting the `accelerated_compute_metrics` option in the beginn CloudWatch agent configuration file to `false`. For more information and an example opt-out configuration, see (Optional) Additional configuration.

Metric name	Dimensions	Description
container_gpu_memory_total	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The total frame buffer size, in bytes, on the GPU(s) allocated to the container.
container_gpu_memory_used	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The bytes of frame buffer used on the GPU(s) allocated to the container.
container_gpu_memory_utilization	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName	The percentage of frame buffer used of the GPU(s) allocated to the container.

Metric name	Dimensions	Description
	ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	
container_gpu_power_draw	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The power usage in watts of the GPU(s) allocated to the container.
container_gpu_temperature	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The temperature in degrees celsius of the GPU(s) allocated to the container.

Metric name	Dimensions	Description
container_gpu_utilization	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The percentage utilization of the GPU(s) allocated to the container.
container_gpu_tensor_core_utilization	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The percentage utilization of the tensor cores on the GPU(s) allocated to the container.
node_gpu_memory_total	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, GpuDevice	The total frame buffer size, in bytes, on the GPU(s) allocated to the node.

Metric name	Dimensions	Description
node_gpu_memory_used	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, GpuDevice	The bytes of frame buffer used on the GPU(s) allocated to the node.
node_gpu_memory_utilization	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, GpuDevice	The percentage of frame buffer used on the GPU(s) allocated to the node.
node_gpu_power_draw	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, GpuDevice	The power usage in watts of the GPU(s) allocated to the node.
node_gpu_temperature	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, GpuDevice	The temperature in degrees celsius of the GPU(s) allocated to the node.

Metric name	Dimensions	Description
node_gpu_utilization	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, GpuDevice	The percentage utilization of the GPU(s) allocated to the node.
node_gpu_tensor_core_utilization	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, GpuDevice	The percentage utilization of the tensor cores on the GPU(s) allocated to the node.
pod_gpu_memory_total	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName . GpuDevice	The total frame buffer size, in bytes, on the GPU(s) allocated to the pod.

Metric name	Dimensions	Description
pod_gpu_memory_used	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName . GpuDevice	The bytes of frame buffer used on the GPU(s) allocated to the pod.
pod_gpu_memory_utilization	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName . GpuDevice	The percentage of frame buffer used of the GPU(s) allocated to the pod.

Metric name	Dimensions	Description
pod_gpu_power_draw	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName . GpuDevice	The power usage in watts of the GPU(s) allocated to the pod.
pod_gpu_temperature	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName . GpuDevice	The temperature in degrees Celsius of the GPU(s) allocated to the pod.

Metric name	Dimensions	Description
pod_gpu_utilization	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The percentage utilization of the GPU(s) allocated to the pod.
pod_gpu_tensor_core_utilization	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The percentage utilization of the tensor cores on the GPU(s) allocated to the pod.

Detailed GPU monitoring

Beginning with version 1.300062.0 of the CloudWatch agent, Container Insights with enhanced observability for Amazon EKS supports detailed GPU monitoring with sub-minute collection intervals. This addresses monitoring gaps for short-duration machine learning inference workloads that may be completely missed by standard collection intervals. The CloudWatch agent must be installed using the CloudWatch Observability EKS add-on version v4.7.0-eksbuild.1 or later. For more information, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart.

By default, GPU metrics are collected and ingested at 60-second intervals. With detailed monitoring enabled, the CloudWatch agent collect GPU metrics at sub-minute intervals (minimum 1 second), but metrics are still ingested to CloudWatch at 1-minute intervals. However, you can query statistical aggregations (such as minimum, maximum, and percentiles like p90) of the sub-minute datapoints within each 1-minute period, providing accurate GPU utilization data and better resource optimization.

Configuration

To enable detailed GPU monitoring, update your CloudWatch agent configuration to include the `accelerated_compute_gpu_metrics_collection_interval` parameter in the `kubernetes` section, as in the following example.

```
{
    "logs": {
        "metrics_collected": {
            "kubernetes": {
                "cluster_name": "MyCluster",
                "enhanced_container_insights": true,
                "accelerated_compute_metrics": true,
                "accelerated_compute_gpu_metrics_collection_interval": 1
            }
        }
    }
}
```

The `accelerated_compute_gpu_metrics_collection_interval` parameter accepts values in seconds, with a minimum value of 1 second. Setting it to 1 enables 1-second collection intervals. If this parameter is not specified, the default 60-second interval is used.

For complete configuration instructions, see Setup guide (AWS CLI).

AWS Neuron metrics for AWS Trainium and AWS Inferentia

Beginning with version `1.300036.0` of the CloudWatch agent, Container Insights with enhanced observability for Amazon EKS collects accelerated computing metrics from AWS Trainium and AWS Inferentia accelerators by default. The CloudWatch agent must be installed using the CloudWatch Observability EKS add-on version `v1.5.0-eksbuild.1` or later. For more information about the add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart. For more information about AWS Trainium, see AWS Trainium. For more information about AWS Inferentia, see AWS Inferentia.

For Container Insights to collect AWS Neuron metrics, you must meet the following prerequisites:

- You must be using Container Insights with enhanced observability for Amazon EKS, with the Amazon CloudWatch Observability EKS add-on version `v1.5.0-eksbuild.1` or later.
- The Neuron driver must be installed on the nodes of the cluster.
- The Neuron device plugin must be installed on the cluster. For example, the Amazon EKS optimized accelerated AMIs are built with the necessary components.

The metrics that are collected are listed in the table in this section. The metrics are collected for AWS Trainium, AWS Inferentia, and AWS Inferentia2.

The CloudWatch agent collects these metrics from the Neuron monitor and does the necessary Kubernetes resource correlation to deliver metrics at the pod and container levels

Metric name	Dimensions	Description

`container_neuroncore_utilization`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`, `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName` , `NeuronDevice` , `NeuronCore`
		NeuronCore utilization, during the captured period of the NeuronCore allocated to the container.
		
		Unit: Percent

`container_neuroncore_memory_usage_constants`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`, `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName`
		The amount of device memory used for constants during training by the NeuronCore that is allocated to the container (or weights during inference).
		
		Unit: Bytes

Metric name	Dimensions	Description
	ClusterName ,Namespace ,PodName, FullPodName , ContainerName ,NeuronDevice ,NeuronCore	
container_neuroncore_memory_usage_model_code	ClusterName ClusterName ,Namespace , PodName, ContainerName ClusterName ,Namespace ,PodName, FullPodName , ContainerName ClusterName ,Namespace ,PodName, FullPodName , ContainerName ,NeuronDevice ,NeuronCore	The amount of device memory used for the models' executable code by the NeuronCore that is allocated to the container. Unit: Bytes
container_neuroncore_memory_usage_model_shared_scratchpad	ClusterName ClusterName ,Namespace , PodName, ContainerName ClusterName ,Namespace ,PodName, FullPodName , ContainerName ClusterName ,Namespace ,PodName, FullPodName , ContainerName ,NeuronDevice ,NeuronCore	The amount of device memory used for the scratchpad shared of the models by the NeuronCore that is allocated to the container. This memory region is reserved for the models. Unit: Bytes

Metric name	Dimensions	Description
container_neuroncore_memory_usage_runtime_memory	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NeuronDevice , NeuronCore	The amount of device memory used for the Neuron runtime by the NeuronCore allocated to the container. Unit: Bytes
container_neuroncore_memory_usage_tensors	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NeuronDevice , NeuronCore	The amount of device memory used for tensors by the NeuronCore allocated to the container. Unit: Bytes

Metric name	Dimensions	Description
container_neuroncore_memory_usage_total	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NeuronDevice , NeuronCore	The total amount of memory used by the NeuronCore allocated to the container. Unit: Bytes
container_neurondevice_hw_ecc_events_total	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NeuronDevice	The number of corrected and uncorrected ECC events for the on-chip SRAM and device memory of the Neuron device on the node. Unit: Count

Metric name	Dimensions	Description
pod_neuroncore_utilization	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice , NeuronCore	The NeuronCore utilization during the captured period of the NeuronCore allocated to the pod. Unit: Percent
pod_neuroncore_memory_usage_constants	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice , NeuronCore	The amount of device memory used for constants during training by the NeuronCore that is allocated to the pod (or weights during inference). Unit: Bytes

Metric name	Dimensions	Description
pod_neuroncore_memory_usage_model_code	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NeuronDevice ,NeuronCore	The amount of device memory used for the models' executable code by the NeuronCore that is allocated to the pod. Unit: Bytes
pod_neuroncore_memory_usage_model_shared_scratchpad	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NeuronDevice ,NeuronCore	The amount of device memory used for the scratchpad shared of the models by the NeuronCore that is allocated to the pod. This memory region is reserved for the models. Unit: Bytes

Metric name	Dimensions	Description
pod_neuroncore_memory_usage_runtime_memory	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice , NeuronCore	The amount of device memory used for the Neuron runtime by the NeuronCore allocated to the pod. Unit: Bytes
pod_neuroncore_memory_usage_tensors	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice , NeuronCore	The amount of device memory used for tensors by the NeuronCore allocated to the pod. Unit: Bytes

Metric name	Dimensions	Description
pod_neuroncore_memory_usage_total	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice , NeuronCore	The total amount of memory used by the NeuronCore allocated to the pod. Unit: Bytes
pod_neurondevice_hw_ecc_events_total	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice	The number of corrected and uncorrected ECC events for the on-chip SRAM and device memory of the Neuron device allocated to a pod. Unit: Bytes

Metric name	Dimensions	Description
node_neuroncore_utilization	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId , NodeName ClusterName ,InstanceType ,InstanceId ,NodeName, NeuronDevice ,NeuronCore	The NeuronCore utilization during the captured period of the NeuronCore allocated to the node. Unit: Percent
node_neuroncore_memory_usage_constants	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId , NodeName ClusterName ,InstanceType ,InstanceId ,NodeName, NeuronDevice ,NeuronCore	The amount of device memory used for constants during training by the NeuronCore that is allocated to the node (or weights during inference). Unit: Bytes
node_neuroncore_memory_usage_model_code	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId , NodeName ClusterName ,InstanceType ,InstanceId ,NodeName, NeuronDevice ,NeuronCore	The amount of device memory used for models' executable code by the NeuronCore that is allocated to the node. Unit: Bytes

Metric name	Dimensions	Description
node_neuroncore_memory_usage_model_shared_scratchpad	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId ,NodeName ClusterName ,InstanceType ,InstanceId ,NodeName,NeuronDevice ,NeuronCore	The amount of device memory used for the scratchpad shared of the models by the NeuronCore that is allocated to the node. This is a memory region reserved for the models. Unit: Bytes
node_neuroncore_memory_usage_runtime_memory	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId ,NodeName ClusterName ,InstanceType ,InstanceId ,NodeName,NeuronDevice ,NeuronCore	The amount of device memory used for the Neuron runtime by the NeuronCore that is allocated to the node. Unit: Bytes
node_neuroncore_memory_usage_tensors	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId ,NodeName ClusterName ,InstanceType ,InstanceId ,NodeName,NeuronDevice ,NeuronCore	The amount of device memory used for tensors by the NeuronCore that is allocated to the node. Unit: Bytes

Metric name	Dimensions	Description
node_neuroncore_memory_usage_total	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId , NodeName ClusterName ,InstanceType ,InstanceId ,NodeName, NeuronDevice ,NeuronCore	The total amount of memory used by the NeuronCore that is allocated to the node. Unit: Bytes
node_neuron_execution_errors_total	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId , NodeName	The total number of execution errors on the node. This is calculated by the CloudWatch agent by aggregating the errors of the following types: generic, numerical ,transient ,model, runtime, and hardware Unit: Count
node_neurondevice_runtime_memory_used_bytes	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId , NodeName	The total Neuron device memory usage in bytes on the node. Unit: Bytes
node_neuron_execution_latency	ClusterName ClusterName ,UltraServer ClusterName ,InstanceId , NodeName	In seconds, the latency for an execution on the node as measured by the Neuron runtime. Unit: Seconds

Metric name	Dimensions	Description
node_neuron device_hw_ecc_events_total	ClusterName ClusterName , UltraServer ClusterName , InstanceId , NodeName ClusterName , InstanceId , NodeName, NeuronDevice	The number of corrected and uncorrected ECC events for the on-chip SRAM and device memory of the Neuron device on the node. Unit: Count

AWS Elastic Fabric Adapter (EFA) metrics

Beginning with version 1.300037.0 of the CloudWatch agent, Container Insights with enhanced observability for Amazon EKS collects AWS Elastic Fabric Adapter (EFA) metrics from Amazon EKS clusters on Linux instances. The CloudWatch agent must be installed using the CloudWatch Observability EKS add-on version v1.5.2-eksbuild.1 or later. For more information about the add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart. For more information about AWS Elastic Fabric Adapter, see Elastic Fabric Adapter.

For Container Insights to collect AWS Elastic Fabric adapter metrics, you must meet the following prerequisites:

- You must be using Container Insights with enhanced observability for Amazon EKS, with the Amazon CloudWatch Observability EKS add-on version v1.5.2-eksbuild.1 or later.
- The EFA device plugin must be installed on the cluster. For more information, see aws-efa-k8s-device-plugin on GitHub.

The metrics that are collected are listed in the following table.

Metric name	Dimensions	Description
container_efa_rx_bytes	ClusterName ClusterName , Namespace , PodName, ContainerName	The number of bytes per second received by the EFA device(s) allocated to the container.

Metric name	Dimensions	Description
	ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	Unit: Bytes/Second
container_efa_tx_bytes	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	The number of bytes per second transmitted by the EFA device(s) allocated to the container. Unit: Bytes/Second
container_efa_rx_dropped	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	The number of packets that were received and then dropped by the EFA device(s) allocated to the container. Unit: Count/Second

Metric name	Dimensions	Description
container_efa_rdma_read_bytes	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	The number of bytes per second received using remote direct memory access read operations by the EFA device(s) allocated to the container. Unit: Bytes/Second
container_efa_rdma_write_bytes	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	The number of bytes per second transmitted using remote direct memory access read operations by the EFA device(s) allocated to the container. Unit: Bytes/Second

Metric name	Dimensions	Description
container_efa_rdma_write_recv_bytes	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	The number of bytes per second received during remote direct memory access write operations by the EFA device(s) allocated to the container. Unit: Bytes/Second
pod_efa_rx_bytes	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second received by the EFA device(s) allocated to the pod. Unit: Bytes/Second

Metric name	Dimensions	Description
pod_efa_tx_bytes	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second transmitted by the EFA device(s) allocated to the pod. Unit: Bytes/Second
pod_efa_rx_dropped	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NetworkInterfaceId	The number of packets that were received and then dropped by the EFA device(s) allocated to the pod. Unit: Count/Second

Metric name	Dimensions	Description
pod_efa_rdma_read_bytes	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second received using remote direct memory access read operations by the EFA device(s) allocated to the pod. Unit: Bytes/Second
pod_efa_rdma_write_bytes	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second transmitted using remote direct memory access read operations by the EFA device(s) allocated to the pod. Unit: Bytes/Second

Metric name	Dimensions	Description
pod_efa_rdma_write_recv_bytes	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second received during remote direct memory access write operations by the EFA device(s) allocated to the pod. Unit: Bytes/Second
node_efa_rx_bytes	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, NetworkInterfaceId	The number of bytes per second received by the EFA device(s) allocated to the node. Unit: Bytes/Second
node_efa_tx_bytes	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, NetworkInterfaceId	The number of bytes per second transmitted by the EFA device(s) allocated to the node. Unit: Bytes/Second

Metric name	Dimensions	Description
node_efa_rx_dropped	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, NetworkInterfaceId	The number of packets that were received and then dropped by the EFA device(s) allocated to the node. Unit: Count/Second
node_efa_rdma_read_bytes	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, NetworkInterfaceId	The number of bytes per second received using remote direct memory access read operations by the EFA device(s) allocated to the node. Unit: Bytes/Second
node_efa_rdma_write_bytes	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, NetworkInterfaceId	The number of bytes per second transmitted using remote direct memory access read operations by the EFA device(s) allocated to the pod. Unit: Bytes/Second
node_efa_rdma_write_recv_bytes	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, NetworkInterfaceId	The number of bytes per second received during remote direct memory access write operations by the EFA device(s) allocated to the node. Unit: Bytes/Second

Amazon SageMaker AI HyperPod metrics

Beginning with version `v2.0.1-eksbuild.1` of the CloudWatch Observability EKS add-on, Container Insights with enhanced observability for Amazon EKS automatically collects Amazon SageMaker AI HyperPod metrics from Amazon EKS clusters. For more information about the add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart. For more information about Amazon SageMaker AI HyperPod, see Amazon SageMaker AI HyperPod.

The metrics that are collected are listed in the following table.

Metric name	Dimensions	Description

`hyperpod_node_health_status_unschedulable`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates if a node is labeled as `Unschedulable` by Amazon SageMaker AI HyperPod. This means that the node is running deep health checks and is not available for running workloads.
		
		Unit: Count

`hyperpod_node_health_status_schedulable`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates if a node is labeled as `Schedulable` by Amazon SageMaker AI HyperPod. This means that the node has passed basic health checks or deep health checks and is available for running workloads.
		
		Unit: Count

`hyperpod_node_health_status_unschedulable_pen`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates if a node is labeled as `UnschedulablePendingReplacement` by HyperPod. This means that the node has failed deep health checks or health monitoring agent checks and requires a replacement.

Metric name	Dimensions	Description
ding_repl acement		If automatic node recovery is enabled, the node will be automatic ally replaced by Amazon SageMaker AI HyperPod. Unit: Count
hyperpod_ node_heal th_status _unschedu lable_pen ding_rebo ot	ClusterName ClusterName ,InstanceId , NodeName	Indicates if a node is labeled as UnschedulablePendi ngReboot by Amazon SageMaker AI HyperPod. This means that the node is running deep health checks and requires a reboot. If automatic node recovery is enabled, the node will be automatic ally rebooted by Amazon SageMaker AI HyperPod. Unit: Count

Amazon EBS NVMe driver metrics

Beginning with version 1.300056.0 of the CloudWatch agent, Container Insights with enhanced observability for Amazon EKS automatically collects Amazon EBS NVMe driver metrics from Amazon EKS clusters on Linux instances. The CloudWatch agent must be installed using the CloudWatch Observability Amazon EKS add-on version 4.1.0 or later. For more information about the add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart. For more information about Amazon EBS, see Amazon EBS detailed performance statistics.

For Container Insights to collect Amazon EBS NVMe driver metrics, you must meet the following prerequisites:

- You must be using Container Insights with enhanced observability for Amazon EKS, with the CloudWatch Observability Amazon EKS add-on version 4.1.0 or later.

- The EBS CSI driver `1.42.0` add-on or Helm chart must be installed on the cluster with metrics enabled.
  - To enable the metrics when you are using Amazon EBS CSI driver add-on, use the following option when you create or update the add-on. `--configuration-values '{ "node": { "enableMetrics": true } }'`
  - To enable the metrics if you are using Helm chart, use the following option when you create or update the add-on. `--set node.enableMetrics=true`

The metrics that are collected are listed in the following table.

Metric name	Dimensions	Description

`node_diskio_ebs_total_read_ops`	`ClusterName`
	`ClusterName ,NodeName, InstanceId`
	`ClusterName ,NodeName, InstanceId VolumeId`
		The total number of completed read operations.

`node_diskio_ebs_total_write_ops`	`ClusterName`
	`ClusterName ,NodeName, InstanceId`
	`ClusterName ,NodeName, InstanceId VolumeId`
		The total number of completed write operations.

`node_diskio_ebs_total_read_bytes`	`ClusterName`
	`ClusterName ,NodeName, InstanceId`
	`ClusterName ,NodeName, InstanceId VolumeId`
		The total number of read bytes transferred.

`node_diskio_ebs_to`	`ClusterName`	The total number of write bytes transferred.

Metric name	Dimensions	Description
tal_write_bytes	ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId VolumeId	
node_diskio_ebs_total_read_time	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId VolumeId	The total time spent, in microseconds, by all completed read operations.
node_diskio_ebs_total_write_time	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId VolumeId	The total time spent, in microseconds, by all completed write operations.
node_diskio_ebs_volume_performance_exceeded_iops	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId VolumeId	The total time, in microseconds, that IOPS demand exceeded the volume's provisioned IOPS performance.
node_diskio_ebs_volume_performance_exceeded_tp	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId VolumeId	The total time, in microseconds, that throughput demand exceeded the volume's provisioned throughput performance.

Metric name	Dimensions	Description
node_diskio_ebs_ec2_instance_performance_exceeded_iops	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId VolumeId	The total time, in microseconds, that the EBS volume exceeded the attached Amazon EC2 instance's maximum IOPS performance.
node_diskio_ebs_ec2_instance_performance_exceeded_tp	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId VolumeId	The total time, in microseconds, that the EBS volume exceeded the attached Amazon EC2 instance's maximum throughput performance.
node_diskio_ebs_volume_queue_length	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId VolumeId	The number of read and write operations waiting to be completed.

Amazon EC2 local instance store NVMe metrics

Beginning with version `1.300069.0` of the CloudWatch agent, Container Insights with enhanced observability for Amazon EKS automatically collects Amazon EC2 local instance store NVMe metrics from Amazon EKS clusters on Linux instances. The CloudWatch agent must be installed using the CloudWatch Observability Amazon EKS add-on version `6.2.0` or later, or the equivalent Helm chart. For more information about the add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart. For more information about Amazon EC2 instance store, see Amazon EC2 instance store.

To collect these metrics, you must meet the following prerequisites:

- You must be using Container Insights with enhanced observability for Amazon EKS, with the CloudWatch Observability Amazon EKS add-on version `6.2.0` or later.
- The `aws-ec2-local-instance-store-csi-driver` EKS add-on or Helm chart must be installed on the cluster with metrics enabled.
  - To enable the metrics when you are using the `aws-ec2-local-instance-store-csi-driver` add-on, use the following option when you create or update the add-on. `--configuration-values '{"metrics":{"enabled":true}}'`
  - To enable the metrics when you are using Helm chart, use the following option when you create or update the add-on. `--set metrics.enabled=true`
- Your cluster must have worker nodes running on EC2 instance types that support instance store volumes. For more information, see Considerations in the Amazon EKS User Guide.

After the prerequisites are met, the CloudWatch agent automatically discovers and collects metrics from the local instance store CSI driver. No additional CloudWatch agent configuration is required.

The following table lists the metrics that are collected.

Metric name	Dimensions	Description

`node_diskio_instance_store_total_read_ops`	`ClusterName`
	`ClusterName ,NodeName, InstanceId`
	`ClusterName ,NodeName, InstanceId ,VolumeId`
		The total number of completed read operations.

`node_diskio_instance_store_total_write_ops`	`ClusterName`
	`ClusterName ,NodeName, InstanceId`
	`ClusterName ,NodeName, InstanceId ,VolumeId`
		The total number of completed write operations.

`node_diskio_instance_store_`	`ClusterName`	The total number of read bytes transferred.

Metric name	Dimensions	Description
total_read_bytes	ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId ,VolumeId	
node_diskio_instance_store_total_write_bytes	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId ,VolumeId	The total number of write bytes transferred.
node_diskio_instance_store_total_read_time	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId ,VolumeId	The total time spent, in seconds, by all completed read operations.
node_diskio_instance_store_total_write_time	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId ,VolumeId	The total time spent, in seconds, by all completed write operations.
node_diskio_instance_store_ec2_instance_performance_exceeded_iops	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId ,VolumeId	The total time, in seconds, that the instance store volume exceeded the attached Amazon EC2 instance's maximum IOPS performance.

Metric name	Dimensions	Description
node_diskio_instance_store_ec2_instance_performance_exceeded_tp	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId ,VolumeId	The total time, in seconds, that the instance store volume exceeded the attached Amazon EC2 instance's maximum throughput performance.
node_diskio_instance_store_volume_queue_length	ClusterName ClusterName ,NodeName, InstanceId ClusterName ,NodeName, InstanceId ,VolumeId	The number of read and write operations waiting to be completed.

Amazon EKS and Kubernetes Container Insights metrics

The following tables list the metrics and dimensions that Container Insights collects for Amazon EKS and Kubernetes. These metrics are in the `ContainerInsights` namespace. For more information, see Metrics.

If you do not see any Container Insights metrics in your console, be sure that you have completed the setup of Container Insights. Metrics do not appear before Container Insights has been set up completely. For more information, see Container Insights.

Metric name	Dimensions	Description
cluster_failed_node_count	ClusterName	The number of failed worker nodes in the cluster. A node is considered failed if it is suffering from any *node conditions*. For more information, see Conditions in the Kubernetes documentation.

Metric name	Dimensions	Description
cluster_node_count	ClusterName	The total number of worker nodes in the cluster.
namespace_number_of_running_pods	Namespace ClusterName ClusterName	The number of pods running per namespace in the resource that is specified by the dimensions that you're using.
node_cpu_limit	ClusterName	The maximum number of CPU units that can be assigned to a single node in this cluster.
node_cpu_reserved_capacity	NodeName, ClusterName , InstanceId ClusterName	The percentage of CPU units that are reserved for node components, such as kubelet, kube-proxy, and Docker. Formula: node_cpu_request / node_cpu_limit **Note** node_cpu_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
node_cpu_usage_total	ClusterName	The number of CPU units being used on the nodes in the cluster.
node_cpu_utilization	NodeName, ClusterName , InstanceId ClusterName	The total percentage of CPU units being used on the nodes in the cluster. Formula: node_cpu_usage_total / node_cpu_limit
node_gpu_limit	ClusterName ClusterName ,InstanceId ,NodeName	The total number of GPU(s) available on the node.
node_gpu_usage_total	ClusterName ClusterName ,InstanceId ,NodeName	The number of GPU(s) being used by the running pods on the node.

Metric name	Dimensions	Description
node_gpu_reserved_capacity	ClusterName ClusterName , InstanceId , NodeName	The percentage of GPU currently being reserved on the node. The formula is, node_gpu_request / node_gpu_limit . **Note** node_gpu_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
node_filesystem_utilization	NodeName, ClusterName , InstanceId ClusterName	The total percentage of file system capacity being used on nodes in the cluster. Formula: node_filesystem_usage / node_filesystem_capacity **Note** node_filesystem_usage and node_filesystem_capacity are not reported directly as metrics, but are fields in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_memory_limit	ClusterName	The maximum amount of memory, in bytes, that can be assigned to a single node in this cluster.

Metric name	Dimensions	Description
node_memory_reserved_capacity	NodeName, ClusterName , InstanceId ClusterName	The percentage of memory currently being reserved on the nodes in the cluster. Formula: node_memory_request / node_memory_limit **Note** node_memory_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_memory_utilization	NodeName, ClusterName , InstanceId ClusterName	The percentage of memory currently being used by the node or nodes. It is the percentage of node memory usage divided by the node memory limitation. Formula: node_memory_working_set / node_memory_limit .

Metric name	Dimensions	Description
node_memory_working_set	ClusterName	The amount of memory, in bytes, being used in the working set of the nodes in the cluster.
node_network_total_bytes	NodeName, ClusterName , InstanceId ClusterName	The total number of bytes per second transmitted and received over the network per node in a cluster. Formula: node_network_rx_bytes + node_network_tx_bytes **Note** node_network_rx_bytes and node_network_tx_bytes are not reported directly as metrics, but are fields in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_number_of_running_containers	NodeName, ClusterName , InstanceId ClusterName	The number of running containers per node in a cluster.

Metric name	Dimensions	Description
node_number_of_running_pods	NodeName, ClusterName , InstanceId ClusterName	The number of running pods per node in a cluster.
pod_cpu_reserved_capacity	PodName, Namespace , ClusterName ClusterName	The CPU capacity that is reserved per pod in a cluster. Formula: pod_cpu_request / node_cpu_limit **Note** pod_cpu_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
pod_cpu_utilization	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName	The percentage of CPU units being used by pods. Formula: pod_cpu_usage_total / node_cpu_limit

Metric name	Dimensions	Description
pod_cpu_utilization_over_pod_limit	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName	The percentage of CPU units being used by pods relative to the pod limit. Formula: pod_cpu_usage_total / pod_cpu_limit
pod_gpu_request	ClusterName ClusterName , Namespace , PodName ClusterName , FullPodName , Namespace , PodName	The GPU requests for the pod. This value must always be equal to pod_gpu_limit .
pod_gpu_limit	ClusterName ClusterName , Namespace , PodName ClusterName , FullPodName , Namespace , PodName	The maximum number of GPU(s) that can be assigned to the pod in a node.
pod_gpu_usage_total	ClusterName ClusterName , Namespace , PodName ClusterName , FullPodName , Namespace , PodName	The number of GPU(s) being allocated on the pod.

