Table of Contents

What is Amazon CloudWatch? 1
Monitor applications and AI agents with CloudWatch Omni 1
Operational visibility with metrics, alarms, and dashboards 2
Application performance monitoring (APM) 2
Infrastructure monitoring 3
Collect, store, and query logs 3
Use the CloudWatch agent to gather metrics, logs, and traces from Amazon EC2 fleets 3
Cross-account monitoring 4
OpenTelemetry support 4
Solutions catalog 4
CloudWatch network monitoring 4
Billing and costs 5
Resources 5
Quickstart 7
Choosing the right path 7
Prerequisites 8
Step 1: Instrumenting your application 10
Step 2: Running the Collector 12
Step 3: Checking that your telemetry arrived 14
Step 4: Creating an alarm and a dashboard widget 16
Troubleshooting telemetry export 17
Clean up resources 19
Keeping costs predictable 19
Next steps 20
Collect and send telemetry 21
OpenTelemetry 21
OTLP Endpoints 23
Getting started 34
Bearer token authentication for Metrics 73
Troubleshooting 85
CloudWatch agent 89
Supported operating systems 92
Prerequisites 93
Download the CloudWatch agent package 97

Verifying the signature of the CloudWatch agent package ... 103
Installing the CloudWatch agent ... 113
Set up the CloudWatch agent with security-enhanced Linux (SELinux) ... 154
Create the CloudWatch agent configuration file ... 157
Start the CloudWatch agent ... 332
Metrics collected by the CloudWatch agent ... 335
Using the CloudWatch agent with related telemetry ... 354
Common scenarios with the CloudWatch agent ... 355
CloudWatch agent credentials preference ... 365
Troubleshooting the CloudWatch agent ... 367
Embedding metrics within logs ... 377
Publishing logs with the embedded metric format ... 379
Viewing your metrics and logs in the console ... 402
Setting alarms on metrics created with the embedded metric format ... 404
CloudWatch pipelines ... 404
Pipeline components ... 405
Pricing ... 406
Region availability ... 406
Creating pipelines ... 408
Managing pipelines ... 412
Supported data sources for CloudWatch ... 412
Processors ... 739
Expression syntax for conditional processing ... 785
Sinks ... 790
CloudWatch pipelines IAM policies and permissions ... 795
Extensions ... 820
Monitoring pipelines ... 822
Troubleshooting ... 829
Managed Prometheus collectors ... 830
Integrate Amazon MSK ... 831
Integrate Amazon OpenSearch Service ... 842
Integrate Amazon EKS ... 845
VPC-connected managed collector ... 847
Scraper configuration ... 851
Monitor collectors ... 853
CloudWatch Omni ... 855

How CloudWatch Omni is organized ... 855
What you can do in CloudWatch Omni ... 856
How Omni relates to CloudWatch ... 857
Get started ... 857
Set up Omni ... 858
Choose your setup path ... 858
After setup ... 860
Set up Omni for a single account ... 861
Set up Omni for your organization ... 865
Control access to your space ... 871
AWS managed policies for CloudWatch Omni ... 904
Send telemetry to CloudWatch Omni ... 908
Where to start ... 908
How telemetry reaches your space ... 909
Forwarding to the Dataset ... 910
Choose how you collect ... 912
Choose an endpoint ... 912
Authentication ... 913
Environment support ... 913
Next steps ... 913
Send application telemetry ... 914
Send AI agent telemetry ... 946
Supported environments, languages, and frameworks ... 967
Ask the Omni agent ... 975
Where you can ask ... 976
What you can ask ... 976
How the agent works with you ... 977
Limitations ... 978
Permissions and data access ... 978
Investigations with the AWS DevOps Agent ... 978
Investigate with the AWS DevOps Agent ... 978
Explore and query your telemetry ... 980
Run your first query ... 980
Query logs and traces with SQL ... 981
Query metrics with PromQL ... 982
Discover fields ... 982

Work with results ... 983
CloudWatch Omni SQL limits ... 983
Act on what you find ... 983
SQL query reference ... 983
Dashboards ... 988
Every dashboard is shared ... 989
Pages and dashboards ... 989
What goes on a dashboard ... 989
Create a dashboard ... 989
Manage your dashboards ... 990
Threads ... 990
What a thread holds ... 990
Start a thread ... 991
Manage your threads ... 991
Collaborate and share ... 991
Alerts ... 991
Alert query ... 992
Thresholds and alert states ... 992
Evaluation timing ... 992
One alert, many series ... 993
Create an alert ... 993
Send notifications ... 994
Manage your alerts ... 994
Investigate a firing alert ... 994
Monitor AI agents ... 995
What you can do ... 996
How an agent run is represented ... 996
Where to start ... 997
Available across two surfaces ... 997
Feature availability by surface ... 998
Where your agent runs ... 998
How Omni relates to AgentCore and generative AI observability ... 999
Protect sensitive data ... 999
Analyze agent behavior ... 1004
Agent traces ... 1005
Agent sessions ... 1009

Agent topology ... 1011
Evaluate agent quality ... 1013
Evaluators and evaluations ... 1015
Datasets ... 1019
Experiments ... 1022
Online evaluations ... 1023
Prompt playground ... 1025
Monitor agents in the web UI ... 1027
Develop with the IDE extension ... 1028
Manage prompts ... 1032
Monitor applications with the application map ... 1034
Find which services need your attention ... 1034
Understand what appears on the map ... 1035
Investigate an application or a service from the map ... 1036
Narrow and organize the map ... 1037
What to watch out for ... 1037
Where to go next ... 1038
Cross-account and cross-Region topology ... 1038
Using Context Graph ... 1039
Monitor a service ... 1055
Application traces ... 1058
Connect Slack ... 1063
Disconnect an integration ... 1066
Who can manage integrations ... 1066
Use Omni skills ... 1066
How skills work with your AWS credentials ... 1067
What your coding agent can do with Omni ... 1067
Install the Omni skills ... 1067
To install and use the Omni skills ... 1068
Security in CloudWatch Omni ... 1068
Data encryption in CloudWatch Omni ... 1069
Identity and access management for CloudWatch Omni ... 1077
Compliance validation for CloudWatch Omni ... 1086
Resilience in CloudWatch Omni ... 1086
Infrastructure security in CloudWatch Omni ... 1087
Interface VPC endpoints (AWS PrivateLink) ... 1088

Configuration and vulnerability analysis in CloudWatch Omni ... 1091
Cross-service confused deputy prevention ... 1092
Security best practices for CloudWatch Omni ... 1094
Opting out of using your data for service improvement ... 1096
IAM policies to use CloudWatch Omni ... 1099
Cross-Region inference in CloudWatch Omni ... 1108
Tutorial: Monitor an application ... 1110
Prerequisites ... 1110
Step 1: Instrument your application ... 1111
Step 2: Send telemetry to CloudWatch ... 1111
Step 3: See your application on the map ... 1112
Step 4: Examine service health ... 1112
Next steps ... 1112
Tutorial: Fix a production quality regression ... 1113
What you will do ... 1113
Prerequisites ... 1114
Choose your agent ... 1115
Phase A: Build and instrument (IDE extension) ... 1117
Phase B: Deploy and observe (Omni web UI) ... 1119
Phase C: Reproduce and fix (IDE extension) ... 1122
Phase D: Verify continuously (Omni web UI) ... 1127
What you keep ... 1127
Dashboards ... 1129
Getting started with automatic dashboards ... 1131
Viewing the cross-service dashboard ... 1132
Removing a service from appearing in the cross-service dashboard ... 1134
Viewing a dashboard for a single service ... 1134
Viewing a dashboard for a resource group ... 1136
Creating a customized dashboard ... 1137
Creating a cross-account cross-Region dashboard with the console ... 1138
Create a cross-account cross-Region dashboard programmatically ... 1139
Creating a graph with metrics from different accounts and Regions ... 1143
Adding an alarm from a different account to a cross-account dashboard ... 1143
Creating dashboards with variables ... 1144
Types of dashboard variables ... 1144
Copying a variable to another dashboard ... 1145

Tutorial: Using a regular expression pattern to switch between Regions 1146
Tutorial: Creating dashboard with the Lambda function name as a variable 1147
Using widgets on dashboards 1149
Adding a graph widget 1151
Removing a graph widget 1154
Graph metrics manually on a dashboard 1154
Editing a graph 1156
Renaming a graph 1162
Moving a graph 1163
Changing the size of graphs 1163
Changing the size of a graph temporarily 1163
Add a metrics explorer widget 1164
Adding a line graph widget 1165
Removing a line graph 1166
Adding a number widget 1166
Removing a number widget 1167
Adding a gauge widget 1167
Removing a gauge widget 1168
Using a custom widget 1168
Adding a text widget 1179
Editing a text widget 1180
Removing a text widget 1180
Adding an alarm 1180
Adding an alarm status widget 1181
Removing an alert widget 1181
Using a data table widget 1181
Linking graphs 1185
Unlinking graphs 1185
Sharing dashboards 1186
Permissions required to share a dashboard 1187
Permissions that are granted to people who you share the dashboard with 1189
Sharing one dashboard with specific users 1190
Sharing a dashboard publicly 1191
Sharing all dashboards using SSO 1192
Setting up SSO 1193
Seeing how many of your dashboards are shared 1194

Seeing which dashboards are shared ... 1194
Stopping dashboard sharing ... 1195
Reviewing and changing shared dashboard permissions ... 1195
Allowing people that you share with to see composite alarms ... 1197
Allow widgets that use PromQL queries to be visible in shared dashboards ... 1198
Allowing people that you share with to see logs table widgets ... 1199
Allowing people that you share with to see custom widgets ... 1200
Using live data ... 1202
Using live data for a dashboard ... 1202
Using live data for a widget ... 1203
Viewing an animated dashboard ... 1203
Add a dashboard to your favorites list ... 1204
Changing the period override setting or refresh interval ... 1204
Changing the time range or time zone format ... 1206
Dashboard Body Structure and Syntax ... 1208
Overall Structure ... 1209
Widgets Array Structure ... 1214
Variables Array Structure ... 1216
Properties of a Log Widget Object ... 1223
Properties of a Metric Widget Object ... 1225
Metric Widget: Format for Each Metric in the Array ... 1231
Properties of a Metrics Explorer Widget Object ... 1246
Properties of an Alarm Status Widget Object ... 1253
Properties of a Chart Widget Object ... 1255
Graph metrics ... 1267
Graph a metric ... 1267
Merge two graphs into one ... 1273
Use dynamic labels ... 1274
Modify the time range or time zone format for a graph ... 1277
Zooming in on a graph ... 1280
Modify the y-axis for a graph ... 1282
Create an alarm from a metric on a graph ... 1283
GetMetricWidgetImage: Metric Widget Structure and Syntax ... 1284
Explore related telemetry ... 1301
What is related telemetry? ... 1302
How to access ... 1302

Navigating related telemetry ... 1303
Using the topology map ... 1306
Finding a specific resource ... 1306
Prerequisites ... 1307
How does CloudWatch find related telemetry? ... 1308
AWS services that support related telemetry ... 1310
Add related information to custom telemetry ... 1324
Metrics ... 1331
Overview ... 1331
OpenTelemetry: open-source native metrics in CloudWatch ... 1331
Two metric models ... 1331
Getting started ... 1332
OpenTelemetry Metrics (Recommended) ... 1332
Overview ... 1333
Publish custom metrics ... 1334
Histogram metrics ... 1338
Query metrics with PromQL ... 1340
Anomaly detection using PromQL ... 1373
Detailed monitoring ... 1374
Pricing and storage ... 1379
Migrate from Classic ... 1381
Vended Metrics in PromQL ... 1383
Resource tags for telemetry ... 1741
Enable resource tags on telemetry ... 1742
Using resource tags for telemetry ... 1743
Disable resource tags on telemetry ... 1937
Troubleshooting ... 1938
CloudWatch Metrics (Classic) ... 1939
Concepts ... 1940
Basic and detailed monitoring ... 1949
Publish custom metrics ... 1951
Query metrics with CloudWatch Metrics Insights ... 1956
View available metrics ... 1992
GetMetricData (Primary API) ... 1997
GetMetricStatistics (Legacy) ... 1999
Use metrics explorer to monitor resources by their tags and properties ... 2004

Search expressions ... 2007
Use metric streams ... 2019
Math expressions ... 2067
Using anomaly detection ... 2114
Query metrics from other data sources ... 2118
Grafana integration ... 2137
Services that publish CloudWatch metrics ... 2137
Alarms ... 2154
Concepts ... 2156
Alarm data queries ... 2156
Alarm evaluation ... 2159
PromQL alarms ... 2177
Log alarms ... 2178
Composite alarms ... 2189
Alarm actions ... 2200
Alarm Mute Rules ... 2205
Limits ... 2217
Getting started ... 2221
Create alarms ... 2221
Acting on alarm changes ... 2261
Configure alarm mute rules ... 2315
Managing alarms ... 2317
Editing or deleting a CloudWatch alarm ... 2318
Hide Auto Scaling alarms ... 2319
Alarms and tagging ... 2320
Viewing and managing muted alarms ... 2320
Common features of CloudWatch alarms ... 2322
Alarm recommendations for AWS services ... 2323
Find and create recommended alarms ... 2324
Recommended PromQL alarms ... 2326
Recommended alarms (Classic) ... 2399
Alarm use cases and examples ... 2503
Create a billing alarm ... 2503
Create a CPU usage alarm ... 2507
Create a load balancer latency alarm ... 2510
Create a storage throughput alarm ... 2512

Create an alarm on Performance Insights counter metrics from an AWS database 2514
Create a Log Alarm on errors 2516
Create a Log Alarm on latency 2517
Create an Auto Scaling action alarm 2518
Telemetry discovery and enablement 2521
What is telemetry discovery and enablement? 2521
Setting up telemetry configuration 2523
Prerequisites and permissions 2524
Enable telemetry configuration for your account 2526
Enable telemetry configuration for your organization 2527
Registering a delegated administrator account for your organization 2529

What is Amazon CloudWatch?

Amazon CloudWatch monitors your Amazon Web Services (AWS) resources and the applications you run on AWS in real time, and offers many tools to give you system-wide observability of your application performance, operational health, and resource utilization.

Topics

- Monitor applications and AI agents with CloudWatch Omni
- Operational visibility with metrics, alarms, and dashboards
- Application performance monitoring (APM)
- Infrastructure monitoring
- Collect, store, and query logs
- Use the CloudWatch agent to gather metrics, logs, and traces from Amazon EC2 fleets
- Cross-account monitoring
- OpenTelemetry support
- Solutions catalog
- Network and internet monitoring
- Billing and costs
- Amazon CloudWatch resources

Monitor applications and AI agents with CloudWatch Omni

CloudWatch Omni is an AI-powered observability experience in CloudWatch for your applications and AI agents. Omni discovers your services and their dependencies from your telemetry. Ask a question in plain language, and Omni writes the query for you, in SQL or PromQL (Prometheus Query Language). For AI agents, Omni scores response quality with evaluators, which catches failures that error rates do not show: an agent can return a well-formed response that is wrong. The scores appear alongside latency, errors, and token usage on the same trace.

Omni is built on CloudWatch and OpenTelemetry, and it does not replace anything you already run. Telemetry you already send to CloudWatch appears in Omni with nothing to reconfigure, and your existing metrics, alarms, and dashboards keep working unchanged. You reach Omni through a dedicated URL for your organization and sign in with the identities you already manage, or work in

the IDE extension for VS Code, Kiro, and Cursor while you develop AI agents. For more information, see *CloudWatch Omni*.

Operational visibility with metrics, alarms, and dashboards

Metrics collect and track key performance data at user-defined intervals. CloudWatch provides two types of metrics: OpenTelemetry Metrics (recommended) and CloudWatch Metrics (Classic). Many AWS services automatically report metrics into CloudWatch, and you can also publish your own custom metrics, either with OpenTelemetry (OTLP) or with the PutMetricData API.

Dashboards offer a unified view of your resources and applications with visualizations of your metrics and logs in a single location. You can also share dashboards across accounts and Regions for enhanced operational awareness. CloudWatch provides curated automatic dashboards for many AWS services, so that you don't have to build them yourself.

You can set up alarms that continuously monitor CloudWatch metrics against user-defined thresholds. They can automatically alert you to breaches of the thresholds, and can also automatically respond to changes in your resources' behavior by triggering automated actions.

Application performance monitoring (APM)

With Application Signals you can automatically detect and monitor your applications' key performance indicators like latency, error rates, and request rates without manual instrumentation or code changes. Application Signals also provides curated dashboards so you can begin monitoring with a minimum of setup.

CloudWatch Synthetics complements this by enabling you to proactively monitor your endpoints and APIs through configurable scripts called *canaries* that simulate user behavior and alert you to availability issues or performance degradation before they impact real users. You can also use CloudWatch RUM to gather performance data from real user sessions.

Use Service Level Objectives (SLOs) in CloudWatch to define, track, and alert on specific reliability targets for your applications, helping you maintain service quality commitments by setting error budgets and monitoring SLO compliance over time.

Infrastructure monitoring

Many AWS services automatically send basic metrics to CloudWatch for free. Services that send metrics are listed here. Additionally, CloudWatch provides additional monitoring capabilities for several key pieces of AWS infrastructure:

- Database Insights allows you to monitor database performance metrics in real time, analyze SQL query performance, and troubleshoot database load issues for AWS database services.
- Lambda Insights provides system-level metrics for Lambda functions, including memory and CPU utilization tracking, and cold start detection and analysis.
- Container Insights allows you to collect and analyze metrics from containerized applications, on Amazon ECS clusters, Amazon EKS clusters, and self-managed Kubernetes clusters on Amazon EC2.

Collect, store, and query logs

CloudWatch Logs offers a suite of powerful features for comprehensive log management and analysis. Logs ingested from AWS services and custom applications are stored in log groups and streams for easy organization. Use CloudWatch Logs Insights to perform interactive, fast queries on your log data, with a choice of three query languages including SQL and PPL. Use log anomaly detection to find unusual patterns in log events in a log group, which can indicate issues. Create metric filters to extract numerical values from logs and generate CloudWatch metrics, which you can use for alerting and dashboards. Set up subscription filters to process and analyze logs in real-time or route them to other services like Amazon S3 or Firehose.

Use the CloudWatch agent to gather metrics, logs, and traces from Amazon EC2 fleets

Use the CloudWatch agent to collect detailed system metrics about processes, CPU, memory, disk usage, and network performance from your fleets of Amazon EC2 instances and on-premises servers. You can also collect and monitor custom metrics from your applications, aggregate logs from multiple sources, and configure alarms based on the collected data. You can also use the agent to gather GPU metrics. The agent supports both Windows and Linux operating systems and can integrate with Systems Manager for centralized configuration management.

Cross-account monitoring

CloudWatch cross-account observability lets you set up a central monitoring account to monitor and troubleshoot applications that span multiple accounts. From the central account, you can view metrics, logs, and traces from source accounts across your organization. This centralized approach enables you to create cross-account dashboards, set up alarms that watch metrics from multiple accounts, and perform root-cause analysis across account boundaries. With CloudWatch cross-account observability, you can link source accounts either individually or link them automatically through AWS Organizations.

OpenTelemetry support

Amazon CloudWatch provides native OTLP endpoints for ingesting metrics, logs, and traces using the OpenTelemetry standard. You can collect telemetry using any OpenTelemetry-compatible SDK or collector and send it directly to CloudWatch without proprietary agents or format conversion. CloudWatch also supports PromQL for querying OpenTelemetry metrics. This open-standards approach lets you use the same instrumentation to send data to CloudWatch and third-party destinations, and query application and AWS infrastructure telemetry together. For more information, see OpenTelemetry.

Solutions catalog

CloudWatch offers a catalog of readily available configurations to help you quickly implement monitoring for various AWS services and common workloads, such as Java Virtual Machines (JVM), NVIDIA GPU, Apache Kafka, Apache Tomcat, and NGINX. These solutions provide focused guidance, including instructions for installing and configuring the CloudWatch agent, deploying pre-defined custom dashboards, and setting up related alarms.

Network and internet monitoring

CloudWatch provides comprehensive network and internet monitoring capabilities through CloudWatch Network Monitoring.

Internet Monitor uses AWS global networking data to analyze internet performance and availability between your applications and end users. With an internet monitor, you can identify or get notifications for increased latency or regional disruptions that impact your customers. Internet monitors work by analyzing your VPC flow logs to provide automated insights about network

traffic patterns and performance. You can also get suggestions for how to optimize application performance for your clients.

Network Flow Monitor displays network performance information gathered by lightweight software agents that you install on your instances. Using a flow monitor, you can quickly visualize packet loss and latency of your network connections over a time frame that you specify. Each monitor also generates a network health indicator (NHI), which tells you whether there were AWS network issues for the network flows tracked by your monitor during the time period that you're evaluating.

When you connect by using Direct Connect, you can use synthetic monitors in Network Synthetic Monitor to proactively monitor network connectivity by running synthetic tests between a VPC and on-premises endpoints. When you create a synthetic monitor, you specify probes by providing a VPC subnet and on-premises IP addresses. AWS creates and manages the infrastructure in the background that is required to perform round-trip time and packet loss measurements with the probes. These tests detect issues with connectivity, DNS, and latency before they impact your applications, so that you can take action to improve your end users' experience.

Billing and costs

For complete information about CloudWatch pricing, see Amazon CloudWatch Pricing.

For information that can help you analyze your bill and possibly optimize and reduce costs, see Analyzing, optimizing, and reducing CloudWatch costs.

Amazon CloudWatch resources

The following related resources can help you as you work with this service.

Resource	Description
Amazon CloudWatch FAQs	The FAQ covers the top questions developers have asked about this product.
AWS Developer Center	A central starting point to find documentation, code examples, release notes, and other information to help you build innovative applications with AWS.

Resource	Description
AWS Management Console	The console allows you to perform most of the functions of Amazon CloudWatch and various other AWS offerings without programming.
Amazon CloudWatch Discussion Forums	Community-based forum for developers to discuss technical questions related to Amazon CloudWatch.
AWS Support	The hub for creating and managing your AWS Support cases. Also includes links to other helpful resources, such as forums, technical FAQs, service health status, and AWS Trusted Advisor.
Amazon CloudWatch product information	The primary web page for information about Amazon CloudWatch.
Contact Us	A central contact point for inquiries concerning AWS billing, account, events, abuse, and so on.

Quickstart: Send metrics, logs, and traces to CloudWatch with OpenTelemetry

In about 20 minutes, you send three signals from one application to CloudWatch: a metric, a log record, and a trace. You see the metric in Query Studio, the log in CloudWatch Logs, and the trace in Transaction Search.

This is the recommended path for new telemetry. You use the OpenTelemetry SDK, then the OpenTelemetry Collector, then the CloudWatch OpenTelemetry Protocol (OTLP) endpoints, and finally Query Studio, CloudWatch Logs, and Transaction Search. This path works the same way on Amazon EKS, Amazon ECS, Amazon EC2, and on-premises servers. The instrumentation that you write here doesn't change when you deploy.

When you finish, you have the following:

- A counter metric and a histogram metric, a log record, and a trace with a span, all emitted by a sample application
- A Collector that signs and forwards all three signals to CloudWatch
- A PromQL query and an alarm for the metric, the log record in CloudWatch Logs, and the trace in Transaction Search

The resources that you create in this quickstart might incur charges to your AWS account. Ingesting metrics, logs, and traces can each incur charges. For more information, see OTel metrics pricing and storage.

Choosing the right path

Use this quickstart for any new custom metric. Use a different approach only if one of the following applies to you.

If you	Use instead
Run in an AWS Region where OTLP metrics ingestion isn't available. For more information	`PutMetricData` or the embedded metric format. For more information, see Publish custom metrics (PutMetricData / EMF).

If you	Use instead
about supported Regions, see Supported AWS Regions.	
Already have alarms and dashboards on an existing custom namespace that you must keep	Keep publishing with `PutMetricData`, and migrate later. For more information, see Migrate from Classic to OTel metrics.
Need a metric from existing log events without changing code	A metric filter on the log group. For more information, see Creating metrics from log events using filters in the *Amazon CloudWatch Logs User Guide*.
Want request rate, errors, and latency without writing code	Application Signals. Add custom metrics only for business events. For more information, see Application Signals.

Prerequisites

Before you begin this quickstart, make sure that you have the following:

- An AWS account and access to Query Studio in the CloudWatch console in a supported AWS Region. This quickstart uses `aa-example-1`. Replace it with your Region everywhere that it appears.
- AWS credentials that the Collector can find. On AWS compute, use an AWS Identity and Access Management (IAM) role. For example, use an instance profile on Amazon EC2, use IAM roles for service accounts or Amazon EKS Pod Identity on Amazon EKS, or use a task role on Amazon ECS. When you test locally, use environment variables. To get credentials for the AWS CLI, see Getting set up with the AWS CLI in the *AWS Command Line Interface User Guide*.
- CloudWatch Transaction Search enabled in your Region. You can send traces to the OTLP traces endpoint only after you enable Transaction Search. For more information, see Transaction Search.
- Docker, to run the Collector.
- Python 3.9 or later, for the sample application. The Java, Go, .NET, and Node.js SDKs work the same way.

Important

Traces that you send to the X-Ray OTLP endpoint require Transaction Search to be enabled. This is a one-time, account-wide setting. It switches all X-Ray span ingestion into CloudWatch Logs collection mode, billed under CloudWatch pricing, with 1 percent of spans indexed for free. Metrics and logs don't require this setting.
To enable Transaction Search, run the following command.

```
aws xray update-trace-segment-destination --destination CloudWatchLogs --region
 aa-example-1
```

To verify, run the following command. The destination is ready when `Status` is `ACTIVE` and `Destination` is `CloudWatchLogs`.

```
aws xray get-trace-segment-destination --region aa-example-1
```

IAM policy for the Collector's role — The Collector needs permissions to send metrics, logs, and traces. Attach the AWS managed policy `CloudWatchAgentServerPolicy` to the Collector's role. This is the simplest option, and it grants everything that the Collector needs for all three signals.

Note

Sending metrics over OTLP uses the `cloudwatch:PutMetricData` permission, even though you never call that API. CloudWatch metrics don't support resource-level permissions, so policies that allow this action set `Resource` to `"*"`. The `CloudWatchAgentServerPolicy` managed policy already includes this permission, along with the permissions for logs and traces.

People who query metrics or create alarms also need the `cloudwatch:GetMetricData` and `cloudwatch:ListMetrics` permissions. For more information, see IAM permissions for PromQL.

Workloads outside AWS can use a bearer token instead of SigV4 for metrics, logs, and traces. Each service needs its own API key. For more information, including the Regions where traces support bearer tokens, see Setting up bearer token authentication for Metrics and Setting up bearer token authentication for traces.

Step 1: Instrumenting your application

Your application sends telemetry to a local Collector, not directly to CloudWatch. The SDK's OTLP exporter doesn't sign requests with SigV4, so CloudWatch rejects direct calls to the endpoints. The Collector handles signing, batching, and retries.

The following command installs the SDK and the OTLP HTTP exporter. The HTTP exporter package provides the metric, span, and log exporters that this quickstart uses.

```
pip install opentelemetry-sdk opentelemetry-exporter-otlp-proto-http
```

Create `app.py`. It records one counter (orders placed) and one histogram (checkout latency), wraps each checkout in a trace span, and writes a log record for each order. All three signals go to the local Collector.

```
import logging, random, time
from opentelemetry import metrics, trace
from opentelemetry._logs import set_logger_provider
from opentelemetry.sdk.resources import Resource
from opentelemetry.sdk.metrics import MeterProvider
from opentelemetry.sdk.metrics.export import PeriodicExportingMetricReader
from opentelemetry.sdk.trace import TracerProvider
from opentelemetry.sdk.trace.export import BatchSpanProcessor
from opentelemetry.sdk._logs import LoggerProvider, LoggingHandler
from opentelemetry.sdk._logs.export import BatchLogRecordProcessor
from opentelemetry.exporter.otlp.proto.http.metric_exporter import OTLPMetricExporter
from opentelemetry.exporter.otlp.proto.http.trace_exporter import OTLPSpanExporter
from opentelemetry.exporter.otlp.proto.http._log_exporter import OTLPLogExporter

# Static metadata goes on the resource, not on every data point
resource = Resource.create({
    "service.name": "checkout",
    "service.version": "1.4.0",
    "deployment.environment": "dev",
})

# Metrics: local Collector; exports every 60 seconds
metric_exporter = OTLPMetricExporter(endpoint="http://localhost:4318/v1/metrics")
reader = PeriodicExportingMetricReader(metric_exporter, export_interval_millis=60000)
metrics.set_meter_provider(MeterProvider(resource=resource, metric_readers=[reader]))
```

```
# Traces: local Collector
trace.set_tracer_provider(TracerProvider(resource=resource))
trace.get_tracer_provider().add_span_processor(
    BatchSpanProcessor(OTLPSpanExporter(endpoint="http://localhost:4318/v1/traces"))
)

# Logs: local Collector, bridged from the Python logging module
logger_provider = LoggerProvider(resource=resource)
logger_provider.add_log_record_processor(
    BatchLogRecordProcessor(OTLPLogExporter(endpoint="http://localhost:4318/v1/logs"))
)
set_logger_provider(logger_provider)
logging.getLogger().addHandler(LoggingHandler(logger_provider=logger_provider))
logging.getLogger().setLevel(logging.INFO)

meter = metrics.get_meter("checkout")
orders = meter.create_counter("orders_placed", unit="1", description="Orders placed")
latency = meter.create_histogram("checkout_duration", unit="s", description="Checkout
 latency")
tracer = trace.get_tracer("checkout")
log = logging.getLogger("checkout")

while True:
    try:
        payment = random.choice(["card", "wallet"])
        with tracer.start_as_current_span("checkout") as span:
            span.set_attribute("payment_method", payment)
            orders.add(1, {"payment_method": payment})
            duration = random.uniform(0.05, 1.2)
            latency.record(duration, {"payment_method": payment})
            log.info("Order placed using %s in %.3fs", payment, duration)
            time.sleep(1)
    except Exception as error:
        print(f"Error recording telemetry: {error}")
```

Important

Use attributes whose values come from a small, fixed set, such as `payment_method`. Never use order IDs, user IDs, or URLs that contain IDs as attribute values.

Step 2: Running the Collector

In this quickstart, you run the Collector locally and give it credentials through environment variables. In production, the Collector runs on your compute platform and uses an IAM role instead, as shown in Next steps.

> **Important**
>
> Sending metrics, logs, and traces to CloudWatch incurs charges. For more information, see OTel metrics pricing and storage.

The Collector receives all three signals from your application and exports each one to its CloudWatch OTLP endpoint. Use a distribution that includes the `sigv4auth` extension, such as the OpenTelemetry Collector Contrib distribution or the AWS Distro for OpenTelemetry (ADOT) Collector.

> **Note**
>
> The CloudWatch agent is an alternative. It can receive OpenTelemetry Protocol (OTLP) data and send it to CloudWatch, so you can use it instead of running a separate OpenTelemetry Collector. For more information, see Collect metrics and traces with OpenTelemetry.

The logs exporter sends to the log group and log stream that you set in the `x-aws-log-group` and `x-aws-log-stream` headers. This example uses a `/otel/quickstart` log group and a `default` stream. Create them in CloudWatch Logs first, or change the values to a log group and stream that already exist.

Create `collector.yaml`. In the following example, replace `aa-example-1` with your Region.

```
extensions:
  sigv4auth/metrics:
    service: monitoring        # always "monitoring" for metrics
    region: aa-example-1
  sigv4auth/logs:
    service: logs              # always "logs" for logs
    region: aa-example-1
  sigv4auth/traces:
    service: xray              # always "xray" for traces
```

```
    region: aa-example-1

receivers:
  otlp:
    protocols:
      grpc:
        endpoint: 0.0.0.0:4317
      http:
        endpoint: 0.0.0.0:4318

processors:
  memory_limiter:
    check_interval: 1s
    limit_percentage: 80         # Valid range: 1-100
    spike_limit_percentage: 20   # Valid range: 1-100
  batch:
    send_batch_size: 200         # Number of records to buffer before sending
    send_batch_max_size: 1000    # Maximum batch size; CloudWatch accepts at most 1,000
 metric data points for each request
    timeout: 10s                 # Maximum time to wait before sending a batch

exporters:
  otlphttp/metrics:            # the endpoints support HTTP only, not gRPC
    metrics_endpoint: https://monitoring.aa-example-1.amazonaws.com/v1/metrics
    compression: gzip
    auth:
      authenticator: sigv4auth/metrics
  otlphttp/logs:               # the endpoints support HTTP only, not gRPC
    logs_endpoint: https://logs.aa-example-1.amazonaws.com/v1/logs
    compression: gzip
    headers:
      x-aws-log-group: /otel/quickstart   # create this log group, or use an existing
 one
      x-aws-log-stream: default           # create this stream, or use an existing one
    auth:
      authenticator: sigv4auth/logs
  otlphttp/traces:             # the endpoints support HTTP only, not gRPC
    traces_endpoint: https://xray.aa-example-1.amazonaws.com/v1/traces
    compression: gzip
    auth:
      authenticator: sigv4auth/traces

service:
  extensions: [sigv4auth/metrics, sigv4auth/logs, sigv4auth/traces]
```

```
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [memory_limiter, batch]
      exporters: [otlphttp/metrics]
    logs:
      receivers: [otlp]
      processors: [memory_limiter, batch]
      exporters: [otlphttp/logs]
    traces:
      receivers: [otlp]
      processors: [memory_limiter, batch]
      exporters: [otlphttp/traces]
```

The logs endpoint writes to an existing log group and log stream. Before you start the Collector, create the log group and stream named in the `x-aws-log-group` and `x-aws-log-stream` headers of your `collector.yaml` logs exporter. Otherwise, CloudWatch rejects your logs with `The specified log group does not exist`.

```
aws logs create-log-group --log-group-name /otel/quickstart --region aa-example-1
aws logs create-log-stream --log-group-name /otel/quickstart --log-stream-name default
 --region aa-example-1
```

Run the Collector locally with your credentials, and then start the application:

```
docker run --rm -p 4317:4317 -p 4318:4318 \
  -v "$PWD/collector.yaml:/etc/otelcol-contrib/config.yaml" \
  -e AWS_ACCESS_KEY_ID -e AWS_SECRET_ACCESS_KEY -e AWS_SESSION_TOKEN \
  otel/opentelemetry-collector-contrib:latest

python app.py
```

In production, pin a Collector version instead of using `latest`. On AWS compute, omit the `-e` flags. The Collector uses the role's credentials.

Step 3: Checking that your telemetry arrived

Data usually appears 1–2 minutes after the first export. Verify each signal in turn.

Metrics — In the CloudWatch console, open Query Studio and run each of the following queries. For more information, see Running a PromQL query in Query Studio.

To	PromQL
Confirm that the series exists	`orders_placed`
Show orders per second, by payment method	`sum by (payment_method) (rate(orders_placed[5m]))`
Show 95th percentile checkout latency	`histogram_quantile(0.95, sum(rate(checkout_duration[5m])))`

The raw `orders_placed` query returns one series for each payment method. Because a counter only increases, each series shows a cumulative total, as in the following example.

```
orders_placed{payment_method="card"}    512
orders_placed{payment_method="wallet"}  488
```

The `sum by (payment_method) (rate(orders_placed[5m]))` query converts those totals to a per-second rate. With the sample application, each series is near 0.5 per second, as in the following example.

```
{payment_method="card"}    0.51
{payment_method="wallet"}  0.49
```

Counters need `rate()` or `increase()`, because a raw counter only increases. You can query gauges directly. CloudWatch stores histograms as native histograms, so you query the metric name directly, without `_bucket` series or an `le` label. For more information, see Querying histogram metrics.

Logs — In the CloudWatch console, open CloudWatch Logs and open the `/otel/quickstart` log group (or the log group that you set in the `x-aws-log-group` header). Each order writes one log record. To search the records, use CloudWatch Logs Insights. For more information, see Analyze log data with CloudWatch Logs Insights in the *Amazon CloudWatch Logs User Guide*.

In Logs Insights, select the `/otel/quickstart` log group and run the following query to find your records:

```
fields @timestamp, severityText, body, traceId, spanId
```

```
| filter @message like /checkout/
| sort @timestamp desc
| limit 50
```

CloudWatch stores the OpenTelemetry log record as JSON, with resource attributes nested under `resource.attributes` (for example, `resource.attributes.service.name`), and the span's `payment_method` attribute is not a field on the log record — it appears in the span and in the log body. If you need to filter by a nested field, run a bare `fields @timestamp, @message | limit 50` query first to see the exact field paths.

Traces — In the CloudWatch console, open Transaction Search and open the Traces view. Each checkout produces one trace with a `checkout` span. If you don't see traces, confirm that Transaction Search is enabled in your Region.

Transaction Search stores spans in the `aws/spans` log group. You can search them in the CloudWatch Transaction Search console, filtered by the `checkout` service, or with a Logs Insights query on `aws/spans`. In Logs Insights, select the `aws/spans` log group and run the following query. This query filters on the top-level span name to avoid nested-field-path issues.

```
fields @timestamp, name, durationNano, attributes.payment_method, status.code, traceId
| filter name = "checkout"
| sort @timestamp desc
| limit 20
```

Each span carries the trace and span IDs that also appear on your log records, so you can pivot between a log line and its trace. CloudWatch enriches spans with Application Signals attributes such as `aws.local.service`.

If you don't see data after 5 minutes, see Troubleshooting telemetry export.

Step 4: Creating an alarm and a dashboard widget

Turn the latency query into an alarm and a dashboard widget, both from Query Studio.

To create an alarm and a dashboard widget

1. Open the CloudWatch console, and then open Query Studio.
2. In Query Studio, run the 95th percentile latency query from Step 3: Checking that your telemetry arrived.

3. From the actions menu, choose **Create alarm**. For more information, see Creating alarms from Query Studio.

   > **Note**
   >
   > If you receive an `AccessDenied` error, verify that the `CloudWatchAgentServerPolicy` managed policy is attached, or that your IAM policy includes the `cloudwatch:GetMetricData` and `cloudwatch:ListMetrics` permissions. For the required permissions, see Prerequisites.

4. Set the condition to greater than **`0.8`** seconds for 3 out of 3 periods.
5. Choose an Amazon SNS topic for notifications.
6. Return to Query Studio, choose **Add to dashboard**, and choose or create a dashboard for the checkout service. For more information, see Adding visualizations to dashboards.
7. (Optional) Add `sum(rate(orders_placed[5m]))` to the same dashboard.
8. (Optional) Turn on anomaly detection for the orders metric, so that a drop in orders alerts you without a fixed threshold. For more information, see Anomaly detection using PromQL.

Troubleshooting telemetry export

Check the Collector logs first. Export errors include the HTTP status code from CloudWatch.

Symptom	Likely cause	Fix
403 on metrics in the Collector logs	The role lacks `cloudwatch:PutMetricData`, or the `sigv4auth` service isn't `monitoring`.	Attach `CloudWatchAgentServerPolicy`, or fix the `service` value.
403 on logs in the Collector logs	The role lacks the logs permissions, or the `sigv4auth` service isn't `logs`.	Attach `CloudWatchAgentServerPolicy`, and set the `logs` `service` to `logs`.
4xx on logs, missing header	The logs exporter doesn't set the `x-aws-log-group` or `x-aws-log-stream` header.	Set both headers on the `otlphttp/logs` exporter to the target log group and stream.

Symptom	Likely cause	Fix
A log event is truncated or rejected	A single request to the logs endpoint is larger than 1 MB.	Reduce the batch size or the size of each log record so that each request stays under 1 MB.
Traces rejected	Transaction Search isn't enabled in the Region.	Enable CloudWatch Transaction Search, and then resend the traces.
403 on traces in the Collector logs	A bearer token was used for traces with a metrics or logs API key, or the X-Ray API key is invalid, inactive, or expired, or its IAM user isn't allowed `xray:CallWithBearerToken` or `xray:PutTraceSegments` .	Use an X-Ray API key with the required permissions, or use SigV4 (the `sigv4auth` extension with the `xray` service). For more information, see Setting up bearer token authentication for traces.
Connection errors to CloudWatch	The exporter is gRPC (`otlp`) instead of `otlphttp`, or the Region in the URL is wrong.	Use `otlphttp`, and use the same Region in the URL and in `sigv4auth` .
The application logs `connection refused`	The Collector isn't running, or port 4318 isn't published.	Start the Collector, and check `-p 4318:4318` .
400, too many data points	A batch has more than 1,000 data points.	Set `send_batch_max_size: 1000`.
400 on some series	A data point has more than 150 labels, or a label value is longer than 1,024 characters.	Drop or shorten attributes in a `transform` processor.
429	More than 500 requests per second for the account, or too many new series.	Send larger batches, and reduce the number of attribute values.

Symptom	Likely cause	Fix
Accepted, but not visible	The data point timestamp is more than 14 days in the past or more than 2 hours in the future.	Check the host clock.

For all limits, see Endpoint limits and restrictions.

Clean up resources

To avoid ongoing charges, delete the resources that you created in this quickstart when you no longer need them:

- Delete the alarm that you created.
- Remove the dashboard widget that you added.
- Delete the `/otel/quickstart` log group and its `default` log stream (or the log group and stream that you used) in CloudWatch Logs.
- Stop the Collector container and the sample application.
- Detach `CloudWatchAgentServerPolicy` from the Collector's role if you attached it only for this quickstart.

Keeping costs predictable

CloudWatch bills OTLP metrics per GB ingested, with 15 months of storage included. Logs and traces are also billed by the volume that you ingest, and Transaction Search has its own charges. Volume grows with the number of data points per series, the number of series, the number of log records, and the number of traces. For more information, see OTel metrics pricing and storage.

To keep costs predictable, keep the following practices in mind:

- **Export every 60 seconds.** Halving the interval roughly doubles the volume.
- **Count your series before you ship.** The number of series for a metric is the product of the number of distinct values of each attribute. For example, 2 payment methods, 3 Regions, and 5 status codes produce 30 series. Adding a user ID makes the number unbounded.

- **Put static metadata on the resource.** As shown in Step 1: Instrumenting your application, service name, version, and environment belong on the resource, not on each data point.
- **Use histograms where you need distributions.** A histogram data point carries more data than a counter or gauge data point. Use histograms for latency and sizes, not for everything.
- **Drop what you don't query.** With a `filter` processor in the Collector, you can remove unused metrics, log records, spans, or attributes before you're billed for them.

Next steps

Your instrumentation stays the same in production. Only where the Collector runs changes.

The following table shows where the Collector runs and which credentials to use in each environment.

Environment	Where the Collector runs	Credentials
Amazon EKS	A DaemonSet or Deployment. Applications send to its Service.	IAM roles for service accounts or Amazon EKS Pod Identity
Amazon ECS	A sidecar container in the task	Task role
Amazon EC2	A service on each instance	Instance profile
On-premises	A service on each host, or a central gateway	IAM Roles Anywhere, or a bearer token for metrics, logs, and traces

Before you go to production, also plan for the following:

- Configure the sending queue and retry settings on each exporter.
- Set up Collector health checks.
- Set up cross-account observability if telemetry from many accounts goes to one monitoring account. For more information, see CloudWatch cross-account observability.

For more ways to send telemetry, see Collect and send telemetry.

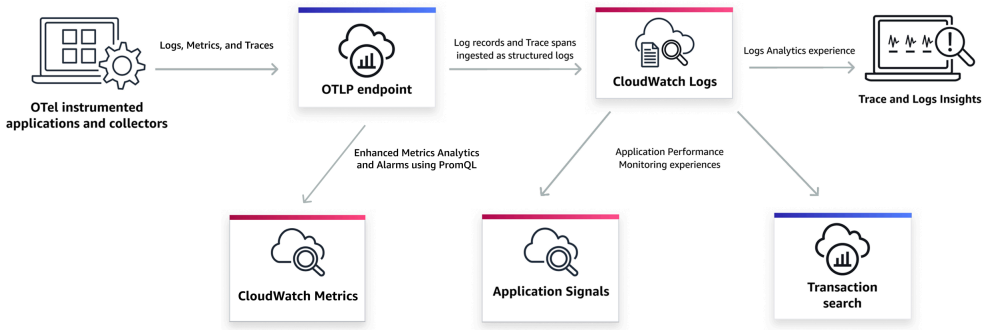
Collect and send telemetry

CloudWatch provides multiple methods to collect and send telemetry data from your applications and infrastructure. For new work, use OpenTelemetry. You send OpenTelemetry metrics, logs, and traces to the CloudWatch OTLP endpoints, either from the CloudWatch agent or from an OpenTelemetry collector. For more information, see OpenTelemetry.

You can also use the CloudWatch agent to collect metrics, logs, and traces from Amazon EC2 instances and on-premises servers. Separately, embedded metric format generates metrics from structured log data, CloudWatch Pipelines transform and route telemetry at scale, and managed Prometheus collectors discover and scrape Prometheus-compatible metrics from your AWS resources without running an agent.