Metric name	Dimensions	Description
pod_gpu_reserved_capacity	ClusterName ClusterName , Namespace , PodName ClusterName , FullPodName , Namespace , PodName	The percentage of GPU currently being reserved for the pod. The formula is - pod_gpu_request / node_gpu_reserved_capacity.
pod_memory_reserved_capacity	PodName, Namespace , ClusterName ClusterName	The percentage of memory that is reserved for pods. Formula: pod_memory_request / node_memory_limit **Note** pod_memory_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_memory_utilization	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName	The percentage of memory currently being used by the pod or pods. Formula: pod_memory_working_set / node_memory_limit
pod_memory_utilization_over_pod_limit	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName	The percentage of memory that is being used by pods relative to the pod limit. If any containers in the pod don't have a memory limit defined, this metric doesn't appear. Formula: pod_memory_working_set / pod_memory_limit

Metric name	Dimensions	Description
pod_network_rx_bytes	PodName, Namespace , ClusterName Namespace ,ClusterName Service, Namespace , ClusterName ClusterName	The number of bytes per second being received over the network by the pod. Formula: sum(pod_interface_network_rx_bytes) **Note** pod_interface_network_rx_bytes is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_network_tx_bytes	PodName, Namespace , ClusterName Namespace ,ClusterName Service, Namespace , ClusterName ClusterName	The number of bytes per second being transmitted over the network by the pod. Formula: sum(pod_interface_network_tx_bytes) **Note** pod_interface_network_tx_bytes is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
pod_number_of_container_restarts	PodName, Namespace , ClusterName	The total number of container restarts in a pod.
service_number_of_running_pods	Service, Namespace , ClusterName ClusterName	The number of pods running the service or services in the cluster.

Kueue metrics

Beginning with version v2.4.0-eksbuild.1 of the the CloudWatch Observability EKS add-on, Container Insights for Amazon EKS supports collecting Kueue metrics from Amazon EKS clusters.

For more information about the add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart.

For information about enabling the metrics, see Enable Kueue metrics to enable them.

The Kueue metrics that are collected are listed in the following table. These metrics are published into the `ContainerInsights/Prometheus` namespace in CloudWatch. Some of these metrics use the following dimensions:

- `ClusterQueue` is the name of the ClusterQueue
- The possible values of `Status` are `active` and `inadmissible`
- The possible values of `Reason` are `Preempted`, `PodsReadyTimeout`, `AdmissionCheck`, `ClusterQueueStopped`, and `InactiveWorkload`
- `Flavor` is the referenced flavor.
- `Resource` refers to cluster computer resources, such as `cpu`, `memory`, `gpu`, and so on.

Metric name	Dimensions	Description

`kueue_pending_workloads`	`ClusterName` , `ClusterQueue` , `Status`
	`ClusterName` , `ClusterQueue`
	`ClusterName` , `Status`
	`ClusterName`
		The number of pending workloads.

`kueue_evicted_workloads_total`	`ClusterName` , `ClusterQueue` , `Reason`
	`ClusterName` , `ClusterQueue`
	`ClusterName` , `Reason`
	`ClusterName`
		The total number of evicted workloads.

`kueue_admitted_act`	`ClusterName` , `ClusterQueue` `ClusterName`	The number of admitted workloads that are active (unsuspended and not finished).

Metric name	Dimensions	Description
ive_workloads		
kueue_cluster_queue_resource_usage	ClusterName ,ClusterQueue , Resource, Flavor ClusterName ,ClusterQueue , Resource ClusterName ,ClusterQueue , Flavor ClusterName ,ClusterQueue ClusterName	Reports the total resource usage of the ClusterQueue.
kueue_cluster_queue_nominal_quota	ClusterName ,ClusterQueue , Resource, Flavor ClusterName ,ClusterQueue , Resource ClusterName ,ClusterQueue , Flavor ClusterName ,ClusterQueue ClusterName	Reports the resource quota of the ClusterQueue.

Container Insights performance log reference

This section includes reference information about how Container Insights uses performance log events to collect metrics. When you deploy Container Insights, it automatically creates a log group for the performance log events. You don't need to create this log group yourself.

Topics

- Container Insights performance log events for Amazon ECS

- Container Insights performance log events for Amazon EKS and Kubernetes
- Relevant fields in performance log events for Amazon EKS and Kubernetes

Container Insights performance log events for Amazon ECS

The following are examples of the performance log events that Container Insights collects from Amazon ECS.

These logs are in CloudWatch Logs, in a log group named `/aws/ecs/containerinsights/`*`CLUSTER_NAME`*`/performance`. Within that log group, each container instance will has a log stream named `AgentTelemetry-`*`CONTAINER_INSTANCE_ID`*.

You can query these logs using queries such as `{ $.Type = "Container" }` to view all container log events.

Type: Container

```
{
 "Version":"0",
 "Type":"Container",
 "ContainerName":"sleep",
 "TaskId":"7ac4dfba69214411b4783a3b8189c9ba",
 "TaskDefinitionFamily":"sleep360",
 "TaskDefinitionRevision":"1",

 "EC2InstanceId":"i-0c470579dbcdbd2f3",
 "ClusterName":"MyCluster",
 "Image":"busybox",
 "ContainerKnownStatus":"RUNNING",
 "Timestamp":1623963900000,
 "CpuUtilized":0.0,
 "CpuReserved":10.0,
 "MemoryUtilized":0,
 "MemoryReserved":10,
 "StorageReadBytes":0,
 "StorageWriteBytes":0,
 "NetworkRxBytes":0,
 "NetworkRxDropped":0,
 "NetworkRxErrors":0,
 "NetworkRxPackets":14,
 "NetworkTxBytes":0,
 "NetworkTxDropped":0,
```

```
 "NetworkTxErrors":0,
 "NetworkTxPackets":0
}
```

Type: Task

Even though the units for `StorageReadBytes` and `StorageWriteBytes` are in Bytes/Second, the values represent the cumulative number of bytes read from and written to storage, respectively.

Relevant fields in performance log events for Amazon EKS and Kubernetes

For Amazon EKS and Kubernetes, the containerized CloudWatch agent emits data as performance log events. This enables CloudWatch to ingest and store high-cardinality data. CloudWatch uses the data in the performance log events to create aggregated CloudWatch metrics at the cluster, node, and pod levels without the need to lose granular details.

The following table lists the fields in these performance log events that are relevant to the collection of Container Insights metric data. You can use CloudWatch Logs Insights to query for any of these fields to collect data or investigate issues. For more information, see Analyze Log Data With CloudWatch Logs Insights.

Type	Log field	Source	Formula or notes
Pod	`pod_cpu_utilization`	Calculated	Formula: `pod_cpu_usage_total / node_cpu_limit`
Pod	`pod_cpu_usage_total` `pod_cpu_usage_total` is reported in millicores.	cadvisor	
Pod	`pod_cpu_limit`	Calculated	Formula: `sum(container_cpu_limit)` `sum(container_cpu_limit)` includes already-completed pods. If any containers in the pod don't have a CPU limit defined, this field doesn't appear in the log event. This

Type	Log field	Source	Formula or notes
			includes init containers.
Pod	pod_cpu_request	Calculated	Formula: sum(container_cpu_request) container_cpu_request isn't guaranteed to be set. Only the ones that are set are included in the sum.
Pod	pod_cpu_utilization_over_pod_limit	Calculated	Formula: pod_cpu_usage_total / pod_cpu_limit
Pod	pod_cpu_reserved_capacity	Calculated	Formula: pod_cpu_request / node_cpu_limit

Type	Log field	Source	Formula or notes
Pod	pod_memory_utilization	Calculated	Formula: pod_memory_working_set / node_memory_limit It is the percentage of pod memory usage over the node memory limitation.
Pod	pod_memory_working_set	cadvisor	
Pod	pod_memory_limit	Calculated	Formula: sum(container_memory_limit) If any containers in the pod don't have a memory limit defined, this field doesn't appear in the log event. This includes init containers.

Type	Log field	Source	Formula or notes
Pod	`pod_memory_request`	Calculated	Formula: `sum(container_memory_request)` `container_memory_request` isn't guaranteed to be set. Only the ones that are set are included in the sum.
Pod	`pod_memory_utilization_over_pod_limit`	Calculated	Formula: `pod_memory_working_set / pod_memory_limit` If any containers in the pod don't have a memory limit defined, this field doesn't appear in the log event. This includes init containers.

Type	Log field	Source	Formula or notes
Pod	pod_memory_reserved_capacity	Calculated	Formula: pod_memory_request / node_memory_limit
Pod	pod_network_tx_bytes	Calculated	Formula: sum(pod_interface_network_tx_bytes) This data is available for all the network interfaces per pod. The CloudWatch agent calculates the total and adds metric extraction rules.
Pod	pod_network_rx_bytes	Calculated	Formula: sum(pod_interface_network_rx_bytes)

Type	Log field	Source	Formula or notes
Pod	pod_network_total_bytes	Calculated	Formula: pod_network_rx_bytes + pod_network_tx_bytes
PodNet	pod_interface_network_rx_bytes	cadvisor	This data is network rx bytes per second of a pod network interface.
PodNet	pod_interface_network_tx_bytes	cadvisor	This data is network tx bytes per second of a pod network interface.
Container	container_cpu_usage_total	cadvisor	
Container	container_cpu_limit	cadvisor	Not guaranteed to be set. It's not emitted if it's not set.
Container	container_cpu_request	cadvisor	Not guaranteed to be set. It's not emitted if it's not set.
Container	container_memory_working_set	cadvisor	

Type	Log field	Source	Formula or notes
Container	container_memory_limit	pod	Not guaranteed to be set. It's not emitted if it's not set.
Container	container_memory_request	pod	Not guaranteed to be set. It's not emitted if it's not set.
Node	node_cpu_utilization	Calculated	Formula: node_cpu_usage_total / node_cpu_limit
Node	node_cpu_usage_total	cadvisor	
Node	node_cpu_limit	/proc	

Type	Log field	Source	Formula or notes
Node	node_cpu_request	Calculated	Formula: sum(pod_cpu_request) For cronjobs, node_cpu_request also includes requests from completed pods. This can lead to a high value for node_cpu_reserved_capacity .
Node	node_cpu_reserved_capacity	Calculated	Formula: node_cpu_request / node_cpu_limit
Node	node_memory_utilization	Calculated	Formula: node_memory_working_set / node_memory_limit
Node	node_memory_working_set	cadvisor	
Node	node_memory_limit	/proc	

Type	Log field	Source	Formula or notes
Node	node_memory_request	Calculated	Formula: sum(pod_memory_request)
Node	node_memory_reserved_capacity	Calculated	Formula: node_memory_request / node_memory_limit
Node	node_network_rx_bytes	Calculated	Formula: sum(node_interface_network_rx_bytes)
Node	node_network_tx_bytes	Calculated	Formula: sum(node_interface_network_tx_bytes)
Node	node_network_total_bytes	Calculated	Formula: node_network_rx_bytes + node_network_tx_bytes
Node	node_number_of_running_pods	Pod List	

Type	Log field	Source	Formula or notes
Node	`node_number_of_running_containers`	Pod List	
NodeNet	`node_interface_network_rx_bytes`	cadvisor	This data is network rx bytes per second of a worker node network interface.
NodeNet	`node_interface_network_tx_bytes`	cadvisor	This data is network tx bytes per second of a worker node network interface.
NodeFS	`node_filesystem_capacity`	cadvisor	
NodeFS	`node_filesystem_usage`	cadvisor	
NodeFS	`node_filesystem_utilization`	Calculated	Formula: `node_filesystem_usage / node_filesystem_capacity` This data is available per device name.

Type	Log field	Source	Formula or notes
Cluster	cluster_failed_node_count	API Server	
Cluster	cluster_node_count	API Server	
Service	service_number_of_running_pods	API Server	
Namespace	namespace_number_of_running_pods	API Server	

Metrics calculation examples

This section includes examples that show how some of the values in the preceding table are calculated.

Suppose that you have a cluster in the following state.

```
Node1
   node_cpu_limit = 4
   node_cpu_usage_total = 3

   Pod1
     pod_cpu_usage_total = 2

     Container1
        container_cpu_limit = 1
        container_cpu_request = 1
        container_cpu_usage_total = 0.8

     Container2
        container_cpu_limit = null
        container_cpu_request = null
        container_cpu_usage_total = 1.2

   Pod2
     pod_cpu_usage_total = 0.4

     Container3
```

```
        container_cpu_limit = 1
        container_cpu_request = 0.5
        container_cpu_usage_total = 0.4

Node2
   node_cpu_limit = 8
   node_cpu_usage_total = 1.5

   Pod3
     pod_cpu_usage_total = 1

     Container4
        container_cpu_limit = 2
        container_cpu_request = 2
        container_cpu_usage_total = 1
```

The following table shows how pod CPU metrics are calculated using this data.

Metric	Formula	Pod1	Pod2	Pod3
pod_cpu_utilization	pod_cpu_usage_total / node_cpu_limit	2 / 4 = 50%	0.4 / 4 = 10%	1 / 8 = 12.5%
pod_cpu_utilization_over_pod_limit	pod_cpu_usage_total / sum(container_cpu_limit)	N/A because CPU limit for Container 2 isn't defined	0.4 / 1 = 40%	1 / 2 = 50%
pod_cpu_reserved_capacity	sum(container_cpu_request) / node_cpu_limit	(1 + 0) / 4 = 25%	0.5 / 4 = 12.5%	2 / 8 = 25%

The following table shows how node CPU metrics are calculated using this data.

Metric	Formula	Node1	Node2
node_cpu_utilization	node_cpu_usage_total / node_cpu_limit	3 / 4 = 75%	1.5 / 8 = 18.75%
node_cpu_reserved_capacity	sum(pod_cpu_request) / node_cpu_limit	1.5 / 4 = 37.5%	2 / 8 = 25%

Container Insights Prometheus metrics monitoring

CloudWatch Container Insights monitoring for Prometheus automates the discovery of Prometheus metrics from containerized systems and workloads. Prometheus is an open-source systems monitoring and alerting toolkit. For more information, see What is Prometheus? in the Prometheus documentation.

Discovering Prometheus metrics is supported for Amazon Elastic Container Service, Amazon Elastic Kubernetes Service and Kubernetes clusters running on Amazon EC2 instances. The Prometheus counter, gauge, and summary metric types are collected.

For Amazon ECS and Amazon EKS clusters, both the EC2 and Fargate launch types are supported. Container Insights automatically collects metrics from several workloads, and you can configure it to collect metrics from any workload.

You can adopt Prometheus as an open-source and open-standard method to ingest custom metrics in CloudWatch. The CloudWatch agent with Prometheus support discovers and collects Prometheus metrics to monitor, troubleshoot, and alarm on application performance degradation and failures faster. This also reduces the number of monitoring tools required to improve observability.

Container Insights Prometheus support involves pay-per-use of metrics and logs, including collecting, storing, and analyzing. For more information, see Amazon CloudWatch Pricing.

Pre-built dashboards for some workloads

The Container Insights Prometheus solution includes pre-built dashboards for the popular workloads that are listed in this section. For sample configurations for these workloads, see (Optional) Set up sample containerized Amazon ECS workloads for Prometheus metric testing and (Optional) Set up sample containerized Amazon EKS workloads for Prometheus metric testing.

You can also configure Container Insights to collect Prometheus metrics from other containerized services and applications by editing the agent configuration file.

Workloads with pre-built dashboards for Amazon EKS clusters and Kubernetes clusters running on Amazon EC2 instances:

- AWS App Mesh
- NGINX
- Memcached
- Java/JMX
- HAProxy

Workloads with pre-built dashboards for Amazon ECS clusters:

- AWS App Mesh
- Java/JMX
- NGINX
- NGINX Plus

Set up and configure Prometheus metrics collection on Amazon ECS clusters

To collect Prometheus metrics from Amazon ECS clusters, you can use the CloudWatch agent as a collector or use the AWS Distro for OpenTelemetry collector. For information about using the AWS Distro for OpenTelemetry collector, see https://aws-otel.github.io/docs/getting-started/container-insights/ecs-prometheus.

The following sections explain how to use the CloudWatch agent as the collector to retrieve Prometheus metrics. You install the CloudWatch agent with Prometheus monitoring on clusters running Amazon ECS, and you can optionally configure the agent to scrape additional targets. These sections also provide optional tutorials for setting up sample workloads to use for testing with Prometheus monitoring.

Container Insights on Amazon ECS supports the following launch type and network mode combinations for Prometheus metrics:

Amazon ECS launch type	Network modes supported
EC2 (Linux)	bridge, host, and awsvpc
Fargate	awsvpc

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

- Install the CloudWatch agent with Prometheus metrics collection on Amazon ECS clusters
- Scraping additional Prometheus sources and importing those metrics
- (Optional) Set up sample containerized Amazon ECS workloads for Prometheus metric testing

Install the CloudWatch agent with Prometheus metrics collection on Amazon ECS clusters

This section explains how to set up the CloudWatch agent with Prometheus monitoring in a cluster running Amazon ECS. After you do this, the agent automatically scrapes and imports metrics for the following workloads running in that cluster.

- AWS App Mesh
- Java/JMX

You can also configure the agent to scrape and import metrics from additional Prometheus workloads and sources.

Set up IAM roles

You need two IAM roles for the CloudWatch agent task definition. If you specify **`CreateIAMRoles=True`** in the CloudFormation stack to have Container Insights create these roles for you, the roles will be created with the correct permissions. If you want to create them yourself or use existing roles, the following roles and permissions are required.

- **CloudWatch agent ECS task role**— The CloudWatch agent container uses this role. It must include the **CloudWatchAgentServerPolicy** policy and a customer-managed policy which contains the following read-only permissions:
  - `ec2:DescribeInstances`
  - `ecs:ListTasks`
  - `ecs:ListServices`
  - `ecs:DescribeContainerInstances`
  - `ecs:DescribeServices`
  - `ecs:DescribeTasks`
  - `ecs:DescribeTaskDefinition`
- **CloudWatch agent ECS task execution role**— This is the role that Amazon ECS requires to launch and execute your containers. Make sure that your task execution role has the **AmazonSSMReadOnlyAccess**, **AmazonECSTaskExecutionRolePolicy**, and **CloudWatchAgentServerPolicy** policies attached. If you want to store more sensitive data for Amazon ECS to use, see Specifying sensitive data.

Install the CloudWatch agent with Prometheus monitoring by using CloudFormation

You use AWS CloudFormation to install the CloudWatch agent with Prometheus monitoring for Amazon ECS clusters. The following list shows the parameters you will use in the CloudFormation template.

- **ECSClusterName**— Specifies the target Amazon ECS cluster.
- **CreateIAMRoles**— Specify **`True`** to create new roles for the Amazon ECS task role and Amazon ECS task execution role. Specify **`False`** to reuse existing roles.
- **TaskRoleName**— If you specified **`True`** for **CreateIAMRoles**, this specifies the name to use for the new Amazon ECS task role. If you specified **`False`** for **CreateIAMRoles**, this specifies the existing role to use as the Amazon ECS task role.
- **ExecutionRoleName**— If you specified **`True`** for **CreateIAMRoles**, this specifies the name to use for the new Amazon ECS task execution role. If you specified **`False`** for **CreateIAMRoles**, this specifies the existing role to use as the Amazon ECS task execution role.
- **ECSNetworkMode**— If you are using EC2 launch type, specify the network mode here. It must be either **`bridge`** or **`host`**.
- **ECSLaunchType**— Specify either **`fargate`** or **`EC2`**.

- **SecurityGroupID**— If the **ECSNetworkMode** is **awsvpc**, specify the security group ID here.
- **SubnetID**— If the **ECSNetworkMode** is **awsvpc**, specify the subnet ID here.

Command samples

This section includes sample CloudFormation commands to install Container Insights with Prometheus monitoring in various scenarios.

Create CloudFormation stack for an Amazon ECS cluster in bridge network mode

```
export AWS_PROFILE=your_aws_config_profile_eg_default
export AWS_DEFAULT_REGION=your_aws_region_eg_ap-southeast-1
export ECS_CLUSTER_NAME=your_ec2_ecs_cluster_name
export ECS_NETWORK_MODE=bridge
export CREATE_IAM_ROLES=True
export ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
export ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-
prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-bridge-host.yaml

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=${ECS_CLUSTER_NAME} \
                 ParameterKey=CreateIAMRoles,ParameterValue=${CREATE_IAM_ROLES} \
                 ParameterKey=ECSNetworkMode,ParameterValue=${ECS_NETWORK_MODE} \
                 ParameterKey=TaskRoleName,ParameterValue=${ECS_TASK_ROLE_NAME} \
                 ParameterKey=ExecutionRoleName,ParameterValue=
${ECS_EXECUTION_ROLE_NAME} \
    --capabilities CAPABILITY_NAMED_IAM \
    --region ${AWS_DEFAULT_REGION} \
    --profile ${AWS_PROFILE}
```

Create CloudFormation stack for an Amazon ECS cluster in host network mode

```
export AWS_PROFILE=your_aws_config_profile_eg_default
export AWS_DEFAULT_REGION=your_aws_region_eg_ap-southeast-1
export ECS_CLUSTER_NAME=your_ec2_ecs_cluster_name
export ECS_NETWORK_MODE=host

```

AWS resources created by the CloudFormation stack

The following table lists the AWS resources that are created when you use CloudFormation to set up Container Insights with Prometheus monitoring on an Amazon ECS cluster.

Resource type	Resource name	Comments
AWS::SSM::Parameter	AmazonCloudWatch-CWAgentConfig-$*ECS_CLUSTER_NAME* -$*ECS_LAUNCH_TYPE* -$*ECS_NETWORK_MODE*	This is the CloudWatch agent with the default App Mesh and Java/JMX embedded metric format definition.
AWS::SSM::Parameter	AmazonCloudWatch-Prometheus ConfigName-$*ECS_CLUSTER_NAME* -$*ECS_LAUNCH_TYPE* -$*ECS_NETWORK_MODE*	This is the Prometheus scraping configuration.
AWS::IAM::Role	**$ECS_TASK_ROLE_NAME**.	The Amazon ECS task role. This is created only if you specified **`True`** for `CREATE_IAM_ROLES` .
AWS::IAM::Role	**${ECS_EXECUTION_ROLE_NAME}**	The Amazon ECS task execution role. This is created only if you specified **`True`** for `CREATE_IAM_ROLES` .
AWS::ECS::TaskDefinition	cwagent-prometheus-$*ECS_CLUSTER_NAME* -$*ECS_LAUNCH_TYPE* -$*ECS_NETWORK_MODE*	
AWS::ECS::Service	cwagent-prometheus-replica-service-$*ECS_LAUNCH_TYPE* -$*ECS_NETWORK_MODE*	

Deleting the CloudFormation stack for the CloudWatch agent with Prometheus monitoring

To delete the CloudWatch agent from an Amazon ECS cluster, enter these commands.

```
export AWS_PROFILE=your_aws_config_profile_eg_default
export AWS_DEFAULT_REGION=your_aws_region_eg_ap-southeast-1
```

```
export CLOUDFORMATION_STACK_NAME=your_cloudformation_stack_name

aws cloudformation delete-stack \
--stack-name ${CLOUDFORMATION_STACK_NAME} \
--region ${AWS_DEFAULT_REGION} \
--profile ${AWS_PROFILE}
```

Scraping additional Prometheus sources and importing those metrics

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. One is for the standard Prometheus configurations as documented in <scrape_config> in the Prometheus documentation. The other is for the CloudWatch agent configuration.

For Amazon ECS clusters, the configurations are integrated with the Parameter Store of AWS Systems Manager by the secrets in the Amazon ECS task definition:

- The secret `PROMETHEUS_CONFIG_CONTENT` is for the Prometheus scrape configuration.
- The secret `CW_CONFIG_CONTENT` is for the CloudWatch agent configuration.

To scrape additional Prometheus metrics sources and import those metrics to CloudWatch, you modify both the Prometheus scrape configuration and the CloudWatch agent configuration, and then re-deploy the agent with the updated configuration.

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Prometheus scrape configuration

The CloudWatch agent supports the standard Prometheus scrape configurations as documented in <scrape_config> in the Prometheus documentation. You can edit this section to update the configurations that are already in this file, and add additional Prometheus scraping targets. By default, the sample configuration file contains the following global configuration lines:

```
global:
  scrape_interval: 1m
```

```
  scrape_timeout: 10s
```

- **scrape_interval**— Defines how frequently to scrape targets.
- **scrape_timeout**— Defines how long to wait before a scrape request times out.

You can also define different values for these settings at the job level, to override the global configurations.

Prometheus scraping jobs

The CloudWatch agent YAML files already have some default scraping jobs configured. For example, in the YAML files for Amazon ECS such as `cwagent-ecs-prometheus-metric-for-bridge-host.yaml`, the default scraping jobs are configured in the `ecs_service_discovery` section.

```
"ecs_service_discovery": {
                  "sd_frequency": "1m",
                  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
                  "docker_label": {
                  },
                  "task_definition_list": [
                    {
                      "sd_job_name": "ecs-appmesh-colors",
                      "sd_metrics_ports": "9901",
                      "sd_task_definition_arn_pattern": ".*:task-definition\/.*-
ColorTeller-(white):[0-9]+",
                      "sd_metrics_path": "/stats/prometheus"
                    },
                    {
                      "sd_job_name": "ecs-appmesh-gateway",
                      "sd_metrics_ports": "9901",
                      "sd_task_definition_arn_pattern": ".*:task-definition/.*-
ColorGateway:[0-9]+",
                      "sd_metrics_path": "/stats/prometheus"
                    }
                  ]
                }
```

Each of these default targets are scraped, and the metrics are sent to CloudWatch in log events using embedded metric format. For more information, see Embedding metrics within logs.

Log events from Amazon ECS clusters are stored in the **/aws/ecs/containerinsights/*cluster_name*/prometheus** log group.

Each scraping job is contained in a different log stream in this log group.

To add a new scraping target, you add a new entry in the `task_definition_list` section under the `ecs_service_discovery` section. of the YAML file, and restart the agent. For an example of this process, see Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics.

CloudWatch agent configuration for Prometheus

The CloudWatch agent configuration file has a `prometheus` section under `metrics_collected` for the Prometheus scraping configuration. It includes the following configuration options:

- **cluster_name**— specifies the cluster name to be added as a label in the log event. This field is optional. If you omit it, the agent can detect the Amazon ECS cluster name.
- **log_group_name**— specifies the log group name for the scraped Prometheus metrics. This field is optional. If you omit it, CloudWatch uses **/aws/ecs/containerinsights/*cluster_name*/prometheus** for logs from Amazon ECS clusters.
- **prometheus_config_path**— specifies the Prometheus scrape configuration file path. If the value of this field starts with `env:` the Prometheus scrape configuration file contents will be retrieved from the container's environment variable. Do not change this field.
- **ecs_service_discovery**— is the section to specify the configurations of the Amazon ECS Prometheus target auto-discovery functions. Two modes are supported to discover the Prometheus targets: discovery based on the container's Docker label or discovery based on the Amazon ECS task definition ARN regular expression. You can use the two modes together and the CloudWatch agent will de-duplicate the discovered targets based on: *{private_ip}:{port}/{metrics_path}*.

  The `ecs_service_discovery` section can contain the following fields:

  - `sd_frequency` is the frequency to discover the Prometheus exporters. Specify a number and a unit suffix. For example, `1m` for once per minute or `30s` for once per 30 seconds. Valid unit suffixes are `ns`, `us`, `ms`, `s`, `m`, and `h`.

    This field is optional. The default is 60 seconds (1 minute).

- `sd_target_cluster` is the target Amazon ECS cluster name for auto-discovery. This field is optional. The default is the name of the Amazon ECS cluster where the CloudWatch agent is installed.
- `sd_cluster_region` is the target Amazon ECS cluster's Region. This field is optional. The default is the Region of the Amazon ECS cluster where the CloudWatch agent is installed. .
- `sd_result_file` is the path of the YAML file for the Prometheus target results. The Prometheus scrape configuration will refer to this file.
- `docker_label` is an optional section that you can use to specify the configuration for Docker label-based service discovery. If you omit this section, Docker label-based discovery is not used. This section can contain the following fields:
  - `sd_port_label` is the container's docker label name that specifies the container port for Prometheus metrics. The default value is `ECS_PROMETHEUS_EXPORTER_PORT`. If the container does not have this Docker label, the CloudWatch agent will skip it.
  - `sd_metrics_path_label` is the container's docker label name that specifies the Prometheus metrics path. The default value is `ECS_PROMETHEUS_METRICS_PATH`. If the container does not have this Docker label, the agent assumes the default path `/metrics`.
  - `sd_job_name_label` is the container's docker label name that specifies the Prometheus scrape job name. The default value is `job`. If the container does not have this docker label, the CloudWatch agent uses the job name in the Prometheus scrape configuration.
- `task_definition_list` is an optional section that you can use to specify the configuration of task definition-based service discovery. If you omit this section, task definition-based discovery is not used. This section can contain the following fields:
  - `sd_task_definition_arn_pattern` is the pattern to use to specify the Amazon ECS task definitions to discover. This is a regular expression.
  - `sd_metrics_ports` lists the containerPort for the Prometheus metrics. Separate the containerPorts with semicolons.
  - `sd_container_name_pattern` specifies the Amazon ECS task container names. This is a regular expression.
  - `sd_metrics_path` specifies the Prometheus metric path. If you omit this, the agent assumes the default path `/metrics`
  - `sd_job_name` specifies the Prometheus scrape job name. If you omit this field, the CloudWatch agent uses the job name in the Prometheus scrape configuration.