Topics

- OpenTelemetry
- Collect metrics, logs, and traces using the CloudWatch agent
- Embedding metrics within logs
- CloudWatch pipelines
- Amazon CloudWatch managed Prometheus collectors



OpenTelemetry

> **Tip**
>
> To learn more about OpenTelemetry on CloudWatch, check out the Cloud Operations Enablement workshop and event series.

OpenTelemetry is an open-source observability framework that provides vendor-agnostic instrumentation for collecting metrics, logs, and traces from your applications. Amazon CloudWatch supports OpenTelemetry natively across all three signal types: metrics queryable with PromQL for flexible analytics, logs searchable with Logs Insights, and traces explorable with Transaction Search. Because all three signals share a common data model with consistent attributes, you can correlate across metrics, logs, and traces to move from detection to root cause faster.

You can send custom OTel metrics directly to CloudWatch and query them using PromQL alongside AWS vended metrics. For the resources and metrics that support this, see Supported AWS resources and metrics for OpenTelemetry enrichment. PromQL gives you flexible and scalable analytics, so you can build dashboards, set CloudWatch Alarms, and explore metrics in Query Studio, the native PromQL console experience. OpenTelemetry metrics also carry rich semantic labels and support higher granularity than traditional CloudWatch metrics. This granularity enables precise filtering, aggregation, and analysis across your applications and infrastructure. OTel logs that you send to CloudWatch are also available in LiveTail for real-time streaming.

For application performance monitoring, CloudWatch Application Signals provides a unified, application-centric view of your services and dependencies. Application Signals uses OTLP traces to help you monitor application health, triage issues, and identify the impact on end users. With Transaction Search, you can explore OTLP spans interactively, find transactions using attributes such as customer identifiers or order numbers, correlate transactions to business events such as failed payments, and trace interactions between application components to establish root cause.

OTLP Endpoints

OpenTelemetry Protocol (OTLP) is a general-purpose telemetry data delivery protocol designed for the OpenTelemetry. CloudWatch OpenTelemetry endpoints are HTTP 1.1 endpoints. You need to configure your OpenTelemetry collector to start sending open telemetry data to CloudWatch. For more information, see Getting started.

Logs endpoint

The logs endpoint follows the pattern `https://logs.AWS Region.amazonaws.com/v1/logs`. For example, for the `US West (Oregon) (us-west-2) Region`, the endpoint will be `https://logs.us-west-2.amazonaws.com/v1/logs`. You can use the above endpoint to forward logs to an existing `LogGroup` and `LogStream`. For more information on setting up `LogGroup` to ingest log data, see Amazon CloudWatch Logs concepts.

You must configure `LogGroup` and `LogStream` when you invoke CloudWatch Logs OpenTelemetry endpoint by setting `x-aws-log-group` and `x-aws-log-stream` HTTP headers to `LogGroup` and `LogStream` name respectively. For more information, see Getting started.

The endpoint supports the following authentication methods:

- **AWS Signature Version 4 (SigV4)** – Recommended for workloads running on AWS. Uses short-term credentials by using IAM roles. For more information, see AWS Signature Version 4 for API requests.
- **Bearer token (API key)** – For workloads running outside AWS or environments that do not support the AWS SDK. Requires bearer token authentication to be enabled on the target log group. For more information, see Setting up bearer token authentication for Logs.

When log event size exceed 1MB, CloudWatch Logs automatically truncates up to 10 fields, starting with the largest fields. Each field is truncated as needed to keep the total event size as close to 1MB as possible. The excess portions are stored as Large Log Objects (LLOs) and LLO reference system fields are added. Optionally, you can specify the field paths that need to be truncated by setting the `x-aws-truncatable-fields` HTTP header. The LLOs can be retrieved and streamed back using the `GetLogObject` API. For more information, see GetLogObject. Support of log events larger than 1MB and LLO experience is available in US East (N. Virginia) US West (Oregon), Europe (Frankfurt), Asia Pacific (Sydney), Asia Pacific (Mumbai), US East (Ohio), Europe (Ireland), Asia Pacific (Tokyo), and Asia Pacific (Singapore).

Metrics endpoint

The metrics endpoint follows the pattern `https://monitoring.AWS Region.amazonaws.com/v1/metrics`. For example, for the US West (Oregon) (us-west-2) Region, the endpoint will be `https://monitoring.us-west-2.amazonaws.com/v1/metrics`.

You need to configure your OpenTelemetry collector to start sending metrics to CloudWatch. The endpoint supports two authentication methods:

- **AWS Signature Version 4 (SigV4)**– The recommended authentication method using short-term credentials. For more information, see AWS Signature Version 4 for API requests.
- **Bearer token (API key)**– For workloads running outside AWS or environments that do not support the AWS SDK. Uses a long-lived API key passed in the `Authorization` header. For more information, see Setting up bearer token authentication for Metrics.

Traces endpoint

The traces endpoint follows the pattern `https://xray.AWS Region.amazonaws.com/v1/traces`. For example, for the US West (Oregon) (us-west-2) Region, the endpoint will be `https://xray.us-west-2.amazonaws.com/v1/traces`.

You need to configure your OpenTelemetry collector to start sending traces to CloudWatch. The endpoint supports two authentication methods:

- **AWS Signature Version 4 (SigV4)**– The recommended authentication method using short-term credentials. For more information, see AWS Signature Version 4 for API requests.
- **Bearer token (API key)**– For workloads running outside AWS or environments that do not support the AWS SDK. Uses a long-lived X-Ray API key passed in the `Authorization` header. For more information, including the supported Regions, see Setting up bearer token authentication for traces in the *X-Ray Developer Guide*.

RUM endpoint

The RUM endpoint follows the pattern `https://dataplane.rum.{AWS Region}.amazonaws.com/v1/rum`. For example, for the US West (Oregon) Region, the endpoint is `https://dataplane.rum.us-west-2.amazonaws.com/v1/rum`. This endpoint handles

client-side telemetry data (only traces and log records with `eventName`) for CloudWatch RUM applications.

To use this endpoint, you must create a RUM app monitor with Mobile platform (Android/ iOS) and use the code snippet generated to instrument your applications. The snippet will pull the RUM Mobile SDKs which are configured with this endpoint. You can configure the SDKs further for RUM to collect telemetry accordingly.

The endpoint supports both authenticated and unauthenticated requests. You can use AWS Signature Version 4 (SigV4) for authenticated requests, or resource-based policies to allow unauthenticated access from mobile applications.

To learn more about the authentication models as defined in their SDKs, see the following:

- iOS applications - AWS Distro for OpenTelemetry (ADOT) iOS SDK.
- Android applications - AWS Distro for OpenTelemetry (ADOT) Android SDK.

Endpoint limits and restrictions

The table lists the common endpoint limits and restrictions for metrics, traces, and logs.

Limit	Endpoint	Additional information
Required collector extension	sigv4authextension	To send metrics, logs, or traces to the OTLP endpoints, use sigv4authextension, or authenticate with a bearer token by using the bearertokenauth extension. See Setting up bearer token authentication for Metrics or Setting up bearer token authentication for Logs, or Setting

Limit	Endpoint	Additional information
		up bearer token authentication for traces.
Supported protocol	HTTP	The endpoint supports only HTTP and doesn't support gRPC
Supported OTLP versions	OTLP 1.x	
Payload format	binary, json	The endpoint accepts requests using binary and json formats
Compression methods	gzip, none	The endpoint only supports gzip and none compression methods

The table lists the endpoint limits and restrictions for traces.

Limit	Traces endpoint	Additional information
Maximum uncompressed bytes / request	5 MB	The OTLP endpoint will reject requests larger than 5MB when payload is uncompressed.
Maximum events / request	10,000 spans	The maximum number of spans in a batch is 10,000. Exceeding this limit

Limit	Traces endpoint	Additional information
		will cause rejection of the API call.
Single resource and scope size	16 KB	Each unique resource and corresponding scope should not exceed 16 KB of size. Exceeding this limit for any resource will cause rejection of the entire API call.
Single span maximum size	200 KB	Spans more than 200KB will be rejected by the endpoint.
Span created timestamps	2 hours in the future and 14 days in the past	None of the spans in the batch can be more than two hours in the future or more than 14 days in the past.
Maximum time gap in events / request	24 hours	

The table lists the endpoint limits and restrictions for metrics.

Limit	Metrics endpoint	Additional information	Error code
Maximum TPS	500	The maximum number of requests per second allowed per account.	429

Limit	Metrics endpoint	Additional information	Error code
Maximum new series creation rate	1,000,000	Maximum number of new series that can be created in a 10-minute window. This limit applies only to creating new metric names, not to ingesting data points for existing metrics.	429 - all metrics in the requests are throttled ; 200 - metrics in the requests are partially throttled
Maximum request size	5 MB	The maximum uncompressed size of the request.	413
Maximum datapoint count	1,000	The maximum number of datapoints sent in a single request. This number is a sum across ResourceMetrics, ScopeMetrics and Metrics.	400
Maximum metadata size	40 KB	The maximum combined size of all labels and label values accepted for a series per datapoint.	400 - all metrics in the requests are invalid; 200 - metrics in the requests are partially invalid

Limit	Metrics endpoint	Additional information	Error code
Maximum attribute value length	1024 characters	The maximum length of a string attribute value. Longer values are rejected with the following message: `Attribute string value exceeds maximum length: 1024`.	400
Maximum label count	150	Maximum number of labels across Resource/Scope/ Datapoint attributes per datapoint.	400 - all metrics in the requests are invalid; 200 - metrics in the requests are partially invalid
Metrics created timestamps	2 hours in the future and 14 days in the past	Metrics can be created with a timestamp that is at most 2 hours in the future and at most 14 days in the past.	400

The table lists the endpoint limits and restrictions for logs.

Limit	Logs endpoint	Additional information
Maximum uncompressed bytes / request	1 MB	The OTLP endpoint will reject requests larger than 1MB when payload is uncompressed.

Limit	Logs endpoint	Additional information
		The maximum request size is 1,048,576 bytes after decompression and deserialization of binary data serialized by Protocol buffers. This size is calculated as the sum of all event messages in UTF-8, plus 26 bytes for each log record.
	20 MB Available only in US East (N. Virginia) US West (Oregon), Europe (Frankfurt), Asia Pacific (Sydney), Asia Pacific (Mumbai), US East (Ohio), Europe (Ireland), Asia Pacific (Tokyo), and Asia Pacific (Singapore).	The maximum request size is 20MB (20,971,520 bytes) after the OTLP payload is decompressed and decoded from JSON format. For logs up to 1MB – These logs have full access to all CloudWatch Logs features including queries and live tail. For logs larger than 1MB – The excess portion is processed as Large Log Objects (LLOs).

Limit	Logs endpoint	Additional information
Request per second	5000	5000 transactions per second per account per Region You can request an increase to the per-second throttling quota by using the Service Quotas service.
Single resource and scope size	16 KB	Each unique resource and corresponding scope should not exceed 16 KB of size. Exceeding this limit for any resource will cause rejection of the entire API call.
Single LogEvent size	1 MB	LogEvent size is calculated as sum of sizes for each LogRecord, Scope and Resource. This quota can't be changed.

Limit	Logs endpoint	Additional information
Logs created timestamps	2 hours in future and 14 days old	The log records in the batch does not have to be in a chronological order. However, the log records in the batch cannot be more than 2 hours in the future and cannot be more than 14 days in the past. Also, none of the log records can be earlier than the retention period of the log group.
Maximum time gap in events / request	24 hours	
Maximum events / request	10,000 logs	The maximum number of log events in a batch is 10,000. Exceeding this limit will cause rejection of the API call.

Limit	Logs endpoint	Additional information
Maximum large log objects / request	1 log record Available in US East (N. Virginia) US West (Oregon), Europe (Frankfurt), Asia Pacific (Sydney), Asia Pacific (Mumbai), US East (Ohio), Europe (Ireland), Asia Pacific (Tokyo), and Asia Pacific (Singapore).	For content exceeding 1MB in a log event, the excess content is stored as LLOs. Limited to 1 log record per request.
Maximum large log objects / record	10 LLOs Available in US East (N. Virginia) US West (Oregon), Europe (Frankfurt), Asia Pacific (Sydney), Asia Pacific (Mumbai), US East (Ohio), Europe (Ireland), Asia Pacific (Tokyo), and Asia Pacific (Singapore).	A single log record can contain up to 10 LLOs.

Note

The account limits for Logs are shared across the SDK and the new Logs endpoint.

Getting started

To get started with OpenTelemetry in CloudWatch, you can choose from several options to send telemetry to the CloudWatch OTLP endpoints. For most customers, the CloudWatch agent is the recommended path. The CloudWatch agent is an AWS-managed OpenTelemetry Collector with CloudWatch components pre-built, and it provides the most integrated monitoring experience in CloudWatch.

You also have the flexibility to use an upstream OpenTelemetry Collector, build your own custom OpenTelemetry Collector, or send telemetry directly to the OTLP endpoint without a collector agent using the AWS Distro for OpenTelemetry (ADOT) SDK. Make an informed choice based on the feature support:

Feature	CloudWatch agent (recommended)	Upstream OpenTelemetry Collector	Custom OpenTelemetry Collector	Collectorless with AWS Distro for OpenTelemetry (ADOT) SDK
Search and analyze spans and trace summaries	Yes	Yes	Yes	Yes
Search and analyze logs summaries	Yes	Yes	Yes	No
CloudWatch entity correlation (resource linkage in the console and service map)	Yes	No	Yes	No
Runtime metrics correlated with your application. For example, JVM metrics	Yes	No	Yes	No
CloudWatch Enhanced Container Insights	Yes	No	No	No
CloudWatch Application Signals (Application	Yes	No	Yes	Yes

Feature	CloudWatch agent (recommended)	Upstream OpenTelemetry Collector	Custom OpenTelemetry Collector	Collectorless with AWS Distro for OpenTelemetry (ADOT) SDK
performance metrics, service discovery, and application map)				
Telemetry supported	Logs, Metrics, Traces	Logs, Metrics, Traces	Logs, Metrics, Traces	Metrics, Traces

> **Note**
>
> Make sure Transaction Search is enabled before you use the OTLP Endpoint for traces.

> **Note**
>
> AWS supports telemetry that you send to AWS destinations through the CloudWatch OTLP endpoints.

- Exporting collector-less telemetry using AWS Distro for OpenTelemetry (ADOT) SDK
- Managed Prometheus collectors

Amazon CloudWatch agent

The CloudWatch agent is built on the OpenTelemetry Collector, so you can use it to receive OpenTelemetry data and send it to the CloudWatch OTLP endpoints. In most cases, this is the recommended way to send OpenTelemetry data to CloudWatch, because a single agent can also power curated experiences such as CloudWatch Application Signals and CloudWatch Enhanced Container Insights. For more information about installing the agent, see Collect metrics, logs, and traces using the CloudWatch agent.

You can configure the agent to send OpenTelemetry data to the CloudWatch OTLP endpoints in two ways:

- **Using the agent configuration file (recommended)** – Add an `opentelemetry` section to your CloudWatch agent configuration file and enable the `otlp` source. The agent receives OTLP metrics, logs, and traces and forwards each signal to the correct CloudWatch OTLP endpoint. The agent sets the endpoints, the Region, and request signing for you, so you do not specify endpoint URLs or a `sigv4auth` extension. For the fields you can set, see CloudWatch agent configuration file: OpenTelemetry section.
- **Appending an OpenTelemetry collector configuration in YAML (advanced)** – Supply an OpenTelemetry collector configuration in YAML and append it to the agent's own configuration. Use this approach when you need components or pipeline topologies that the agent configuration file does not expose.

Send OpenTelemetry data using the agent configuration file

Add an `opentelemetry` section to your CloudWatch agent configuration file and include the `otlp` source under `collect`. When the agent starts with this configuration, it listens for OTLP data and forwards the received metrics, logs, and traces to the CloudWatch OTLP endpoints. For the fields you can set, their defaults, and the minimum agent version, see CloudWatch agent configuration file: OpenTelemetry section.

The following example configures the agent to receive OTLP data over gRPC and HTTP.

```
{
  "opentelemetry": {
    "collect": {
      "otlp": {
        "grpc_endpoint": "0.0.0.0:4317",
        "http_endpoint": "0.0.0.0:4318"
```

```
      }
    }
  }
}
```

Start the agent with this configuration the same way as any other agent configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -c
 file:/tmp/agent.json -s
```

> **Note**
>
> The agent signs requests to the CloudWatch OTLP endpoints with its own credentials. The `CloudWatchAgentServerPolicy` managed policy grants the permissions the agent needs to send metrics, logs, and traces to these endpoints.

Append an OpenTelemetry collector configuration in YAML

For pipelines that the agent configuration file does not expose, you can append an OpenTelemetry collector configuration in YAML. For the append procedure and the OpenTelemetry components that the agent supports, see Appending OpenTelemetry collector configuration files. The following examples show the YAML to append for each signal.

Configuration examples

The following examples send each signal to the corresponding CloudWatch OTLP endpoint using the `otlphttp` exporter and the `sigv4auth` extension. Each component and pipeline name uses a `/cwagent` suffix to avoid conflicts with pipelines that the agent creates automatically. Replace *`region`* with your AWS Region.

Metrics

```
receivers:
  otlp/cwagent:
    protocols:
      http:
        endpoint: 0.0.0.0:4318
processors:
```

```
  batch/cwagent: {}
exporters:
  otlphttp/cwagent:
    metrics_endpoint: https://monitoring.region.amazonaws.com/v1/metrics
    auth:
      authenticator: sigv4auth/cwagent
extensions:
  sigv4auth/cwagent:
    region: "region"
    service: "monitoring"
service:
  extensions: [sigv4auth/cwagent]
  pipelines:
    metrics/cwagent:
      receivers: [otlp/cwagent]
      processors: [batch/cwagent]
      exporters: [otlphttp/cwagent]
```

Logs

```
receivers:
  otlp/cwagent:
    protocols:
      http:
        endpoint: 0.0.0.0:4318
exporters:

```

Example: send application metrics through the CloudWatch agent

This example sends application metrics through the CloudWatch agent to the CloudWatch OpenTelemetry Protocol (OTLP) endpoints. Instrument your application with an OpenTelemetry SDK and export OTLP to the agent that runs alongside it. The agent forwards the metrics to CloudWatch.

You might no longer need a separate collector

If you set up OpenTelemetry metrics collection before the agent's OTLP receiver was available, you might be running a standalone ADOT or OpenTelemetry collector alongside the agent that you no longer need. After you upgrade to agent version 1.300070.0 or later, you can remove that collector. The agent handles AWS SigV4 signing, Region, and endpoint selection, so you no longer need to configure them in a collector. Keep the ADOT SDK and auto-instrumentation that generate telemetry in your application. For more information about configuring the agent's OTLP receiver, see CloudWatch agent configuration file: OpenTelemetry section.

Prerequisites

Before you begin, complete the following prerequisites:

- Install CloudWatch agent version 1.300070.0 or later. Earlier versions do not support the agent's OTLP receiver. Some Linux package repositories offer an earlier version, so check the installed version before you continue. For more information, see CloudWatch agent configuration file: OpenTelemetry section.
- Attach the `CloudWatchAgentServerPolicy` managed policy, which grants the agent permission to send metrics, logs, and traces to the CloudWatch OTLP endpoints. The agent signs these requests with its own credentials.
- Instrument your application with an OpenTelemetry SDK or ADOT, and configure the application to export OTLP to the agent over gRPC (port 4317) or HTTP (port 4318).

Common steps

The following steps are the same regardless of where the agent runs.

1. Configure the agent to receive OTLP data. Add an `opentelemetry` section to your CloudWatch agent configuration file and enable the `otlp` source, as shown in Send OpenTelemetry data using the agent configuration file. The agent forwards the received metrics to the CloudWatch OTLP endpoints.
2. Point your application's OTLP exporter at the local agent instead of the public CloudWatch endpoint (for example, `http://localhost:4318`). The agent forwards the metrics for you. The following Python example uses the OpenTelemetry SDK to export metrics to the agent.

```
from opentelemetry import metrics
from opentelemetry.sdk.metrics import MeterProvider
from opentelemetry.sdk.metrics.export import PeriodicExportingMetricReader
from opentelemetry.exporter.otlp.proto.http.metric_exporter import OTLPMetricExporter

# Point at the local CloudWatch agent, which forwards to CloudWatch
exporter = OTLPMetricExporter(endpoint="http://localhost:4318/v1/metrics")
reader = PeriodicExportingMetricReader(exporter, export_interval_millis=60000)
provider = MeterProvider(metric_readers=[reader])
metrics.set_meter_provider(provider)

# Create and record a metric
meter = metrics.get_meter("my-app")
```

```
counter = meter.create_counter("http_requests_total", description="Total HTTP
 requests")
counter.add(1, {"method": "GET", "path": "/api/users", "status": "200"})
```

3. Verify that your metrics are arriving. Open the CloudWatch console, navigate to **Query Studio**, and run a PromQL query for your metric. For more information, see Verify metrics are arriving and Running PromQL queries in Query Studio.

Amazon EC2

Run the CloudWatch agent on the Amazon EC2 instance, and configure your application to export OTLP to the agent on the same instance. Set the application's OTLP exporter endpoint to `http://localhost:4317` for gRPC or `http://localhost:4318` for HTTP. The agent forwards the metrics to the CloudWatch OTLP endpoints.

Amazon ECS

On Amazon ECS, run the CloudWatch agent as a sidecar container in the same task as your application. You can also run the agent as a daemon service on each container instance. When the agent runs as a sidecar, your application exports OTLP to `localhost` within the task (port 4317 for gRPC or port 4318 for HTTP). When the agent runs as a daemon service, your application exports OTLP to the agent on the host. In both cases, the agent forwards the metrics to the CloudWatch OTLP endpoints.

Amazon EKS

On Amazon EKS, install or upgrade the CloudWatch Observability EKS add-on to version 6.6.0 or later. The add-on runs the CloudWatch agent in your cluster. Earlier versions do not expose the OTLP ports on the agent Service.

You must also supply the agent `opentelemetry` and `otlp` configuration to the add-on through its configuration values. The add-on does not enable the OTLP receiver by default. Supply the following configuration values to the add-on.