- `service_name_list_for_tasks` is an optional section that you can use to specify the configuration of service name-based discovery. If you omit this section, service name-based discovery is not used. This section can contain the following fields:
  - `sd_service_name_pattern` is the pattern to use to specify the Amazon ECS service where tasks are to be discovered. This is a regular expression.
  - `sd_metrics_ports` Lists the `containerPort` for the Prometheus metrics. Separate multiple `containerPorts` with semicolons.
  - `sd_container_name_pattern` specifies the Amazon ECS task container names. This is a regular expression.
  - `sd_metrics_path` specifies the Prometheus metrics path. If you omit this, the agent assumes that the default path `/metrics`.
  - `sd_job_name` specifies the Prometheus scrape job name. If you omit this field, the CloudWatch agent uses the job name in the Prometheus scrape configuration.
- **metric_declaration**— are sections that specify the array of logs with embedded metric format to be generated. There are `metric_declaration` sections for each Prometheus source that the CloudWatch agent imports from by default. These sections each include the following fields:
  - `label_matcher` is a regular expression that checks the value of the labels listed in `source_labels`. The metrics that match are enabled for inclusion in the embedded metric format sent to CloudWatch.

    If you have multiple labels specified in `source_labels`, we recommend that you do not use `^` or `$` characters in the regular expression for `label_matcher`.
  - `source_labels` specifies the value of the labels that are checked by the `label_matcher` line.
  - `label_separator` specifies the separator to be used in the `label_matcher` line if multiple `source_labels` are specified. The default is `;`. You can see this default used in the `label_matcher` line in the following example.
  - `metric_selectors` is a regular expression that specifies the metrics to be collected and sent to CloudWatch.
  - `dimensions` is the list of labels to be used as CloudWatch dimensions for each selected metric.

See the following `metric_declaration` example.

```
"metric_declaration": [
  {
     "source_labels":[ "Service", "Namespace"],
     "label_matcher":"(.*node-exporter.*|.*kube-dns.*);kube-system$",
     "dimensions":[
        ["Service", "Namespace"]
     ],
     "metric_selectors":[
        "^coredns_dns_request_type_count_total$"
     ]
  }
]
```

This example configures an embedded metric format section to be sent as a log event if the following conditions are met:

- The value of `Service` contains either `node-exporter` or `kube-dns`.
- The value of `Namespace` is `kube-system`.
- The Prometheus metric `coredns_dns_request_type_count_total` contains both `Service` and `Namespace` labels.

The log event that is sent includes the following highlighted section:

```
{
   "CloudWatchMetrics":[
      {
         "Metrics":[
            {
               "Name":"coredns_dns_request_type_count_total"
            }
         ],
         "Dimensions":[
            [
               "Namespace",
               "Service"
            ]
         ],
         "Namespace":"ContainerInsights/Prometheus"
      }
   ],
   "Namespace":"kube-system",
```

```
    "Service":"kube-dns",
    "coredns_dns_request_type_count_total":2562,
    "eks_amazonaws_com_component":"kube-dns",
    "instance":"192.168.61.254:9153",
    "job":"kubernetes-service-endpoints",
    ...
}
```

Detailed guide for autodiscovery on Amazon ECS clusters

Prometheus provides dozens of dynamic service-discovery mechanisms as described in <scrape_config>. However there is no built-in service discovery for Amazon ECS. The CloudWatch agent adds this mechanism.

When the Amazon ECS Prometheus service discovery is enabled, the CloudWatch agent periodically makes the following API calls to Amazon ECS and Amazon EC2 frontends to retrieve the metadata of the running ECS tasks in the target ECS cluster.

```
EC2:DescribeInstances
ECS:ListTasks
ECS:ListServices
ECS:DescribeContainerInstances
ECS:DescribeServices
ECS:DescribeTasks
ECS:DescribeTaskDefinition
```

The metadata is used by the CloudWatch agent to scan the Prometheus targets within the ECS cluster. The CloudWatch agent supports three service discovery modes:

- Container Docker label-based service discovery
- ECS task definition ARN regular expression-based service discovery
- ECS service name regular expression-based service discovery

All modes can be used together. CloudWatch agent de-duplicates the discovered targets based on: `{private_ip}:{port}/{metrics_path}`.

All discovered targets are written into a result file specified by the `sd_result_file` configuration field within the CloudWatch agent container. The following is a sample result file:

```
- targets:
```

```
  - 10.6.1.95:32785
  labels:
    __metrics_path__: /metrics
    ECS_PROMETHEUS_EXPORTER_PORT: "9406"
    ECS_PROMETHEUS_JOB_NAME: demo-jar-ec2-bridge-dynamic
    ECS_PROMETHEUS_METRICS_PATH: /metrics
    InstanceType: t3.medium
    LaunchType: EC2
    SubnetId: subnet-123456789012
    TaskDefinitionFamily: demo-jar-ec2-bridge-dynamic-port
    TaskGroup: family:demo-jar-ec2-bridge-dynamic-port
    TaskRevision: "7"
    VpcId: vpc-01234567890
    container_name: demo-jar-ec2-bridge-dynamic-port
    job: demo-jar-ec2-bridge-dynamic
- targets:
  - 10.6.3.193:9404
  labels:
    __metrics_path__: /metrics
    ECS_PROMETHEUS_EXPORTER_PORT_SUBSET_B: "9404"
    ECS_PROMETHEUS_JOB_NAME: demo-tomcat-ec2-bridge-mapped-port
    ECS_PROMETHEUS_METRICS_PATH: /metrics
    InstanceType: t3.medium
    LaunchType: EC2
    SubnetId: subnet-123456789012
    TaskDefinitionFamily: demo-tomcat-ec2-bridge-mapped-port
    TaskGroup: family:demo-jar-tomcat-bridge-mapped-port
    TaskRevision: "12"
    VpcId: vpc-01234567890
    container_name: demo-tomcat-ec2-bridge-mapped-port
    job: demo-tomcat-ec2-bridge-mapped-port
```

You can directly integrate this result file with Prometheus file-based service discovery. For more information about Prometheus file-based service discovery, see <file_sd_config>.

Suppose the result file is written to `/tmp/cwagent_ecs_auto_sd.yaml` The following Prometheus scrape configuration will consume it.

```
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: cwagent-ecs-file-sd-config
```

```
    sample_limit: 10000
    file_sd_configs:
      - files: [ "/tmp/cwagent_ecs_auto_sd.yaml" ]
```

The CloudWatch agent also adds the following additional labels for the discovered targets.

- `container_name`
- `TaskDefinitionFamily`
- `TaskRevision`
- `TaskGroup`
- `StartedBy`
- `LaunchType`
- `job`
- `__metrics_path__`
- Docker labels

When the cluster has the EC2 launch type, the following three labels are added.

- `InstanceType`
- `VpcId`
- `SubnetId`

> **Note**
>
> Docker labels that don't match the regular expression `[a-zA-Z_][a-zA-Z0-9_]*` are filtered out. This matches the Prometheus conventions as listed in `label_name` in Configuration file in the Prometheus documentation.

ECS service discovery configuration examples

This section includes examples that demonstrate ECS service discovery.

Example 1

```
"ecs_service_discovery": {
```

```
  "sd_frequency": "1m",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "docker_label": {
  }
}
```

This example enables Docker label-based service discovery. The CloudWatch agent will query the ECS tasks' metadata once per minute and write the discovered targets into the `/tmp/cwagent_ecs_auto_sd.yaml` file within the CloudWatch agent container.

The default value of `sd_port_label` in the `docker_label` section is `ECS_PROMETHEUS_EXPORTER_PORT`. If any running container in the ECS tasks has a `ECS_PROMETHEUS_EXPORTER_PORT` docker label, the CloudWatch agent uses its value as `container port` to scan all exposed ports of the container. If there is a match, the mapped host port plus the private IP of the container are used to construct the Prometheus exporter target in the following format: `private_ip:host_port`.

The default value of `sd_metrics_path_label` in the `docker_label` section is `ECS_PROMETHEUS_METRICS_PATH`. If the container has this Docker label, its value will be used as the `__metrics_path__` . If the container does not have this label, the default value `/metrics` is used.

The default value of `sd_job_name_label` in the `docker_label` section is `job`. If the container has this Docker label, its value will be appended as one of the labels for the target to replace the default job name specified in the Prometheus configuration. The value of this Docker label is used as the log stream name in the CloudWatch Logs log group.

Example 2

```
"ecs_service_discovery": {
  "sd_frequency": "15s",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "docker_label": {
    "sd_port_label": "ECS_PROMETHEUS_EXPORTER_PORT_SUBSET_A",
    "sd_job_name_label": "ECS_PROMETHEUS_JOB_NAME"
  }
}
```

This example enables Docker label-based service discovery. THe CloudWatch agent will query the ECS tasks' metadata every 15 seconds and write the discovered targets into the `/tmp/`

cwagent_ecs_auto_sd.yaml file within the CloudWatch agent container. The containers with a Docker label of ECS_PROMETHEUS_EXPORTER_PORT_SUBSET_A will be scanned. The value of the docker label ECS_PROMETHEUS_JOB_NAME is used as the job name.

Example 3

```
"ecs_service_discovery": {
  "sd_frequency": "5m",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "task_definition_list": [
    {
      "sd_job_name": "java-prometheus",
      "sd_metrics_path": "/metrics",
      "sd_metrics_ports": "9404; 9406",
      "sd_task_definition_arn_pattern": ".*:task-definition/.*javajmx.*:[0-9]+"
    },
    {
      "sd_job_name": "envoy-prometheus",
      "sd_metrics_path": "/stats/prometheus",
      "sd_container_name_pattern": "^envoy$",
      "sd_metrics_ports": "9901",
      "sd_task_definition_arn_pattern": ".*:task-definition/.*appmesh.*:23"
    }
  ]
}
```

This example enables ECS task definition ARN regular expression-based service discovery. The CloudWatch agent will query the ECS tasks' metadata every five minutes and write the discovered targets into the /tmp/cwagent_ecs_auto_sd.yaml file within the CloudWatch agent container.

Two task definition ARN regular expresion sections are defined:

- For the first section, the ECS tasks with javajmx in their ECS task definition ARN are filtered for the container port scan. If the containers within these ECS tasks expose the container port on 9404 or 9406, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value of sd_metrics_path sets __metrics_path__ to /metrics. So the CloudWatch agent will scrape the Prometheus metrics from private_ip:host_port/metrics, the scraped metrics are sent to the java-prometheus log stream in CloudWatch Logs in the log group /aws/ecs/containerinsights/cluster_name/prometheus.

- For the second section, the ECS tasks with `appmesh` in their ECS task definition ARN and with `version` of `:23` are filtered for the container port scan. For containers with a name of `envoy` that expose the container port on `9901`, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value within these ECS tasks expose the container port on 9404 or 9406, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value of `sd_metrics_path` sets `__metrics_path__` to `/stats/prometheus`. So the CloudWatch agent will scrape the Prometheus metrics from `private_ip:host_port/stats/prometheus`, and send the scraped metrics to the `envoy-prometheus` log stream in CloudWatch Logs in the log group `/aws/ecs/containerinsights/cluster_name/prometheus`.

Example 4

```
"ecs_service_discovery": {
  "sd_frequency": "5m",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "service_name_list_for_tasks": [
    {
      "sd_job_name": "nginx-prometheus",
      "sd_metrics_path": "/metrics",
      "sd_metrics_ports": "9113",
      "sd_service_name_pattern": "^nginx-.*"
    },
    {
      "sd_job_name": "haproxy-prometheus",
      "sd_metrics_path": "/stats/metrics",
      "sd_container_name_pattern": "^haproxy$",
      "sd_metrics_ports": "8404",
      "sd_service_name_pattern": ".*haproxy-service.*"
    }
  ]
}
```

This example enables ECS service name regular expression-based service discovery. The CloudWatch agent will query the ECS services' metadata every five minutes and write the discovered targets into the `/tmp/cwagent_ecs_auto_sd.yaml` file within the CloudWatch agent container.

Two service name regular expresion sections are defined:

- For the first section, the ECS tasks that are associated with ECS services that have names matching the regular expression `^nginx-.*` are filtered for the container port scan. If the containers within these ECS tasks expose the container port on 9113, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value of `sd_metrics_path` sets `__metrics_path__` to `/metrics`. So the CloudWatch agent will scrape the Prometheus metrics from `private_ip:host_port/metrics`, and the scraped metrics are sent to the `nginx-prometheus` log stream in CloudWatch Logs in the log group `/aws/ecs/containerinsights/cluster_name/prometheus`.
- or the second section, the ECS tasks that are associated with ECS services that have names matching the regular expression `.*haproxy-service.*` are filtered for the container port scan. For containers with a name of `haproxy` expose the container port on 8404, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value of `sd_metrics_path` sets `__metrics_path__` to `/stats/metrics`. So the CloudWatch agent will scrape the Prometheus metrics from `private_ip:host_port/stats/metrics`, and the scraped metrics are sent to the `haproxy-prometheus` log stream in CloudWatch Logs in the log group `/aws/ecs/containerinsights/cluster_name/prometheus`.

Example 5

```
"ecs_service_discovery": {
  "sd_frequency": "1m30s",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "docker_label": {
    "sd_port_label": "MY_PROMETHEUS_EXPORTER_PORT_LABEL",
    "sd_metrics_path_label": "MY_PROMETHEUS_METRICS_PATH_LABEL",
    "sd_job_name_label": "MY_PROMETHEUS_METRICS_NAME_LABEL"
  }
  "task_definition_list": [
    {
      "sd_metrics_ports": "9150",
      "sd_task_definition_arn_pattern": "*memcached.*"
    }
  ]
}
```

This example enables both ECS service discovery modes. The CloudWatch agent will query the ECS tasks' metadata every 90 seconds and write the discovered targets into the `/tmp/cwagent_ecs_auto_sd.yaml` file within the CloudWatch agent container.

For the Docker-based service discovery configuration:

- The ECS tasks with Docker label `MY_PROMETHEUS_EXPORTER_PORT_LABEL` will be filtered for Prometheus port scan. The target Prometheus container port is specified by the value of the label `MY_PROMETHEUS_EXPORTER_PORT_LABEL`.
- The value of the docker label `MY_PROMETHEUS_EXPORTER_PORT_LABEL` is used for `__metrics_path__`. If the container does not have this docker label, the default value `/metrics` is used.
- The value of the docker label `MY_PROMETHEUS_EXPORTER_PORT_LABEL` is used as the job label. If the container does not have this Docker label, the job name defined in the Prometheus configuration is used.

For the ECS task definition ARN regular expression-based service discovery configuration:

- The ECS tasks with `memcached` in the ECS task definition ARN are filtered for container port scan. The target Prometheus container port is 9150 as defined by `sd_metrics_ports`. The default metrics path `/metrics` is used. The job name defined in the Prometheus configuration is used.

(Optional) Set up sample containerized Amazon ECS workloads for Prometheus metric testing

To test the Prometheus metric support in CloudWatch Container Insights, you can set up one or more of the following containerized workloads. The CloudWatch agent with Prometheus support automatically collects metrics from each of these workloads. To see the metrics that are collected by default, see Prometheus metrics collected by the CloudWatch agent.

Sample App Mesh workload for Amazon ECS clusters

To collect metrics from a sample Prometheus workload for Amazon ECS, you must be running Container Insights in the cluster. For information about installing Container Insights, see Amazon ECS.

First, follow this walkthrough to deploy the sample color app on your Amazon ECS cluster. After you finish, you will have App Mesh Prometheus metrics exposed on port 9901.

Next, follow these steps to install the CloudWatch agent with Prometheus monitoring on the same Amazon ECS cluster where you installed the color app. The steps in this section install the CloudWatch agent in bridge network mode.

The environment variables `ENVIRONMENT_NAME`, `AWS_PROFILE`, and `AWS_DEFAULT_REGION` that you set in the walkthrough will also be used in the following steps.

To install the CloudWatch agent with Prometheus monitoring for testing

1. Download the CloudFormation template by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/
cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-
bridge-host.yaml
```

2. Set the network mode by entering the following commands.

```
export ECS_CLUSTER_NAME=${ENVIRONMENT_NAME}
export ECS_NETWORK_MODE=bridge
```

3. Create the CloudFormation stack by entering the following commands.

```
aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=${ECS_CLUSTER_NAME} \
                 ParameterKey=CreateIAMRoles,ParameterValue=True \
                 ParameterKey=ECSNetworkMode,ParameterValue=${ECS_NETWORK_MODE} \
                 ParameterKey=TaskRoleName,ParameterValue=CWAgent-Prometheus-
TaskRole-${ECS_CLUSTER_NAME} \
```

```
                  ParameterKey=ExecutionRoleName,ParameterValue=CWAgent-Prometheus-
ExecutionRole-${ECS_CLUSTER_NAME} \
    --capabilities CAPABILITY_NAMED_IAM \
    --region ${AWS_DEFAULT_REGION} \
    --profile ${AWS_PROFILE}
```

4. (Optional) When the CloudFormation stack is created, you see a `CREATE_COMPLETE` message. If you to check the status before you see that message, enter the following command.

```
aws cloudformation describe-stacks \
--stack-name CWAgent-Prometheus-ECS-${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
--query 'Stacks[0].StackStatus' \
--region ${AWS_DEFAULT_REGION} \
--profile ${AWS_PROFILE}
```

Troubleshooting

The steps in the walkthrough use jq to parse the output result of the AWS CLI. For more information about installing jq, see jq. Use the following command to set the default output format of your AWS CLI to JSON so jq can parse it correctly.

```
$ aws configure
```

When the response gets to `Default output format`, enter **`json`**.

Uninstall the CloudWatch agent with Prometheus monitoring

When you are finished testing, enter the following command to uninstall the CloudWatch agent by deleting the CloudFormation stack.

```
aws cloudformation delete-stack \
--stack-name CWAgent-Prometheus-ECS-${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
--region ${AWS_DEFAULT_REGION} \
--profile ${AWS_PROFILE}
```

Sample Java/JMX workload for Amazon ECS clusters

JMX Exporter is an official Prometheus exporter that can scrape and expose JMX mBeans as Prometheus metrics. For more information, see prometheus/jmx_exporter.

The CloudWatch agent with Prometheus support scrapes the Java/JMX Prometheus metrics based on the service discovery configuration in the Amazon ECS cluster. You can configure the JMX Exporter to expose the metrics on a different port or metrics_path. If you do change the port or path, update the default `ecs_service_discovery` section in the CloudWatch agent configuration.

To collect metrics from a sample Prometheus workload for Amazon ECS, you must be running Container Insights in the cluster. For information about installing Container Insights, see Amazon ECS.

To install the Java/JMX sample workload for Amazon ECS clusters

1. Follow the steps in these sections to create your Docker images.
   - Example: Java Jar Application Docker image with Prometheus metrics
   - Example: Apache Tomcat Docker image with Prometheus metrics
2. Specify the following two Docker labels in the Amazon ECS task definition file. You can then run the task definition as an Amazon ECS service or Amazon ECS task in the cluster.
   - Set `ECS_PROMETHEUS_EXPORTER_PORT` to point to the containerPort where the Prometheus metrics are exposed.
   - Set `Java_EMF_Metrics` to `true`. The CloudWatch agent uses this flag to generated the embedded metric format in the log event.

   The following is an example:

```
{
  "family": "workload-java-ec2-bridge",
  "taskRoleArn": "{{task-role-arn}}",
  "executionRoleArn": "{{execution-role-arn}}",
  "networkMode": "bridge",
  "containerDefinitions": [
    {
      "name": "tomcat-prometheus-workload-java-ec2-bridge-dynamic-port",
      "image": "your_docker_image_tag_for_tomcat_with_prometheus_metrics",
      "portMappings": [
        {
          "hostPort": 0,
          "protocol": "tcp",
          "containerPort": 9404
```

```
        }
      ],
      "dockerLabels": {
        "ECS_PROMETHEUS_EXPORTER_PORT": "9404",
        "Java_EMF_Metrics": "true"
      }
    }
  ],
  "requiresCompatibilities": [
    "EC2"  ],
  "cpu": "256",
  "memory": "512"
  }
```

The default setting of the CloudWatch agent in the CloudFormation template enables both docker label-based service discovery and task definition ARN-based service discovery. To view these default settings, see line 65 of the CloudWatch agent YAML configuration file. The containers with the `ECS_PROMETHEUS_EXPORTER_PORT` label will be auto-discovered based on the specified container port for Prometheus scraping.

The default setting of the CloudWatch agent also has the `metric_declaration` setting for Java/JMX at line 112 of the same file. All Docker labels of the target containers will be added as additional labels in the Prometheus metrics and sent to CloudWatch Logs. For the Java/JMX containers with Docker label `Java_EMF_Metrics="true"`, the embedded metric format will be generated.

Sample NGINX workload for Amazon ECS clusters

The NGINX Prometheus exporter can scrape and expose NGINX data as Prometheus metrics. This example uses the exporter in tandem with the NGINX reverse proxy service for Amazon ECS.

For more information about the NGINX Prometheus exporter, see nginx-prometheus-exporter on Github. For more information about the NGINX reverse proxy, see ecs-nginx-reverse-proxy on Github.

The CloudWatch agent with Prometheus support scrapes the NGINX Prometheus metrics based on the service discovery configuration in the Amazon ECS cluster. You can configure the NGINX Prometheus Exporter to expose the metrics on a different port or path. If you change the port or path, update the `ecs_service_discovery` section in the CloudWatch agent configuration file.

Install the NGINX reverse proxy sample workload for Amazon ECS clusters

Follow these steps to install the NGINX reverse proxy sample workload.

Create the Docker images

To create the Docker images for the NGINX reverse proxy sample workload

1. Download the following folder from the NGINX reverse proxy repo: https://github.com/awslabs/ecs-nginx-reverse-proxy/tree/master/reverse-proxy/.
2. Find the app directory and build an image from that directory:

```
docker build -t web-server-app ./path-to-app-directory
```

3. Build a custom image for NGINX. First, create a directory with the following two files:

   - A sample Dockerfile:

```
FROM nginx
COPY nginx.conf /etc/nginx/nginx.conf
```

   - An `nginx.conf` file, modified from https://github.com/awslabs/ecs-nginx-reverse-proxy/tree/master/reverse-proxy/:

```
events {
  worker_connections 768;
}

http {
  # Nginx will handle gzip compression of responses from the app server
  gzip on;
  gzip_proxied any;
  gzip_types text/plain application/json;
  gzip_min_length 1000;

  server{
    listen 8080;
    location /stub_status {
        stub_status   on;
    }
  }
```

```
  server {
    listen 80;

    # Nginx will reject anything not matching /api
    location /api {
      # Reject requests with unsupported HTTP method
      if ($request_method !~ ^(GET|POST|HEAD|OPTIONS|PUT|DELETE)$) {
        return 405;
      }

      # Only requests matching the whitelist expectations will
      # get sent to the application server
      proxy_pass http://app:3000;
      proxy_http_version 1.1;
      proxy_set_header Upgrade $http_upgrade;
      proxy_set_header Connection 'upgrade';
      proxy_set_header Host $host;
      proxy_set_header X-Forwarded-For $proxy_add_x_forwarded_for;
      proxy_cache_bypass $http_upgrade;
    }
  }
}
```

> **Note**
>
> `stub_status` must be enabled on the same port that `nginx-prometheus-exporter` is configured to scrape metrics from. In our example task definition, `nginx-prometheus-exporter` is configured to scrape metrics from port 8080.

4. Build an image from files in your new directory:

```
docker build -t nginx-reverse-proxy ./path-to-your-directory
```

5. Upload your new images to an image repository for later use.

Create the task definition to run NGINX and the web server app in Amazon ECS

Next, you set up the task definition.

This task definition enables the collection and export of NGINX Prometheus metrics. The NGINX container tracks input from the app, and exposes that data to port 8080, as set in `nginx.conf`.

The NGINX prometheus exporter container scrapes these metrics, and posts them to port 9113, for use in CloudWatch.

To set up the task definition for the NGINX sample Amazon ECS workload

1. Create a task definition JSON file with the following content. Replace *your-customized-nginx-iamge* with the image URI for your customized NGINX image, and replace *your-web-server-app-image* with the image URI for your web server app image.

```
{
  "containerDefinitions": [
    {
      "name": "nginx",
      "image": "your-customized-nginx-image",
      "memory": 256,
      "cpu": 256,
      "essential": true,
      "portMappings": [
        {
          "containerPort": 80,
          "protocol": "tcp"
        }
      ],
      "links": [
        "app"
      ]
    },
    {
      "name": "app",
      "image": "your-web-server-app-image",
      "memory": 256,
      "cpu": 256,
      "essential": true
    },
    {
      "name": "nginx-prometheus-exporter",
      "image": "docker.io/nginx/nginx-prometheus-exporter:0.8.0",
      "memory": 256,
      "cpu": 256,
      "essential": true,
      "command": [
        "-nginx.scrape-uri",
        "http://nginx:8080/stub_status"
```

```
    ],
    "links":[
      "nginx"
    ],
      "portMappings":[
        {
          "containerPort": 9113,
          "protocol": "tcp"
        }
      ]
    }
  ],
  "networkMode": "bridge",
  "placementConstraints": [],
  "family": "nginx-sample-stack"
}
```

2. Register the task definition by entering the following command.

```
aws ecs register-task-definition --cli-input-json file://path-to-your-task-definition-json
```

3. Create a service to run the task by entering the following command:

   Be sure not to change the service name. You will be running a CloudWatch agent service using a configuration that searches for tasks using the name patterns of the services that started them. For example, for the CloudWatch agent to find the task launched by this command, you can specify the value of `sd_service_name_pattern` to be `^nginx-service$`. The next section provides more details.

```
aws ecs create-service \
 --cluster your-cluster-name \
 --service-name nginx-service \
 --task-definition nginx-sample-stack:1 \
 --desired-count 1
```

Configure the CloudWatch agent to scrape NGINX Prometheus metrics

The final step is to configure the CloudWatch agent to scrape the NGINX metrics. In this example, the CloudWatch agent discovers the task through the service name pattern, and the port 9113, where the exporter exposes the prometheus metrics for NGINX. With the task discovered and the

metrics available, the CloudWatch agent begins posting the collected metrics to the log stream **nginx-prometheus-exporter**.

To configure the CloudWatch agent to scrape the NGINX metrics

1. Download the latest version of the necessary YAML file by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-bridge-host.yaml
```

2. Open the file with a text editor, and find the full CloudWatch agent confguration in the `value` key in the `resource:CWAgentConfigSSMParameter` section. Then, in the `ecs_service_discovery` section, add the following `service_name_list_for_tasks` section.

```
"service_name_list_for_tasks": [
  {
    "sd_job_name": "nginx-prometheus-exporter",
    "sd_metrics_path": "/metrics",
    "sd_metrics_ports": "9113",
    "sd_service_name_pattern": "^nginx-service$"
   }
],
```

3. In the same file, add the following section in the `metric_declaration` section to allow NGINX metrics. Be sure to follow the existing indentation pattern.

```
{
  "source_labels": ["job"],
  "label_matcher": ".*nginx.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily", "ServiceName"]],
  "metric_selectors": [
    "^nginx_.*$"
  ]
},
```

4. If you don't already have the CloudWatch agent deployed in this cluster, skip to step 8.

   If you already have the CloudWatch agent deployed in the Amazon ECS cluster by using AWS CloudFormation, you can create a change set by entering the following commands:

```
ECS_CLUSTER_NAME=your_cluster_name
AWS_REGION=your_aws_region
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION \
    --change-set-name nginx-scraping-support
```

5. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.

6. Revew the newly-created changeset **nginx-scraping-support**. You should see one change applied to the **CWAgentConfigSSMParameter** resource. Run the changeset and restart the CloudWatch agent task by entering the following command:

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 0 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

7. Wait about 10 seconds, and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

8. If you are installing the CloudWatch agent with Prometheus metric collecting on the cluster for the first time, enter the following commands.

```
ECS_CLUSTER_NAME=your_cluster_name
```

```
AWS_REGION=your_aws_region
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION
```

Viewing your NGINX metrics and logs

You can now view the NGINX metrics being collected.

To view the metrics for your sample NGINX workload

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the Region where your cluster is running, choose **Metrics** in the left navigation pane. Find the **ContainerInsights/Prometheus** namespace to see the metrics.
3. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group **/aws/containerinsights/*your_cluster_name*/prometheus**, in the log stream *nginx-prometheus-exporter*.

Sample NGINX Plus workload for Amazon ECS clusters

NGINX Plus is the commerical version of NGINX. You must have a licence to use it. For more information, see NGINX Plus

The NGINX Prometheus exporter can scrape and expose NGINX data as Prometheus metrics. This example uses the exporter in tandem with the NGINX Plus reverse proxy service for Amazon ECS.

For more information about the NGINX Prometheus exporter, see nginx-prometheus-exporter on Github. For more information about the NGINX reverse proxy, see ecs-nginx-reverse-proxy on Github.

The CloudWatch agent with Prometheus support scrapes the NGINX Plus Prometheus metrics based on the service discovery configuration in the Amazon ECS cluster. You can configure the NGINX Prometheus Exporter to expose the metrics on a different port or path. If you change the port or path, update the `ecs_service_discovery` section in the CloudWatch agent configuration file.

Install the NGINX Plus reverse proxy sample workload for Amazon ECS clusters

Follow these steps to install the NGINX reverse proxy sample workload.