```
{
  "agent": {
    "config": {
      "opentelemetry": {
        "collect": {
          "otlp": {
            "grpc_endpoint": "0.0.0.0:4317",
```

```
            "http_endpoint": "0.0.0.0:4318"
          }
        }
      }
    }
  }
}
```

After the add-on rolls out, the `cloudwatch-agent` Service exposes ports 4317 and 4318. Your application pods export OTLP to the agent Service, and the agent forwards the metrics to the CloudWatch OTLP endpoints.

> **Supplying agent.config replaces the default configuration**
>
> When you supply `agent.config`, the add-on replaces its default agent configuration rather than merging with it. A configuration that contains only the `opentelemetry` section removes the Application Signals ports (4315, 4316, and 2000) and the `cwa-server` port (4311) from the Service. If you also use Application Signals or Container Insights, include those settings in the configuration that you supply so that you do not lose them.

OpenTelemetry Collector

The OpenTelemetry Collector is an open source, vendor-agnostic agent that receives, processes, and exports telemetry data. It acts as a central pipeline between your applications and Amazon CloudWatch, collecting metrics, logs, and traces from multiple sources and sending them to CloudWatch using the OpenTelemetry Protocol (OTLP).

Using the OpenTelemetry Collector with CloudWatch provides the following benefits:

- Collect telemetry from multiple applications and hosts through a single agent, reducing the number of connections to CloudWatch.
- Process and filter telemetry before sending it to CloudWatch, including adding or removing attributes, batching data, and sampling traces.
- Use the same collector configuration across AWS, on-premises, and other cloud environments, providing a consistent telemetry pipeline regardless of where your applications run.
- Send metrics to CloudWatch with rich labels that are available to query using the Prometheus Query Language (PromQL) in CloudWatch Query Studio.

Supported receivers

The OpenTelemetry Collector supports a wide range of receivers for ingesting telemetry data. You can use OpenTelemetry receivers such as the OTLP receiver for applications instrumented with OpenTelemetry SDKs, or Prometheus receivers to scrape metrics from existing Prometheus exporters. Common Prometheus receivers used with CloudWatch include:

- Prometheus receiver, for scraping any Prometheus-compatible endpoint
- Host Metrics receiver, for collecting system-level metrics from the host
- Kubernetes Cluster receiver, for collecting cluster-level metrics from the Kubernetes API server

You can configure multiple receivers in a single collector, allowing you to collect both OpenTelemetry and Prometheus metrics and send them to CloudWatch through the same pipeline. For the full list of available receivers, see the OpenTelemetry Collector repository.

Getting started

Prerequisite – If using the OTLP endpoint for tracing, make sure that Transaction Search is enabled.

Steps:

1. Download the latest release of the OpenTelemetry Collector distribution. For more information, see the OpenTelemetry Collector releases.
2. Install the OpenTelemetry Collector on your host. The collector runs on any operating system and platform. For more information, see Install the Collector.
3. Configure AWS credentials on your Amazon EC2 or on-premises host. The collector uses these credentials to authenticate with CloudWatch when sending telemetry data. See below for details.

   Setup IAM permissions for Amazon EC2

   Follow the below procedure to attach the `CloudWatchAgentServerPolicy` IAM policy to the IAM role of your Amazon EC2 instance.

   1. Open the IAM console at https://console.aws.amazon.com/iam/.
   2. Choose **Roles** and find and select the role used by your Amazon EC2 instance.
   3. Under the **Permissions** tab, choose **Add permissions**, **Attach policies**.
   4. Using the search box, search for `CloudWatchAgentServerPolicy` policy.
   5. Select the **CloudWatchAgentServerPolicy** policy and choose **Add permissions**.

Setup IAM permissions for on-premises hosts

You can create an IAM user that can be used to provide permissions to your on-premise hosts.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Users**, **Create User**.
3. Under **User details**,for **User name**, enter a name for the new IAM user. This is the sign-in name for AWS that will be used to authenticate your host.
4. Choose **Next**.
5. On the **Set permissions** page, under **Permissions options**, select **Attach policies directly**.
6. From the **Permissions policies** list, select the **CloudWatchAgentServerPolicy** policy to add to your user.
7. Choose **Next**.
8. On the **Review and create** page, make sure that you are satisfied with the user name and that the **CloudWatchAgentServerPolicy** policy is under the **Permissions summary**.
9. Choose **Create user**.
10. **Create and retrieve your AWS access key and secret key** – In the navigation pane in the IAM console, choose **Users** and then select the user name of the user that you created in the previous step.
11. On the user's page, choose the **Security credentials** tab.
12. Under the **Access keys** section, choose **Create access key**.
13. For **Create access key Step 1**, choose **Command Line Interface (CLI)**.
14. For **Create access key Step 2**, optionally enter a tag and then choose **Next**.
15. For **Create access key Step 3,** select **Download .csv file** to save a .csv file with your IAM user's access key and secret access key. You need this information for the next steps.
16. Choose **Done**.
17. Configure your AWS credentials in your on-premises host by entering the following command. Replace *ACCESS_KEY_ID* and *SECRET_ACCESS_ID* with your newly generated access key and secret access key from the .csv file that you downloaded in the previous step.

```
$ aws configure
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

Tip

For on-premises hosts that send metrics, logs, or traces, you can use bearer token authentication as a simpler alternative to configuring AWS access keys. Bearer tokens don't require the `aws configure` step or credential files on the host. For more information, see Setting up bearer token authentication for Metrics and Setting up bearer token authentication for traces.

4. Setup AWS credentials for your Amazon EKS or Kubernetes clusters. The easiest way to get started with Amazon EKS is to use the EKS OTel Container Insights add-on. If you prefer to use the OpenTelemetry Collector directly, follow the procedure below to set up AWS credentials for your Amazon EKS or Kubernetes clusters to send telemetry to CloudWatch.

   Setup IAM permissions for Amazon EKS

   1. Create an IAM OIDC identity provider for your cluster using the following command.

      ```
      eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} --region
       ${REGION} --approve
      ```

   2. Assign IAM roles to Kubernetes service account for OTel Collector using the following command.

      ```
      eksctl create iamserviceaccount \
      --name ${COLLECTOR_SERVICE_ACCOUNT}\
      --namespace ${NAMESPACE} \
      --cluster ${CLUSTER_NAME} \
      --region ${REGION} \
      --attach-policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy \
      --approve \
      ```

```
--override-existing-serviceaccounts
```

Setup IAM permissions for Kubernetes

1. Configure your AWS credentials in your on-premises host by entering the following command. Replace *ACCESS_KEY_ID* and *SECRET_ACCESS_ID* with your newly generated access key and secret access key from the .csv file that you downloaded in the previous step. By default, the credential file is saved under */home/user/.aws/credentials.*.

   ```
   aws configure
   AWS Access Key ID [None]: ACCESS_KEY_ID
   AWS Secret Access Key [None]: SECRET_ACCESS_ID
   Default region name [None]: MY_REGION
   Default output format [None]: json
   ```

2. Edit OpenTelemetry Collector resource to add the newly created AWS credentials secret by using the command: `kubectl edit OpenTelemetryCollector` *otel_collector*

3. Using the file editor, add the AWS credentials into the OpenTelemetryCollector container by adding the following configuration to the top of the deployment. Replace the path */home/user/.aws/credentials* with the location of your local AWS credentials file.

   ```
    spec:
   volumeMounts:
   - mountPath: /rootfs
   volumeMounts:
   - name: aws-credentials
   mountPath: /root/.aws
   readOnly: true
   volumes:
   - hostPath:
   path: /home/user/.aws/credentials
   name: aws-credentials
   ```

5. Configure the OTLP exporter in your collector configuration to send telemetry to the CloudWatch endpoint. See examples below.

Authenticate with a bearer token (API key)

If you don't need to configure AWS credentials on the host – for example, when running on non-AWS infrastructure, other cloud providers, or CI/CD pipelines – you can use bearer token authentication instead of SigV4. Bearer tokens are supported for the metrics, logs, and traces endpoints (separate API keys are required for each service).

For setup instructions, see Setting up bearer token authentication for Metrics. For logs, see Setting up bearer token authentication for Logs. For traces, including the Regions where bearer tokens are supported, see Setting up bearer token authentication for traces in the *X-Ray Developer Guide*.

For a collector configuration example using bearer tokens, see the bearer token metrics example in the collector configuration examples below.

Collector configuration examples

Copy and paste the content below to configure your collector to send logs and traces to the OTLP endpoints.

```
receivers:
  otlp:
    protocols:
      grpc:
        endpoint: 0.0.0.0:4317
      http:
        endpoint: 0.0.0.0:4318

exporters:
  otlphttp/logs:
    compression: gzip
    logs_endpoint: logs_otlp_endpoint
    headers:
      x-aws-log-group: ency_log_group
      x-aws-log-stream: default
    auth:
      authenticator: sigv4auth/logs

  otlphttp/traces:
    compression: gzip
    traces_endpoint: traces_otlp_endpoint
    auth:
      authenticator: sigv4auth/traces
```

```
extensions:
  sigv4auth/logs:
    region: "region"
    service: "logs"
  sigv4auth/traces:
    region: "region"
    service: "xray"

service:
  telemetry:
  extensions: [sigv4auth/logs, sigv4auth/traces]
  pipelines:
    logs:
      receivers: [otlp]
      exporters: [otlphttp/logs]
    traces:
      receivers: [otlp]
      exporters: [otlphttp/traces]
```

The following is an example to send logs and traces using sigv4 to us-east-1.

```
receivers:
  otlp:
    protocols:
      grpc:
        endpoint: 0.0.0.0:4317
      http:
        endpoint: 0.0.0.0:4318

exporters:
  otlphttp/logs:
    compression: gzip
    logs_endpoint: https://logs.us-east-1.amazonaws.com/v1/logs
    headers:
      x-aws-log-group: MyApplicationLogs
      x-aws-log-stream: default
    auth:
      authenticator: sigv4auth/logs

  otlphttp/traces:
    compression: gzip
```

```
    traces_endpoint: https://xray.us-east-1.amazonaws.com/v1/traces
    auth:
      authenticator: sigv4auth/traces

extensions:
  sigv4auth/logs:
    region: "us-east-1"
    service: "logs"
  sigv4auth/traces:
    region: "us-east-1"
    service: "xray"

service:
  telemetry:
  extensions: [sigv4auth/logs, sigv4auth/traces]
  pipelines:
    logs:
     receivers: [otlp]
      exporters: [otlphttp/logs]
    traces:
      receivers: [otlp]
      exporters: [otlphttp/traces]
```

Note

Configure your OpenTelemetry SDKs to *always_on* sampling configuration to reliably record 100% spans and get full visibility into your critical applications with CloudWatch Application Signals. For more information, see an OpenTelemetry Java SDK sampler configuration example. For an example on setting up OpenTelemetry Collector with X-Ray OTLP endpoint, see the application signals demo repository.

Copy and paste the content below to configure your collector to send metrics to the OTLP endpoints.

```
receivers:
  otlp:
    protocols:
      http:
```

```
        endpoint: "0.0.0.0:4318"

processors:
  batch:
    send_batch_size: 200
    timeout: 10s

exporters:
  otlphttp:
    tls:
      insecure: false
    endpoint: metrics_otlp_endpoint
    auth:
      authenticator: sigv4auth

extensions:
  sigv4auth:
    service: "monitoring"
    region: "region"

service:
  extensions: [sigv4auth]
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [batch]
      exporters: [otlphttp]
```

The following is an example to send metrics using sigv4 to us-east-1.

```
receivers:
  otlp:
    protocols:
      http:
        endpoint: "0.0.0.0:4318"

processors:
  batch:
    send_batch_size: 200
    timeout: 10s

exporters:
```

```
  otlphttp:
    tls:
      insecure: false
    endpoint: "https://monitoring.us-east-1.amazonaws.com/v1/metrics:443"
    auth:
      authenticator: sigv4auth

extensions:
  sigv4auth:
    service: "monitoring"
    region: "us-east-1"

service:
  extensions: [sigv4auth]
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [batch]
      exporters: [otlphttp]
```

Metrics with bearer token authentication

The following is an example to send metrics using a bearer token to us-east-1. For setup instructions and security best practices, see Setting up bearer token authentication for Metrics.

```
extensions:
  bearertokenauth:
    filename: "/etc/otel/cw-api-key"

receivers:
  otlp:
    protocols:
      http:
        endpoint: "0.0.0.0:4318"

processors:
  batch:
    send_batch_size: 200
    timeout: 10s

exporters:
  otlphttp:
```

```
    tls:
      insecure: false
    endpoint: "https://monitoring.us-east-1.amazonaws.com/v1/metrics"
    auth:
      authenticator: bearertokenauth

service:
  extensions: [bearertokenauth]
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [batch]
      exporters: [otlphttp]
```

Important

Never hardcode API keys directly in collector configuration files. Use `filename` to read from a mounted secret, or `${env:VAR}` to read from an environment variable injected by your secrets manager.

Note

Unlike SigV4, bearer tokens don't require AWS credentials files, IAM roles, or IRSA configuration. The collector can run on any platform without AWS SDK dependencies.

Build your own custom OpenTelemetry Collector

You can build your own custom OpenTelemetry Collector to get the best application observability experience in CloudWatch with OpenTelemetry. In this setup, you need to build your own OpenTelemetry Collector with open source CloudWatch components.

Prerequisite

Make sure *Transaction Search* is enabled in CloudWatch. For more information, see Transaction Search.

Build your own collector

You can build your own collector with the following configuration to monitor your application in CloudWatch with OpenTelemetry. For more information, see Building a custom collector.

The common configuration for CloudWatch.

```
dist:
  name: otelcol-dev
  description: OTel Collector for sending telemetry to CloudWatch.
  output_path: ./otelcol-dev
extensions:
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/extension/
sigv4authextension v0.111.0
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/extension/awsproxy
 v0.113.0
exporters:
  - gomod: go.opentelemetry.io/collector/exporter/otlpexporter v0.111.0
  - gomod: go.opentelemetry.io/collector/exporter/otlphttpexporter v0.111.0
receivers:
  - gomod: go.opentelemetry.io/collector/receiver/otlpreceiver v0.111.0
```

Additional configuration for traces.

```
# Enable Tracing
dist:
  name: otelcol-dev
  description: OTel Collector for sending telemetry to CloudWatch.
  output_path: ./otelcol-dev
extensions:
    #Include common configurations and your custom extensions

exporters:
    #Include common configurations and your custom extensions

receivers:
  - gomod: go.opentelemetry.io/collector/receiver/otlpreceiver v0.111.0
processors:
  - gomod: github.com/amazon-contributing/opentelemetry-collector-contrib/processor/
awsapplicationsignalsprocessor v0.113.0
```

```
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/processor/
resourcedetectionprocessor v0.113.0
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/processor/
metricstransformprocessor v0.113.0
replaces:
  - github.com/open-telemetry/opentelemetry-collector-contrib/internal/aws/awsutil
 v0.113.0 => github.com/amazon-contributing/opentelemetry-collector-contrib/internal/
aws/awsutil v0.113.0
  - github.com/open-telemetry/opentelemetry-collector-contrib/internal/aws/cwlogs
 v0.113.0 => github.com/amazon-contributing/opentelemetry-collector-contrib/internal/
aws/cwlogs v0.113.0
  - github.com/open-telemetry/opentelemetry-collector-contrib/exporter/awsemfexporter
 v0.113.0 => github.com/amazon-contributing/opentelemetry-collector-contrib/exporter/
awsemfexporter v0.113.0
  - github.com/openshift/api v3.9.0+incompatible => github.com/openshift/api
 v0.0.0-20180801171038-322a19404e37
```

Note

Note the following:

- After the collector is built, deploy and configure the custom collector in a host or kubernetes environment by following the procedure under OpenTelemetry Collector.
- For information on setting up custom OpenTelemetry collector with Application Signals Processor, see an Application Signals custom configurationexample. Application Signals Processor only supports the latest versions of the OpenTelemetry Collectors for custom builds. For information on the supported versions, see opentelemetry-collector-contrib repository.

Collect telemetry from compiled applications using eBPF

You cannot instrument some applications by adding an OpenTelemetry SDK to the source. Examples include compiled binaries (such as Go, Rust, or C/C++), third-party or vendor binaries whose source you do not own, and applications whose libraries an in-process agent cannot attach to. For these applications, you can use eBPF-based auto-instrumentation to generate OpenTelemetry telemetry without changing application code. You then send that telemetry to CloudWatch through the CloudWatch agent.

Important

The CloudWatch agent is the OTLP receiver and exporter (the collection layer). It does not instrument your application. You pair the agent with a separate eBPF instrumentation tool that produces OTLP data. The open source OpenTelemetry project for this is OpenTelemetry eBPF Instrumentation (OBI) on the OpenTelemetry website. eBPF attaches probes at the kernel, network, and TLS layers. As a result, it captures HTTP, HTTPS, and gRPC traffic and produces rate, errors, and duration (RED) metrics and trace spans without per-library code changes. For the languages, runtime versions, and libraries that OBI supports, see the OBI documentation. Coverage might vary by language and library, including which client and server spans it produces. Validate the specific frameworks your application uses before you rely on this approach.

Understanding how it works

The telemetry flows through the following pipeline.

1. eBPF auto-instrumentation generates telemetry without a code change and emits OTLP.
2. The CloudWatch agent, which is built on the OpenTelemetry Collector, receives the OTLP data. For more information, see Amazon CloudWatch agent.
3. The agent forwards traces to AWS X-Ray (Transaction Search) and metrics to CloudWatch.

Determining when to use this approach

Consider this approach in the following cases:

- You have compiled binaries that you cannot add an SDK to.
- You have vendor or third-party code that you do not own.
- You must keep an existing third-party monitoring agent in place.
- You want RED metrics and traces without a code change or a redeploy of the application.

Completing the prerequisites

Before you begin, complete the following prerequisites:

- Install CloudWatch agent version 1.300070.0 or later. Earlier versions do not support the agent's OTLP receiver. On Amazon EKS, use the CloudWatch Observability EKS add-on version 6.6.0 or later so that the agent Service exposes the OTLP ports.
- Attach the `CloudWatchAgentServerPolicy` managed policy. The agent signs requests to the CloudWatch OTLP endpoints with its own credentials.
- Enable Transaction Search so that spans reach the X-Ray OTLP endpoint. For more information, see Transaction Search.
- The eBPF instrumentation tool runs on Linux and requires a kernel with eBPF support and a set of Linux capabilities (such as CAP_BPF). The exact capabilities depend on the instrumentation tool and which features you enable, so grant the least privilege the tool documents rather than running it fully privileged. See the OBI documentation.
- If the agent runs in a subnet without internet egress, make sure it can reach every endpoint it exports to. These endpoints are CloudWatch for metrics and X-Ray for traces (which Transaction Search uses). If you use the logs path, the agent must also reach CloudWatch Logs. In a private network, you typically provide this reachability with interface VPC endpoints (AWS PrivateLink). For the CloudWatch interface VPC endpoints, see Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints. For the X-Ray VPC endpoint, see Using X-Ray with interface VPC endpoints.

Step 1: Configure the CloudWatch agent to receive OTLP data

Add an `opentelemetry` section to your CloudWatch agent configuration file and include the `otlp` source under `collect`. Bind the receiver to `127.0.0.1` so that the agent accepts OTLP only from the local host. In containerized deployments where producers run outside the agent's own container network—for example an Amazon ECS sidecar, or the Amazon EKS add-on's `cloudwatch-agent` Service—set the endpoints to `0.0.0.0` instead. The task, pod, or Service boundary then controls what can reach the ports.

```
{
  "opentelemetry": {
    "collect": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
```

```
}
```

The agent forwards traces to X-Ray and metrics to CloudWatch automatically. For the full agent OTLP configuration, see Amazon CloudWatch agent.

Run one OTLP receiver per host

Run a single OTLP receiver—the CloudWatch agent—for each host network namespace, and have every telemetry producer (your eBPF instrumentation and any OpenTelemetry SDKs) export to it. Only one process can bind the default OTLP ports (4317 and 4318) in a given network namespace, so a second collector that also uses the defaults fails to start. If you previously ran a separate OpenTelemetry or ADOT collector, remove it when you move collection to the agent. The eBPF instrumentation is a producer that exports OTLP, so it does not open the OTLP receiver ports. On Amazon EKS, each pod has its own network namespace, so this conflict occurs only when a pod uses host networking or a host port. If two receivers must coexist, the ports are configurable—set `grpc_endpoint` and `http_endpoint` to non-default values.

Step 2: Point the eBPF instrumentation at the agent

Configure the eBPF tool's OTLP exporter to send to the local agent, using gRPC on port 4317 or HTTP on port 4318 (for example, `http://localhost:4318`). The following deployment notes apply:

- **Amazon EC2**—Run the agent and the eBPF tool on the same instance, and export OTLP to `localhost`.
- **Amazon EKS**—The CloudWatch Observability EKS add-on runs the agent and exposes ports 4317 and 4318 on the `cloudwatch-agent` Service. Run the eBPF instrumentation as a DaemonSet and point its exporter at that Service.

For the eBPF tool's own configuration, see the OBI documentation.

Step 3: Verify your telemetry

Verify that your telemetry is arriving:

- **Metrics**—Open the CloudWatch console, go to **Query Studio**, and run a PromQL query for your metric. OpenTelemetry metric names keep their dots in CloudWatch Query Studio, so query by

the metric's OpenTelemetry name with the __name__ matcher rather than a Prometheus-style normalized name—for example, {__name__="http.server.request.duration"} (the actual name depends on what your instrumentation emits).

- **Traces and spans**—Use Transaction Search. For more information, see Transaction Search.

> **Running alongside an existing monitoring agent**
>
> eBPF-based instrumentation runs out of process and does not inject into the application process. As a result, it can typically run alongside an existing in-process monitoring agent that does not instrument the same compiled runtime. Because eBPF tools require elevated privileges and some monitoring agents also use eBPF, validate resource usage and probe behavior in a test environment before you deploy to production.

Exporting collector-less telemetry using AWS Distro for OpenTelemetry (ADOT) SDK

You can use the ADOT SDKs to go collector-less and to send metrics, traces and logs directly to the OTLP endpoints.

> **Note**
>
> Application Signals includes Transaction Search capabilities. To avoid duplicate costs, disable Application Signals in the ADOT SDK and keep `OTEL_AWS_APPLICATION_SIGNALS_ENABLED` set to false (default setting).

Topics

- Prerequisite
- Set up IAM permissions for your role
- Configure your credentials providers
- Enabling ADOT SDKs

Prerequisite

If you are using traces, make sure Transaction Search is enabled to send spans to the X-Ray OTLP endpoint. For more information, see Getting started with Transaction Search.

Set up IAM permissions for your role

Follow these steps to attach the necessary IAM policies to your role:

Traces:

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles** and find and select your configured role.
3. Under the **Permissions** tab, choose **Add permissions**, then **Attach policies**.
4. Using the search box, search for the `AWSXrayWriteOnlyPolicy`.
5. Select the `AWSXrayWriteOnlyPolicy` policy and choose **Add permissions**.