Create the Docker images

To create the Docker images for the NGINX Plus reverse proxy sample workload

1. Download the following folder from the NGINX reverse proxy repo: https://github.com/awslabs/ecs-nginx-reverse-proxy/tree/master/reverse-proxy/.
2. Find the app directory and build an image from that directory:

   ```
   docker build -t web-server-app ./path-to-app-directory
   ```

3. Build a custom image for NGINX Plus. Before you can build the image for NGINX Plus, you need to obtain the key named `nginx-repo.key` and the SSL certificate `nginx-repo.crt` for your licensed NGINX Plus. Create a directory and store in it your `nginx-repo.key` and `nginx-repo.crt` files.

   In the directory that you just created, create the following two files:

   - A sample Dockerfile with the following content. This Docker file is adopted from a sample file provided at https://docs.nginx.com/nginx/admin-guide/installing-nginx/installing-nginx-docker/#docker_plus_image. The important change that we make is that we load a separate file, called `nginx.conf`, which will be created in the next step.

     ```
     FROM debian:buster-slim

     LABEL maintainer="NGINX Docker Maintainers <docker-maint@nginx.com>"

     # Define NGINX versions for NGINX Plus and NGINX Plus modules
     ```

```
# Uncomment this block and the versioned nginxPackages block in the main RUN
# instruction to install a specific release
# ENV NGINX_VERSION 21
# ENV NJS_VERSION 0.3.9
# ENV PKG_RELEASE 1~buster

# Download certificate and key from the customer portal (https://cs.nginx.com
 (https://cs.nginx.com/))
# and copy to the build context
COPY nginx-repo.crt /etc/ssl/nginx/
COPY nginx-repo.key /etc/ssl/nginx/
# COPY nginx.conf /etc/ssl/nginx/nginx.conf

RUN set -x \
# Create nginx user/group first, to be consistent throughout Docker variants
&& addgroup --system --gid 101 nginx \
&& adduser --system --disabled-login --ingroup nginx --no-create-home --home /
nonexistent --gecos "nginx user" --shell /bin/false --uid 101 nginx \
&& apt-get update \
&& apt-get install --no-install-recommends --no-install-suggests -y ca-
certificates gnupg1 \

```

- An `nginx.conf` file, modified from https://github.com/awslabs/ecs-nginx-reverse-proxy/tree/master/reverse-proxy/nginx.

```
events {
  worker_connections 768;
}

http {
  # Nginx will handle gzip compression of responses from the app server
  gzip on;
  gzip_proxied any;
  gzip_types text/plain application/json;
  gzip_min_length 1000;

  upstream backend {
    zone name 10m;
    server app:3000    weight=2;
    server app2:3000    weight=1;
  }

  server{
    listen 8080;
    location /api {
      api write=on;
    }
  }

  match server_ok {
    status 100-599;
  }

  server {
    listen 80;
    status_zone zone;
    # Nginx will reject anything not matching /api
    location /api {
      # Reject requests with unsupported HTTP method
      if ($request_method !~ ^(GET|POST|HEAD|OPTIONS|PUT|DELETE)$) {
        return 405;
      }

      # Only requests matching the whitelist expectations will
      # get sent to the application server
      proxy_pass http://backend;
      health_check uri=/lorem-ipsum match=server_ok;
      proxy_http_version 1.1;
```

```
        proxy_set_header Upgrade $http_upgrade;
        proxy_set_header Connection 'upgrade';
        proxy_set_header Host $host;
        proxy_set_header X-Forwarded-For $proxy_add_x_forwarded_for;
        proxy_cache_bypass $http_upgrade;
      }
    }
}
```

4. Build an image from files in your new directory:

```
docker build -t nginx-plus-reverse-proxy ./path-to-your-directory
```

5. Upload your new images to an image repository for later use.

Create the task definition to run NGINX Plus and the web server app in Amazon ECS

Next, you set up the task definition.

This task definition enables the collection and export of NGINX Plus Prometheus metrics. The NGINX container tracks input from the app, and exposes that data to port 8080, as set in `nginx.conf`. The NGINX prometheus exporter container scrapes these metrics, and posts them to port 9113, for use in CloudWatch.

To set up the task definition for the NGINX sample Amazon ECS workload

1. Create a task definition JSON file with the following content. Replace *your-customized-nginx-plus-image* with the image URI for your customized NGINX Plus image, and replace *your-web-server-app-image* with the image URI for your web server app image.

```
{
  "containerDefinitions": [
    {
      "name": "nginx",
      "image": "your-customized-nginx-plus-image",
      "memory": 256,
      "cpu": 256,
      "essential": true,
      "portMappings": [
        {
          "containerPort": 80,
          "protocol": "tcp"
```

```
        }
      ],
      "links": [
        "app",
        "app2"
      ]
    },
    {
      "name": "app",
      "image": "your-web-server-app-image",
      "memory": 256,
      "cpu": 128,
      "essential": true
    },
    {
      "name": "app2",
      "image": "your-web-server-app-image",
      "memory": 256,
      "cpu": 128,
      "essential": true
    },
    {
      "name": "nginx-prometheus-exporter",
      "image": "docker.io/nginx/nginx-prometheus-exporter:0.8.0",
      "memory": 256,
      "cpu": 256,
      "essential": true,
      "command": [
        "-nginx.plus",
        "-nginx.scrape-uri",
         "http://nginx:8080/api"
    ],
    "links":[
      "nginx"
    ],
      "portMappings":[
        {
          "containerPort": 9113,
          "protocol": "tcp"
        }
      ]
    }
  ],
  "networkMode": "bridge",
```

```
  "placementConstraints": [],
  "family": "nginx-plus-sample-stack"
}
```

2. Register the task definition:

```
aws ecs register-task-definition --cli-input-json file://path-to-your-task-definition-json
```

3. Create a service to run the task by entering the following command:

```
aws ecs create-service \
 --cluster your-cluster-name \
 --service-name nginx-plus-service \
 --task-definition nginx-plus-sample-stack:1 \
 --desired-count 1
```

Be sure not to change the service name. We will be running a CloudWatch agent service using a configuration that searches for tasks using the name patterns of the services that started them. For example, for the CloudWatch agent to find the task launched by this command, you can specify the value of `sd_service_name_pattern` to be `^nginx-plus-service$`. The next section provides more details.

Configure the CloudWatch agent to scrape NGINX Plus Prometheus metrics

The final step is to configure the CloudWatch agent to scrape the NGINX metrics. In this example, the CloudWatch agent discovers the task through the service name pattern, and the port 9113, where the exporter exposes the prometheus metrics for NGINX. With the task discovered and the metrics available, the CloudWatch agent begins posting the collected metrics to the log stream **nginx-prometheus-exporter**.

To configure the CloudWatch agent to scrape the NGINX metrics

1. Download the latest version of the necessary YAML file by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-bridge-host.yaml
```

2. Open the file with a text editor, and find the full CloudWatch agent confguration in the `value` key in the `resource:CWAgentConfigSSMParameter` section. Then, in the `ecs_service_discovery` section, add the following `service_name_list_for_tasks` section.

```
"service_name_list_for_tasks": [
  {
    "sd_job_name": "nginx-plus-prometheus-exporter",
    "sd_metrics_path": "/metrics",
    "sd_metrics_ports": "9113",
    "sd_service_name_pattern": "^nginx-plus.*"
   }
],
```

3. In the same file, add the following section in the `metric_declaration` section to allow NGINX Plus metrics. Be sure to follow the existing indentation pattern.

```
{
  "source_labels": ["job"],
  "label_matcher": "^nginx-plus.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily", "ServiceName"]],
  "metric_selectors": [
    "^nginxplus_connections_accepted$",
    "^nginxplus_connections_active$",
    "^nginxplus_connections_dropped$",
    "^nginxplus_connections_idle$",
    "^nginxplus_http_requests_total$",
    "^nginxplus_ssl_handshakes$",
    "^nginxplus_ssl_handshakes_failed$",
    "^nginxplus_up$",
    "^nginxplus_upstream_server_health_checks_fails$"
  ]
},
{
  "source_labels": ["job"],
  "label_matcher": "^nginx-plus.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily", "ServiceName",
 "upstream"]],
  "metric_selectors": [
    "^nginxplus_upstream_server_response_time$"
  ]
},
```

```
{
  "source_labels": ["job"],
  "label_matcher": "^nginx-plus.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily", "ServiceName", "code"]],
  "metric_selectors": [
    "^nginxplus_upstream_server_responses$",
    "^nginxplus_server_zone_responses$"
  ]
},
```

4. If you don't already have the CloudWatch agent deployed in this cluster, skip to step 8.

   If you already have the CloudWatch agent deployed in the Amazon ECS cluster by using AWS CloudFormation, you can create a change set by entering the following commands:

```
ECS_CLUSTER_NAME=your_cluster_name
AWS_REGION=your_aws_region
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION \
    --change-set-name nginx-plus-scraping-support
```

5. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.

6. Revew the newly-created changeset **nginx-plus-scraping-support**. You should see one change applied to the **CWAgentConfigSSMParameter** resource. Run the changeset and restrt the CloudWatch agent task by entering the following command:

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 0 \
```

```
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

7. Wait about 10 seconds, and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

8. If you are installing the CloudWatch agent with Prometheus metric collecting on the cluster for the first time, enter the following commands.

```
ECS_CLUSTER_NAME=your_cluster_name
AWS_REGION=your_aws_region
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION
```

Viewing your NGINX Plus metrics and logs

You can now view the NGINX Plus metrics being collected.

To view the metrics for your sample NGINX workload

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the Region where your cluster is running, choose **Metrics** in the left navigation pane. Find the **ContainerInsights/Prometheus** namespace to see the metrics.

3. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group **/aws/containerinsights/*your_cluster_name*/prometheus**, in the log stream *nginx-plus-prometheus-exporter*.

Tutorial for adding a new Prometheus scrape target: Memcached on Amazon ECS

This tutorial provides a hands-on introduction to scrape the Prometheus metrics of a sample Memcached application on an Amazon Amazon ECS cluster with the EC2 launch type. The Memcached Prometheus exporter target will be auto-discovered by the CloudWatch agent by ECS task definition-based service discovery.

Memcached is a general-purpose distributed memory caching system. It is often used to speed up dynamic database-driven websites by caching data and objects in RAM to reduce the number of times an external data source (such as a database or API) must be read. For more infromation, see What is Memcached?

The memchached_exporter (Apache License 2.0) is one of the Prometheus official exporters. By default the memcache_exporter serves on port 0.0.0.0:9150 at `/metrics`.

The Docker images in the following two Docker Hub repositories are used in this tutorial:

- Memcached
- prom/memcached-exporter

Prerequisite

To collect metrics from a sample Prometheus workload for Amazon ECS, you must be running Container Insights in the cluster. For information about installing Container Insights, see Amazon ECS.

Topics

- Set the Amazon ECS EC2 cluster environment variables
- Install the sample Memcached workload
- Configure the CloudWatch agent to scrape Memcached Prometheus metrics
- Viewing your Memcached metrics

Set the Amazon ECS EC2 cluster environment variables

To set the Amazon ECS EC2 cluster environment variables

1. Install the Amazon ECS CLI if you haven't already done so. For more information, see Installing the Amazon ECS CLI.
2. Set the new Amazon ECS cluster name and Region. For example:

```
ECS_CLUSTER_NAME=ecs-ec2-memcached-tutorial
AWS_DEFAULT_REGION=ca-central-1
```

3. (Optional) If you don't already have an Amazon ECS cluster with the EC2 launch type where you want to install the sample Memcached workload and CloudWatch agent, you can create one by entering the following command.

```
ecs-cli up --capability-iam --size 1 \
--instance-type t3.medium \
--cluster $ECS_CLUSTER_NAME \
--region $AWS_REGION
```

The expected result of this command is as follows:

```
WARN[0000] You will not be able to SSH into your EC2 instances without a key pair.
INFO[0000] Using recommended Amazon Linux 2 AMI with ECS Agent 1.44.4 and Docker
 version 19.03.6-ce
INFO[0001] Created cluster                               cluster=ecs-ec2-memcached-
tutorial region=ca-central-1
INFO[0002] Waiting for your cluster resources to be created...
INFO[0002] Cloudformation stack status
 stackStatus=CREATE_IN_PROGRESS
INFO[0063] Cloudformation stack status
 stackStatus=CREATE_IN_PROGRESS
INFO[0124] Cloudformation stack status
 stackStatus=CREATE_IN_PROGRESS
VPC created: vpc-xxxxxxxxxxxxxxxxx
Security Group created: sg-xxxxxxxxxxxxxxxxx
Subnet created: subnet-xxxxxxxxxxxxxxxxx
Subnet created: subnet-xxxxxxxxxxxxxxxxx
Cluster creation succeeded.
```

Install the sample Memcached workload

To install the sample Memcached workload which exposes the Prometheus metrics

1. Download the Memcached CloudFormation template by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/
cwagent-prometheus/sample_traffic/memcached/memcached-traffic-sample.yaml
```

2. Set the IAM role names to be created for Memcached by entering the following commands.

```
MEMCACHED_ECS_TASK_ROLE_NAME=memcached-prometheus-demo-ecs-task-role-name
MEMCACHED_ECS_EXECUTION_ROLE_NAME=memcached-prometheus-demo-ecs-execution-role-name
```

3. Install the sample Memcached workload by entering the following command. This sample installs the workload in `host` network mode.

```
MEMCACHED_ECS_NETWORK_MODE=host

aws cloudformation create-stack --stack-name Memcached-Prometheus-Demo-ECS-
$ECS_CLUSTER_NAME-EC2-$MEMCACHED_ECS_NETWORK_MODE \
    --template-body file://memcached-traffic-sample.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=ECSNetworkMode,ParameterValue=
$MEMCACHED_ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=
$MEMCACHED_ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$MEMCACHED_ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION
```

The CloudFormation stack creates four resources:

- One ECS task role
- One ECS task execution role
- One Memcached task definition
- One Memcached service

In the Memcached task definition, two containers are defined:

- The primary container runs a simple Memcached application and opens port 11211 for access.
- The other container runs the Redis OSS exporter process to expose the Prometheus metrics on port 9150. This is the container to be discovered and scraped by the CloudWatch agent.

Configure the CloudWatch agent to scrape Memcached Prometheus metrics

To configure the CloudWatch agent to scrape Memcached Prometheus metrics

1. Download the latest version of `cwagent-ecs-prometheus-metric-for-awsvpc.yaml` by entering the following command.

   ```
   curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-awsvpc.yaml
   ```

2. Open the file with a text editor, and find the full CloudWatch agent configuration behind the `value` key in the `resource:CWAgentConfigSSMParameter` section.

   Then, in the `ecs_service_discovery` section, add the following configuration into the `task_definition_list` section.

   ```
   {
       "sd_job_name": "ecs-memcached",
       "sd_metrics_ports": "9150",
       "sd_task_definition_arn_pattern": ".*:task-definition/memcached-prometheus-demo.*:[0-9]+"
   },
   ```

   For the `metric_declaration` section, the default setting does not allow any Memcached metrics. Add the following section to allow Memcached metrics. Be sure to follow the existing indentation pattern.

   ```
   {
     "source_labels": ["container_name"],
     "label_matcher": "memcached-exporter-.*",
     "dimensions": [["ClusterName", "TaskDefinitionFamily"]],
     "metric_selectors": [
   ```

```
    "^memcached_current_(bytes|items|connections)$",
    "^memcached_items_(reclaimed|evicted)_total$",
    "^memcached_(written|read)_bytes_total$",
    "^memcached_limit_bytes$",
    "^memcached_commands_total$"
  ]
},
{
  "source_labels": ["container_name"],
  "label_matcher": "memcached-exporter-.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily","status","command"],
 ["ClusterName", "TaskDefinitionFamily","command"]],
  "metric_selectors": [
    "^memcached_commands_total$"
  ]
},
```

3. If you already have the CloudWatch agent deployed in the Amazon ECS cluster by CloudFormation, you can create a change set by entering the following commands.

```
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION \
    --change-set-name memcached-scraping-support
```

4. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.

5. Review the newly created changeset `memcached-scraping-support`. You should see one change applied to the `CWAgentConfigSSMParameter` resource. Execute the changeset and restart the CloudWatch agent task by entering the following commands.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 0 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

6. Wait about 10 seconds, and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

7. If you are installing the CloudWatch agent with Prometheus metric collecting for the cluster for the first time, please enter the following commands:

```
ECS_NETWORK_MODEE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION
```

Viewing your Memcached metrics

This tutorial sends the following metrics to the **ECS/ContainerInsights/Prometheus** namespace in CloudWatch. You can use the CloudWatch console to see the metrics in that namespace.

Metric name	Dimensions
memcached_current_items	ClusterName ,TaskDefinitionFamily
memcached_current_connections	ClusterName ,TaskDefinitionFamily
memcached_limit_bytes	ClusterName ,TaskDefinitionFamily
memcached_current_bytes	ClusterName ,TaskDefinitionFamily
memcached_written_bytes_total	ClusterName ,TaskDefinitionFamily
memcached_read_bytes_total	ClusterName ,TaskDefinitionFamily
memcached_items_evicted_total	ClusterName ,TaskDefinitionFamily
memcached_items_reclaimed_total	ClusterName ,TaskDefinitionFamily
memcached_commands_total	ClusterName ,TaskDefinitionFamily ClusterName ,TaskDefinitionFamily, command ClusterName ,TaskDefinitionFamily, status, command

> **Note**
>
> The value of the **command** dimension can be: `delete`, `get`, `cas`, `set`, `decr`, `touch`, `incr`, or `flush`.
> The value of the **status** dimension can be `hit`, `miss`, or `badval`.

You can also create a CloudWatch dashboard for your Memcached Prometheus metrics.

To create a dashboard for Memcached Prometheus metrics

1. Create environment variables, replacing the values below to match your deployment.

```
DASHBOARD_NAME=your_memcached_cw_dashboard_name
ECS_TASK_DEF_FAMILY=memcached-prometheus-demo-$ECS_CLUSTER_NAME-EC2-
$MEMCACHED_ECS_NETWORK_MOD
```

2. Enter the following command to create the dashboard.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-
container-insights/latest/ecs-task-definition-templates/deployment-mode/
replica-service/cwagent-prometheus/sample_cloudwatch_dashboards/memcached/
cw_dashboard_memcached.json \
| sed "s/{{YOUR_AWS_REGION}}/$AWS_REGION/g" \
| sed "s/{{YOUR_CLUSTER_NAME}}/$ECS_CLUSTER_NAME/g" \
| sed "s/{{YOUR_TASK_DEF_FAMILY}}/$ECS_TASK_DEF_FAMILY/g" \
| xargs -0 aws cloudwatch put-dashboard --dashboard-name ${DASHBOARD_NAME} --region
 $AWS_REGION --dashboard-body
```

Tutorial for scraping Redis OSS Prometheus metrics on Amazon ECS Fargate

This tutorial provides a hands-on introduction to scrape the Prometheus metrics of a sample Redis OSS application in an Amazon ECS Fargate cluster. The Redis OSS Prometheus exporter target will be auto-discovered by the CloudWatch agent with Prometheus metric support based on the container's Docker labels.

Redis OSS (https://redis.io/) is an open source (BSD licensed), in-memory data structure store, used as a database, cache and message broker. For more information, see redis.

redis_exporter (MIT License licensed) is used to expose the Redis OSS prometheus metrics on the specified port (default: 0.0.0.0:9121). For more information, see redis_exporter.

The Docker images in the following two Docker Hub repositories are used in this tutorial:

- redis
- redis_exporter

Prerequisite

To collect metrics from a sample Prometheus workload for Amazon ECS, you must be running Container Insights in the cluster. For information about installing Container Insights, see Amazon ECS.

Topics

- Set the Amazon ECS Fargate cluster environment variable
- Set the network environment variables for the Amazon ECS Fargate cluster
- Install the sample Redis OSS workload
- Configure the CloudWatch agent to scrape Redis OSS Prometheus metrics
- Viewing your Redis OSS metrics

Set the Amazon ECS Fargate cluster environment variable

To set the Amazon ECS Fargate cluster environment variable

1. Install the Amazon ECS CLI if you haven't already done so. For more information, see Installing the Amazon ECS CLI.
2. Set the new Amazon ECS cluster name and Region. For example:

```
ECS_CLUSTER_NAME=ecs-fargate-redis-tutorial
AWS_DEFAULT_REGION=ca-central-1
```

3. (Optional) If you don't already have an Amazon ECS Fargate cluster where you want to install the sample Redis OSS workload and CloudWatch agent, you can create one by entering the following command.

```
ecs-cli up --capability-iam \
```

```
--cluster $ECS_CLUSTER_NAME \
--launch-type FARGATE \
--region $AWS_DEFAULT_REGION
```

The expected result of this command is as follows:

```
INFO[0000] Created cluster   cluster=ecs-fargate-redis-tutorial region=ca-central-1
INFO[0001] Waiting for your cluster resources to be created...
INFO[0001] Cloudformation stack status   stackStatus=CREATE_IN_PROGRESS
VPC created: vpc-xxxxxxxxxxxxxxxx
Subnet created: subnet-xxxxxxxxxxxxxxxx
Subnet created: subnet-xxxxxxxxxxxxxxxx
Cluster creation succeeded.
```

Set the network environment variables for the Amazon ECS Fargate cluster

To set the network environment variables for the Amazon ECS Fargate cluster

1. Set your VPC and subnet ID of the Amazon ECS cluster. If you created a new cluster in the previous procedure, you'll see these values in the result of the final command. Otherwise, use the IDs of the existing cluster that you are going to use with Redis.

   ```
   ECS_CLUSTER_VPC=vpc-xxxxxxxxxxxxxxxxx
   ECS_CLUSTER_SUBNET_1=subnet-xxxxxxxxxxxxxxxxx
   ECS_CLUSTER_SUBNET_2=subnet-xxxxxxxxxxxxxxxxx
   ```

2. In this tutorial, you install the Redis OSS application and the CloudWatch agent in the default security group of the Amazon ECS cluster's VPC. The default security group allows all network connection within the same security group so the CloudWatch agent can scrape the Prometheus metrics exposed on the Redis OSS containers. In a real production environment, you might want to create dedicated security groups for the Redis OSS application and CloudWatch agent and set customized permissions for them.

   Enter the following command to get the default security group ID.

   ```
   aws ec2 describe-security-groups \
   --filters Name=vpc-id,Values=$ECS_CLUSTER_VPC  \
   --region $AWS_DEFAULT_REGION
   ```

Then set the Fargate cluster deafult security group variable by entering the following command, replacing *my-default-security-group* with the value you found from the previous command.

```
ECS_CLUSTER_SECURITY_GROUP=my-default-security-group
```

Install the sample Redis OSS workload

To install the sample Redis OSS workload which exposes the Prometheus metrics

1. Download the Redis OSS CloudFormation template by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/
cwagent-prometheus/sample_traffic/redis/redis-traffic-sample.yaml
```

2. Set the IAM role names to be created for Redis OSS by entering the following commands.

```
REDIS_ECS_TASK_ROLE_NAME=redis-prometheus-demo-ecs-task-role-name
REDIS_ECS_EXECUTION_ROLE_NAME=redis-prometheus-demo-ecs-execution-role-name
```

3. Install the sample Redis OSS workload by entering the following command.

```
aws cloudformation create-stack --stack-name Redis-Prometheus-Demo-ECS-
$ECS_CLUSTER_NAME-fargate-awsvpc \
    --template-body file://redis-traffic-sample.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=SecurityGroupID,ParameterValue=
$ECS_CLUSTER_SECURITY_GROUP \
                 ParameterKey=SubnetID,ParameterValue=$ECS_CLUSTER_SUBNET_1 \
                 ParameterKey=TaskRoleName,ParameterValue=$REDIS_ECS_TASK_ROLE_NAME
 \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$REDIS_ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_DEFAULT_REGION
```

The CloudFormation stack creates four resources:

- One ECS task role
- One ECS task execution role
- One Redis OSS task definition
- One Redis OSS service

In the Redis OSS task definition, two containers are defined:

- The primary container runs a simple Redis OSS application and opens port 6379 for access.
- The other container runs the Redis OSS exporter process to expose the Prometheus metrics on port 9121. This is the container to be discovered and scraped by the CloudWatch agent. The following Docker label is defined so that the CloudWatch agent can discover this container based on it.

```
ECS_PROMETHEUS_EXPORTER_PORT: 9121
```

Configure the CloudWatch agent to scrape Redis OSS Prometheus metrics

To configure the CloudWatch agent to scrape Redis OSS Prometheus metrics

1. Download the latest version of `cwagent-ecs-prometheus-metric-for-awsvpc.yaml` by entering the following command.

   ```
   curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
   insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/
   cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-
   awsvpc.yaml
   ```

2. Open the file with a text editor, and find the full CloudWatch agent configuration behind the `value` key in the `resource:CWAgentConfigSSMParameter` section.

   Then, in the `ecs_service_discovery` section shown here, the `docker_label`-based service discovery is enabled with the default settings which are based on `ECS_PROMETHEUS_EXPORTER_PORT`, which matches the Docker label we defined in the Redis OSS ECS task definition. So we do not need to make any changes in this section:

   ```
   ecs_service_discovery": {
     "sd_frequency": "1m",
   ```

```
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
*  "docker_label": {
  },*
  ...
```

For the `metric_declaration` section, the default setting does not allow any Redis OSS metrics. Add the following section to allow Redis OSS metrics. Be sure to follow the existing indentation pattern.

```
{
  "source_labels": ["container_name"],
  "label_matcher": "^redis-exporter-.*$",
  "dimensions": [["ClusterName","TaskDefinitionFamily"]],
  "metric_selectors": [
    "^redis_net_(in|out)put_bytes_total$",
    "^redis_(expired|evicted)_keys_total$",
    "^redis_keyspace_(hits|misses)_total$",
    "^redis_memory_used_bytes$",
    "^redis_connected_clients$"
  ]
},
{
  "source_labels": ["container_name"],
  "label_matcher": "^redis-exporter-.*$",
  "dimensions": [["ClusterName","TaskDefinitionFamily","cmd"]],
  "metric_selectors": [
    "^redis_commands_total$"
  ]
},
{
  "source_labels": ["container_name"],
  "label_matcher": "^redis-exporter-.*$",
  "dimensions": [["ClusterName","TaskDefinitionFamily","db"]],
  "metric_selectors": [
    "^redis_db_keys$"
  ]
},
```

3. If you already have the CloudWatch agent deployed in the Amazon ECS cluster by CloudFormation, you can create a change set by entering the following commands.

```
ECS_LAUNCH_TYPE=FARGATE
```

```
CREATE_IAM_ROLES=True
ECS_CLUSTER_SUBNET=$ECS_CLUSTER_SUBNET_1
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-
$ECS_CLUSTER_NAME-$ECS_LAUNCH_TYPE-awsvpc \
    --template-body file://cwagent-ecs-prometheus-metric-for-awsvpc.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSLaunchType,ParameterValue=$ECS_LAUNCH_TYPE \
                 ParameterKey=SecurityGroupID,ParameterValue=
$ECS_CLUSTER_SECURITY_GROUP \
                 ParameterKey=SubnetID,ParameterValue=$ECS_CLUSTER_SUBNET \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region ${AWS_DEFAULT_REGION} \
    --change-set-name redis-scraping-support
```

4. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.

5. Review the newly created changeset `redis-scraping-support`. You should see one change applied to the `CWAgentConfigSSMParameter` resource. Execute the changeset and restart the CloudWatch agent task by entering the following commands.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 0 \
--service cwagent-prometheus-replica-service-$ECS_LAUNCH_TYPE-awsvpc \
--region ${AWS_DEFAULT_REGION}
```

6. Wait about 10 seconds, and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service cwagent-prometheus-replica-service-$ECS_LAUNCH_TYPE-awsvpc \
--region ${AWS_DEFAULT_REGION}
```

7. If you are installing the CloudWatch agent with Prometheus metric collecting for the cluster for the first time, please enter the following commands:

```
ECS_LAUNCH_TYPE=FARGATE
```

```
CREATE_IAM_ROLES=True
ECS_CLUSTER_SUBNET=$ECS_CLUSTER_SUBNET_1
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
$ECS_CLUSTER_NAME-$ECS_LAUNCH_TYPE-awsvpc \
    --template-body file://cwagent-ecs-prometheus-metric-for-awsvpc.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSLaunchType,ParameterValue=$ECS_LAUNCH_TYPE \
                 ParameterKey=SecurityGroupID,ParameterValue=
$ECS_CLUSTER_SECURITY_GROUP \
                 ParameterKey=SubnetID,ParameterValue=$ECS_CLUSTER_SUBNET \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region ${AWS_DEFAULT_REGION}
```

Viewing your Redis OSS metrics

This tutorial sends the following metrics to the **ECS/ContainerInsights/Prometheus** namespace in CloudWatch. You can use the CloudWatch console to see the metrics in that namespace.