Logs:

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles** and find and select your configured role.
3. Under the **Permissions** tab, choose **Add permissions**, then **Create inline policy**.
4. Select **CloudWatch Logs** for the service and under **Actions allowed**, filter and select:

```
logs:PutLogEvents
logs:DescribeLogGroups
logs:DescribeLogStreams
```

5. The following is an example IAM policy that grants the required permissions:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CloudWatchLogsAccess",
            "Effect": "Allow",
            "Action": [
```

```
                "logs:PutLogEvents",
                "logs:DescribeLogGroups",
                "logs:DescribeLogStreams"

            ],
            "Resource": [
                "arn:aws:logs:*:*:log-group:*"
            ]
        }
    ]
}
```

Configure your credentials providers

ADOT uses the AWS SDKs to automatically discover valid credentials required to export your telemetry data to AWS. For guidance on configuring credentials for your specific environment, refer to the documentation on how the AWS SDKS retrieves credentials.

Setting up IAM credentials for on-premise hosts:

Configure your AWS credentials in your on-premises host by entering the following command. Replace **ACCESS_KEY_ID** and **SECRET_ACCESS_KEY** with the credentials for your configured IAM role or user.

```
$ aws configure
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

Enabling ADOT SDKs

You can enable logs and traces for your application to be sent directly to the OTLP endpoints from AWS Distro for OpenTelemetry (ADOT) SDK on Java, Node.js, Python, and .Net.

> **Note**
>
> When you send traces directly to the OTLP endpoint without using a collector, the SDK defaults to `parentbased_always_on`, which samples 100% of traces. This can result in up to 20x higher ingestion volume and costs compared to the recommended 5% sampling rate.

If you plan to use Transaction Search for 100% trace visibility, no action is needed. If you want to moderate trace ingestion, configure a local sampler by setting the following environment variables before starting your application:

```
export OTEL_TRACES_SAMPLER="parentbased_traceidratio"
export OTEL_TRACES_SAMPLER_ARG="0.05"
```

The example above samples 5% of traces. Adjust the value of `OTEL_TRACES_SAMPLER_ARG` between `0` and `1` to set the sampling rate appropriate for your workload.
For more information about sampler configuration options, see OTEL_TRACES_SAMPLER in the OpenTelemetry documentation.

Java

Note

You must use **ADOT Java Agent version 2.11.2 or later** for these features to be available.

1. Download the latest version of the AWS Distro for OpenTelemetry Java auto-instrumentation agent. You can download the latest version by using this command:

   ```
   curl -L -O https://github.com/aws-observability/aws-otel-java-instrumentation/
   releases/latest/download/aws-opentelemetry-agent.jar
   ```

   You can view information about all released versions at aws-otel-java-instrumentation Releases.
2. To enable the different exporter that directly sends telemetry to the OTLP endpoints and to optimize benefits, use the following environment variables before you start your application:

   Traces:

   - Set `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` to specify the X-Ray OTLP traces endpoint: `https://xray.[AWSRegion].amazonaws.com/v1/traces`

For example:

```
export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT="https://xray.us-
west-2.amazonaws.com/v1/traces"
```

- Set `OTEL_TRACES_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_EXPORTER_OTLP_TRACES_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_RESOURCE_ATTRIBUTES` variable to specify the following information as key-value pairs. These environment variables are used by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.:
  - (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used.
  - (Optional) `deployment.environment` sets the environment that the application runs in. This will be displayed as the **Hosted In** environment of your application.
  - (Optional) To enable log correlation, in `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace `$YOUR_APPLICATION_LOG_GROUP` with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

Logs:

- Set `OTEL_EXPORTER_OTLP_LOGS_ENDPOINT` to specify the CloudWatch OTLP logs endpoint: `https://logs.[`*`AWSRegion`*`].amazonaws.com/v1/logs`

  For example:

```
export OTEL_EXPORTER_OTLP_LOGS_ENDPOINT="https://logs.us-west-2.amazonaws.com/
v1/logs"
```

- Set `OTEL_EXPORTER_OTLP_LOGS_HEADERS` to specify the log group and log stream (note: these must created **before** running ADOT) you want to export your logs to: `x-aws-log-group=[CW-LOG-GROUP-NAME],x-aws-log-stream=[CW-LOG-STREAM-NAME]`

  For example:

```
export OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-
stream=default
```

- Set `OTEL_LOGS_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_EXPORTER_OTLP_LOGS_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).

3. Set `JAVA_TOOL_OPTIONS` to specify the path where the AWS Distro for OpenTelemetry Java auto-instrumentation agent is stored. For example:

```
export JAVA_TOOL_OPTIONS=" -javaagent:$AWS_ADOT_JAVA_INSTRUMENTATION_PATH"
export AWS_ADOT_JAVA_INSTRUMENTATION_PATH="./aws-opentelemetry-agent.jar"
```

4. Your application should now be running with ADOT Java instrumentation and will generate spans and logs. Spans will be stored in the `aws/spans` CloudWatch log group, while logs will be stored in the log group specified in the `OTEL_EXPORTER_OTLP_LOGS_HEADERS` header. You can also view the logs and metrics correlated with your spans in the CloudWatch Traces and Metrics Console.
5. Start your application with the environment variables listed in the previous step. The following is an example of a starting script.

```
JAVA_TOOL_OPTIONS=" -javaagent:$AWS_ADOT_JAVA_INSTRUMENTATION_PATH" \
OTEL_METRICS_EXPORTER=none \
OTEL_TRACES_EXPORTER=otlp \
OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces \
OTEL_LOGS_EXPORTER=otlp \
```

```
OTEL_EXPORTER_OTLP_LOGS_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_LOGS_ENDPOINT=https://logs.us-east-1.amazonaws.com/v1/logs \
OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-
stream=default
OTEL_RESOURCE_ATTRIBUTES="service.name=$YOUR_SVC_NAME" \
java -jar $MY_JAVA_APP.jar
```

Node.js

> **Note**
>
> You must use **ADOT JavaScript version 0.7.0 or later** for these features to be available.

1. Download the latest version of the AWS Distro for OpenTelemetry JavaScript auto-instrumentation. Install it by running the following command.

   ```
   npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation
   ```

   You can view information about all released versions at aws-otel-js-instrumentation Releases.
2. To enable the different exporter that directly sends telemetry to the OTLP endpoints and to optimize benefits, use the following environment variables before you start your application:

   Traces:

   - Set `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` to specify the X-Ray OTLP traces endpoint: `https://xray.[AWSRegion].amazonaws.com/v1/traces`

     For example:

     ```
     export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT="https://xray.us-
     west-2.amazonaws.com/v1/traces"
     ```
   - Set `OTEL_TRACES_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
   - Set `OTEL_EXPORTER_OTLP_TRACES_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).

- Set `OTEL_RESOURCE_ATTRIBUTES` variable to specify the following information as key-value pairs. These environment variables are used by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.:
  - (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used.
  - (Optional) `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application.
  - (Optional) To enable log correlation, in `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace `$YOUR_APPLICATION_LOG_GROUP` with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

Logs:

- Set `OTEL_EXPORTER_OTLP_LOGS_ENDPOINT` to specify the CloudWatch OTLP logs endpoint: `https://logs.[`*`AWSRegion`*`].amazonaws.com/v1/logs`

  For example:

  ```
  export OTEL_EXPORTER_OTLP_LOGS_ENDPOINT="https://logs.us-west-2.amazonaws.com/v1/logs"
  ```

- Set `OTEL_EXPORTER_OTLP_LOGS_HEADERS` to specify the log group and log stream (note: these must created **before** running ADOT) you want to export your logs to: `x-aws-log-group=[CW-LOG-GROUP-NAME],x-aws-log-stream=[CW-LOG-STREAM-NAME]`

  For example:

```
export OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-
stream=default
```

- Set `OTEL_LOGS_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_EXPORTER_OTLP_LOGS_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).

3. Your application should now be running with ADOT JavaScript instrumentation and will generate spans and logs. Spans will be stored in the `aws/spans` CloudWatch log group, while logs will be stored in the log group specified in the `OTEL_EXPORTER_OTLP_LOGS_HEADERS` header. You can also view the logs and metrics correlated with your spans in the CloudWatch Traces and Metrics Console.
4. Start your application with the environment variables listed in the previous step. The following is an example of a starting script.

   Replace `$SVC_NAME` with your application name. This will be displayed as the name of the application.

```
OTEL_METRICS_EXPORTER=none \
OTEL_TRACES_EXPORTER=otlp \
OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces \
OTEL_LOGS_EXPORTER=otlp \
OTEL_EXPORTER_OTLP_LOGS_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_LOGS_ENDPOINT=https://logs.us-east-1.amazonaws.com/v1/logs \
OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-
stream=default
OTEL_RESOURCE_ATTRIBUTES="service.name=$YOUR_SVC_NAME" \
node --require '@aws/aws-distro-opentelemetry-node-autoinstrumentation/register'
 your-application.js
```

Python

> **Note**
>
> You must use **ADOT Python version 0.10.0 or later** and have **`botocore`** installed for these features to be available.

1. Download the latest version of the AWS Distro for OpenTelemetry Python auto-instrumentation. Install it by running the following command.

   ```
   pip install aws-opentelemetry-distro
   ```

   You can view information about all released versions at aws-otel-python-instrumentation Releases.

2. To enable the different exporter that directly sends telemetry to the OTLP endpoints and to optimize benefits, use the following environment variables before you start your application:

   For both traces and logs configurations, you must set the following environment variables:

   - `OTEL_PYTHON_DISTRO` to `aws_distro`
   - `OTEL_PYTHON_CONFIGURATOR` to `aws_configurator`

   Traces:

   - Set `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` to specify the X-Ray OTLP traces endpoint: `https://xray.[`*`AWSRegion`*`].amazonaws.com/v1/traces`

     For example:

     ```
     export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT="https://xray.us-
     west-2.amazonaws.com/v1/traces"
     ```

   - Set `OTEL_TRACES_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).

- Set `OTEL_EXPORTER_OTLP_TRACES_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_RESOURCE_ATTRIBUTES` variable to specify the following information as key-value pairs. These environment variables are used by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.:
  - (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used.
  - (Optional) `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application.
  - (Optional) To enable log correlation, in `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace `$YOUR_APPLICATION_LOG_GROUP` with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

Logs:

- Set `OTEL_PYTHON_LOGGING_AUTO_INSTRUMENTATION_ENABLED` to `true`
- Set `OTEL_EXPORTER_OTLP_LOGS_ENDPOINT` to specify the CloudWatch OTLP logs endpoint: `https://logs.[AWSRegion].amazonaws.com/v1/logs`

  For example:

```
export OTEL_EXPORTER_OTLP_LOGS_ENDPOINT="https://logs.us-west-2.amazonaws.com/
v1/logs"
```

- Set `OTEL_EXPORTER_OTLP_LOGS_HEADERS` to specify the log group and log stream (note: these must created **before** running ADOT) you want to export your logs to: `x-`

`aws-log-group=[CW-LOG-GROUP-NAME],x-aws-log-stream=[CW-LOG-STREAM-NAME]`

For example:

```
export OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-stream=default
```

- Set `OTEL_LOGS_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_EXPORTER_OTLP_LOGS_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).

3. Your application should now be running with ADOT Python instrumentation and will generate spans and logs. Spans will be stored in the `aws/spans` CloudWatch log group, while logs will be stored in the log group specified in the `OTEL_EXPORTER_OTLP_LOGS_HEADERS` header. You can also view the logs and metrics correlated with your spans in the CloudWatch Traces and Metrics Console.
4. Start your application with the environment variables listed in the previous step. The following is an example of a starting script.

   Replace `$SVC_NAME` with your application name. This will be displayed as the name of the application.

   Replace `$PYTHON_APP` with the location and name of your application.

```
OTEL_METRICS_EXPORTER=none \
OTEL_TRACES_EXPORTER=otlp \
OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/traces \
OTEL_LOGS_EXPORTER=otlp \
OTEL_EXPORTER_OTLP_LOGS_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_LOGS_ENDPOINT=https://logs.us-east-1.amazonaws.com/v1/logs \
OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-stream=default
OTEL_PYTHON_LOGGING_AUTO_INSTRUMENTATION_ENABLED=true
OTEL_RESOURCE_ATTRIBUTES="service.name=$YOUR_SVC_NAME" \
opentelemetry-instrument python $MY_PYTHON_APP.py
```

.Net

> **Note**
>
> - **ADOT .NET version 1.8.0 or later** is required for these features to be available.
> - Compression is currently not supported.
> - Logs is currently not supported.

Download the latest version of the AWS Distro for OpenTelemetry .NET auto-instrumentation package. You can view information about all released versions at aws-otel-dotnet-instrumentation Releases.

To enable the different exporters that directly sends telemetry to the OTLP endpoints and to optimize benefits, use the following environment variables before you start your application (replace `dotnet-service-name` in the `OTEL_RESOURCE_ATTRIBUTES` environment variable with the service name of your choice):

Traces:

- You **MUST** set `OTEL_TRACES_EXPORTER` to none
- You **MUST** set `OTEL_AWS_SIG_V4_ENABLED` to `true`

  This feature is **not enabled automatically in .NET**. The environment variable is required specifically to identify this use case within the .NET instrumentation. This requirement is unique to .NET and does **not apply to other supported languages**.

The following is an example setup for Linux.

```
export INSTALL_DIR=OpenTelemetryDistribution
export CORECLR_ENABLE_PROFILING=1
export CORECLR_PROFILER={918728DD-259F-4A6A-AC2B-B85E1B658318}
export CORECLR_PROFILER_PATH=${INSTALL_DIR}/linux-x64/
OpenTelemetry.AutoInstrumentation.Native.so
export DOTNET_ADDITIONAL_DEPS=${INSTALL_DIR}/AdditionalDeps
export DOTNET_SHARED_STORE=${INSTALL_DIR}/store
export DOTNET_STARTUP_HOOKS=${INSTALL_DIR}/net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll
```

```
export OTEL_DOTNET_AUTO_HOME=${INSTALL_DIR}

export
 OTEL_DOTNET_AUTO_PLUGINS="AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"
export OTEL_TRACES_EXPORTER=none
export OTEL_AWS_SIG_V4_ENABLED=true

export OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
export OTEL_METRICS_EXPORTER=none
export OTEL_LOGS_EXPORTER=none
export OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf
export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces
```

The following is an example setup for Windows Server:

```
$env:INSTALL_DIR = "OpenTelemetryDistribution"
$env:CORECLR_ENABLE_PROFILING = 1
$env:CORECLR_PROFILER = "{918728DD-259F-4A6A-AC2B-B85E1B658318}"
$env:CORECLR_PROFILER_PATH = Join-Path $env:INSTALL_DIR "win-x64/
OpenTelemetry.AutoInstrumentation.Native.dll"
$env:DOTNET_ADDITIONAL_DEPS = Join-Path $env:INSTALL_DIR "AdditionalDeps"
$env:DOTNET_SHARED_STORE = Join-Path $env:INSTALL_DIR "store"
$env:DOTNET_STARTUP_HOOKS = Join-Path $env:INSTALL_DIR "net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll"
$env:OTEL_DOTNET_AUTO_HOME = $env:INSTALL_DIR
$env:OTEL_DOTNET_AUTO_PLUGINS =
 "AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"

$env:OTEL_TRACES_EXPORTER=none
$env:OTEL_AWS_SIG_V4_ENABLED=true

$env:OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
$env:OTEL_METRICS_EXPORTER=none
$env:OTEL_LOGS_EXPORTER=none
$env:OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf
$env:OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces
```

1. Start your application with the environment variables listed in the previous step.

2. (Optional) Alternatively, you can use the installation scripts provided to help installation and setup of AWS Distro for OpenTelemetry .NET auto-instrumentation package.

   For Linux, download and install the Bash installation script from the GitHub releases page:

   ```
   # Download and Install
   curl -L -O https://github.com/aws-observability/aws-otel-dotnet-instrumentation/
   releases/latest/download/aws-otel-dotnet-install.sh
   chmod +x ./aws-otel-dotnet-install.sh
   ./aws-otel-dotnet-install.sh
   # Instrument
   . $HOME/.otel-dotnet-auto/instrument.shexport
    OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
   ```

   For Windows Server, download and install the PowerShell installation script from the GitHub releases page:

   ```
   # Download and Install
   $module_url = "https://github.com/aws-observability/aws-otel-dotnet-
   instrumentation/releases/latest/download/AWS.Otel.DotNet.Auto.psm1"
   $download_path = Join-Path $env:temp "AWS.Otel.DotNet.Auto.psm1"
   Invoke-WebRequest -Uri $module_url -OutFile $download_path
   Import-Module $download_path
   Install-OpenTelemetryCore
   # Instrument
   Import-Module $download_path
   Register-OpenTelemetryForCurrentSession -OTelServiceName "dotnet-service-name"
   Register-OpenTelemetryForIIS
   ```

   You can find the NuGet package of the AWS Distro for OpenTelemetry .NET auto-instrumentation package in the official NuGet repository. Be sure to check the README file for instructions.

Managed Prometheus collectors

Amazon CloudWatch managed Prometheus collectors provide a fully managed, agentless way to collect Prometheus-compatible metrics from your AWS resources and deliver them to the CloudWatch OTLP endpoint. You don't install, patch, or scale any collection infrastructure yourself, and you query the collected metrics with PromQL.

For more information, including how to integrate Amazon MSK, Amazon EKS, Amazon OpenSearch Service, and other VPC-based sources, see Amazon CloudWatch managed Prometheus collectors.

Setting up bearer token authentication for Metrics

Note

This page covers bearer token authentication for the CloudWatch Metrics OTLP endpoint. For CloudWatch Logs bearer token authentication, see Setting up bearer token authentication for Logs in the *CloudWatch Logs User Guide*.

Before you can send metrics using bearer token authentication with the CloudWatch OTLP endpoint, you need to:

- Create an IAM user with CloudWatch Metrics permissions
- Generate service-specific credentials (API key)

Important

We recommend using SigV4 authentication with short-term credentials for all workloads where this is possible. SigV4 provides the strongest security posture. Restrict the use of API keys (bearer tokens) to scenarios where short-term credential-based authentication is not feasible, such as sending metrics from non-AWS environments, third-party vendors, or platforms that do not support the AWS SDK. When you are ready to incorporate CloudWatch Metrics into applications with greater security requirements, switch to short-term credentials. For more information, see Alternatives to long-term access keys in the *IAM User Guide*.

Important

The CloudWatch OTLP endpoint requires TLS (HTTPS). Bearer token requests sent over plain HTTP are rejected. Always use `https://monitoring.`*`AWS Region`*`.amazonaws.com/v1/metrics` when configuring your client.

Option 1: Quick start using the AWS console

The AWS Management Console provides a streamlined workflow to generate API keys for OTLP endpoint access.

To set up OTLP endpoint access using the console

1. Sign in to the AWS Management Console.
2. Navigate to **CloudWatch** > **Settings** > **Global**.
3. In the API Keys section, choose **Generate API key**.
4. For **API key expiration**, do one of the following:
   - Select an API key expiration duration of **1**, **5**, **30**, **90**, or **365** days.
   - Choose **Custom duration** to specify a custom API key expiration date.
   - Select **Never expires** (not recommended).
5. Choose **Generate API key**.

The console automatically:

- Creates a new IAM user with appropriate permissions
- Attaches the CloudWatchAPIKeyAccess managed policy (includes `cloudwatch:PutMetricData` and `cloudwatch:CallWithBearerToken` permissions)
- Generates service-specific credentials (API key)

To save and verify your API key

1. Copy and securely save the displayed credentials:
   - **API Key ID** (Service-specific credential ID)
   - **API Key Secret** (Bearer token)

   The console also offers the option to store your API key directly in AWS Secrets Manager during generation. If you choose to store in Secrets Manager, the key is automatically updated on reset and deleted on key deletion.

> **Important**
>
> Save the API Key Secret immediately. You can't retrieve it later. If you lose it, you must generate a new API key.

2. Send a test metric to verify your setup:

```
curl -X POST "https://monitoring.us-east-1.amazonaws.com/v1/metrics" \
     -H "Content-Type: application/json" \
     -H "Authorization: Bearer YOUR_API_KEY" \
     -d '{"resourceMetrics":[]}'
```

Option 2: Manual setup

If you prefer more control over the IAM configuration or need to customize permissions, you can set up the OTLP endpoint access manually.

Step 1: Create an IAM user

Create an IAM user for metric ingestion:

To create an IAM user for metric ingestion

1. Sign in to the AWS Management Console and navigate to IAM.
2. In the left navigation pane, choose **Users**.
3. Choose **Create user**.
4. Enter a user name (for example, **`cloudwatch-metrics-api-key-user`**).
5. Choose **Next**.
6. Attach one of the following IAM policies:

   Option A: Use the managed policy (recommended)

   Attach the CloudWatchAPIKeyAccess managed policy.