Metric Name	Dimensions	
redis_net_input_bytes_total	ClusterName, TaskDefinitionFamily	
redis_net_output_bytes_total	ClusterName, TaskDefinitionFamily	
redis_expired_keys_total	ClusterName, TaskDefinitionFamily	

Metric Name	Dimensions	
redis_evicted_keys_total	ClusterName, TaskDefinitionFamily	
redis_keyspace_hits_total	ClusterName, TaskDefinitionFamily	
redis_keyspace_misses_total	ClusterName, TaskDefinitionFamily	
redis_memory_used_bytes	ClusterName, TaskDefinitionFamily	
redis_connected_clients	ClusterName, TaskDefinitionFamily	
redis_commands_total	ClusterName ,TaskDefinitionFamily , cmd	
redis_db_keys	ClusterName ,TaskDefinitionFamily , db	

Note

The value of the **cmd** dimension can be: append, client, command, config, dbsize, flushall, get, incr, info, latency, or slowlog.
The value of the **db** dimension can be db0 to db15.

You can also create a CloudWatch dashboard for your Redis OSS Prometheus metrics.

To create a dashboard for Redis OSS Prometheus metrics

1. Create environment variables, replacing the values below to match your deployment.

```
DASHBOARD_NAME=your_cw_dashboard_name
ECS_TASK_DEF_FAMILY=redis-prometheus-demo-$ECS_CLUSTER_NAME-fargate-awsvpc
```

2. Enter the following command to create the dashboard.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/sample_cloudwatch_dashboards/redis/cw_dashboard_redis.json \
| sed "s/{{YOUR_AWS_REGION}}/${REGION_NAME}/g" \
| sed "s/{{YOUR_CLUSTER_NAME}}/${CLUSTER_NAME}/g" \
| sed "s/{{YOUR_NAMESPACE}}/${NAMESPACE}/g" \
```

Set up and configure Prometheus metrics collection on Amazon EKS and Kubernetes clusters

To collect Prometheus metrics from clusters running Amazon EKS or Kubernetes, you can use the CloudWatch agent as a collector or use the AWS Distro for OpenTelemetry collector. For information about using the AWS Distro for OpenTelemetry collector, see https://aws-otel.github.io/docs/getting-started/container-insights/eks-prometheus.

The following sections explain how to collect Prometheus metrics using the CloudWatch agent. They explain how to install the CloudWatch agent with Prometheus monitoring on clusters running Amazon EKS or Kubernetes, and how to configure the agent to scrape additional targets. They also provide optional tutorials for setting up sample workloads to use for testing with Prometheus monitoring.

Topics

- Install the CloudWatch agent with Prometheus metrics collection on Amazon EKS and Kubernetes clusters

Install the CloudWatch agent with Prometheus metrics collection on Amazon EKS and Kubernetes clusters

This section explains how to set up the CloudWatch agent with Prometheus monitoring in a cluster running Amazon EKS or Kubernetes. After you do this, the agent automatically scrapes and imports metrics for the following workloads running in that cluster.

- AWS App Mesh
- NGINX

- Memcached
- Java/JMX
- HAProxy
- Fluent Bit

You can also configure the agent to scrape and import additional Prometheus workloads and sources.

Before following these steps to install the CloudWatch agent for Prometheus metric collection, you must have a cluster running on Amazon EKS or a Kubernetes cluster running on an Amazon EC2 instance.

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

- Install the CloudWatch agent with Prometheus metrics collection on Amazon EKS and Kubernetes clusters
- Scraping additional Prometheus sources and importing those metrics
- (Optional) Set up sample containerized Amazon EKS workloads for Prometheus metric testing

Install the CloudWatch agent with Prometheus metrics collection on Amazon EKS and Kubernetes clusters

This section explains how to set up the CloudWatch agent with Prometheus monitoring in a cluster running Amazon EKS or Kubernetes. After you do this, the agent automatically scrapes and imports metrics for the following workloads running in that cluster.

- AWS App Mesh
- NGINX
- Memcached

- Java/JMX
- HAProxy
- Fluent Bit

You can also configure the agent to scrape and import additional Prometheus workloads and sources.

Before following these steps to install the CloudWatch agent for Prometheus metric collection, you must have a cluster running on Amazon EKS or a Kubernetes cluster running on an Amazon EC2 instance.

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

- Setting up IAM roles
- Installing the CloudWatch agent to collect Prometheus metrics

Setting up IAM roles

The first step is to set up the necessary IAM role in the cluster. There are two methods:

- Set up an IAM role for a service account, also known as a *service role*. This method works for both the EC2 launch type and the Fargate launch type.
- Add an IAM policy to the IAM role used for the cluster. This works only for the EC2 launch type.

Set up a service role (EC2 launch type and Fargate launch type)

To set up a service role, enter the following command. Replace *MyCluster* with the name of the cluster.

```
eksctl create iamserviceaccount \
 --name cwagent-prometheus \
```

```
--namespace amazon-cloudwatch \
 --cluster MyCluster \
--attach-policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy \
--approve \
--override-existing-serviceaccounts
```

Add a policy to the node group's IAM role (EC2 launch type only)

To set up the IAM policy in a node group for Prometheus support

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. You need to find the prefix of the IAM role name for the cluster. To do this, select the check box next to the name of an instance that is in the cluster, and choose **Actions**, **Security**, **Modify IAM Role**. Then copy the prefix of the IAM role, such as `eksctl-dev303-workshop-nodegroup`.
4. Open the IAM console at https://console.aws.amazon.com/iam/.
5. In the navigation pane, choose **Roles**.
6. Use the search box to find the prefix that you copied earlier in this procedure, and choose that role.
7. Choose **Attach policies**.
8. Use the search box to find **CloudWatchAgentServerPolicy**. Select the check box next to **CloudWatchAgentServerPolicy**, and choose **Attach policy**.

Installing the CloudWatch agent to collect Prometheus metrics

You must install the CloudWatch agent in the cluster to collect the metrics. How to install the agent differs for Amazon EKS clusters and Kubernetes clusters.

Delete previous versions of the CloudWatch agent with Prometheus support

If you have already installed a version of the CloudWatch agent with Prometheus support in your cluster, you must delete that version by entering the following command. This is necessary only for previous versions of the agent with Prometheus support. You do not need to delete the CloudWatch agent that enables Container Insights without Prometheus support.

```
kubectl delete deployment cwagent-prometheus -n amazon-cloudwatch
```

Installing the CloudWatch agent on Amazon EKS clusters with the EC2 launch type

To install the CloudWatch agent with Prometheus support on an Amazon EKS cluster, follow these steps.

To install the CloudWatch agent with Prometheus support on an Amazon EKS cluster

1. Enter the following command to check whether the `amazon-cloudwatch` namespace has already been created:

   ```
   kubectl get namespace
   ```

2. If `amazon-cloudwatch` is not displayed in the results, create it by entering the following command:

   ```
   kubectl create namespace amazon-cloudwatch
   ```

3. To deploy the agent with the default configuration and have it send data to the AWS Region that it is installed in, enter the following command:

   ```
   kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-
   container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/
   service/cwagent-prometheus/prometheus-eks.yaml
   ```

   To have the agent send data to a different Region instead, follow these steps:

   a. Download the YAML file for the agent by entering the following command:

      ```
      curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-
      container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/
      service/cwagent-prometheus/prometheus-eks.yaml
      ```

   b. Open the file with a text editor, and search for the `cwagentconfig.json` block of the file.

   c. Add the highlighted lines, specifying the Region that you want:

      ```
      cwagentconfig.json: |
          {
            "agent": {
              "region": "us-east-2"
            },
      ```

```
      "logs": { ...
```

d. Save the file and deploy the agent using your updated file.

```
kubectl apply -f prometheus-eks.yaml
```

Installing the CloudWatch agent on Amazon EKS clusters with the Fargate launch type

To install the CloudWatch agent with Prometheus support on an Amazon EKS cluster with the Fargate launch type, follow these steps.

To install the CloudWatch agent with Prometheus support on an Amazon EKS cluster with the Fargate launch type

1. Enter the following command to create a Fargate profile for the CloudWatch agent so that it can run inside the cluster. Replace *MyCluster* with the name of the cluster.

   ```
   eksctl create fargateprofile --cluster MyCluster \
   --name amazon-cloudwatch \
   --namespace amazon-cloudwatch
   ```

2. To install the CloudWatch agent, enter the following command. Replace *MyCluster* with the name of the cluster. This name is used in the log group name that stores the log events collected by the agent, and is also used as a dimension for the metrics collected by the agent.

   Replace *region* with the name of the Region where you want the metrics to be sent. For example, `us-west-1`.

   ```
   curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
   insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
   prometheus/prometheus-eks-fargate.yaml |
   sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" |
   kubectl apply -f -
   ```

Installing the CloudWatch agent on a Kubernetes cluster

To install the CloudWatch agent with Prometheus support on a cluster running Kubernetes, enter the following command:

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/prometheus-k8s.yaml |
sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" |
kubectl apply -f -
```

Replace *MyCluster* with the name of the cluster. This name is used in the log group name that stores the log events collected by the agent, and is also used as a dimension for the metrics collected by the agent.

Replace *region* with the name of the AWS Region where you want the metrics to be sent. For example, **us-west-1**.

Verify that the agent is running

On both Amazon EKS and Kubernetes clusters, you can enter the following command to confirm that the agent is running.

```
kubectl get pod -l "app=cwagent-prometheus" -n amazon-cloudwatch
```

If the results include a single CloudWatch agent pod in the `Running` state, the agent is running and collecting Prometheus metrics. By default the CloudWatch agent collects metrics for App Mesh, NGINX, Memcached, Java/JMX, and HAProxy every minute. For more information about those metrics, see Prometheus metrics collected by the CloudWatch agent. For instructions on how to see your Prometheus metrics in CloudWatch, see Viewing your Prometheus metrics

You can also configure the CloudWatch agent to collect metrics from other Prometheus exporters. For more information, see Scraping additional Prometheus sources and importing those metrics.

Scraping additional Prometheus sources and importing those metrics

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. One is for the standard Prometheus configurations as documented in <scrape_config> in the Prometheus documentation. The other is for the CloudWatch agent configuration.

For Amazon EKS clusters, the configurations are defined in `prometheus-eks.yaml` (for the EC2 launch type) or `prometheus-eks-fargate.yaml` (for the Fargate launch type) as two config maps:

- The `name: prometheus-config` section contains the settings for Prometheus scraping.
- The `name: prometheus-cwagentconfig` section contains the configuration for the CloudWatch agent. You can use this section to configure how the Prometheus metrics are collected by CloudWatch. For example, you specify which metrics are to be imported into CloudWatch, and define their dimensions.

For Kubernetes clusters running on Amazon EC2 instances, the configurations are defined in the `prometheus-k8s.yaml` YAML file as two config maps:

- The `name: prometheus-config` section contains the settings for Prometheus scraping.
- The `name: prometheus-cwagentconfig` section contains the configuration for the CloudWatch agent.

To scrape additional Prometheus metrics sources and import those metrics to CloudWatch, you modify both the Prometheus scrape configuration and the CloudWatch agent configuration, and then re-deploy the agent with the updated configuration.

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Prometheus scrape configuration

The CloudWatch agent supports the standard Prometheus scrape configurations as documented in <scrape_config> in the Prometheus documentation. You can edit this section to update the configurations that are already in this file, and add additional Prometheus scraping targets. By default, the sample configuration file contains the following global configuration lines:

```
global:
  scrape_interval: 1m
  scrape_timeout: 10s
```

- **scrape_interval**— Defines how frequently to scrape targets.
- **scrape_timeout**— Defines how long to wait before a scrape request times out.

You can also define different values for these settings at the job level, to override the global configurations.

Prometheus scraping jobs

The CloudWatch agent YAML files already have some default scraping jobs configured. For example, in `prometheus-eks.yaml`, the default scraping jobs are configured in the `job_name` lines in the `scrape_configs` section. In this file, the following default `kubernetes-pod-jmx` section scrapes JMX exporter metrics.

```
- job_name: 'kubernetes-pod-jmx'
   sample_limit: 10000
   metrics_path: /metrics
   kubernetes_sd_configs:
   - role: pod
   relabel_configs:
   - source_labels: [__address__]
     action: keep
     regex: '.*:9404$'
   - action: labelmap
     regex: __meta_kubernetes_pod_label_(.+)
   - action: replace
     source_labels:
     - __meta_kubernetes_namespace
     target_label: Namespace
   - source_labels: [__meta_kubernetes_pod_name]
     action: replace
     target_label: pod_name
   - action: replace
     source_labels:
     - __meta_kubernetes_pod_container_name
     target_label: container_name
   - action: replace
     source_labels:
     - __meta_kubernetes_pod_controller_name
     target_label: pod_controller_name
   - action: replace
     source_labels:
     - __meta_kubernetes_pod_controller_kind
     target_label: pod_controller_kind
   - action: replace
     source_labels:
     - __meta_kubernetes_pod_phase
```

```
        target_label: pod_phase
```

Each of these default targets are scraped, and the metrics are sent to CloudWatch in log events using embedded metric format. For more information, see Embedding metrics within logs.

Log events from Amazon EKS and Kubernetes clusters are stored in the **/aws/containerinsights/*cluster_name*/prometheus** log group in CloudWatch Logs. Log events from Amazon ECS clusters are stored in the **/aws/ecs/containerinsights/*cluster_name*/prometheus** log group.

Each scraping job is contained in a different log stream in this log group. For example, the Prometheus scraping job `kubernetes-pod-appmesh-envoy` is defined for App Mesh. All App Mesh Prometheus metrics from Amazon EKS and Kubernetes clusters are sent to the log stream named **/aws/containerinsights/*cluster_name*>prometheus/kubernetes-pod-appmesh-envoy/**.

To add a new scraping target, you add a new `job_name` section to the `scrape_configs` section of the YAML file, and restart the agent. For an example of this process, see Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics.

CloudWatch agent configuration for Prometheus

The CloudWatch agent configuration file has a `prometheus` section under `metrics_collected` for the Prometheus scraping configuration. It includes the following configuration options:

- **cluster_name**— specifies the cluster name to be added as a label in the log event. This field is optional. If you omit it, the agent can detect the Amazon EKS or Kubernetes cluster name.
- **log_group_name**— specifies the log group name for the scraped Prometheus metrics. This field is optional. If you omit it, CloudWatch uses **/aws/containerinsights/*cluster_name*/prometheus** for logs from Amazon EKS and Kubernetes clusters.
- **prometheus_config_path**— specifies the Prometheus scrape configuration file path. If the value of this field starts with `env:` the Prometheus scrape configuration file contents will be retrieved from the container's environment variable. Do not change this field.
- **ecs_service_discovery**— is the section to specify the configuration for Amazon ECS Prometheus service discovery. For more information, see Detailed guide for autodiscovery on Amazon ECS clusters.

  The `ecs_service_discovery` section can contain the following fields:

- `sd_frequency` is the frequency to discover the Prometheus exporters. Specify a number and a unit suffix. For example, `1m` for once per minute or `30s` for once per 30 seconds. Valid unit suffixes are `ns`, `us`, `ms`, `s`, `m`, and `h`.

  This field is optional. The default is 60 seconds (1 minute).
- `sd_target_cluster` is the target Amazon ECS cluster name for auto-discovery. This field is optional. The default is the name of the Amazon ECS cluster where the CloudWatch agent is installed.
- `sd_cluster_region` is the target Amazon ECS cluster's Region. This field is optional. The default is the Region of the Amazon ECS cluster where the CloudWatch agent is installed. .
- `sd_result_file` is the path of the YAML file for the Prometheus target results. The Prometheus scrape configuration will refer to this file.
- `docker_label` is an optional section that you can use to specify the configuration for Docker label-based service discovery. If you omit this section, Docker label-based discovery is not used. This section can contain the following fields:
  - `sd_port_label` is the container's docker label name that specifies the container port for Prometheus metrics. The default value is `ECS_PROMETHEUS_EXPORTER_PORT`. If the container does not have this Docker label, the CloudWatch agent will skip it.
  - `sd_metrics_path_label` is the container's docker label name that specifies the Prometheus metrics path. The default value is `ECS_PROMETHEUS_METRICS_PATH`. If the container does not have this Docker label, the agent assumes the default path `/metrics`.
  - `sd_job_name_label` is the container's docker label name that specifies the Prometheus scrape job name. The default value is `job`. If the container does not have this docker label, the CloudWatch agent uses the job name in the Prometheus scrape configuration.
- `task_definition_list` is an optional section that you can use to specify the configuration of task definition-based service discovery. If you omit this section, task definition-based discovery is not used. This section can contain the following fields:
  - `sd_task_definition_arn_pattern` is the pattern to use to specify the Amazon ECS task definitions to discover. This is a regular expression.
  - `sd_metrics_ports` lists the containerPort for the Prometheus metrics. Separate the containerPorts with semicolons.
  - `sd_container_name_pattern` specifies the Amazon ECS task container names. This is a regular expression.

  - `sd_metrics_path` specifies the Prometheus metric path. If you omit this, the agent assumes the default path `/metrics`
  - `sd_job_name` specifies the Prometheus scrape job name. If you omit this field, the CloudWatch agent uses the job name in the Prometheus scrape configuration.

- **metric_declaration**— are sections that specify the array of logs with embedded metric format to be generated. There are `metric_declaration` sections for each Prometheus source that the CloudWatch agent imports from by default. These sections each include the following fields:
  - `label_matcher` is a regular expression that checks the value of the labels listed in `source_labels`. The metrics that match are enabled for inclusion in the embedded metric format sent to CloudWatch.

    If you have multiple labels specified in `source_labels`, the agent recommend that you do not use ^ or $ characters in the regular expression for `label_matcher`.
  - `source_labels` specifies the value of the labels that are checked by the `label_matcher` line.
  - `label_separator` specifies the separator to be used in the `label_matcher` line if multiple `source_labels` are specified. The default is `;`. You can see this default used in the `label_matcher` line in the following example.
  - `metric_selectors` is a regular expression that specifies the metrics to be collected and sent to CloudWatch.
  - `dimensions` is the list of labels to be used as CloudWatch dimensions for each selected metric.

See the following `metric_declaration` example.

```
"metric_declaration": [
  {
     "source_labels":[ "Service", "Namespace"],
     "label_matcher":"(.*node-exporter.*|.*kube-dns.*);kube-system",
     "dimensions":[
        ["Service", "Namespace"]
     ],
     "metric_selectors":[
        "^coredns_dns_request_type_count_total$"
     ]
  }
```

```
]
```

This example configures an embedded metric format section to be sent as a log event if the following conditions are met:

- The value of `Service` contains either `node-exporter` or `kube-dns`.
- The value of `Namespace` is `kube-system`.
- The Prometheus metric `coredns_dns_request_type_count_total` contains both `Service` and `Namespace` labels.

The log event that is sent includes the following highlighted section:

```
{
   "CloudWatchMetrics":[
      {
         "Metrics":[
            {
               "Name":"coredns_dns_request_type_count_total"
            }
         ],
         "Dimensions":[
            [
               "Namespace",
               "Service"
            ]
         ],
         "Namespace":"ContainerInsights/Prometheus"
      }
   ],
   "Namespace":"kube-system",
   "Service":"kube-dns",
   "coredns_dns_request_type_count_total":2562,
   "eks_amazonaws_com_component":"kube-dns",
   "instance":"192.168.61.254:9153",
   "job":"kubernetes-service-endpoints",
   ...
}
```

Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics

The Kubernetes API Server exposes Prometheus metrics on endpoints by default. The official example for the Kubernetes API Server scraping configuration is available on Github.

The following tutorial shows how to do the following steps to begin importing Kubernetes API Server metrics into CloudWatch:

- Adding the Prometheus scraping configuration for Kubernetes API Server to the CloudWatch agent YAML file.
- Configuring the embedded metric format metrics definitions in the CloudWatch agent YAML file.
- (Optional) Creating a CloudWatch dashboard for the Kubernetes API Server metrics.

> **Note**
>
> The Kubernetes API Server exposes gauge, counter, histogram, and summary metrics. In this release of Prometheus metrics support, CloudWatch imports only the metrics with gauge, counter, and summary types.

To start collecting Kubernetes API Server Prometheus metrics in CloudWatch

1. Download the latest version of the `prometheus-eks.yaml`, `prometheus-eks-fargate.yaml`, or `prometheus-k8s.yaml` file by entering one of the following commands.

   For an Amazon EKS cluster with the EC2 launch type, enter the following command:

   ```
   curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks.yaml
   ```

   For an Amazon EKS cluster with the Fargate launch type, enter the following command:

   ```
   curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks-fargate.yaml
   ```

   For a Kubernetes cluster running on an Amazon EC2 instance, enter the following command:

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/prometheus-k8s.yaml
```

2. Open the file with a text editor, find the `prometheus-config` section, and add the following section inside of that section. Then save the changes:

```
    # Scrape config for API servers
    - job_name: 'kubernetes-apiservers'
      kubernetes_sd_configs:
        - role: endpoints
          namespaces:
            names:
              - default
      scheme: https
      tls_config:
        ca_file: /var/run/secrets/kubernetes.io/serviceaccount/ca.crt
        insecure_skip_verify: true
      bearer_token_file: /var/run/secrets/kubernetes.io/serviceaccount/token
      relabel_configs:
      - source_labels: [__meta_kubernetes_service_name,
 __meta_kubernetes_endpoint_port_name]
        action: keep
        regex: kubernetes;https
      - action: replace
        source_labels:
        - __meta_kubernetes_namespace
        target_label: Namespace
      - action: replace
        source_labels:
        - __meta_kubernetes_service_name
        target_label: Service
```

3. While you still have the YAML file open in the text editor, find the `cwagentconfig.json` section. Add the following subsection and save the changes. This section puts the API server metrics onto the CloudWatch agent allow list. Three types of API Server metrics are added to the allow list:

   - etcd object counts
   - API Server registration controller metrics
   - API Server request metrics

```
{"source_labels": ["job", "resource"],
  "label_matcher": "^kubernetes-apiservers;(services|daemonsets.apps|
deployments.apps|configmaps|endpoints|secrets|serviceaccounts|replicasets.apps)",
  "dimensions": [["ClusterName","Service","resource"]],
  "metric_selectors": [
  "^etcd_object_counts$"
  ]
},
{"source_labels": ["job", "name"],
   "label_matcher": "^kubernetes-apiservers;APIServiceRegistrationController$",
   "dimensions": [["ClusterName","Service","name"]],
   "metric_selectors": [
   "^workqueue_depth$",
   "^workqueue_adds_total$",
   "^workqueue_retries_total$"
  ]
},
{"source_labels": ["job","code"],
  "label_matcher": "^kubernetes-apiservers;2[0-9]{2}$",
  "dimensions": [["ClusterName","Service","code"]],
  "metric_selectors": [
   "^apiserver_request_total$"
  ]
},
{"source_labels": ["job"],
  "label_matcher": "^kubernetes-apiservers",
  "dimensions": [["ClusterName","Service"]],
  "metric_selectors": [
  "^apiserver_request_total$"
  ]
},
```

4. If you already have the CloudWatch agent with Prometheus support deployed in the cluster, you must delete it by entering the following command:

```
kubectl delete deployment cwagent-prometheus -n amazon-cloudwatch
```

5. Deploy the CloudWatch agent with your updated configuration by entering one of the following commands. For an Amazon EKS cluster with the EC2 launch type, enter:

```
kubectl apply -f prometheus-eks.yaml
```

For an Amazon EKS cluster with the Fargate launch type, enter the following command. Replace *MyCluster* and *region* with values to match your deployment.

```
cat prometheus-eks-fargate.yaml \
| sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" \
| kubectl apply -f -
```

For a Kubernetes cluster, enter the following command. Replace *MyCluster* and *region* with values to match your deployment.

```
cat prometheus-k8s.yaml \
| sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" \
| kubectl apply -f -
```

After you have done this, you should see a new log stream named **kubernetes-apiservers** in the **/aws/containerinsights/*cluster_name*/prometheus** log group. This log stream should include log events with an embedded metric format definition like the following:

```
{
   "CloudWatchMetrics":[
      {
         "Metrics":[
            {
               "Name":"apiserver_request_total"
            }
         ],
         "Dimensions":[
            [
               "ClusterName",
               "Service"
            ]
         ],
         "Namespace":"ContainerInsights/Prometheus"
      }
   ],
   "ClusterName":"my-cluster-name",
   "Namespace":"default",
```

```
    "Service":"kubernetes",
    "Timestamp":"1592267020339",
    "Version":"0",
    "apiserver_request_count":0,
    "apiserver_request_total":0,
    "code":"0",
    "component":"apiserver",
    "contentType":"application/json",
    "instance":"192.0.2.0:443",
    "job":"kubernetes-apiservers",
    "prom_metric_type":"counter",
    "resource":"pods",
    "scope":"namespace",
    "verb":"WATCH",
    "version":"v1"
}
```

You can view your metrics in the CloudWatch console in the **ContainerInsights/Prometheus** namespace. You can also optionally create a CloudWatch dashboard for your Prometheus Kubernetes API Server metrics.

(Optional) Creating a dashboard for Kubernetes API Server metrics

To see Kubernetes API Server metrics in your dashboard, you must have first completed the steps in the previous sections to start collecting these metrics in CloudWatch.

To create a dashboard for Kubernetes API Server metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Make sure you have the correct AWS Region selected.
3. In the navigation pane, choose **Dashboards**.
4. Choose **Create Dashboard**. Enter a name for the new dashboard, and choose **Create dashboard**.
5. In **Add to this dashboard**, choose **Cancel**.
6. Choose **Actions**, **View/edit source**.
7. Download the following JSON file: Kubernetes API Dashboard source.
8. Open the JSON file that you downloaded with a text editor, and make the following changes:

   - Replace all the `{{YOUR_CLUSTER_NAME}}` strings with the exact name of your cluster. Make sure not to add whitespaces before or after the text.

- Replace all the `{{YOUR_AWS_REGION}}` strings with the name of the Region where the metrics are collected. For example `us-west-2`. Be sure not to add whitespaces before or after the text.

9. Copy the entire JSON blob and paste it into the text box in the CloudWatch console, replacing what is already in the box.
10. Choose **Update**, **Save dashboard**.

(Optional) Set up sample containerized Amazon EKS workloads for Prometheus metric testing

To test the Prometheus metric support in CloudWatch Container Insights, you can set up one or more of the following containerized workloads. The CloudWatch agent with Prometheus support automatically collects metrics from each of these workloads. To see the metrics that are collected by default, see Prometheus metrics collected by the CloudWatch agent.

Before you can install any of these workloads, you must install Helm 3.x by entering the following commands:

```
brew install helm
```

For more information, see Helm.

Topics

- Set up AWS App Mesh sample workload for Amazon EKS and Kubernetes
- Set up NGINX with sample traffic on Amazon EKS and Kubernetes
- Set up memcached with a metric exporter on Amazon EKS and Kubernetes

Set up AWS App Mesh sample workload for Amazon EKS and Kubernetes

Prometheus support in CloudWatch Container Insights supports AWS App Mesh. The following sections explain how to set up App Mesh.

Topics

- Set up AWS App Mesh sample workload on an Amazon EKS cluster with the EC2 launch type or a Kubernetes cluster
- Set up AWS App Mesh sample workload on an Amazon EKS cluster with the Fargate launch type

Set up AWS App Mesh sample workload on an Amazon EKS cluster with the EC2 launch type or a Kubernetes cluster

Use these instructions if you are setting up App Mesh on a cluster running Amazon EKS with the EC2 launch type, or a Kubernetes cluster.

Configure IAM permissions

You must add the **AWSAppMeshFullAccess** policy to the IAM role for your Amazon EKS or Kubernetes node group. On Amazon EKS, this node group name looks similar to `eksctl-integ-test-eks-prometheus-NodeInstanceRole-ABCDEFHIJKL`. On Kubernetes, it might look similar to `nodes.integ-test-kops-prometheus.k8s.local`.

Install App Mesh

To install the App Mesh Kubernetes controller, follow the instructions in App Mesh Controller.

Install a sample application

aws-app-mesh-examples contains several Kubernetes App Mesh walkthroughs. For this tutorial, you install a sample color application that shows how http routes can use headers for matching incoming requests.

To use a sample App Mesh application to test Container Insights

1. Install the application using these instructions: https://github.com/aws/aws-app-mesh-examples/tree/main/walkthroughs/howto-k8s-http-headers.
2. Launch a curler pod to generate traffic:

   ```
   kubectl -n default run -it curler --image=tutum/curl /bin/bash
   ```

3. Curl different endpoints by changing HTTP headers. Run the curl command multiple times, as shown:

   ```
   curl -H "color_header: blue" front.howto-k8s-http-headers.svc.cluster.local:8080/;
    echo;
   ```

```
curl -H "color_header: red" front.howto-k8s-http-headers.svc.cluster.local:8080/;
 echo;

curl -H "color_header: yellow" front.howto-k8s-http-
headers.svc.cluster.local:8080/; echo;
```

4. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
5. In the AWS Region where your cluster is running, choose **Metrics** in the navigation pane. The metric are in the **ContainerInsights/Prometheus** namespace.
6. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group `/aws/containerinsights/your_cluster_name/prometheus` in the log stream `kubernetes-pod-appmesh-envoy`.

Deleting the App Mesh test environment

When you have finished using App Mesh and the sample application, use the following commands to delete the unnecessary resources. Delete the sample application by entering the following command:

```
cd aws-app-mesh-examples/walkthroughs/howto-k8s-http-headers/
kubectl delete -f _output/manifest.yaml
```

Delete the App Mesh controller by entering the following command:

```
helm delete appmesh-controller -n appmesh-system
```

Set up AWS App Mesh sample workload on an Amazon EKS cluster with the Fargate launch type

Use these instructions if you are setting up App Mesh on a cluster running Amazon EKS with the Fargate launch type.

Configure IAM permissions

To set up IAM permissions, enter the following command. Replace *MyCluster* with the name of your cluster.

```
eksctl create iamserviceaccount --cluster MyCluster \
 --namespace howto-k8s-fargate \
 --name appmesh-pod \
 --attach-policy-arn arn:aws:iam::aws:policy/AWSAppMeshEnvoyAccess \
```

```
--attach-policy-arn arn:aws:iam::aws:policy/AWSCloudMapDiscoverInstanceAccess \
--attach-policy-arn arn:aws:iam::aws:policy/AWSXRayDaemonWriteAccess \
--attach-policy-arn arn:aws:iam::aws:policy/CloudWatchLogsFullAccess \
--attach-policy-arn arn:aws:iam::aws:policy/AWSAppMeshFullAccess \
--attach-policy-arn arn:aws:iam::aws:policy/AWSCloudMapFullAccess \
--override-existing-serviceaccounts \
--approve
```

Install App Mesh

To install the App Mesh Kubernetes controller, follow the instructions in App Mesh Controller. Be sure to follow the instructions for Amazon EKS with the Fargate launch type.

Install a sample application

aws-app-mesh-examples contains several Kubernetes App Mesh walkthroughs. For this tutorial, you install a sample color application that works for Amazon EKS clusters with the Fargate launch type.

To use a sample App Mesh application to test Container Insights

1. Install the application using these instructions: https://github.com/aws/aws-app-mesh-examples/tree/main/walkthroughs/howto-k8s-fargate.

   Those instructions assume that you are creating a new cluster with the correct Fargate profile. If you want to use an Amazon EKS cluster that you've already set up, you can use the following commands to set up that cluster for this demonstration. Replace *MyCluster* with the name of your cluster.

   ```
   eksctl create iamserviceaccount --cluster MyCluster \
    --namespace howto-k8s-fargate \
    --name appmesh-pod \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSAppMeshEnvoyAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSCloudMapDiscoverInstanceAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSXRayDaemonWriteAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/CloudWatchLogsFullAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSAppMeshFullAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSCloudMapFullAccess \
    --override-existing-serviceaccounts \
    --approve
   ```

   ```
   eksctl create fargateprofile --cluster MyCluster \
   ```

```
--namespace howto-k8s-fargate --name howto-k8s-fargate
```

2. Port forward the front application deployment:

```
kubectl -n howto-k8s-fargate port-forward deployment/front 8080:8080
```

3. Curl the front app:

```
while true; do  curl -s http://localhost:8080/color; sleep 0.1; echo ; done
```

4. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
5. In the AWS Region where your cluster is running, choose **Metrics** in the navigation pane. The metric are in the **ContainerInsights/Prometheus** namespace.
6. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group `/aws/containerinsights/your_cluster_name/prometheus` in the log stream `kubernetes-pod-appmesh-envoy`.

Deleting the App Mesh test environment

When you have finished using App Mesh and the sample application, use the following commands to delete the unnecessary resources. Delete the sample application by entering the following command:

```
cd aws-app-mesh-examples/walkthroughs/howto-k8s-fargate/
kubectl delete -f _output/manifest.yaml
```

Delete the App Mesh controller by entering the following command:

```
helm delete appmesh-controller -n appmesh-system
```

Set up NGINX with sample traffic on Amazon EKS and Kubernetes

NGINX is a web server that can also be used as a load balancer and reverse proxy. For more information about how Kubernetes uses NGINX for ingress , see kubernetes/ingress-nginx.

To install Ingress-NGINX with a sample traffic service to test Container Insights Prometheus support

1. Enter the following command to add the Helm ingress-nginx repo:

```
helm repo add ingress-nginx https://kubernetes.github.io/ingress-nginx
```

2. Enter the following commands:

```
kubectl create namespace nginx-ingress-sample

helm install my-nginx ingress-nginx/ingress-nginx \
--namespace nginx-ingress-sample \
--set controller.metrics.enabled=true \
--set-string controller.metrics.service.annotations."prometheus\.io/port"="10254" \
--set-string controller.metrics.service.annotations."prometheus\.io/scrape"="true"
```

3. Check whether the services started correctly by entering the following command:

```
kubectl get service -n nginx-ingress-sample
```

   The output of this command should display several columns, including an `EXTERNAL-IP` column.

4. Set an `EXTERNAL-IP` variable to the value of the `EXTERNAL-IP` column in the row of the NGINX ingress controller.

```
EXTERNAL_IP=your-nginx-controller-external-ip
```

5. Start some sample NGINX traffic by entering the following command.

```
SAMPLE_TRAFFIC_NAMESPACE=nginx-sample-traffic
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/sample_traffic/nginx-traffic/nginx-traffic-sample.yaml |
sed "s/{{external_ip}}/$EXTERNAL_IP/g" |
sed "s/{{namespace}}/$SAMPLE_TRAFFIC_NAMESPACE/g" |
kubectl apply -f -
```

6. Enter the following command to confirm that all three pods are in the `Running` status.

```
kubectl get pod -n $SAMPLE_TRAFFIC_NAMESPACE
```

   If they are running, you should soon see metrics in the **ContainerInsights/Prometheus** namespace.

To uninstall NGINX and the sample traffic application

1. Delete the sample traffic service by entering the following command:

```
kubectl delete namespace $SAMPLE_TRAFFIC_NAMESPACE
```

2. Delete the NGINX egress by the Helm release name.

```
helm uninstall my-nginx --namespace nginx-ingress-sample
kubectl delete namespace nginx-ingress-sample
```

Set up memcached with a metric exporter on Amazon EKS and Kubernetes

memcached is an open-source memory object caching system. For more information, see What is Memcached?.

If you are running memcached on a cluster with the Fargate launch type, you need to set up a Fargate profile before doing the steps in this procedure. To set up the profile, enter the following command. Replace *MyCluster* with the name of your cluster.

```
eksctl create fargateprofile --cluster MyCluster \
--namespace memcached-sample --name memcached-sample
```

To install memcached with a metric exporter to test Container Insights Prometheus support

1. Enter the following command to add the repo:

```
helm repo add bitnami https://charts.bitnami.com/bitnami
```

2. Enter the following command to create a new namespace:

```
kubectl create namespace memcached-sample
```

3. Enter the following command to install Memcached

```
helm install my-memcached bitnami/memcached --namespace memcached-sample \
--set metrics.enabled=true \
--set-string serviceAnnotations.prometheus\\.io/port="9150" \
--set-string serviceAnnotations.prometheus\\.io/scrape="true"
```

4. Enter the following command to confirm the annotation of the running service:

```
kubectl describe service my-memcached-metrics -n memcached-sample
```

You should see the following two annotations:

```
Annotations:   prometheus.io/port: 9150
               prometheus.io/scrape: true
```

To uninstall memcached

- Enter the following commands:

```
helm uninstall my-memcached --namespace memcached-sample
kubectl delete namespace memcached-sample
```

Set up Java/JMX sample workload on Amazon EKS and Kubernetes

JMX Exporter is an official Prometheus exporter that can scrape and expose JMX mBeans as Prometheus metrics. For more information, see prometheus/jmx_exporter.

Container Insights can collect predefined Prometheus metrics from Java Virtual Machine (JVM), Java, and Tomcat (Catalina) using the JMX Exporter.

Default Prometheus scrape configuration

By default, the CloudWatch agent with Prometheus support scrapes the Java/JMX Prometheus metrics from `http://CLUSTER_IP:9404/metrics` on each pod in an Amazon EKS or Kubernetes cluster. This is done by `role:` pod discovery of Prometheus `kubernetes_sd_config`. 9404 is the default port allocated for JMX Exporter by Prometheus. For more information about `role:` pod discovery, see pod. You can configure the JMX Exporter to expose the metrics on a different port or metrics_path. If you do change the port or path, update the default jmx scrape_config in the CloudWatch agent config map. Run the following command to get the current CloudWatch agent Prometheus configuration:

```
kubectl describe cm prometheus-config -n amazon-cloudwatch
```

The fields to change are the `/metrics` and `regex: '.*:9404$'` fields, as highlighted in the following example.

```
job_name: 'kubernetes-jmx-pod'
sample_limit: 10000
metrics_path: /metrics
kubernetes_sd_configs:
- role: pod
relabel_configs:
- source_labels: [__address__]
  action: keep
  regex: '.*:9404$'
- action: replace
  regex: (.+)
  source_labels:
```

Other Prometheus scrape configuration

If you expose your application running on a set of pods with Java/JMX Prometheus exporters by a Kubernetes Service, you can also switch to use `role: service` discovery or `role: endpoint` discovery of Prometheus `kubernetes_sd_config`. For more information about these discovery methods, see service, endpoints, and <kubernetes_sd_config>..

More meta labels are provided by these two service discovery modes which could be useful for you to build the CloudWatch metrics dimensions. For example, you can relabel `__meta_kubernetes_service_name` to `Service` and include it into your metrics' dimension. For more informatio about customizing your CloudWatch metrics and their dimensions, see CloudWatch agent configuration for Prometheus.

Docker image with JMX Exporter

Next, build a Docker image. The following sections provide two example Dockerfiles.

When you have built the image, load it into Amazon EKS or Kubernetes, and then run the following command to verify that Prometheus metrics are exposed by `JMX_EXPORTER` on port 9404. Replace *`$JAR_SAMPLE_TRAFFIC_POD`* with the running pod name and replace *`$JAR_SAMPLE_TRAFFIC_NAMESPACE`* with your application namespace.

If you are running JMX Exporter on a cluster with the Fargate launch type, you also need to set up a Fargate profile before doing the steps in this procedure. To set up the profile, enter the following command. Replace *`MyCluster`* with the name of your cluster.

```
eksctl create fargateprofile --cluster MyCluster \
--namespace $JAR_SAMPLE_TRAFFIC_NAMESPACE\
 --name $JAR_SAMPLE_TRAFFIC_NAMESPACE
```

```
kubectl exec $JAR_SAMPLE_TRAFFIC_POD -n $JARCAT_SAMPLE_TRAFFIC_NAMESPACE -- curl
 http://localhost:9404
```

Example: Apache Tomcat Docker image with Prometheus metrics

Apache Tomcat server exposes JMX mBeans by default. You can integrate JMX Exporter with Tomcat to expose JMX mBeans as Prometheus metrics. The following example Dockerfile shows the steps to build a testing image:

```
# From Tomcat 9.0 JDK8 OpenJDK
FROM tomcat:9.0-jdk8-openjdk

RUN mkdir -p /opt/jmx_exporter

COPY ./jmx_prometheus_javaagent-0.12.0.jar /opt/jmx_exporter
COPY ./config.yaml /opt/jmx_exporter
COPY ./setenv.sh /usr/local/tomcat/bin
COPY your web application.war /usr/local/tomcat/webapps/

RUN chmod  o+x /usr/local/tomcat/bin/setenv.sh

ENTRYPOINT ["catalina.sh", "run"]
```

The following list explains the four COPY lines in this Dockerfile.

- Download the latest JMX Exporter jar file from https://github.com/prometheus/jmx_exporter.
- `config.yaml` is the JMX Exporter configuration file. For more information, see https://github.com/prometheus/jmx_exporter#Configuration.

  Here is a sample configuration file for Java and Tomcat:

  ```
  lowercaseOutputName: true
  lowercaseOutputLabelNames: true

  rules:
  ```

```
- pattern: 'java.lang<type=OperatingSystem><>(FreePhysicalMemorySize|
TotalPhysicalMemorySize|FreeSwapSpaceSize|TotalSwapSpaceSize|SystemCpuLoad|
ProcessCpuLoad|OpenFileDescriptorCount|AvailableProcessors)'
  name: java_lang_OperatingSystem_$1
  type: GAUGE

- pattern: 'java.lang<type=Threading><>(TotalStartedThreadCount|ThreadCount)'
  name: java_lang_threading_$1
  type: GAUGE

- pattern: 'Catalina<type=GlobalRequestProcessor, name=\"(\w+-\w+)-(\d+)\"><>(\w+)'
  name: catalina_globalrequestprocessor_$3_total
  labels:
    port: "$2"
    protocol: "$1"
  help: Catalina global $3
  type: COUNTER

- pattern: 'Catalina<j2eeType=Servlet, WebModule=//([-a-zA-Z0-9+&@#/%?=~_|!:.,;]*[-
a-zA-Z0-9+&@#/%=~_|]), name=([-a-zA-Z0-9+/$%~_-|!.]*), J2EEApplication=none,
 J2EEServer=none><>(requestCount|maxTime|processingTime|errorCount)'
  name: catalina_servlet_$3_total
  labels:
    module: "$1"
    servlet: "$2"
  help: Catalina servlet $3 total
  type: COUNTER

- pattern: 'Catalina<type=ThreadPool, name="(\w+-\w+)-(\d+)"><>(currentThreadCount|
currentThreadsBusy|keepAliveCount|pollerThreadCount|connectionCount)'
  name: catalina_threadpool_$3
  labels:
    port: "$2"
    protocol: "$1"
  help: Catalina threadpool $3
  type: GAUGE

- pattern: 'Catalina<type=Manager, host=([-a-zA-Z0-9+&@#/%?=~_|!:.,;]*[-a-zA-
Z0-9+&@#/%=~_|]), context=([-a-zA-Z0-9+/$%~_-|!.]*)><>(processingTime|sessionCounter|
rejectedSessions|expiredSessions)'
  name: catalina_session_$3_total
  labels:
    context: "$2"
    host: "$1"
```

```
  help: Catalina session $3 total
  type: COUNTER

- pattern: ".*"
```

- `setenv.sh` is a Tomcat startup script to start the JMX exporter along with Tomcat and expose Prometheus metrics on port 9404 of the localhost. It also provides the JMX Exporter with the `config.yaml` file path.

```
$ cat setenv.sh
export JAVA_OPTS="-javaagent:/opt/jmx_exporter/
jmx_prometheus_javaagent-0.12.0.jar=9404:/opt/jmx_exporter/config.yaml $JAVA_OPTS"
```

- your web application.war is your web application `war` file to be loaded by Tomcat.

Build a Docker image with this configuration and upload it to an image repository.

Example: Java Jar Application Docker image with Prometheus metrics

The following example Dockerfile shows the steps to build a testing image:

```
# Alpine Linux with OpenJDK JRE
FROM openjdk:8-jre-alpine

RUN mkdir -p /opt/jmx_exporter

COPY ./jmx_prometheus_javaagent-0.12.0.jar /opt/jmx_exporter
COPY ./SampleJavaApplication-1.0-SNAPSHOT.jar /opt/jmx_exporter
COPY ./start_exporter_example.sh /opt/jmx_exporter
COPY ./config.yaml /opt/jmx_exporter

RUN chmod -R o+x /opt/jmx_exporter
RUN apk add curl

ENTRYPOINT exec /opt/jmx_exporter/start_exporter_example.sh
```

The following list explains the four `COPY` lines in this Dockerfile.

- Download the latest JMX Exporter jar file from https://github.com/prometheus/jmx_exporter.
- `config.yaml` is the JMX Exporter configuration file. For more information, see https://github.com/prometheus/jmx_exporter#Configuration.

Here is a sample configuration file for Java and Tomcat:

```
lowercaseOutputName: true
lowercaseOutputLabelNames: true

rules:
- pattern: 'java.lang<type=OperatingSystem><>(FreePhysicalMemorySize|
TotalPhysicalMemorySize|FreeSwapSpaceSize|TotalSwapSpaceSize|SystemCpuLoad|
ProcessCpuLoad|OpenFileDescriptorCount|AvailableProcessors)'

rejectedSessions|expiredSessions)'
  name: catalina_session_$3_total
  labels:
    context: "$2"
    host: "$1"
  help: Catalina session $3 total
  type: COUNTER

- pattern: ".*"
```

- `start_exporter_example.sh` is the script to start the JAR application with the Prometheus metrics exported. It also provides the JMX Exporter with the `config.yaml` file path.

```
$ cat start_exporter_example.sh
java -javaagent:/opt/jmx_exporter/jmx_prometheus_javaagent-0.12.0.jar=9404:/
opt/jmx_exporter/config.yaml -cp  /opt/jmx_exporter/SampleJavaApplication-1.0-
SNAPSHOT.jar com.gubupt.sample.app.App
```

- SampleJavaApplication-1.0-SNAPSHOT.jar is the sample Java application jar file. Replace it with the Java application that you want to monitor.

Build a Docker image with this configuration and upload it to an image repository.

Set up HAProxy with a metric exporter on Amazon EKS and Kubernetes

HAProxy is an open-source proxy application. For more information, see HAProxy.

If you are running HAProxy on a cluster with the Fargate launch type, you need to set up a Fargate profile before doing the steps in this procedure. To set up the profile, enter the following command. Replace *MyCluster* with the name of your cluster.

```
eksctl create fargateprofile --cluster MyCluster \
--namespace haproxy-ingress-sample --name haproxy-ingress-sample
```

To install HAProxy with a metric exporter to test Container Insights Prometheus support

1. Enter the following command to add the Helm incubator repo:

```
helm repo add haproxy-ingress https://haproxy-ingress.github.io/charts
```

2. Enter the following command to create a new namespace:

```
kubectl create namespace haproxy-ingress-sample
```

3. Enter the following commands to install HAProxy:

```
helm install haproxy haproxy-ingress/haproxy-ingress \
--namespace haproxy-ingress-sample \
--set defaultBackend.enabled=true \
--set controller.stats.enabled=true \
--set controller.metrics.enabled=true \
--set-string controller.metrics.service.annotations."prometheus\.io/port"="9101" \
--set-string controller.metrics.service.annotations."prometheus\.io/scrape"="true"
```

4. Enter the following command to confirm the annotation of the service:

```
kubectl describe service haproxy-haproxy-ingress-metrics -n haproxy-ingress-sample
```

   You should see the following annotations.

```
Annotations:   prometheus.io/port: 9101
               prometheus.io/scrape: true
```

To uninstall HAProxy

- Enter the following commands:

```
helm uninstall haproxy --namespace haproxy-ingress-sample
kubectl delete namespace haproxy-ingress-sample
```

Tutorial for adding a new Prometheus scrape target: Redis OSS on Amazon EKS and Kubernetes clusters

This tutorial provides a hands-on introduction to scrape the Prometheus metrics of a sample Redis OSS application on Amazon EKS and Kubernetes. Redis OSS (https://redis.io/) is an open source (BSD licensed), in-memory data structure store, used as a database, cache and message broker. For more information, see redis.

redis_exporter (MIT License licensed) is used to expose the Redis OSS Prometheus metrics on the specified port (default: 0.0.0.0:9121). For more information, see redis_exporter.

The Docker images in the following two Docker Hub repositories are used in this tutorial:

- redis
- redis_exporter

To install a sample Redis OSS workload which exposes Prometheus metrics

1. Set the namespace for the sample Redis OSS workload.

```
REDIS_NAMESPACE=redis-sample
```

2. If you are running Redis OSS on a cluster with the Fargate launch type, you need to set up a Fargate profile. To set up the profile, enter the following command. Replace *MyCluster* with the name of your cluster.

```
eksctl create fargateprofile --cluster MyCluster \
--namespace $REDIS_NAMESPACE --name $REDIS_NAMESPACE
```

3. Enter the following command to install the sample Redis OSS workload.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/sample_traffic/redis/redis-traffic-sample.yaml \
| sed "s/{{namespace}}/$REDIS_NAMESPACE/g" \
| kubectl apply -f -
```

4. The installation includes a service named `my-redis-metrics` which exposes the Redis OSS Prometheus metric on port 9121 Enter the following command to get the details of the service:

```
kubectl describe service/my-redis-metrics  -n $REDIS_NAMESPACE
```

   In the `Annotations` section of the results, you'll see two annotations which match the Prometheus scrape configuration of the CloudWatch agent, so that it can auto-discover the workloads:

```
prometheus.io/port: 9121
```

```
prometheus.io/scrape: true
```

The related Prometheus scrape configuration can be found in the `- job_name: kubernetes-service-endpoints` section of `kubernetes-eks.yaml` or `kubernetes-k8s.yaml`.

To start collecting Redis OSS Prometheus metrics in CloudWatch

1. Download the latest version of the of `kubernetes-eks.yaml` or `kubernetes-k8s.yaml` file by entering one of the following commands. For an Amazon EKS cluster with the EC2 launch type, enter this command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks.yaml
```

For an Amazon EKS cluster with the Fargate launch type, enter this command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks-fargate.yaml
```

For a Kubernetes cluster running on an Amazon EC2 instance, enter this command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-k8s.yaml
```

2. Open the file with a text editor, and find the `cwagentconfig.json` section. Add the following subsection and save the changes. Be sure that the indentation follows the existing pattern.

```
{
  "source_labels": ["pod_name"],
  "label_matcher": "^redis-instance$",
  "dimensions": [["Namespace","ClusterName"]],
  "metric_selectors": [
    "^redis_net_(in|out)put_bytes_total$",
    "^redis_(expired|evicted)_keys_total$",
```

```
    "^redis_keyspace_(hits|misses)_total$",
    "^redis_memory_used_bytes$",
    "^redis_connected_clients$"
  ]
},
{
  "source_labels": ["pod_name"],
  "label_matcher": "^redis-instance$",
  "dimensions": [["Namespace","ClusterName","cmd"]],
  "metric_selectors": [
    "^redis_commands_total$"
  ]
},
{
  "source_labels": ["pod_name"],
  "label_matcher": "^redis-instance$",
  "dimensions": [["Namespace","ClusterName","db"]],
  "metric_selectors": [
    "^redis_db_keys$"
  ]
},
```

The section you added puts the Redis OSS metrics onto the CloudWatch agent allow list. For a list of these metrics, see the following section.

3. If you already have the CloudWatch agent with Prometheus support deployed in this cluster, you must delete it by entering the following command.

```
kubectl delete deployment cwagent-prometheus -n amazon-cloudwatch
```

4. Deploy the CloudWatch agent with your updated configuration by entering one of the following commands. Replace *MyCluster* and *region* to match your settings.

   For an Amazon EKS cluster with the EC2 launch type, enter this command.

```
kubectl apply -f prometheus-eks.yaml
```

   For an Amazon EKS cluster with the Fargate launch type, enter this command.

```
cat prometheus-eks-fargate.yaml \
| sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" \
| kubectl apply -f -
```

For a Kubernetes cluster, enter this command.

```
cat prometheus-k8s.yaml \
| sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" \
| kubectl apply -f -
```

Viewing your Redis OSS Prometheus metrics

This tutorial sends the following metrics to the **ContainerInsights/Prometheus** namespace in CloudWatch. You can use the CloudWatch console to see the metrics in that namespace.

Metric name	Dimensions	
redis_net_input_bytes_total	ClusterName, Namespace	
redis_net_output_bytes_total	ClusterName, Namespace	
redis_expired_keys_total	ClusterName, Namespace	
redis_evicted_keys_total	ClusterName, Namespace	
redis_keyspace_hits_total	ClusterName, Namespace	
redis_keyspace_misses_total	ClusterName, Namespace	

Metric name	Dimensions	
redis_memory_used_bytes	ClusterName, Namespace	
redis_connected_clients	ClusterName, Namespace	
redis_commands_total	ClusterName, Namespace , cmd	
redis_db_keys	ClusterName, Namespace , db	

Note

The value of the **cmd** dimension can be: append, client, command, config, dbsize, flushall, get, incr, info, latency, or slowlog.
The value of the **db** dimension can be db0 to db15.

You can also create a CloudWatch dashboard for your Redis OSS Prometheus metrics.

To create a dashboard for Redis OSS Prometheus metrics

1. Create environment variables, replacing the values below to match your deployment.

```
DASHBOARD_NAME=your_cw_dashboard_name
REGION_NAME=your_metric_region_such_as_us-east-1
CLUSTER_NAME=your_k8s_cluster_name_here
NAMESPACE=your_redis_service_namespace_here
```

2. Enter the following command to create the dashboard.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/sample_cloudwatch_dashboards/redis/cw_dashboard_redis.json \
| sed "s/{{YOUR_AWS_REGION}}/${REGION_NAME}/g" \
| sed "s/{{YOUR_CLUSTER_NAME}}/${CLUSTER_NAME}/g" \
| sed "s/{{YOUR_NAMESPACE}}/${NAMESPACE}/g" \
```

Prometheus metric type conversion by the CloudWatch Agent

The Prometheus client libraries offer four core metric types:

- Counter
- Gauge
- Summary
- Histogram

The CloudWatch agent supports the counter, gauge, and summary metric types.

The Prometheus metrics with the unsupported histogram metric type are dropped by the CloudWatch agent. For more information, see Logging dropped Prometheus metrics.

Gauge metrics

A Prometheus gauge metric is a metric that represents a single numerical value that can arbitrarily go up and down. The CloudWatch agent scrapes gauge metrics and send these values out directly.

Counter metrics

A Prometheus counter metric is a cumulative metric that represents a single monotonically increasing counter whose value can only increase or be reset to zero. The CloudWatch agent calculates a delta from the previous scrape and sends the delta value as the metric value in the log event. So the CloudWatch agent will start to produce one log event from the second scrape and continue with subsequent scrapes, if any.

Summary metrics

A Prometheus summary metric is a complex metric type which is represented by multiple data points. It provides a total count of observations and a sum of all observed values. It calculates configurable quantiles over a sliding time window.

The sum and count of a summary metric are cumulative, but the quantiles are not. The following example shows the variance of quantiles.

```
# TYPE go_gc_duration_seconds summary
go_gc_duration_seconds{quantile="0"} 7.123e-06
go_gc_duration_seconds{quantile="0.25"} 9.204e-06
go_gc_duration_seconds{quantile="0.5"} 1.1065e-05
go_gc_duration_seconds{quantile="0.75"} 2.8731e-05
```

```
go_gc_duration_seconds{quantile="1"} 0.003841496
go_gc_duration_seconds_sum 0.37630427
go_gc_duration_seconds_count 9774
```

The CloudWatch agent handles the sum and count of a summary metric in the same way as it handles counter metrics, as described in the previous section. The CloudWatch agent preserves the quantile values as they are originally reported.

Prometheus metrics collected by the CloudWatch agent

The CloudWatch agent with Prometheus support automatically collects metrics from several services and workloads. The metrics that are collected by default are listed in the following sections. You can also configure the agent to collect more metrics from these services, and to collect Prometheus metrics from other applications and services. For more information about collecting additional metrics, see CloudWatch agent configuration for Prometheus.

Prometheus metrics collected from Amazon EKS and Kubernetes clusters are in the **ContainerInsights/Prometheus** namespace. Prometheus metrics collected from Amazon ECS clusters are in the **ECS/ContainerInsights/Prometheus** namespace.

Prometheus metrics for App Mesh

The following metrics are automatically collected from App Mesh .