   Option B: Create a custom policy

   Create and attach the following IAM policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CloudWatchMetricsAPIs",
            "Effect": "Allow",
            "Action": [
                "cloudwatch:CallWithBearerToken",
                "cloudwatch:PutMetricData"
            ],
            "Resource": "*"
        },
        {
            "Sid": "KMSDecryptForCMKDatasets",
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Condition": {
                "StringLike": {
                    "kms:ViaService": "cloudwatch.*.amazonaws.com",
                    "kms:EncryptionContext:aws:cloudwatch:arn":
 "arn:aws:cloudwatch:*:*:dataset/*"
                }
            },
            "Resource": "arn:aws:kms:*:*:key/*"
        }
    ]
}
```

7. Choose **Next** and then choose **Create user**.

> **Note**
>
> The KMS permissions are required if you plan to send metrics to datasets that use customer-managed KMS keys (CMK). The conditions restrict KMS access to only keys used through the CloudWatch service for dataset resources.

Step 2: Generate service-specific credentials (API key)

Generate the CloudWatch Metrics API key using the CreateServiceSpecificCredential API. You can also use the create-service-specific-credential AWS CLI command. For the credential age, you can specify a value between 1–36600 days. If you don't specify a credential age, the API key won't expire.

To generate an API key with an expiration of 30 days:

```
aws iam create-service-specific-credential \
    --user-name cloudwatch-metrics-api-key-user \
    --service-name cloudwatch.amazonaws.com \
    --credential-age-days 30
```

The response is a ServiceSpecificCredential object. The `ServiceCredentialSecret` value is your CloudWatch Metrics API key (bearer token).

> **Important**
>
> Store the `ServiceCredentialSecret` value securely. You can't retrieve it later. If you lose it, you must generate a new API key.

Step 3: Send metrics

You can immediately send metrics to the OTLP endpoint using your bearer token:

```
curl -X POST "https://monitoring.us-east-1.amazonaws.com/v1/metrics" \
     -H "Content-Type: application/json" \
     -H "Authorization: Bearer YOUR_API_KEY" \
     -d '{"resourceMetrics":[]}'
```

The endpoint accepts both `application/json` and `application/x-protobuf` content types.

Control permissions for generating and using CloudWatch Metrics API keys

Controlling the generation of CloudWatch Metrics API keys

The `iam:CreateServiceSpecificCredential` action controls the generation of a service-specific key (such as a CloudWatch Metrics API key). You can scope this action to IAM users as a resource to limit the users for which a key can be generated.

You can use the following condition keys to impose conditions on the permission for the `iam:CreateServiceSpecificCredential` action:

- `iam:ServiceSpecificCredentialAgeDays` — Lets you specify, in the condition, the key's expiration time in days.
- `iam:ServiceSpecificCredentialServiceName` — Lets you specify, in the condition, the name of a service.

Controlling the usage of CloudWatch Metrics API keys

The `cloudwatch:CallWithBearerToken` action controls the use of a CloudWatch Metrics API key. To prevent an identity from using CloudWatch Metrics API keys, attach a policy that denies the `cloudwatch:CallWithBearerToken` action to the IAM user associated with the key.

> **Note**
>
> Bearer tokens for CloudWatch Metrics can only be used with the OTLP metrics ingestion endpoint (`https://monitoring.`*`AWS Region`*`.amazonaws.com/v1/metrics`). They cannot be used to call any other CloudWatch API or endpoint, including query APIs (`GetMetricData`, `ListMetrics`, `DescribeAlarms`), the PromQL query endpoint, the OTLP traces endpoint, or the OTLP logs endpoint.

Example policies

Prevent an identity from generating and using CloudWatch Metrics API keys:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyCWMetricsAPIKeys",
            "Effect": "Deny",
            "Action": [
                "iam:CreateServiceSpecificCredential",
                "cloudwatch:CallWithBearerToken"
            ],
            "Resource": "*"
        }
    ]
```

```
}
```

> **Warning**
>
> This policy prevents the creation of credentials for all AWS services that support creating service-specific credentials. For more information, see Service-specific credentials for IAM users in the *IAM User Guide*.

Prevent an identity from using CloudWatch Metrics API keys:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": "cloudwatch:CallWithBearerToken",
            "Resource": "*"
        }
    ]
}
```

Allow the creation of CloudWatch Metrics keys only if they expire within 90 days:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceSpecificCredential",
            "Resource": "arn:aws:iam::123456789012:user/username",
            "Condition": {
                "StringEquals": {
                    "iam:ServiceSpecificCredentialServiceName":
 "cloudwatch.amazonaws.com"
                },
                "NumericLessThanEquals": {
                    "iam:ServiceSpecificCredentialAgeDays": "90"
                }
            }
        }
    ]
```

```
}
```

Using bearer tokens with the OpenTelemetry Collector

When using bearer tokens, you do not need the `sigv4auth` extension. Use the bearertokenauth extension to securely provide your API key from a file or environment variable:

```
extensions:
  bearertokenauth:
    filename: "/etc/otel/cw-api-key"

exporters:
  otlphttp:
    tls:
      insecure: false
    endpoint: https://monitoring.us-east-1.amazonaws.com/v1/metrics
    auth:
      authenticator: bearertokenauth

receivers:
  otlp:
    protocols:
      http:
        endpoint: 0.0.0.0:4318

processors:
  batch:
    send_batch_size: 200
    timeout: 10s

service:
  extensions: [bearertokenauth]
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [batch]
      exporters: [otlphttp]
```

Alternatively, you can reference an environment variable instead of a file:

```
extensions:
  bearertokenauth:
```

```
    token: "${env:CW_API_KEY}"
```

Important

Never hardcode API keys directly in collector configuration files. Configuration files are often committed to version control or stored in deployment manifests. Use `filename` to read from a mounted secret, or `${env:VAR}` to read from an environment variable injected by your secrets manager.

Note

With bearer token authentication, you do not need the `sigv4auth` extension, AWS credentials files, IAM roles, or IRSA configuration. This makes the collector configuration portable across any environment — AWS, on-premises, or other cloud providers.

Rotating API keys

Regularly rotating your API keys reduces the risk of unauthorized access. You should recommend establishing a rotation schedule that aligns with your organization's security policies.

Rotation process

To rotate an API key without interrupting metric delivery, follow this procedure:

To rotate an API key

1. Create a new (secondary) credential for the IAM user:

```
aws iam create-service-specific-credential \
    --user-name cloudwatch-metrics-api-key-user \
    --service-name cloudwatch.amazonaws.com \
    --credential-age-days 90
```

Note

IAM allows a maximum of 2 service-specific credentials per IAM user per service. Delete or deactivate old credentials before creating new ones if you have reached this limit.

2. (Optional) Store the new credential in AWS Secrets Manager for secure retrieval and automated rotation.
3. Update your OpenTelemetry Collector configuration or application to use the new API key.
4. Set the original credential to inactive:

```
aws iam update-service-specific-credential \
    --user-name cloudwatch-metrics-api-key-user \
    --service-specific-credential-id ACCA1234EXAMPLE1234 \
    --status Inactive
```

5. Verify that metric delivery is not impacted. Send a test request using the new key and confirm you receive an HTTP 200 response. You can also monitor your application's existing CloudWatch metrics to confirm data continues to arrive.
6. After confirming successful delivery with the new key, delete the previous credential:

```
aws iam delete-service-specific-credential \
    --service-specific-credential-id ACCA1234EXAMPLE1234
```

Monitoring key expiration

To check the creation date and status of your existing API keys, use the [list-service-specific-credentials] command:

```
aws iam list-service-specific-credentials \
    --user-name cloudwatch-metrics-api-key-user \
    --service-name cloudwatch.amazonaws.com
```

The response includes `CreateDate` and `Status` for each credential. Use this information to identify keys that are approaching expiration or have been active longer than your rotation policy allows.

Responding to a compromised API key

If you suspect that an API key has been compromised, take the following steps immediately:

To respond to a compromised API key

1. **Deactivate the key immediately** to prevent further unauthorized use:

```
aws iam update-service-specific-credential \
    --user-name cloudwatch-metrics-api-key-user \
    --service-specific-credential-id ACCA1234EXAMPLE1234 \
    --status Inactive
```

2. **Review CloudTrail logs** to determine the scope of unauthorized access. See the section called "Logging API key usage with CloudTrail" for how to enable auditing of API key usage.
3. **Create a replacement key** following the rotation process described in the section called "Rotation process".
4. **Delete the compromised key** after the replacement is in place:

```
aws iam delete-service-specific-credential \
    --service-specific-credential-id ACCA1234EXAMPLE1234
```

5. **Attach a deny policy** if you need to immediately block all bearer token access for the IAM user while you investigate:

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Deny",
        "Action": "cloudwatch:CallWithBearerToken",
        "Resource": "*"
    }
}
```

Note

To carry out these actions through the API, you must authenticate with AWS credentials and not with a CloudWatch Metrics API key. Bearer tokens can only be used for metric ingestion, not for IAM management operations.

You can also use the following IAM API operations to manage compromised keys:

- ResetServiceSpecificCredential — Reset the key to generate a new password without deleting the credential. The key must not have expired.

Security best practices for API keys

Follow these best practices to protect your CloudWatch Metrics API keys:

- **Never embed API keys in source code.** Do not hard-code API keys in application code, collector configuration files, or version control systems. Use the `bearertokenauth` extension with `filename` or `${env:VAR}` to inject secrets at runtime.
- **Use a secrets manager.** Store API keys in AWS Secrets Manager or an equivalent secrets management solution. This enables centralized access control, audit logging, and automated rotation.
- **Set an expiration on all keys.** Always specify a `--credential-age-days` value when creating API keys. To enforce a maximum key lifetime across your organization, use the `iam:ServiceSpecificCredentialAgeDays` IAM condition key.
- **Apply least-privilege permissions.** Use the managed CloudWatchAPIKeyAccess policy as a starting point and restrict further as needed.
- **Enable CloudTrail logging.** Audit API key usage by enabling CloudTrail data events for `AWS::CloudWatch::Dataset`. See the section called “Logging API key usage with CloudTrail”.
- **Monitor with IAM Access Analyzer.** Use IAM Access Analyzer to identify unused credentials and overly permissive policies associated with your API key IAM users.
- **Rotate keys regularly.** Establish a rotation schedule and follow the process described in the section called “Rotating API keys”.

Logging API key usage with CloudTrail

You can use AWS CloudTrail to log data events for CloudWatch Metrics OTLP ingestion. CloudWatch emits `AWS::CloudWatch::Dataset` data events for calls to the OTLP endpoint, enabling you to audit metric ingestion activity including API key usage.

> **Note**
>
> The S3 bucket that you specify for the trail must have a bucket policy that allows CloudTrail to write log files to it. For more information, see Amazon S3 bucket policy for CloudTrail in the *AWS CloudTrail User Guide*.

To enable CloudTrail logging for CloudWatch Metrics API key usage

1. Create a trail:

```
aws cloudtrail create-trail \
    --name cloudwatch-metrics-api-key-audit \
    --s3-bucket-name my-cloudtrail-bucket \
    --region us-east-1
```

2. Configure advanced event selectors to capture CloudWatch Metrics write (ingestion) data events:

```
aws cloudtrail put-event-selectors \
    --region us-east-1 \
    --trail-name cloudwatch-metrics-api-key-audit \
    --advanced-event-selectors '[{
        "Name": "CloudWatch Metrics write data events",
        "FieldSelectors": [
            { "Field": "eventCategory", "Equals": ["Data"] },
            { "Field": "resources.type", "Equals": ["AWS::CloudWatch::Dataset"] },
            { "Field": "readOnly", "Equals": ["false"] }
        ]
    }]'
```

3. Start trail logging:

```
aws cloudtrail start-logging \
    --name cloudwatch-metrics-api-key-audit \
    --region us-east-1
```

The `readOnly: false` filter limits logging to write operations (PutMetricData), which includes all OTLP ingestion calls. To identify bearer token usage among these events, query your trail logs (through Athena or CloudTrail Lake) and filter by the IAM user name associated with your API key (for example, `cloudwatch-metrics-api-key-user`). Events from OTLP ingestion include `AdditionalEventData.protocol` set to `OTLP` in the event payload, which you can use in post-hoc queries to distinguish them from classic PutMetricData SDK calls.

Troubleshooting

The following are the common troubleshooting scenarios and solutions for OTLP endpoint.

Issue	Description	Solution
Non-existing AWS credentials when launching OCB collector	Collector throws the following error when starting. *Error: invalid configuration: extensions::sigv4auth: could not retrieve credential provider: failed to refresh cached credentials, no EC2 IMDS role found, operation error ec2imds: GetMetadata, request canceled, context deadline exceeded*.	Enter the correct credentials.
Invalid AWS credentials	Collector throws HTTP Status Code 403, Message=The security token included in the request is invalid., Details=[]" when sending requests though OTLP endpoint.	Refresh the AWS credentials on the collector server.
Transactions Search disabled	Collector throws Message=The OTLP API is supported with CloudWatch Logs as a Trace Segment Destination.	Make sure Transaction Search is enabled in CloudWatch before using the OTLP endpoint for traces. For more information, see Transaction Search.

Issue	Description	Solution
Batching and timeout issues	Collector throws one of these issues: • max elapsed time expired failed to make an HTTP request • io.opentelemetry.exporter.internal.http.HttpExporter - Failed to export spans. The request could not be executed. Full error message: timeout • io.opentelemetry.exporter.internal.grpc.GrpcExporter - Failed to export spans. Server responded with gRPC status code 2. Error message: timeout • rpc error: code = DeadlineExceeded desc = context deadline exceeded • rpc error: code = ResourceExhausted desc = Too many requests", "dropped_items": 1024	Tune batching and timeout policies using batchprocessor.

Issue	Description	Solution
Retry issues	Transient network issues between the collector and OTLP endpoint. • rpc error: code = Unavailable desc = error reading from server: read tcp • rpc error: code = Unavailable desc = unexpected HTTP status code received from server: 502 (Bad Gateway); • rpc error: code = Unavailable desc = unexpected HTTP status code received from server: 503 (Service Unavailable)	Tune retry policy using exporter.
Payload rejected	NA	Make sure the payload sent to the trace endpoint is within the limits and restrictions. For more information, see Endpoint limits and restrictions.

Issue	Description	Solution
No auth header injected to outgoing export requests in ADOT	Generic 403 error, "Missing Authentication Token": Example: `ERROR:opentelemetry.exporter.otlp.proto.http.trace_exporter:Failed to export batch code: 403, reason: Missing Authentication Token`	• Verify that you're using the correct supported version of ADOT. • Make sure your credentials are set up correctly by following the standard AWS SDK credential provider chain
Logs or spans not appearing in CloudWatch log groups	No logs or spans are appearing in the expected CloudWatch log groups (`aws/spans` for spans and your specified custom log group for logs).	Make sure that the library to be instrumented is supported by auto-instrumentation. See supported libraries for Java, Python, JavaScript and .NET.

Collect metrics, logs, and traces using the CloudWatch agent

The CloudWatch agent is a software component that collects metrics, logs, and traces from your Amazon EC2 instances, on-premises servers, and containerized applications. It enables you to monitor your infrastructure and applications more comprehensively than the basic monitoring provided by default.

The CloudWatch agent enables you to do the following:

- Collect internal system-level metrics from Amazon EC2 instances across operating systems. The metrics can include in-guest metrics, in addition to the metrics for Amazon EC2 instances. For a list of additional metrics that you can collect, see Metrics collected by the CloudWatch agent.
- Collect system-level metrics from on-premises servers. These can include servers in a hybrid environment as well as servers not managed by AWS.
- Retrieve custom metrics from your applications or services using the `StatsD` and `collectd` protocols. `StatsD` is supported on both Linux servers and servers running Windows Server. `collectd` is supported only on Linux servers.
- Collect logs from Amazon EC2 instances and on-premises servers, running either Linux or Windows Server.

  > **Note**
  >
  > The CloudWatch agent does not support collecting logs from FIFO pipes.

- Send the metrics to either CloudWatch or Amazon Managed Service for Prometheus, or to both. The CloudWatch agent configuration file contains a `metrics_destinations` parameter in the `metrics` section. You can specify `cloudwatch`, `amp`, or both in this parameter.
- Version 1.300031.0 and later can be used to enable CloudWatch Application Signals. For more information, see Application Signals.
- Version 1.300025.0 and later can collect traces from OpenTelemetry or X-Ray client SDKs, and send them to X-Ray.

  Using the CloudWatch agent allows you to collect traces without needing to run a separate trace collection daemon, helping to reduce the number of agents that you run and manage.

Metrics that the CloudWatch agent publishes as CloudWatch metrics can be viewed in CloudWatch just as any other CloudWatch metrics. The default CloudWatch namespace for these metrics is `CWAgent`, although you can specify a different namespace when you configure the agent.

Metrics that the CloudWatch agent forwards to the CloudWatch OTLP endpoints are stored as OpenTelemetry metrics. These metrics don't use a CloudWatch namespace. Instead, you identify them by metric name and labels, and you query them with PromQL. For more information about OpenTelemetry metrics, see OpenTelemetry Metrics (Recommended). For information about querying these metrics, see Query metrics with PromQL.

The logs collected by the CloudWatch agent are processed and stored in Amazon CloudWatch Logs, just like logs collected by the older CloudWatch Logs agent. For information about CloudWatch Logs pricing, see Amazon CloudWatch Pricing.

Metrics collected by the CloudWatch agent are billed as custom metrics. For more information about CloudWatch metrics pricing, see Amazon CloudWatch Pricing.

The CloudWatch agent is open-source under the MIT license, and is hosted on GitHub. If you would like to build, customize or contribute to the CloudWatch agent, see the GitHub repository for the latest instructions. If you think you've found a potential security issue, do not post it on GitHub or any public forum. Instead, follow the instructions at Vulnerability Reporting or email AWS security directly.

For information about forwarding application metrics, traces, and logs through the CloudWatch agent using the OpenTelemetry Protocol (OTLP), see Example: send application metrics through the CloudWatch agent.

You can download and install the CloudWatch agent manually using the command line, or you can integrate it with AWS Systems Manager. The general flow of installing the CloudWatch agent is as follows:

1. Create IAM roles or users that enable the agent to collect metrics from the server and optionally to integrate with AWS Systems Manager.
2. Download the agent package.
3. Modify the CloudWatch agent configuration file and specify the metrics that you want to collect.
4. Install and start the agent on your servers.

Contents

- Supported operating systems
- Prerequisites
- Download the CloudWatch agent package
- Verifying the signature of the CloudWatch agent package
- Installing the CloudWatch agent
- Set up the CloudWatch agent with security-enhanced Linux (SELinux)
- Create the CloudWatch agent configuration file
- Starting the CloudWatch agent

- Metrics collected by the CloudWatch agent
- Using the CloudWatch agent with related telemetry
- Common scenarios with the CloudWatch agent
- CloudWatch agent credentials preference
- Troubleshooting the CloudWatch agent

Supported operating systems

The CloudWatch agent is supported on the following operating systems:

x86-64 architecture

- Amazon Linux 2023
- Amazon Linux 2
- Ubuntu Server versions 26.04, 25.04, 24.04, and 22.04
- Red Hat Enterprise Linux (RHEL) versions 10, 9, and 8
- Debian version 12
- SUSE Linux Enterprise Server (SLES) versions 16 and 15
- Oracle Linux versions 9 and 8
- AlmaLinux versions 10, 9, and 8
- Rocky Linux versions 10, 9, and 8
- macOS computers: EC2 M1 Mac1 instances, and computers running macOS 14 (Sonoma), macOS 13 (Ventura), and macOS 12 (Monterey)
- Windows Server 2025, Windows Server 2022, Windows Server 2019, and Windows Server 2016
- Windows 11
- 64-bit Windows 10

ARM64 architecture

- Amazon Linux 2023
- Amazon Linux 2
- Ubuntu Server version 22.04

- Red Hat Enterprise Linux (RHEL) versions 9 and 8
- Debian versions 13 and 12
- SUSE Linux Enterprise Server (SLES) versions 16 and 15
- macOS computers: macOS 14 (Sonoma), macOS 13 (Ventura), and macOS 12 (Monterey)

Prerequisites

Make sure the following prerequisites are completed before installing the CloudWatch agent for the first time.

IAM roles and users for CloudWatch agent

Access to AWS resources requires permissions. You create an IAM role, an IAM user, or both to grant permissions that the CloudWatch agent needs to write metrics to CloudWatch.

Create an IAM role for Amazon EC2 instances

If you're going to run the CloudWatch agent on Amazon EC2 instances, create an IAM role with the necessary permissions.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Under **Trusted entity type**, verify that **AWS service** is selected. For **Use case**, choose **EC2**. Choose **Next**.
5. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy.
6. Choose **Next**.
7. For **Role name**, enter a name for the role, such as `CloudWatchAgentServerRole`. Choose **Create role**.

(Optional) If the agent is going to send logs to CloudWatch Logs and you want the agent to be able to set retention policies for these log groups, you need to add the `logs:PutRetentionPolicy` permission to the role.

Create IAM user for on-premises servers

If you're going to run the CloudWatch agent on on-premises servers, create an IAM user with the necessary permissions.

> **Note**
>
> This scenario requires IAM users with programmatic access and long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Users** and then **Add users**.
3. Enter the user name for the new user. Select **Access key - Programmatic access** and choose **Next: Permissions**.
4. Choose **Attach existing policies directly**.
5. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy. Choose **Next: Tags**.
6. (Optional) Create tags for the new IAM user. Choose **Next: Review**. Confirm that the correct policy is listed and choose **Create user**.
7. Next to the name of the new user, choose **Show**. Copy the access key and secret key to a file so that you can use them when installing the agent. Choose **Close**.

Attach an IAM role to an Amazon EC2 instance

To enable the CloudWatch agent to send data from an Amazon EC2 instance, you must attach the IAM role you created to the instance.

For more information about attaching an IAM role to an instance, see Attaching an IAM Role to an Instance in the Amazon Elastic Compute Cloud User Guide.

Allowing the CloudWatch agent to set log retention policy

You can configure the CloudWatch agent to set the retention policy for log groups that it sends log events to. If you do this, you must grant the `logs:PutRetentionPolicy` to the IAM role or user

that the agent uses. The agent uses an IAM role to run on Amazon EC2 instances, and uses an IAM user for on-premises servers.

To grant log retention permissions to the agent's IAM role

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Roles**.
3. In the search box, enter the beginning of the name of the CloudWatch agent's IAM role. You chose this name when you created the role. It might be named `CloudWatchAgentServerRole`.

   When you see the role, choose the name of the role.
4. In the **Permissions** tab, choose **Add permissions**, **Create inline policy**.
5. Choose the **JSON** tab and copy the following policy into the box, replacing the default JSON in the box:

   JSON

   ```
   {
     "Version":"2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": "logs:PutRetentionPolicy",
         "Resource": "*"
       }
     ]
   }
   ```
6. Choose **Review policy**.
7. For **Name**, enter **`CloudWatchAgentPutLogsRetention`** or something similar, and choose **Create policy**.

To grant log retention permissions to the agent's IAM user

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

2. In the left navigation pane, choose **Users**.
3. In the search box, enter the beginning of the name of the CloudWatch agent's IAM user. You chose this name when you created the user.

   When you see the user, choose the name of the user.
4. In the **Permissions** tab, choose **Add inline policy**.
5. Choose the **JSON** tab and copy the following policy into the box, replacing the default JSON in the box:

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "logs:PutRetentionPolicy",
      "Resource": "*"
    }
  ]
}
```

6. Choose **Review policy**.
7. For **Name**, enter **`CloudWatchAgentPutLogsRetention`** or something similar, and choose **Create policy**.

Network requirements

> **Note**
>
> When the server is in a public subnet make sure there is access to an internet gateway. When the server is in a private subnet, access is through the NAT gateways or VPC Endpoint. For more information about NAT gateways, see https://docs.aws.amazon.com/vpc/latest/userguide/vpc-nat-gateway.html.

Your Amazon EC2 instances must have outbound internet access to send data to CloudWatch or CloudWatch Logs. For more information about how to configure internet access, see Internet Gateways in the Amazon VPC User Guide.

Using VPC endpoints

If you're using a VPC and want to use CloudWatch agent without public internet access, you can configure VPC endpoints for CloudWatch and CloudWatch Logs.

The endpoints and ports to configure on your proxy are as follows:

- If you're using the agent to collect metrics, you must add the CloudWatch endpoints for the appropriate Regions to the allow list. These endpoints are listed in Amazon CloudWatch endpoints and quotas.
- If you're using the agent to collect logs, you must add the CloudWatch Logs endpoints for the appropriate Regions to the allow list. These endpoints are listed in Amazon CloudWatch Logs endpoints and quotas.
- If you're using Systems Manager to install the agent or Parameter Store to store your configuration file, you must add the Systems Manager endpoints for the appropriate Regions to the allow list. These endpoints are listed in AWS Systems Manager endpoints and quotas.