Prometheus metrics for App Mesh on Amazon EKS and Kubernetes clusters

Metric name	Dimensions	
envoy_http_downstream_rq_total	ClusterName, Namespace	

Metric name	Dimensions
envoy_http_downstream_rq_xx	ClusterName, Namespace ClusterName, Namespace , envoy_http_conn_manager_prefix, envoy_response_code_class
envoy_cluster_upstream_cx_rx_bytes_total	ClusterName, Namespace
envoy_cluster_upstream_cx_tx_bytes_total	ClusterName, Namespace
envoy_cluster_membership_healthy	ClusterName, Namespace
envoy_cluster_membership_total	ClusterName, Namespace
envoy_server_memory_heap_size	ClusterName, Namespace
envoy_server_memory_allocated	ClusterName, Namespace
envoy_cluster_upstream_cx_connect_timeout	ClusterName, Namespace

Metric name	Dimensions	
envoy_cluster_upstream_rq_pending_failure_eject	ClusterName, Namespace	
envoy_cluster_upstream_rq_pending_overflow	ClusterName, Namespace	
envoy_cluster_upstream_rq_timeout	ClusterName, Namespace	
envoy_cluster_upstream_rq_try_per_timeout	ClusterName, Namespace	
envoy_cluster_upstream_rq_rx_reset	ClusterName, Namespace	
envoy_cluster_upstream_cx_destroy_local_with_active_rq	ClusterName, Namespace	

Metric name	Dimensions	
envoy_cluster_upstream_cx_destroy_remote_active_rq	ClusterName, Namespace	
envoy_cluster_upstream_rq_maintenance_mode	ClusterName, Namespace	
envoy_cluster_upstream_flow_control_paused_reading_total	ClusterName, Namespace	
envoy_cluster_upstream_flow_control_resumed_reading_total	ClusterName, Namespace	
envoy_cluster_upstream_flow_control_backed_up_total	ClusterName, Namespace	

Metric name	Dimensions
envoy_cluster_upstream_flow_control_drained_total	ClusterName, Namespace
envoy_cluster_upstream_rq_retry	ClusterName, Namespace
envoy_cluster_upstream_rq_retry_success	ClusterName, Namespace
envoy_cluster_upstream_rq_retry_overflow	ClusterName, Namespace
envoy_server_live	ClusterName, Namespace
envoy_server_uptime	ClusterName, Namespace

Prometheus metrics for App Mesh on Amazon ECS clusters

Metric name	Dimensions
envoy_http_downstream_rq_total	ClusterName, TaskDefinitionFamily

Metric name	Dimensions	
envoy_http_downstream_rq_xx	ClusterName, TaskDefinitionFamily	
envoy_cluster_upstream_cx_rx_bytes_total	ClusterName, TaskDefinitionFamily	
envoy_cluster_upstream_cx_tx_bytes_total	ClusterName, TaskDefinitionFamily	
envoy_cluster_membership_healthy	ClusterName, TaskDefinitionFamily	
envoy_cluster_membership_total	ClusterName, TaskDefinitionFamily	
envoy_server_memory_heap_size	ClusterName, TaskDefinitionFamily	
envoy_server_memory_allocated	ClusterName, TaskDefinitionFamily	
envoy_cluster_upstream_cx_connect_timeout	ClusterName, TaskDefinitionFamily	

Metric name	Dimensions	
envoy_cluster_upstream_rq_pending_failure_eject	ClusterName, TaskDefinitionFamily	
envoy_cluster_upstream_rq_pending_overflow	ClusterName, TaskDefinitionFamily	
envoy_cluster_upstream_rq_timeout	ClusterName, TaskDefinitionFamily	
envoy_cluster_upstream_rq_try_per_timeout	ClusterName, TaskDefinitionFamily	
envoy_cluster_upstream_rq_rx_reset	ClusterName, TaskDefinitionFamily	
envoy_cluster_upstream_cx_destroy_local_with_active_rq	ClusterName, TaskDefinitionFamily	

Metric name	Dimensions
envoy_cluster_upstream_cx_destroy_remote_active_rq	ClusterName, TaskDefinitionFamily
envoy_cluster_upstream_rq_maintenance_mode	ClusterName, TaskDefinitionFamily
envoy_cluster_upstream_flow_control_paused_reading_total	ClusterName, TaskDefinitionFamily
envoy_cluster_upstream_flow_control_resumed_reading_total	ClusterName, TaskDefinitionFamily
envoy_cluster_upstream_flow_control_backed_up_total	ClusterName, TaskDefinitionFamily

Metric name	Dimensions
envoy_cluster_upstream_flow_control_drained_total	ClusterName, TaskDefinitionFamily
envoy_cluster_upstream_rq_retry	ClusterName, TaskDefinitionFamily
envoy_cluster_upstream_rq_retry_success	ClusterName, TaskDefinitionFamily
envoy_cluster_upstream_rq_retry_overflow	ClusterName, TaskDefinitionFamily
envoy_server_live	ClusterName, TaskDefinitionFamily
envoy_server_uptime	ClusterName, TaskDefinitionFamily
envoy_http_downstream_rq_xx	ClusterName, TaskDefinitionFamily, envoy_http_conn_manager_prefix, envoy_response_code_class ClusterName, TaskDefinitionFamily, envoy_response_code_class

Note

TaskDefinitionFamily is the Kubernetes namespace of the mesh.

The value of envoy_http_conn_manager_prefix can be ingress, egress, or admin. The value of envoy_response_code_class can be 1 (stands for 1xx), 2 stands for 2xx), 3 stands for 3xx), 4 stands for 4xx), or 5 stands for 5xx).

Prometheus metrics for NGINX

The following metrics are automatically collected from NGINX on Amazon EKS and Kubernetes clusters.

Metric name	Dimensions	
nginx_ingress_controller_nginx_process_cpu_seconds_total	ClusterName, Namespace , Service	
nginx_ingress_controller_success	ClusterName, Namespace , Service	
nginx_ingress_controller_requests	ClusterName, Namespace , Service	
nginx_ingress_controller_nginx_process_connections	ClusterName, Namespace , Service	
nginx_ingress_controller_nginx_proce	ClusterName, Namespace , Service	

Metric name	Dimensions	
ss_connections_total		
nginx_ingress_controller_nginx_process_resident_memory_bytes	ClusterName, Namespace , Service	
nginx_ingress_controller_config_last_reload_successful	ClusterName, Namespace , Service	
nginx_ingress_controller_requests	ClusterName, Namespace , Service, status	

Prometheus metrics for Memcached

The following metrics are automatically collected from Memcached on Amazon EKS and Kubernetes clusters.

Metric name	Dimensions	
memcached_current_items	ClusterName, Namespace , Service	

Metric name	Dimensions
memcached_current_connections	ClusterName, Namespace , Service
memcached_limit_bytes	ClusterName, Namespace , Service
memcached_current_bytes	ClusterName, Namespace , Service
memcached_written_bytes_total	ClusterName, Namespace , Service
memcached_read_bytes_total	ClusterName, Namespace , Service
memcached_items_evicted_total	ClusterName, Namespace , Service
memcached_items_reclaimed_total	ClusterName, Namespace , Service
memcached_commands_total	ClusterName, Namespace , Service ClusterName, Namespace , Service, command ClusterName, Namespace , Service, status, command

Prometheus metrics for Java/JMX

Metrics collected on Amazon EKS and Kubernetes clusters

On Amazon EKS and Kubernetes clusters, Container Insights can collect the following predefined Prometheus metrics from the Java Virtual Machine (JVM), Java, and Tomcat (Catalina) using the JMX Exporter. For more information, see prometheus/jmx_exporter on Github.

Java/JMX on Amazon EKS and Kubernetes clusters

Metric name	Dimensions	
jvm_classes_loaded	ClusterName ,Namespace	
jvm_threads_current	ClusterName ,Namespace	
jvm_threads_daemon	ClusterName ,Namespace	
java_lang_operatingsystem_totalswapspacesize	ClusterName ,Namespace	
java_lang_operatingsystem_systemcpuload	ClusterName ,Namespace	
java_lang_operatingsystem_processcpuload	ClusterName ,Namespace	
java_lang_operatingsystem_freeswapspacesize	ClusterName ,Namespace	

Metric name	Dimensions	
java_lang_operatingsystem_totalphysicalmemorysize	ClusterName ,Namespace	
java_lang_operatingsystem_freephysicalmemorysize	ClusterName ,Namespace	
java_lang_operatingsystem_openfiledescriptorcount	ClusterName ,Namespace	
java_lang_operatingsystem_availableprocessors	ClusterName ,Namespace	
jvm_memory_bytes_used	ClusterName ,Namespace ,area	
jvm_memory_pool_bytes_used	ClusterName ,Namespace ,pool	

Note

The values of the `area` dimension can be heap or nonheap.

The values of the pool dimension can be Tenured Gen, Compress Class Space, Survivor Space, Eden Space, Code Cache, or Metaspace.

Tomcat/JMX on Amazon EKS and Kubernetes clusters

In addition to the Java/JMX metrics in the previous table, the following metrics are also collected for the Tomcat workload.

Metric name	Dimensions	
catalina_manager_activesessions	ClusterName ,Namespace	
catalina_manager_rejectedsessions	ClusterName ,Namespace	
catalina_globalrequestprocessor_bytesreceived	ClusterName ,Namespace	
catalina_globalrequestprocessor_bytessent	ClusterName ,Namespace	
catalina_globalrequestprocessor_requestcount	ClusterName ,Namespace	

Metric name	Dimensions	
catalina_globalrequestprocessor_errorcount	ClusterName ,Namespace	
catalina_globalrequestprocessor_processingtime	ClusterName ,Namespace	

Java/JMX on Amazon ECS clusters

Metric name	Dimensions	
jvm_classes_loaded	ClusterName ,TaskDefinitionFamily	
jvm_threads_current	ClusterName ,TaskDefinitionFamily	
jvm_threads_daemon	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_totalswapspacesize	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_systemcpuload	ClusterName ,TaskDefinitionFamily	

Metric name	Dimensions	
java_lang_operatingsystem_processcpuload	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_freeswapspacesize	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_totalphysicalmemorysize	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_freephysicalmemorysize	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_openfiledescriptorcount	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_availableprocessors	ClusterName ,TaskDefinitionFamily	

Metric name	Dimensions	
jvm_memory_bytes_used	ClusterName , TaskDefinitionFamily, area	
jvm_memory_pool_bytes_used	ClusterName , TaskDefinitionFamily, pool	

> **Note**
>
> The values of the area dimension can be heap or nonheap.
> The values of the pool dimension can be Tenured Gen, Compress Class Space, Survivor Space, Eden Space, Code Cache, or Metaspace.

Tomcat/JMX on Amazon ECS clusters

In addition to the Java/JMX metrics in the previous table, the following metrics are also collected for the Tomcat workload on Amazon ECS clusters.

Metric name	Dimensions	
catalina_manager_activesessions	ClusterName , TaskDefinitionFamily	
catalina_manager_rejectedsessions	ClusterName , TaskDefinitionFamily	
catalina_globalrequestprocessor_bytesreceived	ClusterName , TaskDefinitionFamily	

Metric name	Dimensions	
catalina_globalrequestprocessor_bytessent	ClusterName ,TaskDefinitionFamily	
catalina_globalrequestprocessor_requestcount	ClusterName ,TaskDefinitionFamily	
catalina_globalrequestprocessor_errorcount	ClusterName ,TaskDefinitionFamily	
catalina_globalrequestprocessor_processingtime	ClusterName ,TaskDefinitionFamily	

Prometheus metrics for HAProxy

The following metrics are automatically collected from HAProxy on Amazon EKS and Kubernetes clusters.

The metrics collected depend on which version of HAProxy Ingress that you are using. For more information about HAProxy Ingress and its versions, see haproxy-ingress.

Metric name	Dimensions	Availability
haproxy_backend_bytes_in_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_backend_bytes_out_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_backend_connection_errors_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_backend_connections_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_backend_current_sessions	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_backend_http_responses_total	ClusterName , Namespace , Service, code, backend	All versions of HAProxy Ingress
haproxy_backend_status	ClusterName , Namespace , Service	Only in versions 0.10 or later of HAProxy Ingress
haproxy_backend_up	ClusterName , Namespace , Service	Only in versions of HAProxy Ingress earlier than 0.10

Metric name	Dimensions	Availability
haproxy_frontend_bytes_in_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_bytes_out_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_connections_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_current_sessions	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_http_requests_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_http_responses_total	ClusterName , Namespace , Service, code, frontend	All versions of HAProxy Ingress
haproxy_frontend_request_errors_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress

Metric name	Dimensions	Availability
haproxy_frontend_requests_denied_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress

Note

The values of the code dimension can be 1xx, 2xx, 3xx, 4xx, 5xx, or other.
The values of the backend dimension can be:

- http-default-backend, http-shared-backend, or httpsback-shared-backend for HAProxy Ingress version 0.0.27 or earlier.
- _default_backend for HAProxy Ingress versions later than 0.0.27.

The values of the frontend dimension can be:

- httpfront-default-backend, httpfront-shared-frontend, or httpfronts for HAProxy Ingress version 0.0.27 or earlier.
- _front_http or _front_https for HAProxy Ingress versions later than 0.0.27.

Viewing your Prometheus metrics

You can monitor and alarm on all your Prometheus metrics including the curated pre-aggregated metrics from App Mesh, NGINX, Java/JMX, Memcached, and HAProxy, and any other manually configured Prometheus exporter you may have added. For more information about collecting metrics from other Prometheus exporters, see Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics.

In the CloudWatch console, Container Insights provides the following pre-built reports:

- For Amazon EKS and Kubernetes clusters, there are pre-built reports for App Mesh, NGINX, HAPROXY, Memcached, and Java/JMX.
- For Amazon ECS clusters, there are pre-built reports for App Mesh and Java/JMX.

Container Insights also provides custom dashboards for each of the workloads that Container Insights collects curated metrics from. You can download these dashboards from GitHub

To see all your Prometheus metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. In the list of namespaces, choose **ContainerInsights/Prometheus** or **ECS/ContainerInsights/Prometheus**.
4. Choose one of the sets of dimensions in the following list. Then select the checkbox next to the metrics that you want to see.

To see pre-built reports on your Prometheus metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Performance Monitoring**.
3. In the drop-down box near the top of the page, choose any of the Prometheus options.

   In the other drop-down box, choose a cluster to view

AWS also provides custom dashboards for NGINX, App Mesh, Memcached, HAProxy, and Java/JMX.

To use a custom dashboard that Amazon has provided

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose **Create Dashboard**. Enter a name for the new dashboard, and choose **Create dashboard**.
4. In **Add to this dashboard**, choose **Cancel**.
5. Choose **Actions**, **View/edit source**.
6. Download one of the following JSON files:

   - NGINX custom dashboard source on Github.
   - App Mesh custom dashboard source on Github.
   - Memcached custom dashboard source on Github
   - HAProxy-Ingress custom dashboard source on Github

- Java/JMX custom dashboard source on Github.

7. Open the JSON file that you downloaded with a text editor, and make the following changes:

   - Replace all the `{{YOUR_CLUSTER_NAME}}` strings with the exact name of your cluster. Make sure not to add whitespaces before or after the text.
   - Replace all the `{{YOUR_REGION}}` strings with the AWS Region where your cluster is running. For example, **`us-west-1`** Make sure not to add whitespaces before or after the text.
   - Replace all the `{{YOUR_NAMESPACE}}` strings with the exact namespace of your workload.
   - Replace all the `{{YOUR_SERVICE_NAME}}` strings with the exact service name of your workload. For example, **`haproxy-haproxy-ingress-controller-metrics`**

8. Copy the entire JSON blob and paste it into the text box in the CloudWatch console, replacing what is already in the box.
9. Choose **Update**, **Save dashboard**.

Prometheus metrics troubleshooting

This section provides help for troubleshooting your Prometheus metrics setup.

Prometheus metrics troubleshooting on Amazon ECS

This section provides help for troubleshooting your Prometheus metrics setup on Amazon ECS clusters.

I don't see Prometheus metrics sent to CloudWatch Logs

The Prometheus metrics should be ingested as log events in the log group **/aws/ecs/containerinsights/cluster-name/Prometheus**. If the log group is not created or the Prometheus metrics are not sent to the log group, you will need to first check whether the Prometheus targets have been successfully discovered by the CloudWatch agent. And next check the security group and permission settings of the CloudWatch agent. The following steps guide you to do the debugging.

Step 1: Enable the CloudWatch agent debugging mode

First, change the CloudWatch agent to debug mode by adding the following bold lines to your CloudFormation template file, `cwagent-ecs-prometheus-metric-for-bridge-host.yaml` or `cwagent-ecs-prometheus-metric-for-awsvpc.yaml`. Then save the file.

```
cwagentconfig.json: |
    {
      "agent": {
        "debug": true
      },
      "logs": {
        "metrics_collected": {
```

Create a new CloudFormation changeset against the existing stack. Set other parameters in the changeset to the same values as in your existing CloudFormation stack. The following example is for a CloudWatch agent installed in an Amazon ECS cluster using the EC2 launch type and the bridge network mode.

```
ECS_NETWORK_MODE=bridge
 CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name
NEW_CHANGESET_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=$ECS_EXECUTION_ROLE_NAME
 \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION \
    --change-set-name $NEW_CHANGESET_NAME
```

Go to the CloudFormation console to review the new changeset, `$NEW_CHANGESET_NAME`. There should be one change applied to the **CWAgentConfigSSMParameter** resource. Execute the changeset and restart the CloudWatch agent task by entering the following commands.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
```

```
--desired-count 0 \
--service your_service_name_here \
--region $AWS_REGION
```

Wait about 10 seconds and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service your_service_name_here \
--region $AWS_REGION
```

Step 2: Check the ECS service discovery logs

The ECS task definition of the CloudWatch agent enables the logs by default in the section below. The logs are sent to CloudWatch Logs in the log group **/ecs/ecs-cwagent-prometheus**.

```
LogConfiguration:
  LogDriver: awslogs
    Options:
      awslogs-create-group: 'True'
      awslogs-group: "/ecs/ecs-cwagent-prometheus"
      awslogs-region: !Ref AWS::Region
      awslogs-stream-prefix: !Sub 'ecs-${ECSLaunchType}-awsvpc'
```

Filter the logs by the string `ECS_SD_Stats` to get the metrics related to the ECS service discovery, as shown in the following example.

```
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_DescribeContainerInstances: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_DescribeInstancesRequest: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_DescribeTaskDefinition: 2
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_DescribeTasks: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_ListTasks: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: Exporter_DiscoveredTargetCount: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: LRUCache_Get_EC2MetaData: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: LRUCache_Get_TaskDefinition: 2
2020-09-1T01:53:14Z D! ECS_SD_Stats: LRUCache_Size_ContainerInstance: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: LRUCache_Size_TaskDefinition: 2
2020-09-1T01:53:14Z D! ECS_SD_Stats: Latency: 43.399783ms
```

The meaning of each metric for a particular ECS service discovery cycle is as follows:

- **AWSCLI_DescribeContainerInstances** – the number of `ECS::DescribeContainerInstances` API calls made.
- **AWSCLI_DescribeInstancesRequest** – the number of `ECS::DescribeInstancesRequest` API calls made.
- **AWSCLI_DescribeTaskDefinition** – the number of `ECS::DescribeTaskDefinition` API calls made.
- **AWSCLI_DescribeTasks** – the number of `ECS::DescribeTasks` API calls made.
- **AWSCLI_ListTasks** – the number of `ECS::ListTasks` API calls made.
- **ExporterDiscoveredTargetCount** – the number of Prometheus targets that were discovered and successfully exported into the target result file within the container.
- **LRUCache_Get_EC2MetaData** – the number of times that container instances metadata was retrieved from the cache.
- **LRUCache_Get_TaskDefinition** – the number of times that ECS task definition metadata was retrieved from the cache.
- **LRUCache_Size_ContainerInstance** – the number of unique container instance's metadata cached in memory.
- **LRUCache_Size_TaskDefinition** – the number of unique ECS task definitions cached in memory.
- **Latency** – how long the service discovery cycle takes.

Check the value of `ExporterDiscoveredTargetCount` to see whether the discovered Prometheus targets match your expectations. If not, the possible reasons are as follows:

- The configuration of ECS service discovery might not match your application's setting. For the Docker label-based service discovery, your target containers may not have the necessary Docker label configured in the CloudWatch agent to auto discover them. For the ECS task definition ARN regular expression-based service discovery, the regex setting in the CloudWatch agent may not match your application's task definition.
- The CloudWatch agent's ECS task role might not have permission to retrieve the metadata of ECS tasks. Check that the CloudWatch agent has been granted the following read-only permissions:
  - `ec2:DescribeInstances`
  - `ecs:ListTasks`
  - `ecs:DescribeContainerInstances`
  - `ecs:DescribeTasks`

- `ecs:DescribeTaskDefinition`

Step 3: Check the network connection and the ECS task role policy

If there are still no log events sent to the target CloudWatch Logs log group even though the value of `Exporter_DiscoveredTargetCount` indicates that there are discovered Prometheus targets, this could be caused by one of the following:

- The CloudWatch agent might not be able to connect to the Prometheus target ports. Check the security group setting behind the CloudWatch agent. The private IP should alow the CloudWatch agent to connect to the Prometheus exporter ports.
- The CloudWatch agent's ECS task role might not have the **CloudWatchAgentServerPolicy** managed policy. The CloudWatch agent's ECS task role needs to have this policy to be able to send the Prometheus metrics as log events. If you used the sample CloudFormation template to create the IAM roles automatically, both the ECS task role and the ECS execution role are granted with the least privilege to perform the Prometheus monitoring.

Prometheus metrics troubleshooting on Amazon EKS and Kubernetes clusters

This section provides help for troubleshooting your Prometheus metrics setup on Amazon EKS and Kubernetes clusters.

General troubleshooting steps on Amazon EKS

To confirm that the CloudWatch agent is running, enter the following command.

```
kubectl get pod -n amazon-cloudwatch
```

The output should include a row with `cwagent-prometheus-`*`id`* in the `NAME` column and `Running` in the `STATUS column.`

To display details about the running pod, enter the following command. Replace *`pod-name`* with the complete name of your pod that has a name that starts with `cw-agent-prometheus`.

```
kubectl describe pod pod-name -n amazon-cloudwatch
```

If you have CloudWatch Container Insights installed, you can use CloudWatch Logs Insights to query the logs from the CloudWatch agent collecting the Prometheus metrics.

To query the application logs

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **CloudWatch Logs Insights**.
3. Select the log group for the application logs, **/aws/containerinsights/*cluster-name*/application**
4. Replace the search query expression with the following query, and choose **Run query**

```
fields ispresent(kubernetes.pod_name) as haskubernetes_pod_name, stream,
 kubernetes.pod_name, log |
filter haskubernetes_pod_name and kubernetes.pod_name like /cwagent-prometheus
```

You can also confirm that Prometheus metrics and metadata are being ingested as CloudWatch Logs events.

To confirm that Prometheus data is being ingested

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **CloudWatch Logs Insights**.
3. Select the **/aws/containerinsights/*cluster-name*/prometheus**
4. Replace the search query expression with the following query, and choose **Run query**

```
fields @timestamp, @message | sort @timestamp desc | limit 20
```

Logging dropped Prometheus metrics

This release does not collect Prometheus metrics of the histogram type. You can use the CloudWatch agent to check whether any Prometheus metrics are being dropped because they are histogram metrics. You can also log a list of the first 500 Prometheus metrics that are dropped and not sent to CloudWatch because they are histogram metrics.

To see whether any metrics are being dropped, enter the following command:

```
kubectl logs -l "app=cwagent-prometheus" -n amazon-cloudwatch --tail=-1
```

If any metrics are being dropped, you will see the following lines in the `/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log` file.

```
I! Drop Prometheus metrics with unsupported types. Only Gauge, Counter and Summary are
 supported.
I! Please enable CWAgent debug mode to view the first 500 dropped metrics
```

If you see those lines and want to know what metrics are being dropped, use the following steps.

To log a list of dropped Prometheus metrics

1. Change the CloudWatch agent to debug mode by adding the following bold lines to your `prometheus-eks.yaml` or `prometheus-k8s.yaml`file, and save the file.

   ```
   {
         "agent": {
           "debug": true
         },
   ```

   This section of the file should then look like this:

   ```
   cwagentconfig.json: |
       {
         "agent": {
           "debug": true
         },
         "logs": {
           "metrics_collected": {
   ```

2. Reinstall the CloudWatch agent to enable debug mode by entering the following commands:

   ```
   kubectl delete deployment cwagent-prometheus -n amazon-cloudwatch
   kubectl apply -f prometheus.yaml
   ```

   The dropped metrics are logged in the CloudWatch agent pod.

3. To retrieve the logs from the CloudWatch agent pod, enter the following command:

   ```
   kubectl logs -l "app=cwagent-prometheus" -n amazon-cloudwatch --tail=-1
   ```

Or, if you have Container Insights Fluentd logging installed, the logs are also saved in the CloudWatch Logs log group **/aws/containerinsights/*cluster_name*/application**.

To query these logs, you can follow the steps for querying the application logs in General troubleshooting steps on Amazon EKS.

Where are the Prometheus metrics ingested as CloudWatch Logs log events?

The CloudWatch agent creates a log stream for each Prometheus scrape job configuration. For example, in the `prometheus-eks.yaml` and `prometheus-k8s.yaml` files, the line `job_name: 'kubernetes-pod-appmesh-envoy'` scrapes App Mesh metrics. The Prometheus target is defined as `kubernetes-pod-appmesh-envoy`. So all App Mesh Prometheus metrics are ingested as CloudWatch Logs events in the log stream **kubernetes-pod-appmesh-envoy** under the log group named **/aws/containerinsights/cluster-name/Prometheus**.

I don't see Amazon EKS or Kubernetes Prometheus metrics in CloudWatch metrics

First, make sure that the Prometheus metrics are ingested as log events in the log group **/aws/containerinsights/cluster-name/Prometheus**. Use the information in Where are the Prometheus metrics ingested as CloudWatch Logs log events? to help you check the target log stream. If the log stream is not created or there are no new log events in the log stream, check the following:

- Check that the Prometheus metrics exporter endpoints are set up correctly
- Check that the Prometheus scraping configurations in the `config map: cwagent-prometheus` section of the CloudWatch agent YAML file is correct. The configuration should be the same as it would be in a Prometheus configuration file. For more information, see <scrape_config> in the Prometheus documentation.

If the Prometheus metrics are ingested as log events correctly, check that the embedded metric format settings are added into the log events to generate the CloudWatch metrics.

```
"CloudWatchMetrics":[
   {
      "Metrics":[
         {
            "Name":"envoy_http_downstream_cx_destroy_remote_active_rq"
         }
      ],
```

```
      "Dimensions":[
         [
            "ClusterName",
            "Namespace"
         ]
      ],
      "Namespace":"ContainerInsights/Prometheus"
   }
],
```

For more information about embedded metric format, see Specification: Embedded metric format.

If there is no embedded metric format in the log events, check that the `metric_declaration` section is configured correctly in the `config map: prometheus-cwagentconfig` section of the CloudWatch agent installation YAML file. For more information, see Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics.

Integration with Application Insights

Amazon CloudWatch Application Insights helps you monitor your applications and identifies and sets up key metrics, logs, and alarms across your application resources and technology stack. For more information, see Detect common application problems with CloudWatch Application Insights.

You can enable Application Insights to gather additional data from your containerized applications and microservices. If you haven't done this already, you can enable it by choosing **Auto-configure Application Insights** below the performance view in the Container Insights dashboard.

If you have already set up CloudWatch Application Insights to monitor your containerized applications, the Application Insights dashboard appears below the Container Insights dashboard.

For more information about Application Insights and containerized applications, see Enable Application Insights for Amazon ECS and Amazon EKS resource monitoring.

Viewing Amazon ECS lifecycle events within Container Insights

You can view Amazon ECS lifecycle events within the Container Insights console. This helps you correlate your container metrics, logs, and events in a single view to give you a more complete operational visibility.

The events include container instance state change events, task state change events, and service action events. They are automatically sent by Amazon ECS to Amazon EventBridge and are also

collected in CloudWatch in event log format. For more information about these events, see Amazon ECS events.

Standard Container Insights pricing applies for Amazon ECS Lifecycle events. For more information, see Amazon CloudWatch Pricing.

To configure the table of lifecycle events and create rules for a cluster, you must have the `events:PutRule`, `events:PutTargets`, and `logs:CreateLogGroup` permissions. You must also make sure that there is a resource policy that enables EventBridge to create the log stream and send logs to CloudWatch Logs. If this resource policy doesn't exist, you can enter the following command to create it:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogStream",
        "logs:PutLogEvents"
      ],
      "Principal": {
        "Service": ["events.amazonaws.com", "delivery.logs.amazonaws.com"]
      },
      "Resource": "arn:aws:logs:us-east-1:111122223333:log-group:/aws/events/ecs/
containerinsights/*:*",
      "Condition": {
        "StringEquals": {
        "aws:SourceAccount": "111122223333"
        },
        "ArnLike": {
        "aws:SourceArn": "arn:aws:events:us-east-1:111122223333:rule/
eventsToLog*"
        }
      },
      "Sid": "TrustEventBridgeToStoreECSLifecycleLogEvents"
    }
  ]
}
```

You can use the following command to check whether you already have this policy, and to confirm that attaching it worked correctly.

```
aws logs describe-resource-policies --region region --output json
```

To view the table of lifecycle events, you must have the `events:DescribeRule`, `events:ListTargetsByRule`, and `logs:DescribeLogGroups` permissions.

To view Amazon ECS lifecycle events in the CloudWatch Container Insights console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Insights**, **Container Insights**.
3. Choose **View performance dashboards**.
4. In the next drop-down, choose either **ECS Clusters**, **ECS Services**, or **ECS Tasks**.
5. If you chose **ECS Services** or **ECS Tasks** in the previous step, choose the **Lifecycle events** tab.
6. At the bottom of the page, if you see **Configure lifecycle events**, choose it to create EventBridge rules for your cluster.

   The events are displayed below the container insights panes and above the Application Insights section. To run extra analytics and create additional visualizations on these events, choose **View in Logs Insights** in the Lifecycle Events table.

Troubleshooting Container Insights

The following sections can help if you're having trouble issues with Container Insights.

Failed deployment on Amazon EKS or Kubernetes

If the agent doesn't deploy correctly on a Kubernetes cluster, try the following:

- Run the following command to get the list of pods.

  ```
  kubectl get pods -n amazon-cloudwatch
  ```

- Run the following command and check the events at the bottom of the output.

  ```
  kubectl describe pod pod-name -n amazon-cloudwatch
  ```

- Run the following command to check the logs.

```
kubectl logs pod-name -n amazon-cloudwatch
```

Unauthorized panic: Cannot retrieve cadvisor data from kubelet

If your deployment fails with the error `Unauthorized panic: Cannot retrieve cadvisor data from kubelet`, your kubelet might not have Webhook authorization mode enabled. This mode is required for Container Insights. For more information, see Setup guide (AWS CLI).

Deploying Container Insights on a deleted and re-created cluster on Amazon ECS

If you delete an existing Amazon ECS cluster that does not have Container Insights enabled, and you re-create it with the same name, you can't enable Container Insights on this new cluster at the time you re-create it. You can enable it by re-creating it, and then entering the following command:

```
aws ecs update-cluster-settings --cluster myCICluster --settings name=container
 Insights,value=enabled
```

Invalid endpoint error

If you see an error message similar to the following, check to make sure that you replaced all the placeholders such as *cluster-name* and *region-name* in the commands that you are using with the correct information for your deployment.