Download the CloudWatch agent package

> **Note**
>
> To download the CloudWatch agent, your connection must use TLS 1.2 or later.

The CloudWatch agent is available as a package in Amazon Linux 2023 and Amazon Linux 2. If you are using this operating system, you can install the package by entering the following command. You must also make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** attached.

```
sudo yum install amazon-cloudwatch-agent
```

On all supported operating systems, you can download and install the CloudWatch agent using the command line.

For each download link, there is a general link as well as links for each AWS Region.

If you use the Region-specific links, replace the default Region (*us-east-1*) with the appropriate Region for your account. For example, for Amazon Linux 2023 and Amazon Linux 2 and the x86-64 architecture, three of the valid download links are:

- `https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`
- `https://amazoncloudwatch-agent-us-east-1.s3.us-east-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`
- `https://amazoncloudwatch-agent-eu-central-1.s3.eu-central-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`

You can also download a README file about the latest changes to the agent, and a file that indicates the version number that is available for download. These files are in the following locations:

> **Note**
>
> If you use the Region-specific links, replace the default Region (*us-east-1*) with the appropriate Region for your account.

- `https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/RELEASE_NOTES` or `https://amazoncloudwatch-agent-`*us-east-1*`.s3.`*us-east-1*`.amazonaws.com/info/latest/RELEASE_NOTES`
- `https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/CWAGENT_VERSION` or `https://amazoncloudwatch-agent-`*us-east-1*`.s3.`*us-east-1*`.amazonaws.com/info/latest/CWAGENT_VERSION`

Verifying the signature of the CloudWatch agent package

GPG signature files are included for CloudWatch agent packages on Linux servers. You can use a public key to verify the agent download file is original and unmodified.

For Windows Server, you can use the MSI to verify the signature. For macOS computers, the signature is included in the agent download package.

To find the correct signature file, use the following table. For each architecture and operating system, you can see a general link and links for each Region.

If you use the Region-specific links, replace the default Region (*us-east-1*) with the appropriate Region for your account. For example, for Amazon Linux 2023 and Amazon Linux 2 and the x86-64 architecture, three of the valid links are:

- `https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm.sig`
- `https://amazoncloudwatch-agent-us-east-1.s3.us-east-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`
- `https://amazoncloudwatch-agent-eu-central-1.s3.eu-central-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`

Note

To download the CloudWatch agent, your connection must use TLS 1.2 or later.

To verify the CloudWatch agent package on a Linux server

1. Download the public key.

```
shell$ wget https://amazoncloudwatch-agent.s3.amazonaws.com/assets/amazon-
cloudwatch-agent.gpg
```

2. Import the public key into your keyring.

```
shell$  gpg --import amazon-cloudwatch-agent.gpg
gpg: key 3B789C72: public key "Amazon CloudWatch Agent" imported
gpg: Total number processed: 1
gpg: imported: 1 (RSA: 1)
```

   Make a note of the key value, as you need it in the next step. In the preceding example, the key value is 3B789C72.

3. Verify the fingerprint by running the following command, replacing *key-value* with the value from the preceding step:

```
shell$  gpg --fingerprint key-value
pub   2048R/3B789C72 2017-11-14
      Key fingerprint = 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
uid                  Amazon CloudWatch Agent
```

   The fingerprint string should be equal to the following:

```
9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72
```

If the fingerprint string doesn't match, don't install the agent. Contact Amazon Web Services.

After you have verified the fingerprint, you can use it to verify the signature of the CloudWatch agent package.

4. Download the package signature file using **wget**. To determine the correct signature file, see the preceding table.

```
wget Signature File Link
```

5. To verify the signature, run **gpg --verify**.

```
shell$ gpg --verify signature-filename agent-download-filename
gpg: Signature made Wed 29 Nov 2017 03:00:59 PM PST using RSA key ID 3B789C72
gpg: Good signature from "Amazon CloudWatch Agent"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
```

If the output includes the phrase BAD `signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

To verify the CloudWatch agent package on a server running Windows Server

1. Download and install GnuPG for Windows from https://gnupg.org/download/. When installing, include the **Shell Extension (GpgEx)** option.

   You can perform the remaining steps in Windows PowerShell.

2. Download the public key.

```
PS> wget https://amazoncloudwatch-agent.s3.amazonaws.com/assets/amazon-cloudwatch-
agent.gpg -OutFile amazon-cloudwatch-agent.gpg
```

3. Import the public key into your keyring.

```
PS>  gpg --import amazon-cloudwatch-agent.gpg
gpg: key 3B789C72: public key "Amazon CloudWatch Agent" imported
gpg: Total number processed: 1
gpg: imported: 1 (RSA: 1)
```

   Make a note of the key value because you need it in the next step. In the preceding example, the key value is 3B789C72.

4. Verify the fingerprint by running the following command, replacing *key-value* with the value from the preceding step:

```
PS>  gpg --fingerprint key-value
pub   rsa2048 2017-11-14 [SC]
      9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
uid           [ unknown] Amazon CloudWatch Agent
```

   The fingerprint string should be equal to the following:

   `9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72`

   If the fingerprint string doesn't match, don't install the agent. Contact Amazon Web Services.

   After you have verified the fingerprint, you can use it to verify the signature of the CloudWatch agent package.

5. Download the package signature file using wget. To determine the correct signature file, see CloudWatch Agent Download Links.

6. To verify the signature, run **gpg --verify**.

```
PS> gpg --verify sig-filename agent-download-filename
gpg: Signature made 11/29/17 23:00:45 Coordinated Universal Time
gpg:                using RSA key D58167303B789C72
gpg: Good signature from "Amazon CloudWatch Agent" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
```

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

To verify the CloudWatch agent package on a macOS computer

- There are two methods for signature verification on macOS.
  - Verify the fingerprint by running the following command.

```
pkgutil --check-signature amazon-cloudwatch-agent.pkg
```

You should see a result similar to the following.

```
Package "amazon-cloudwatch-agent.pkg":
        Status: signed by a developer certificate issued by Apple for
 distribution
        Signed with a trusted timestamp on: 2020-10-02 18:13:24 +0000
        Certificate Chain:
        1. Developer ID Installer: AMZN Mobile LLC (94KV3E626L)
        Expires: 2024-10-18 22:31:30 +0000
        SHA256 Fingerprint:
        81 B4 6F AF 1C CA E1 E8 3C 6F FB 9E 52 5E 84 02 6E 7F 17 21 8E FB
        0C 40 79 13 66 8D 9F 1F 10 1C

 ------------------------------------------------------------------------
        2. Developer ID Certification Authority
        Expires: 2027-02-01 22:12:15 +0000
        SHA256 Fingerprint:
        7A FC 9D 01 A6 2F 03 A2 DE 96 37 93 6D 4A FE 68 09 0D 2D E1 8D 03
        F2 9C 88 CF B0 B1 BA 63 58 7F

 ------------------------------------------------------------------------
        3. Apple Root CA
        Expires: 2035-02-09 21:40:36 +0000
        SHA256 Fingerprint:
        B0 B1 73 0E CB C7 FF 45 05 14 2C 49 F1 29 5E 6E DA 6B CA ED 7E 2C
```

```
        68 C5 BE 91 B5 A1 10 01 F0 24
```

- Or, download and use the .sig file To use this method, follow these steps.
  - Install the GPG application to your macOS host by entering the following command.

    ```
    brew install GnuPG
    ```

- Download the package signature file using curl. To determine the correct signature file, see CloudWatch Agent Download Links.
- To verify the signature, run **gpg --verify**.

  ```
  PS> gpg --verify sig-filename agent-download-filename
  gpg: Signature made 11/29/17 23:00:45 Coordinated Universal Time
  gpg:                using RSA key D58167303B789C72
  gpg: Good signature from "Amazon CloudWatch Agent" [unknown]
  gpg: WARNING: This key is not certified with a trusted signature!
  gpg:          There is no indication that the signature belongs to the owner.
  Primary key fingerprint: 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
  ```

  If the output includes the phrase BAD `signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and avoid using the downloaded file.

  Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

Installing the CloudWatch agent

You can install the CloudWatch agent on your Amazon EC2 instances, on-premises servers, and in containerized environments to collect metrics, logs, and traces. The agent supports Linux, Windows, and macOS operating systems. There are several ways to install the agent, including using Systems Manager, from the CloudWatch console, installing from the command line, or installing using a configuration file. Before installing, make sure you have the required IAM permissions and network access configured.

Topics

- Install and Configure Amazon CloudWatch Agent with Workload Detection in the CloudWatch console
- Manual installation on Amazon EC2
- Install the CloudWatch agent using AWS Systems Manager
- Install the CloudWatch agent on on-premises servers
- Install the CloudWatch agent on Azure
- Install the CloudWatch agent on Google Cloud
- Install the CloudWatch agent on new instances using CloudFormation

Install and Configure Amazon CloudWatch Agent with Workload Detection in the CloudWatch console

Introduction

You can use the CloudWatch Getting Started console to install and configure the CloudWatch agent on Amazon EC2 instances. The Amazon CloudWatch agent is a lightweight software component that collects system-level metrics, logs, and traces from your Amazon EC2 instances. By automating the collection and delivery of monitoring data to CloudWatch, the agent enables you to gain actionable insights, optimize resource utilization, and make sure your applications are running smoothly with minimal configuration effort.

Configure the CloudWatch agent with pre-defined, workload-specific configurations that leverage automatic workload detection to identify running applications and services on your instances. You can customize data collection with specific metrics, logs, and traces, enabling you to monitor application performance and troubleshoot issues effectively.

How it Works

The CloudWatch agent detects workloads running on your Amazon EC2 instances through automatic workload detection capabilities. This feature identifies running applications and services on your instances, enabling intelligent monitoring without manual configuration.

Observability solutions provide pre-defined, workload-specific configurations tailored to common applications such as Apache Kafka, Apache Tomcat, Java Virtual Machines (JVM), NGINX, and NVIDIA GPU workloads. These solutions streamline the monitoring setup by automatically collecting the right metrics, logs, and traces specific to each detected workload, eliminating the need for manual instrumentation and configuration.

When workload detection is enabled, the agent analyzes your instance environment and automatically selects relevant pre-configured monitoring templates. These configurations are optimized by AWS subject-matter experts to capture the most important telemetry data for each workload type, ensuring you have comprehensive observability from the start.

Prerequisites

SSM Agent installation (required)

You must have AWS Systems Manager (SSM) agent installed on your Amazon EC2 instances. SSM agent comes pre-installed on most AWS-supplied Amazon Machine Images (AMIs), If you need to manually install or update the SSM agent, refer to the Systems Manager documentation.

> **Note**
>
> Default Host Management Configuration (DHMC) is a Systems Manager feature that automatically grants Amazon EC2 instances permissions to connect to Systems Manager without requiring you to manually attach an IAM instance profile to each instance. If your Amazon EC2 instances are using DHMC and the CloudWatch agent installation process attaches the CloudWatch policy to your instances, it can take up to 30 minutes for the new policy to take effect. This delay can postpone the publication of metrics, logs, and traces to CloudWatch. To mitigate, you can create your Amazon EC2 instances with an IAM role that contains the AmazonSSMManagedInstanceCore policy.

Workload Detection (Recommended)

Workload detection is an opt-in feature that automatically identifies running applications and services on your instances. We recommend turning on workload detection to take advantage of pre-configured, workload-specific monitoring templates. You can enable workload detection in the CloudWatch console settings.

Getting started

Open the Getting Started with Amazon CloudWatch agent page in the Amazon CloudWatch console: https://console.aws.amazon.com/cloudwatch/home#cloudwatch-agent

Manual instance deployment for CloudWatch Agent

Manually select up to 50 instances for CloudWatch agent installation and configuration. This targeted approach allows you to enhance monitoring for specific Amazon EC2 instances.

Tag-based deployment for CloudWatch Agent

Use tag-based deployment to install and configure the CloudWatch agent on fleets of Amazon EC2 instances. This method applies to all current and future instances with matching tags.

Tag-based configuration

Tag-based configurations allow you to efficiently organize, view, and modify configurations, helping you to manage CloudWatch agent and its configuration across fleets of Amazon EC2 instances.

CloudWatch agent installation

Install the CloudWatch agent to collect metrics, logs, and traces from Amazon EC2 instances and on-premises hosts. This telemetry provides important health and performance data about your infrastructure and applications.

CloudWatch agent configuration

Configure the CloudWatch agent with pre-defined, workload-specific configurations. You can customize data collection with specific metrics, logs, and traces, enabling you to monitor application performance and troubleshoot issues effectively.

Costs

Additional metrics that you add during this process are billed as custom metrics. For more information about CloudWatch metrics pricing, see Amazon CloudWatch Pricing.

Manual installation on Amazon EC2

> **Note**
>
> Make sure the prerequisites are completed before installing the CloudWatch agent for the first time.

Topics

- Installing on Amazon Linux using the package manager
- Installing on Amazon Linux using the command line
- Installing on Windows
- Installing on macOS

Installing on Amazon Linux using the package manager

The CloudWatch agent is available as a package in Amazon Linux 2023 and Amazon Linux 2. If you are using one of these operating systems, you can install the package by entering the following command:

```
sudo yum install amazon-cloudwatch-agent
```

You must also make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** attached.

Installing on Amazon Linux using the command line

On all supported Linux operating systems, you can download and install the CloudWatch agent using the command line.

1. Download the CloudWatch agent. For a Linux server, enter the following command. For `download-link`, use the appropriate download link from the table below.

   ```
   wget download-link
   ```

Architecture	Platform	Download link
x86-64	Amazon Linux 2023 and Amazon Linux 2	https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm
ARM64	Amazon Linux 2023 and Amazon Linux 2	https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/arm64/latest/amazon-cloudwatch-agent.rpm

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the signature of the CloudWatch agent package.
3. Install the package. If you downloaded an RPM package on a Linux server, change to the directory containing the package and enter the following:

```
sudo rpm -U ./amazon-cloudwatch-agent.rpm
```

If you downloaded a DEB package on a Linux server, change to the directory containing the package and enter the following:

```
sudo dpkg -i -E ./amazon-cloudwatch-agent.deb
```

Installing on Windows

On Windows Server, you can download and install the CloudWatch agent using the command line.

1. Download the following file:

   ```
   https://amazoncloudwatch-agent.s3.amazonaws.com/windows/amd64/latest/amazon-cloudwatch-agent.msi
   ```

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the signature of the CloudWatch agent package.
3. Install the package. Change to the directory containing the package and enter the following:

   ```
   msiexec /i amazon-cloudwatch-agent.msi
   ```

   This command also works from within PowerShell. For more information about MSI command options, see Command-Line Options in the Microsoft Windows documentation.

Installing on macOS

On macOS computers, you can download and install the CloudWatch agent using the command line.

1. Download the appropriate package for your architecture:

   ```
   https://amazoncloudwatch-agent.s3.amazonaws.com/darwin/amd64/latest/amazon-cloudwatch-agent.pkg
   ```

   For ARM64 architecture:

```
https://amazoncloudwatch-agent.s3.amazonaws.com/darwin/arm64/latest/amazon-
cloudwatch-agent.pkg
```

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the signature of the CloudWatch agent package.
3. Install the package. Change to the directory containing the package and enter the following:

```
sudo installer -pkg ./amazon-cloudwatch-agent.pkg -target /
```

Install the CloudWatch agent using AWS Systems Manager

Using AWS Systems Manager makes it easier to install the CloudWatch agent on a fleet of Amazon EC2 instances. You can download the agent into one server and create your CloudWatch agent configuration file for all servers in the fleet. Then you can use Systems Manager to install the agent on the other servers, using the configuration file that you created. Use the following topics to install and run the CloudWatch agent using AWS Systems Manager.

Topics

- Install or update the SSM Agent
- Verify Systems Manager prerequisites
- Verify internet access
- Download the CloudWatch agent package to your first instance
- Create and modify the agent configuration file
- Install and start the CloudWatch agent on additional EC2 instances using your agent configuration
- Install the CloudWatch agent on additional EC2 instances using your agent configuration
- (Optional) Modify the common configuration and named profile for CloudWatch agent

Install or update the SSM Agent

On an Amazon EC2 instance, the CloudWatch agent requires that the instance is running version 2.2.93.0 or later of the SSM Agent. Before you install the CloudWatch agent, update or install SSM Agent on the instance if you haven't already done so.

For information about installing or updating SSM Agent on an instance running Linux, see Installing and Configuring SSM Agent on Linux Instances in the *AWS Systems Manager User Guide*.

For information about installing or updating the SSM Agent, see Working with SSM Agent in the *AWS Systems Manager User Guide*.

Verify Systems Manager prerequisites

Before you use Systems Manager Run Command to install and configure the CloudWatch agent, verify that your instances meet the minimum Systems Manager requirements. For more information, see Systems Manager Prerequisites in the *AWS Systems Manager User Guide*.

Verify internet access

Your Amazon EC2 instances must be able to connect to CloudWatch endpoints. This can be by Internet Gateway, NAT gateway, or CloudWatch Interface VPC endpoints. For more information about how to configure internet access, see Internet Gateways in the *Amazon VPC User Guide*.

The endpoints and ports to configure on your proxy are as follows:

- If you're using the agent to collect metrics, you must allow list the CloudWatch endpoints for the appropriate Regions. These endpoints are listed in Amazon CloudWatch in the *Amazon Web Services General Reference*.
- If you're using the agent to collect logs, you must allow list the CloudWatch Logs endpoints for the appropriate Regions. These endpoints are listed in Amazon CloudWatch Logs in the *Amazon Web Services General Reference*.
- If you're using Systems Manager to install the agent or Parameter Store to store your configuration file, you must allow list the Systems Manager endpoints for the appropriate Regions. These endpoints are listed in AWS Systems Manager in the *Amazon Web Services General Reference*.

Download the CloudWatch agent package to your first instance

Use the following steps to download the CloudWatch agent package using Systems Manager.

To download the CloudWatch agent using Systems Manager

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

-or-

If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.

3. Choose **Run command**.
4. In the **Command document** list, choose **AWS-ConfigureAWSPackage**.
5. In the **Targets** area, choose the instance to install the CloudWatch agent on. If you don't see a specific instance, it might not be configured as a managed instance for use with Systems Manager. For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the *AWS Systems Manager User Guide*.
6. In the **Action** list, choose **Install**.
7. In the **Name** field, enter *AmazonCloudWatchAgent*.
8. Keep **Version** set to **latest** to install the latest version of the agent.
9. Choose **Run**.
10. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully installed.

Create and modify the agent configuration file

After you have downloaded the CloudWatch agent, you must create the configuration file before you start the agent on any servers.

If you're going to save your agent configuration file in the Systems Manager Parameter Store, you must use an EC2 instance to save to the Parameter Store. Additionally, you must first attach to that instance the `CloudWatchAgentAdminRole` IAM role. For more information about attaching roles, see Attaching an IAM Role to an Instance in the *Amazon EC2 User Guide*.

For more information about creating the CloudWatch agent configuration file, see Create the CloudWatch agent configuration file.

Install and start the CloudWatch agent on additional EC2 instances using your agent configuration

After you have a CloudWatch agent configuration saved in Parameter Store, you can use it when you install the agent on other servers.

For each of these servers, follow the steps listed previously in this section to verify the Systems Manager prerequisites, the version of the SSM Agent, and internet access. Then use the following instructions to install the CloudWatch agent on the additional instances, using the CloudWatch agent configuration file that you have created.

Step 1: Download and install the CloudWatch agent

To be able to send the CloudWatch data to a different Region, make sure that the IAM role that you attached to this instance has permissions to write the CloudWatch data in that Region.

Following is an example of using the `aws configure` command to create a named profile for the CloudWatch agent. This example assumes that you are using the default profile name of `AmazonCloudWatchAgent`.

To create the AmazonCloudWatchAgent profile for the CloudWatch agent

- On Linux servers, type the following command and follow the prompts:

  ```
  sudo aws configure --profile AmazonCloudWatchAgent
  ```

  On Windows Server, open PowerShell as an administrator, type the following command and follow the prompts.

  ```
  aws configure --profile AmazonCloudWatchAgent
  ```

Install the CloudWatch agent on additional EC2 instances using your agent configuration

After you have a CloudWatch agent configuration saved in Parameter Store, you can use it when you install the agent on other servers.

For each of these servers, follow the steps listed previously in this section to verify the Systems Manager prerequisites, the version of the SSM Agent, and internet access. Then use the following instructions to install the CloudWatch agent on the additional instances, using the CloudWatch agent configuration file that you have created.

Step 1: Download and install the CloudWatch agent

You need to install the agent on each server where you will run the agent. The CloudWatch agent is available as a package in Amazon Linux 2023 and Amazon Linux 2. If you are using this operating system, you can use Systems Manager to install the package by using the following steps.

> **Note**
>
> You must also make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** attached. For more information, see Prerequisites.

To use Systems Manager to install the CloudWatch agent package

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, select **AWS-RunShellScript**. Then paste the following into **Command parameters**.

   ```
   sudo yum install amazon-cloudwatch-agent
   ```
5. Choose **Run**

On all supported operating systems, you can download the CloudWatch agent package using either Systems Manager Run Command or an Amazon S3 download link.

> **Note**
>
> When you install or update the CloudWatch agent, only the **Uninstall and reinstall** option is supported. You can't use the **In-place update** option.

Systems Manager Run Command enables you to manage the configuration of your instances. You specify a Systems Manager document, specify parameters, and execute the command on one or more instances. SSM Agent on the instance processes the command and configures the instance as specified.

To download the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **AWS-ConfigureAWSPackage**.
5. In the **Targets** area, choose the instance on which to install the CloudWatch agent. If you do not see a specific instance, it might not be configured for Run Command. For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the *AWS Systems Manager User Guide*.
6. In the **Action** list, choose **Install**.
7. In the **Name** box, enter `AmazonCloudWatchAgent`.
8. Keep **Version** set to **latest** to install the latest version of the agent.
9. Choose **Run**.
10. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully installed.

Step 2: Start the CloudWatch agent using your agent configuration file

Follow these steps to start the agent using Systems Manager Run Command.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

To start the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.

3. Choose **Run command**.
4. In the **Command document** list, choose **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, choose the instance where you installed the CloudWatch agent.
6. In the **Action** list, choose **configure**.
7. In the **Optional Configuration Source** list, choose **ssm**.
8. In the **Optional Configuration Location** box, enter the name of the Systems Manager parameter name of the agent configuration file that you created and saved to Systems Manager Parameter Store, as explained in Create the CloudWatch agent configuration file.
9. In the **Optional Restart** list, choose **yes** to start the agent after you have finished these steps.
10. Choose **Run**.
11. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully started.