```
"log": "2020-04-02T08:36:16Z E! cloudwatchlogs: code: InvalidEndpointURL, message:
 invalid endpoint uri, original error: &url.Error{Op:\"parse\", URL:\"https://
logs.{{region_name}}.amazonaws.com/\", Err:\"{\"}, &awserr.baseError{code:
\"InvalidEndpointURL\", message:\"invalid endpoint uri\", errs:[]error{(*url.Error)
(0xc0008723c0)}}\n",
```

Metrics don't appear in the console

If you don't see any Container Insights metrics in the AWS Management Console, be sure that you have completed the setup of Container Insights. Metrics don't appear before Container Insights has been set up completely. For more information, see Container Insights.

Pod metrics missing on Amazon EKS or Kubernetes after upgrading cluster

This section might be useful if all or some pod metrics are missing after you deploy the CloudWatch agent as a daemonset on a new or upgraded cluster, or you see an error log with the message `W! No pod metric collected`.

These errors can be caused by changes in the container runtime, such as containerd or the Docker systemd cgroup driver. You can usually solve this by updating your deployment manifest so that the containerd socket from the host is mounted into the container. See the following example:

```
# For full example see https://github.com/aws-samples/amazon-cloudwatch-container-
insights/blob/latest/k8s-deployment-manifest-templates/deployment-mode/daemonset/
container-insights-monitoring/cwagent/cwagent-daemonset.yaml
apiVersion: apps/v1
kind: DaemonSet
metadata:
  name: cloudwatch-agent
  namespace: amazon-cloudwatch
spec:
  template:
    spec:
      containers:
        - name: cloudwatch-agent
# ...
          # Don't change the mountPath
          volumeMounts:
# ...
            - name: dockersock
              mountPath: /var/run/docker.sock
              readOnly: true
            - name: varlibdocker
              mountPath: /var/lib/docker
              readOnly: true
            - name: containerdsock # NEW mount
              mountPath: /run/containerd/containerd.sock
              readOnly: true
# ...
      volumes:
# ...
        - name: dockersock
          hostPath:
            path: /var/run/docker.sock
        - name: varlibdocker
```

```
          hostPath:
            path: /var/lib/docker
        - name: containerdsock # NEW volume
          hostPath:
            path: /run/containerd/containerd.sock
```

No pod metrics when using Bottlerocket for Amazon EKS

Bottlerocket is a Linux-based open source operating system that is purpose-built by AWS for running containers.

Bottlerocket uses a different `containerd` path on the host, so you need to change the volumes to its location. If you don't, you see an error in the logs that includes `W! No pod metric collected`. See the following example.

```
volumes:
  # ...
    - name: containerdsock
      hostPath:
        # path: /run/containerd/containerd.sock
        # bottlerocket does not mount containerd sock at normal place
        # https://github.com/bottlerocket-os/bottlerocket/
commit/91810c85b83ff4c3660b496e243ef8b55df0973b
        path: /run/dockershim.sock
```

No container filesystem metrics when using the containerd runtime for Amazon EKS or Kubernetes

This is a known issue and is being worked on by community contributors. For more information, see Disk usage metric for containerd and container file system metrics is not supported by cadvisor for containerd on GitHub.

Unexpected log volume increase from CloudWatch agent when collecting Prometheus metrics

This was a regression introduced in version 1.247347.6b250880 of the CloudWatch agent. This regression has already been fixed in more recent versions of the agent. It's impact was limited to scenarios where customers collected the logs of the CloudWatch agent itself and were also using Prometheus. For more information, see [prometheus] agent is printing all the scraped metrics in log on GitHub.

Latest docker image mentioned in release notes not found from Dockerhub

The release note and tag on Github are updated before the actual release internally. It usually takes 1-2 weeks to see the latest Docker image on registries after the version number on Github is bumped. There is no nightly release for the CloudWatch agent container image. You can build the image directly from source at the following location: https://github.com/aws/amazon-cloudwatch-agent/tree/main/amazon-cloudwatch-container-insights/cloudwatch-agent-dockerfile

CrashLoopBackoff error on the CloudWatch agent

If you see a `CrashLoopBackOff` error for the CloudWatch agent, make sure that your IAM permissions are set correctly. For more information, see Setup guide (AWS CLI).

CloudWatch agent or Fluentd pod stuck in pending

If you have a CloudWatch agent or Fluentd pod stuck in `Pending` or with a `FailedScheduling` error, determine if your nodes have enough compute resources based on the number of cores and amount of RAM required by the agents. Enter the following command to describe the pod:

```
kubectl describe pod cloudwatch-agent-85ppg -n amazon-cloudwatch
```

Building your own CloudWatch agent Docker image

You can build your own CloudWatch agent Docker image by referring to the Dockerfile located at https://github.com/aws-samples/amazon-cloudwatch-container-insights/blob/latest/cloudwatch-agent-dockerfile/Dockerfile.

The Dockerfile supports building multi-architecture images directly using `docker buildx`.

Deploying other CloudWatch agent features in your containers

You can deploy additional monitoring features in your containers using the CloudWatch agent. These features include the following:

- **Embedded Metric Format**— For more information, see Embedding metrics within logs.
- **StatsD**— For more information, see Retrieve custom metrics with StatsD.

Instructions and necessary files are located on GitHub at the following locations:

- For Amazon ECS containers, see Example Amazon ECS task definitions based on deployment modes.
- For Amazon EKS and Kubernetes containers, see Example Kubernetes YAML files based on deployment modes.

Lambda Insights

CloudWatch Lambda Insights is a monitoring and troubleshooting solution for serverless applications running on AWS Lambda. The solution collects, aggregates, and summarizes system-level metrics including CPU time, memory, disk, and network. It also collects, aggregates, and summarizes diagnostic information such as cold starts and Lambda worker shutdowns to help you isolate issues with your Lambda functions and resolve them quickly.

Lambda Insights uses a new CloudWatch Lambda extension, which is provided as a Lambda layer. When you install this extension on a Lambda function, it collects system-level metrics and emits a single performance log event for every invocation of that Lambda function. CloudWatch uses embedded metric formatting to extract metrics from the log events.

> **Note**
>
> The Lambda Insights agent is supported only on Lambda runtimes that use Amazon Linux 2 and Amazon Linux 2023.

For more information about Lambda extensions, see Using AWS Lambda extensions. For more information about embedded metric format, see Embedding metrics within logs.

You can use Lambda Insights with any Lambda function that uses a Lambda runtime that supports Lambda extensions. For a list of these runtimes, see Lambda Extensions API.

Pricing

For each Lambda function enabled for Lambda Insights, you only pay for what you use for metrics and logs. For a pricing example, see Amazon CloudWatch Pricing.

You are charged for the execution time consumed by the Lambda extension, in 1ms increments. For more information about Lambda pricing, see AWS Lambda Pricing.

Get started with Lambda Insights

To enable Lambda Insights on a Lambda function, you can use a one-click toggle in the Lambda console. Alternatively, you can use the AWS CLI, CloudFormation, the AWS Serverless Application Model CLI, or the AWS Cloud Development Kit (AWS CDK).

The following sections provide detailed instructions for completing these steps.

Topics

- Available versions of the Lambda Insights extension
- Using the console to enable Lambda Insights on an existing Lambda function
- Use the AWS CLI to enable Lambda Insights on an existing Lambda function
- Use the AWS SAM CLI to enable Lambda Insights on an existing Lambda function
- Use CloudFormation to enable Lambda Insights on an existing Lambda function
- Use the AWS CDK to enable Lambda Insights on an existing Lambda function
- Use Serverless Framework to enable Lambda Insights on an existing Lambda function
- Enable Lambda Insights on a Lambda container image deployment
- Update the Lambda Insights extension version on a function

Available versions of the Lambda Insights extension

This section lists the versions of the Lambda Insights extension, and the ARNs to use for these extensions in each AWS Region.

Topics

- x86-64 platforms
- ARM64 platforms

x86-64 platforms

This section lists the versions of the Lambda Insights extension for x86-64 platforms, and the ARNs to use for these extensions in each AWS Region.

> **Important**
>
> Lambda Insights extensions 1.0.317.0 and later don't support Amazon Linux 1.

1.0.776.0

Version 1.0.776.0 fixes a packaging issue introduced during a build system migration. In previous versions, the extension RPM bundled a wrapper script instead of the compiled binary. This version correctly packages the compiled binary. This resolves issues that prevented the extension from running.

This fix also ensures that the RPM correctly declares the required shared library dependencies. These dependencies (libc, libgcc_s, libpthread, libdl) are needed by the binary at runtime.

ARNs for version 1.0.776.0

The following table lists the ARNs to use for this version of the extension in each AWS Region where it is available.

Region	ARN
US East (N. Virginia)	`arn:aws:lambda:us-east-1:580247275435:layer:LambdaInsightsExtension:66`
US East (Ohio)	`arn:aws:lambda:us-east-2:580247275435:layer:LambdaInsightsExtension:71`
US West (N. California)	`arn:aws:lambda:us-west-1:580247275435:layer:LambdaInsightsExtension:66`

1.0.660.0

Version 1.0.660.0 includes Lambda Insights extension support for Lambda functions running on Lambda Managed Instances. For functions running on Lambda Managed Instances, the extension will send an EMF log event once every minute, creating 12 CloudWatch Metrics at one-minute granularity.

ARNs for version 1.0.660.0

The following table lists the ARNs to use for this version of the extension in each AWS Region where it is available.

Region	ARN
US East (N. Virginia)	arn:aws:lambda:us-east-1:580247275435:layer:LambdaInsightsExtension:64
US East (Ohio)	arn:aws:lambda:us-east-2:580247275435:layer:LambdaInsightsExtension:64
US West (N. California)	arn:aws:lambda:us-west-1:580247275435:layer:LambdaInsightsExtension:64
US West (Oregon)	arn:aws:lambda:us-west-2:580247275435:layer:LambdaInsightsExtension:64
Africa (Cape Town)	arn:aws:lambda:af-south-1:012438385374:layer:LambdaInsightsExtension:56
Asia Pacific (Hong Kong)	arn:aws:lambda:ap-east-1:519774774795:layer:LambdaInsightsExtension:56
Asia Pacific (Hyderabad)	arn:aws:lambda:ap-south-2:891564319516:layer:LambdaInsightsExtension:38
Asia Pacific (Jakarta)	arn:aws:lambda:ap-southeast-3:439286490199:layer:LambdaInsightsExtension:40
Asia Pacific (Malaysia)	arn:aws:lambda:ap-southeast-5:590183865173:layer:LambdaInsightsExtension:13
Asia Pacific (Melbourne)	arn:aws:lambda:ap-southeast-4:158895979263:layer:LambdaInsightsExtension:33
Asia Pacific (Mumbai)	arn:aws:lambda:ap-south-1:580247275435:layer:LambdaInsightsExtension:62

AWS GovCloud (US-West)	arn:aws-us-gov:lambda:us-gov-west-1:751350123760:layer:LambdaInsightsExtension:24
Asia Pacific (New Zealand)	arn:aws:lambda:ap-southeast-6:727646510379:layer:LambdaInsightsExtension:1
Asia Pacific (Taipei)	arn:aws:lambda:ap-east-2:145023102084:layer:LambdaInsightsExtension:8

1.0.404.0

Version 1.0.404.0 reduces the binary size of the Lambda Insights extension from ~10MB to ~6MB, and subsequently reduces the zip size of the Lambda Insights extension layer from ~4MB to ~2.7MB. It also reduces the overall memory consumption of the agent from ~10MB to ~7MB.

ARNs for version 1.0.404.0

The following table lists the ARNs to use for this version of the extension in each AWS Region where it is available.

Region	ARN
US East (N. Virginia)	arn:aws:lambda:us-east-1:580247275435:layer:LambdaInsightsExtension:56

Region	ARN
US East (Ohio)	arn:aws:lambda:us-east-2:580247275435:layer:LambdaInsightsExtension:56
US West (N. California)	arn:aws:lambda:us-west-1:580247275435:layer:LambdaInsightsExtension:56
US West (Oregon)	arn:aws:lambda:us-west-2:580247275435:layer:LambdaInsightsExtension:56
Africa (Cape Town)	arn:aws:lambda:af-south-1:012438385374:layer:LambdaInsightsExtension:47
Asia Pacific (Thailand)	arn:aws:lambda:ap-southeast-7:761018874580:layer:LambdaInsightsExtension:3

1.0.391.0

> **Important**
>
> Version 1.0.391.0 changes how Lambda Insights collects and reports thread usage. In previous versions of the extension, the `threads_max` metric reported the maximum number of threads running in the process that has the process ID of 1. Starting with version 1.0.391.0, this metric reports the maximum number of threads that were running at any point of time during the function's execution, across all processes in the execution environment. This includes the Lambda function's processes, extensions' processes, system/runtime specific processes, and so on. This makes the `threads_max` metric more comprehensive while assessing the remaining threads left for your use. For more information about thread and process quotas, see Lambda quotas.

Version 1.0.391.0 also adds support for the Asia Pacific (Thailand) and Mexico (Central) Regions.

ARNs for version 1.0.391.0

The following table lists the ARNs to use for this version of the extension in each AWS Region where it is available.

Region	ARN
US East (N. Virginia)	`arn:aws:lambda:us-east-1:580247275435:layer:LambdaInsightsExtension:55`
US East (Ohio)	`arn:aws:lambda:us-east-2:580247275435:layer:LambdaInsightsExtension:55`
US West (N. California)	`arn:aws:lambda:us-west-1:580247275435:layer:LambdaInsightsExtension:55`
US West (Oregon)	`arn:aws:lambda:us-west-2:580247275435:layer:LambdaInsightsExtension:55`
Africa (Cape Town)	`arn:aws:lambda:af-south-1:012438385374:layer:LambdaInsightsExtension:46`

Region	ARN
Asia Pacific (Thailand)	arn:aws:lambda:ap-southeast-7:761018874580:layer:LambdaInsightsExtension:2

1.0.333.0

Version 1.0.333.0 includes bug fixes.

ARNs for version 1.0.333.0

The following table lists the ARNs to use for this version of the extension in each AWS Region where it is available.

Region	ARN
US East (N. Virginia)	arn:aws:lambda:us-east-1:580247275435:layer:LambdaInsightsExtension:53
US East (Ohio)	arn:aws:lambda:us-east-2:580247275435:layer:LambdaInsightsExtension:53

Region	ARN
US West (N. California)	arn:aws:lambda:us-west-1:580247275435:layer:LambdaInsightsExtension:53
US West (Oregon)	arn:aws:lambda:us-west-2:580247275435:layer:LambdaInsightsExtension:53
Africa (Cape Town)	arn:aws:lambda:af-south-1:012438385374:layer:LambdaInsightsExtension:44
Asia Pacific (Hong Kong)	arn:aws:lambda:ap-east-1:519774774795:layer:LambdaInsightsExtension:44
Asia Pacific (Hyderabad)	arn:aws:lambda:ap-south-2:891564319516:layer:LambdaInsightsExtension:26
Asia Pacific (Jakarta)	arn:aws:lambda:ap-southeast-3:439286490199:layer:LambdaInsightsExtension:30
Asia Pacific (Malaysia)	arn:aws:lambda:ap-southeast-5:590183865173:layer:LambdaInsightsExtension:1
Asia Pacific (Melbourne)	arn:aws:lambda:ap-southeast-4:158895979263:layer:LambdaInsightsExtension:21
Asia Pacific (Mumbai)	arn:aws:lambda:ap-south-1:580247275435:layer:LambdaInsightsExtension:51
Asia Pacific (Osaka)	arn:aws:lambda:ap-northeast-3:194566237122:layer:LambdaInsightsExtension:34
Asia Pacific (Seoul)	arn:aws:lambda:ap-northeast-2:580247275435:layer:LambdaInsightsExtension:52
Asia Pacific (Singapore)	arn:aws:lambda:ap-southeast-1:580247275435:layer:LambdaInsightsExtension:53

Region	ARN
Asia Pacific (Sydney)	arn:aws:lambda:ap-southeast-2:580247275435:layer:LambdaInsightsExtension:53
Asia Pacific (Tokyo)	arn:aws:lambda:ap-northeast-1:580247275435:layer:LambdaInsightsExtension:80
Canada (Central)	arn:aws:lambda:ca-central-1:580247275435:layer:LambdaInsightsExtension:52
Canada West (Calgary)	arn:aws:lambda:ca-west-1:946466191631:layer:LambdaInsightsExtension:13
China (Beijing)	arn:aws-cn:lambda:cn-north-1:488211338238:layer:LambdaInsightsExtension:43
China (Ningxia);	arn:aws-cn:lambda:cn-northwest-1:488211338238:layer:LambdaInsightsExtension:43
Europe (Frankfurt)	arn:aws:lambda:eu-central-1:580247275435:layer:LambdaInsightsExtension:53
Europe (Ireland)	arn:aws:lambda:eu-west-1:580247275435:layer:LambdaInsightsExtension:53
Europe (London)	arn:aws:lambda:eu-west-2:580247275435:layer:LambdaInsightsExtension:53
Europe (Milan)	arn:aws:lambda:eu-south-1:339249233099:layer:LambdaInsightsExtension:44
Europe (Paris)	arn:aws:lambda:eu-west-3:580247275435:layer:LambdaInsightsExtension:52
Europe (Spain)	arn:aws:lambda:eu-south-2:352183217350:layer:LambdaInsightsExtension:28

Region	ARN
Europe (Stockholm)	`arn:aws:lambda:eu-north-1:580247275435:layer:LambdaInsightsExtension:50`
Europe (Zurich)	`arn:aws:lambda:eu-central-2:033019950311:layer:LambdaInsightsExtension:27`
Israel (Tel Aviv)	`arn:aws:lambda:il-central-1:459530977127:layer:LambdaInsightsExtension:21`
Middle East (Bahrain)	`arn:aws:lambda:me-south-1:285320876703:layer:LambdaInsightsExtension:44`
Middle East (UAE)	`arn:aws:lambda:me-central-1:732604637566:layer:LambdaInsightsExtension:27`
South America (São Paulo)	`arn:aws:lambda:sa-east-1:580247275435:layer:LambdaInsightsExtension:52`
AWS GovCloud (US-East)	`arn:aws-us-gov:lambda:us-gov-east-1:122132214140:layer:LambdaInsightsExtension:21`
AWS GovCloud (US-West)	`arn:aws-us-gov:lambda:us-gov-west-1:751350123760:layer:LambdaInsightsExtension:21`

1.0.317.0

Version 1.0.317.0 includes the removal of support for the Amazon Linux 1 platform, and bug fixes. It also includes support for AWS GovCloud (US) Regions.

ARNs for version 1.0.317.0

The following table lists the ARNs to use for this version of the extension in each AWS Region where it is available.

Region	ARN
US East (N. Virginia)	arn:aws:lambda:us-east-1:580247275435:layer:LambdaInsightsExtension:52
US East (Ohio)	arn:aws:lambda:us-east-2:580247275435:layer:LambdaInsightsExtension:52
US West (N. California)	arn:aws:lambda:us-west-1:580247275435:layer:LambdaInsightsExtension:52
US West (Oregon)	arn:aws:lambda:us-west-2:580247275435:layer:LambdaInsightsExtension:52
Africa (Cape Town)	arn:aws:lambda:af-south-1:012438385374:layer:LambdaInsightsExtension:43
Asia Pacific (Hong Kong)	arn:aws:lambda:ap-east-1:519774774795:layer:LambdaInsightsExtension:43
Asia Pacific (Hyderabad)	arn:aws:lambda:ap-south-2:891564319516:layer:LambdaInsightsExtension:25
Asia Pacific (Jakarta)	arn:aws:lambda:ap-southeast-3:439286490199:layer:LambdaInsightsExtension:29
Asia Pacific (Melbourne)	arn:aws:lambda:ap-southeast-4:158895979263:layer:LambdaInsightsExtension:20
Asia Pacific (Mumbai)	arn:aws:lambda:ap-south-1:580247275435:layer:LambdaInsightsExtension:50
Asia Pacific (Osaka)	arn:aws:lambda:ap-northeast-3:194566237122:layer:LambdaInsightsExtension:33
Asia Pacific (Seoul)	arn:aws:lambda:ap-northeast-2:580247275435:layer:LambdaInsightsExtension:51

Region	ARN
Asia Pacific (Singapore)	arn:aws:lambda:ap-southeast-1:580247275435:layer:LambdaInsightsExtension:52
Asia Pacific (Sydney)	arn:aws:lambda:ap-southeast-2:580247275435:layer:LambdaInsightsExtension:52
Asia Pacific (Tokyo)	arn:aws:lambda:ap-northeast-1:580247275435:layer:LambdaInsightsExtension:79
Canada (Central)	arn:aws:lambda:ca-central-1:580247275435:layer:LambdaInsightsExtension:51
Canada West (Calgary)	arn:aws:lambda:ca-west-1:946466191631:layer:LambdaInsightsExtension:12
China (Beijing)	arn:aws-cn:lambda:cn-north-1:488211338238:layer:LambdaInsightsExtension:42
China (Ningxia);	arn:aws-cn:lambda:cn-northwest-1:488211338238:layer:LambdaInsightsExtension:42
Europe (Frankfurt)	arn:aws:lambda:eu-central-1:580247275435:layer:LambdaInsightsExtension:52
Europe (Ireland)	arn:aws:lambda:eu-west-1:580247275435:layer:LambdaInsightsExtension:52
Europe (London)	arn:aws:lambda:eu-west-2:580247275435:layer:LambdaInsightsExtension:52
Europe (Milan)	arn:aws:lambda:eu-south-1:339249233099:layer:LambdaInsightsExtension:43
Europe (Paris)	arn:aws:lambda:eu-west-3:580247275435:layer:LambdaInsightsExtension:51

Region	ARN
Europe (Spain)	arn:aws:lambda:eu-south-2:352183217350:layer:LambdaInsightsExtension:27
Europe (Stockholm)	arn:aws:lambda:eu-north-1:580247275435:layer:LambdaInsightsExtension:49
Europe (Zurich)	arn:aws:lambda:eu-central-2:033019950311:layer:LambdaInsightsExtension:26
Israel (Tel Aviv)	arn:aws:lambda:il-central-1:459530977127:layer:LambdaInsightsExtension:20
Middle East (Bahrain)	arn:aws:lambda:me-south-1:285320876703:layer:LambdaInsightsExtension:43
Middle East (UAE)	arn:aws:lambda:me-central-1:732604637566:layer:LambdaInsightsExtension:26
South America (São Paulo)	arn:aws:lambda:sa-east-1:580247275435:layer:LambdaInsightsExtension:51
AWS GovCloud (US-East)	arn:aws-us-gov:lambda:us-gov-east-1:122132214140:layer:LambdaInsightsExtension:19
AWS GovCloud (US-West)	arn:aws-us-gov:lambda:us-gov-west-1:751350123760:layer:LambdaInsightsExtension:19

1.0.295.0

Version 1.0.295.0 includes dependency updates for all the compatible runtimes.

ARNs for version 1.0.295.0

The following table lists the ARNs to use for this version of the extension in each AWS Region where it is available.

Region	ARN
US East (N. Virginia)	`arn:aws:lambda:us-east-1:580247275435:layer:LambdaInsightsExtension:51`
US East (Ohio)	`arn:aws:lambda:us-east-2:580247275435:layer:LambdaInsightsExtension:51`
US West (N. California)	`arn:aws:lambda:us-west-1:580247275435:layer:LambdaInsightsExtension:51`
US West (Oregon)	`arn:aws:lambda:us-west-2:580247275435:layer:LambdaInsightsExtension:51`
Africa (Cape Town)	`arn:aws:lambda:af-south-1:012438385374:layer:LambdaInsightsExtension:42`
Asia Pacific (Hong Kong)	`arn:aws:lambda:ap-east-1:519774774795:layer:LambdaInsightsExtension:42`
Asia Pacific (Hyderabad)	`arn:aws:lambda:ap-south-2:891564319516:layer:LambdaInsightsExtension:24`
Asia Pacific (Jakarta)	`arn:aws:lambda:ap-southeast-3:439286490199:layer:LambdaInsightsExtension:28`
Asia Pacific (Melbourne)	`arn:aws:lambda:ap-southeast-4:158895979263:layer:LambdaInsightsExtension:19`
Asia Pacific (Mumbai)	`arn:aws:lambda:ap-south-1:580247275435:layer:LambdaInsightsExtension:49`
Asia Pacific (Osaka)	`arn:aws:lambda:ap-northeast-3:194566237122:layer:LambdaInsightsExtension:32`
Asia Pacific (Seoul)	`arn:aws:lambda:ap-northeast-2:580247275435:layer:LambdaInsightsExtension:50`

Region	ARN
Asia Pacific (Singapore)	arn:aws:lambda:ap-southeast-1:580247275435:layer:LambdaInsightsExtension:51
Asia Pacific (Sydney)	arn:aws:lambda:ap-southeast-2:580247275435:layer:LambdaInsightsExtension:51
Asia Pacific (Tokyo)	arn:aws:lambda:ap-northeast-1:580247275435:layer:LambdaInsightsExtension:78
Canada (Central)	arn:aws:lambda:ca-central-1:580247275435:layer:LambdaInsightsExtension:50
Canada West (Calgary)	arn:aws:lambda:ca-west-1:946466191631:layer:LambdaInsightsExtension:11
China (Beijing)	arn:aws-cn:lambda:cn-north-1:488211338238:layer:LambdaInsightsExtension:41
China (Ningxia);	arn:aws-cn:lambda:cn-northwest-1:488211338238:layer:LambdaInsightsExtension:41
Europe (Frankfurt)	arn:aws:lambda:eu-central-1:580247275435:layer:LambdaInsightsExtension:51
Europe (Ireland)	arn:aws:lambda:eu-west-1:580247275435:layer:LambdaInsightsExtension:51
Europe (London)	arn:aws:lambda:eu-west-2:580247275435:layer:LambdaInsightsExtension:51
Europe (Milan)	arn:aws:lambda:eu-south-1:339249233099:layer:LambdaInsightsExtension:42
Europe (Paris)	arn:aws:lambda:eu-west-3:580247275435:layer:LambdaInsightsExtension:50

Region	ARN
Europe (Spain)	arn:aws:lambda:eu-south-2:352183217350:layer:LambdaInsightsExtension:26
Europe (Stockholm)	arn:aws:lambda:eu-north-1:580247275435:layer:LambdaInsightsExtension:48
Europe (Zurich)	arn:aws:lambda:eu-central-2:033019950311:layer:LambdaInsightsExtension:25
Israel (Tel Aviv)	arn:aws:lambda:il-central-1:459530977127:layer:LambdaInsightsExtension:19
Middle East (Bahrain)	arn:aws:lambda:me-south-1:285320876703:layer:LambdaInsightsExtension:42
Middle East (UAE)	arn:aws:lambda:me-central-1:732604637566:layer:LambdaInsightsExtension:25
South America (São Paulo)	arn:aws:lambda:sa-east-1:580247275435:layer:LambdaInsightsExtension:50

1.0.275.0

Version 1.0.275.0 includes important dependency updates for all the compatible runtimes.

ARNs for version 1.0.275.0

The following table lists the ARNs to use for this version of the extension in each AWS Region where it is available.

Region	ARN
US East (N. Virginia)	arn:aws:lambda:us-east-1:580247275435:layer:LambdaInsightsExtension:49
US East (Ohio)	arn:aws:lambda:us-east-2:580247275435:layer:LambdaInsightsExtension:49

Region	ARN
US West (N. California)	arn:aws:lambda:us-west-1:580247275435:layer:LambdaInsightsExtension:49
US West (Oregon)	arn:aws:lambda:us-west-2:580247275435:layer:LambdaInsightsExtension:49
Africa (Cape Town)	arn:aws:lambda:af-south-1:012438385374:layer:LambdaInsightsExtension:40
Asia Pacific (Hong Kong)	arn:aws:lambda:ap-east-1:519774774795:layer:LambdaInsightsExtension:40
Asia Pacific (Hyderabad)	arn:aws:lambda:ap-south-2:891564319516:layer:LambdaInsightsExtension:22
Asia Pacific (Jakarta)	arn:aws:lambda:ap-southeast-3:439286490199:layer:LambdaInsightsExtension:26
Asia Pacific (Melbourne)	arn:aws:lambda:ap-southeast-4:158895979263:layer:LambdaInsightsExtension:17
Asia Pacific (Mumbai)	arn:aws:lambda:ap-south-1:580247275435:layer:LambdaInsightsExtension:47
Asia Pacific (Osaka)	arn:aws:lambda:ap-northeast-3:194566237122:layer:LambdaInsightsExtension:30
Asia Pacific (Seoul)	arn:aws:lambda:ap-northeast-2:580247275435:layer:LambdaInsightsExtension:48
Asia Pacific (Singapore)	arn:aws:lambda:ap-southeast-1:580247275435:layer:LambdaInsightsExtension:49
Asia Pacific (Sydney)	arn:aws:lambda:ap-southeast-2:580247275435:layer:LambdaInsightsExtension:49

Region	ARN
Asia Pacific (Tokyo)	arn:aws:lambda:ap-northeast-1:580247275435:layer:LambdaInsightsExtension:76
Canada (Central)	arn:aws:lambda:ca-central-1:580247275435:layer:LambdaInsightsExtension:48