(Optional) Modify the common configuration and named profile for CloudWatch agent

The CloudWatch agent includes a configuration file called `common-config.toml`. You can use this file to optionally specify proxy and Region information.

On a server running Linux, this file is in the `/opt/aws/amazon-cloudwatch-agent/etc` directory. On a server running Windows Server, this file is in the `C:\ProgramData\Amazon\AmazonCloudWatchAgent` directory.

The default `common-config.toml` is as follows:

```
# This common-config is used to configure items used for both ssm and cloudwatch access

## Configuration for shared credential.
## Default credential strategy will be used if it is absent here:
##            Instance role is used for EC2 case by default.
##            AmazonCloudWatchAgent profile is used for onPremise case by default.
# [credentials]
#    shared_credential_profile = "{profile_name}"
#    shared_credential_file= "{file_name}"
```

```
## Configuration for proxy.
## System-wide environment-variable will be read if it is absent here.
## i.e. HTTP_PROXY/http_proxy; HTTPS_PROXY/https_proxy; NO_PROXY/no_proxy
## Note: system-wide environment-variable is not accessible when using ssm run-command.
## Absent in both here and environment-variable means no proxy will be used.
# [proxy]
#    http_proxy = "{http_url}"
#    https_proxy = "{https_url}"
#    no_proxy = "{domain}"
```

All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually, or by using the `RunShellScript` Run Command in Systems Manager:

- `shared_credential_profile` – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, `AmazonCloudWatchAgent` is used.

  On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different AWS Region. To do so, specify a named profile that includes a `region` field specifying the name of the Region to send to.

  If you specify a `shared_credential_profile`, you must also remove the # from the beginning of the `[credentials]` line.
- `shared_credential_file` – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is `/root/.aws` on Linux and is `C:\\Users\\Administrator\\.aws` on Windows Server.

  The first example below shows the syntax of a valid `shared_credential_file` line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the \ characters.

  ```
  shared_credential_file= "/usr/username/credentials"
  ```

  ```
  shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
  ```

  If you specify a `shared_credential_file`, you must also remove the # from the beginning of the `[credentials]` line.

- Proxy settings – If your servers use HTTP or HTTPS proxies to contact AWS services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

Install the CloudWatch agent on on-premises servers

If you downloaded the CloudWatch agent on a computer and created your agent configuration file, you can use that configuration file to install the agent in other on-premises servers.

Download the CloudWatch agent on an on-premises server

You can download the CloudWatch agent package using either Systems Manager Run Command or an Amazon S3 download link.

Download using Systems Manager

To use Systems Manager Run Command, you must register your on-premises server with Amazon EC2 Systems Manager. For more information, see Setting Up Systems Manager in Hybrid Environments in the *AWS Systems Manager User Guide*.

If you have already registered your server, update SSM Agent to the latest version.

For information about updating SSM Agent on a server running Linux, see Install SSM Agent for a Hybrid Environment (Linux) in the *AWS Systems Manager User Guide*.

For information about updating the SSM Agent on a server running Windows Server, see Install SSM Agent for a Hybrid Environment (Windows) in the *AWS Systems Manager User Guide*.

To use the SSM Agent to download the CloudWatch agent package on an on-premises server

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, select the button next to **AWS-ConfigureAWSPackage**.

5. In the **Targets** area, select the server to install the CloudWatch agent on. If you don't see a specific server, it might not be configured for Run Command. For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the *AWS Systems Manager User Guide*.
6. In the **Action** list, choose **Install**.
7. In the **Name** box, enter *AmazonCloudWatchAgent*.
8. Keep **Version** blank to install the latest version of the agent.
9. Choose **Run**.

   The agent package is downloaded, and the next steps are to configure and start it.

(Installing on an on-premises server) Specify IAM credentials and AWS Region

To enable the CloudWatch agent to send data from an on-premises server, you must specify the access key and secret key of the IAM user that you created earlier.

You also must specify the AWS Region to send the metrics to, using the `region` field.

Following is an example of this file.

```
[AmazonCloudWatchAgent]
aws_access_key_id=my_access_key
aws_secret_access_key=my_secret_key
region = us-west-1
```

For *my_access_key* and *my_secret_key*, use the keys from the IAM user that doesn't have the permissions to write to Systems Manager Parameter Store.

If you name this profile `AmazonCloudWatchAgent`, you don't need to do anything more. Optionally, you can give it a different name and specify that name as the value for `shared_credential_profile` in the `common-config.toml` file, which is explained in the following section.

Following is an example of using the **aws configure** command to create a named profile for the CloudWatch agent. This example assumes that you're using the default profile name of `AmazonCloudWatchAgent`.

To create the AmazonCloudWatchAgent profile for the CloudWatch agent

1. If you haven't already done so, install the AWS Command Line Interface on the server. For more information, see Installing the AWS CLI.
2. On Linux servers, enter the following command and follow the prompts:

   ```
   sudo aws configure --profile AmazonCloudWatchAgent
   ```

   On Windows Server, open PowerShell as an administrator, enter the following command, and follow the prompts.

   ```
   aws configure --profile AmazonCloudWatchAgent
   ```

(Optional) Modifying the common configuration and named profile for CloudWatch agent

The CloudWatch agent includes a configuration file called `common-config.toml`. You can optionally use this file to specify proxy and Region information.

On a server running Linux, this file is in the `/opt/aws/amazon-cloudwatch-agent/etc` directory. On a server running Windows Server, this file is in the `C:\ProgramData\Amazon\AmazonCloudWatchAgent` directory.

The default `common-config.toml` is as follows:

```
# This common-config is used to configure items used for both ssm and cloudwatch access

## Configuration for shared credential.
## Default credential strategy will be used if it is absent here:
##            Instance role is used for EC2 case by default.
##            AmazonCloudWatchAgent profile is used for onPremise case by default.
# [credentials]
#    shared_credential_profile = "{profile_name}"
#    shared_credential_file= "{file_name}"

## Configuration for proxy.
## System-wide environment-variable will be read if it is absent here.
## i.e. HTTP_PROXY/http_proxy; HTTPS_PROXY/https_proxy; NO_PROXY/no_proxy
## Note: system-wide environment-variable is not accessible when using ssm run-command.
## Absent in both here and environment-variable means no proxy will be used.
```

```
# [proxy]
#    http_proxy = "{http_url}"
#    https_proxy = "{https_url}"
#    no_proxy = "{domain}"
```

All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually, or by using the `RunShellScript` Run Command in Systems Manager:

- `shared_credential_profile` – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, `AmazonCloudWatchAgent` is used. For more information about creating this profile, see (Installing on an on-premises server) Specify IAM credentials and AWS Region.

  On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different AWS Region. To do so, specify a named profile that includes a `region` field specifying the name of the Region to send to.

  If you specify a `shared_credential_profile`, you must also remove the # from the beginning of the `[credentials]` line.

- `shared_credential_file` – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is `/root/.aws` on Linux and is `C:\\Users\\Administrator\\.aws` on Windows Server.

  The first example below shows the syntax of a valid `shared_credential_file` line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the \ characters.

  ```
  shared_credential_file= "/usr/username/credentials"
  ```

  ```
  shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
  ```

  If you specify a `shared_credential_file`, you must also remove the # from the beginning of the `[credentials]` line.

- Proxy settings – If your servers use HTTP or HTTPS proxies to contact AWS services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

Install the CloudWatch agent on Azure

You can run the Amazon CloudWatch agent on Azure to collect metrics, logs, and traces. The agent sends this telemetry to Amazon CloudWatch in your AWS account. This page covers two environments:

- Azure Virtual Machines – You install the agent package directly on the machine.
- Azure Kubernetes Service (AKS) – You install the agent through the Amazon CloudWatch Observability Helm chart.

For each environment, you can either use the onboarding scripts or follow the manual steps.

> **Finding your Azure resource ID**
>
> The onboarding scripts identify your virtual machine or cluster by its full Azure resource ID (`CWAGENT_AZURE_RESOURCE_ID`). You can find the resource ID on the resource's Properties page in the Azure portal, or retrieve it by running `az vm show` (or `az aks show`) with `--query id --output tsv`.

How the agent authenticates from Azure

We recommend that you federate an Azure identity to an AWS IAM role so that the agent uses temporary credentials. This approach avoids storing long-lived AWS access keys on the virtual machine or cluster, which reduces your security risk. The exact mechanism depends on the environment:

- On a virtual machine, the Azure managed identity issues OpenID Connect (OIDC) tokens. The agent obtains a token from the Azure Instance Metadata Service and calls `AssumeRoleWithWebIdentity` to obtain temporary AWS credentials.
- On AKS, the cluster's workload identity issues the OIDC token through a projected service account token, and the agent assumes the role in the same way.

In both cases, your AWS account needs the following:

- An IAM OIDC identity provider for the Azure issuer
- An IAM role that trusts the issuer and has the CloudWatchAgentServerPolicy managed policy attached

Azure Virtual Machines

On an Azure virtual machine, you install the agent package in the same way as on an on-premises server. The virtual machine authenticates to AWS with a managed identity that is federated to an AWS IAM role.

Automated setup (recommended)

The CloudWatch agent provides onboarding scripts that automate the setup. The scripts assign the Azure managed identity, install the agent, and create the AWS IAM role and trust policy. The scripts configure the agent with a default OpenTelemetry configuration. This configuration collects host metrics (such as CPU, memory, disk, and network) and starts an OpenTelemetry Protocol (OTLP) receiver for metrics, logs, and traces from applications on the machine. The agent enriches all of this telemetry and forwards it to the CloudWatch OTLP endpoints.

Run the Azure step first, then the AWS trust step. Provide the role ARN that the AWS trust step creates or updates (by default, `arn:aws:iam::`*`account-id`*`:role/CloudWatchAgentServerRole`).

> **Reusing an existing IAM role**
>
> Both scripts are safe to run even if the IAM role already exists. The AWS trust step merges the Azure trust into the role's existing trust policy instead of replacing it, so other trust statements remain. It attaches `CloudWatchAgentServerPolicy` only if the role doesn't already have it, and leaves the role's other policies unchanged.

To set up the agent on an Azure virtual machine using the onboarding scripts

1. On a machine with the Azure CLI signed in (for example, Azure Cloud Shell), run the Azure step with the role ARN and the AWS Region. The script assigns the virtual machine's managed identity, installs and starts the agent, and prints the Azure tenant ID.

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/
scripts/azure/setup.sh | \
  CWAGENT_PLATFORM=azure_vm \
  CWAGENT_AZURE_RESOURCE_ID=vm-resource-id \
  CWAGENT_AWS_ROLE_ARN=role-arn \
  CWAGENT_AWS_REGION=region \
  sh
```

2. On a machine with AWS credentials that have IAM write access to the target account (for example, AWS CloudShell), run the AWS trust step with the tenant ID from the previous step. The script creates the role, attaches `CloudWatchAgentServerPolicy`, and adds the Azure web-identity trust.

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/
scripts/aws/setup.sh | \
  CWAGENT_PLATFORM=azure_vm \
  CWAGENT_AZURE_TENANT_ID=tenant-id \
  CWAGENT_AWS_ROLE_ARN=role-arn \
  CWAGENT_AWS_REGION=region \
  sh
```

Manual setup

To assign a managed identity to the virtual machine

> **Active Azure CLI subscription**
>
> The following `az` commands act on the subscription that is active in the Azure CLI. Confirm it with `az account show`, or switch with `az account set --subscription subscription-id`, before you run them.

1. Assign a system-assigned managed identity to the virtual machine.

```
az vm identity assign --resource-group resource-group --name vm-name
```

2. Retrieve the Azure tenant ID to use in the next procedure.

```
az account show --query tenantId --output tsv
```

To create the IAM role in your AWS account

1. Register the Microsoft Entra ID issuer as an IAM OIDC identity provider. The audience (`--client-id-list`) is `https://management.azure.com/`. You don't need to supply a thumbprint. IAM retrieves the top intermediate certificate authority (CA) thumbprint of the issuer's server certificate.

```
aws iam create-open-id-connect-provider \
  --url https://sts.windows.net/tenant-id/ \
  --client-id-list https://management.azure.com/
```

2. Create a trust policy that allows the Azure identity to assume the role. Save it to a file named `trust-policy.json`. Replace *account-id* with your AWS account ID and *tenant-id* with the Azure tenant ID.

> **Reusing an existing IAM role**
>
> If you reuse an existing role, merge this policy with the role's existing trust policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": { "Federated": "arn:aws:iam::account-id:oidc-provider/
sts.windows.net/tenant-id/" },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": { "StringEquals": { "sts.windows.net/tenant-id/:aud": "https://
management.azure.com/" } }
    }
  ]
}
```

3. Create the role and attach the CloudWatchAgentServerPolicy managed policy. Note the role ARN that the first command returns.

```
aws iam create-role --role-name role-name --assume-role-policy-document file://
trust-policy.json
aws iam attach-role-policy --role-name role-name --policy-arn
 arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

To install and start the agent

1. Download and install the agent on the virtual machine, in the same way as on an on-premises server. See Install the CloudWatch agent on on-premises servers.

2. Set the AWS Region and the ARN of the role to assume, then start the agent with the default OpenTelemetry configuration (`default:otel`). The default OpenTelemetry configuration reads the role ARN from the `CWAGENT_ROLE_ARN` environment variable.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a set-env -e
 AWS_REGION=region
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a set-env -e
 CWAGENT_ROLE_ARN=role-arn
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m auto -c default:otel -s
```

Azure Kubernetes Service (AKS)

On AKS, you install the agent through the Amazon CloudWatch Observability Helm chart. The cluster authenticates to AWS with workload identity that is federated to an AWS IAM role.

Automated setup (recommended)

The onboarding scripts automate the setup. The scripts configure the cluster's workload identity, install the chart, and create the AWS IAM role and trust policy. The chart installs the agent with a default OpenTelemetry configuration. This configuration enables OTel Container Insights and starts an OTLP receiver for metrics, logs, and traces from applications in the cluster. The agent enriches all of this telemetry and forwards it to the CloudWatch OTLP endpoints.

Run the Azure step first, then the AWS trust step. The AWS trust step needs the cluster's OIDC issuer URL, which is available only after the Azure step enables the issuer. Provide the role ARN that the AWS trust step creates or updates (by default, `arn:aws:iam::account-id:role/CloudWatchAgentServerRole`).

> **Reusing an existing IAM role**
>
> Both scripts are safe to run even if the IAM role already exists. The AWS trust step merges the Azure trust into the role's existing trust policy instead of replacing it, so other trust statements remain. It attaches `CloudWatchAgentServerPolicy` only if the role doesn't already have it, and leaves the role's other policies unchanged.

To set up the agent on AKS using the onboarding scripts

1. On a machine with the Azure CLI signed in (for example, Azure Cloud Shell), run the Azure step with the role ARN and the AWS Region. The script enables the OIDC issuer and workload identity on the cluster, installs the agent, and prints the cluster's OIDC issuer URL.

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/
scripts/azure/setup.sh | \
  CWAGENT_PLATFORM=azure_aks \
  CWAGENT_AZURE_RESOURCE_ID=cluster-resource-id \
  CWAGENT_AWS_ROLE_ARN=role-arn \
  CWAGENT_AWS_REGION=region \
  sh
```

2. On a machine with AWS credentials that have IAM write access to the target account (for example, AWS CloudShell), run the AWS trust step with the OIDC issuer URL from the previous step. The script creates the role, attaches `CloudWatchAgentServerPolicy`, and federates the cluster issuer.

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/
scripts/aws/setup.sh | \
  CWAGENT_PLATFORM=azure_aks \
  CWAGENT_AZURE_OIDC_ISSUER=issuer-url \
  CWAGENT_AWS_ROLE_ARN=role-arn \
  CWAGENT_AWS_REGION=region \
  sh
```

Manual setup

To enable workload identity on the cluster

> **Active Azure CLI subscription**
>
> The following `az` commands act on the subscription that is active in the Azure CLI. Confirm it with `az account show`, or switch with `az account set --subscription` *`subscription-id`*, before you run them.

1. Enable the OIDC issuer and workload identity on the AKS cluster.

```
az aks update \
  --resource-group resource-group \
  --name cluster-name \
  --enable-oidc-issuer \
  --enable-workload-identity
```

2. Retrieve the cluster's OIDC issuer URL to use in the next procedure.

```
az aks show \
  --resource-group resource-group \
  --name cluster-name \
  --query oidcIssuerProfile.issuerUrl --output tsv
```

To create the IAM role in your AWS account

1. Register the cluster's OIDC issuer as an IAM OIDC identity provider. The audience (`--client-id-list`) is `sts.amazonaws.com`.

```
aws iam create-open-id-connect-provider --url issuer-url --client-id-list
 sts.amazonaws.com
```

2. Create a trust policy that allows the agent's service account to assume the role. Save it to a file named `trust-policy.json`. Replace *account-id* with your AWS account ID and *issuer-host* with the issuer URL without the `https://` prefix.

> **Reusing an existing IAM role**
>
> If you reuse an existing role, merge this policy with the role's existing trust policy. Each statement is identified by its cluster-specific OIDC provider principal and its `Condition` block, not by a `Sid`, so you don't need to set or preserve one.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```
      "Principal": { "Federated": "arn:aws:iam::account-id:oidc-provider/issuer-
host" },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": { "StringEquals": { "issuer-host:sub":
 "system:serviceaccount:amazon-cloudwatch:cloudwatch-agent", "issuer-host:aud":
 "sts.amazonaws.com" } }
    }
  ]
}
```

3. Create the role and attach the CloudWatchAgentServerPolicy managed policy. Note the role ARN that the first command returns.

```
aws iam create-role --role-name role-name --assume-role-policy-document file://
trust-policy.json
aws iam attach-role-policy --role-name role-name --policy-arn
 arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

To install the agent

1. Add the Amazon CloudWatch Observability Helm chart repository and install the chart. Set `k8sMode`, `roleArn`, `region`, and `clusterName`. Enable OTel Container Insights and assign the default OpenTelemetry configuration to the node agent.

```
helm repo add aws-observability https://aws-observability.github.io/helm-charts
helm repo update

helm upgrade --install amazon-cloudwatch-observability aws-observability/amazon-
cloudwatch-observability \
  --set k8sMode=AKS \
  --set roleArn=role-arn \
  --set region=region \
  --set clusterName=cluster-name \
  --set containerInsights.enabled=false \
  --set containerLogs.enabled=false \
  --set otelContainerInsights.enabled=true \
  --set otelContainerInsights.logs.enabled=true \
  --set-string 'agents[0].name=cloudwatch-agent' \
  --set-string 'agents[0].config=default:otel' \
  --set-string 'agents[1].name=cloudwatch-agent-cluster-scraper' \
  --set-string 'agents[1].mode=deployment' \
```

```
  --set-string 'agents[1].config=default' \
  --namespace amazon-cloudwatch --create-namespace
```

2. List every `agents[]` entry as shown. The Helm `--set` flag replaces a whole list element, so if you omit the cluster-scraper entry, you remove it.

Install the CloudWatch agent on Google Cloud

You can run the Amazon CloudWatch agent on Google Cloud to collect metrics, logs, and traces. The agent sends this telemetry to Amazon CloudWatch in your AWS account. This page covers two environments:

- Google Compute Engine (GCE) – You install the agent package directly on the instance.
- Google Kubernetes Engine (GKE) – You install the agent through the Amazon CloudWatch Observability Helm chart.

For each environment, you can either use the onboarding scripts or follow the manual steps.

> **Identifying your instance or cluster**
>
> The onboarding scripts identify your instance or cluster by project, location, and name. The project comes from `CWAGENT_GCP_PROJECT`, or from the Google Cloud CLI default when you omit it. The location (`CWAGENT_GCP_LOCATION`) is the zone for an instance, and the zone or region for a cluster.

How the agent authenticates from Google Cloud

We recommend that you federate a Google Cloud identity to an AWS IAM role so that the agent uses temporary credentials. This approach avoids storing long-lived AWS access keys on the instance or cluster, which reduces your security risk. The exact mechanism depends on the environment:

- On an instance, the attached service account issues OpenID Connect (OIDC) tokens. The agent obtains a token from the GCE metadata server and calls `AssumeRoleWithWebIdentity` to obtain temporary AWS credentials.
- On GKE, the cluster issues the OIDC token through a projected service account token, and the agent assumes the role in the same way.

In both cases, your AWS account needs an IAM role that trusts the Google Cloud identity and has the CloudWatchAgentServerPolicy managed policy attached.

> **Google is a built-in identity provider**
>
> For instances, you don't create an IAM OIDC identity provider. IAM has Google built in, so the trust policy names `accounts.google.com` directly. For GKE, you do register the cluster's OIDC issuer as an IAM OIDC identity provider.

Google Compute Engine (GCE)

On a GCE instance, you install the agent package in the same way as on an on-premises server. The instance authenticates to AWS with its attached service account, which is federated to an AWS IAM role.

> **The instance needs a service account**
>
> Instances receive the project's default service account when you create them, unless you opt out. Attaching a service account to an existing instance requires stopping the instance first, so neither the scripts nor the manual steps change it for you.

Automated setup (recommended)

The CloudWatch agent provides onboarding scripts that automate the setup. The scripts read the instance's service account, install the agent, and create the AWS IAM role and trust policy. The scripts configure the agent with a default OpenTelemetry configuration. This configuration collects host metrics (such as CPU, memory, disk, and network). It also starts an OpenTelemetry Protocol (OTLP) receiver for metrics, logs, and traces from applications on the instance. The agent enriches all of this telemetry and forwards it to the CloudWatch OTLP endpoints.

Run the Google Cloud step first, then the AWS trust step. Provide the role ARN that the AWS trust step creates or updates (by default, `arn:aws:iam::`*`account-id`*`:role/CloudWatchAgentServerRole`).

> **Reusing an existing IAM role**
>
> Both scripts are safe to run even if the IAM role already exists. The AWS trust step merges the Google trust into the role's existing trust policy instead of replacing it, so other trust

statements remain. It attaches `CloudWatchAgentServerPolicy` only if the role doesn't already have it, and leaves the role's other policies unchanged.

To set up the agent on a GCE instance using the onboarding scripts

1. On a machine with the Google Cloud CLI signed in (for example, Cloud Shell), run the Google Cloud step with the role ARN and the AWS Region. The script reads the instance's service account, installs and starts the agent, and prints the service account unique ID.

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/
scripts/gcp/setup.sh | \
  CWAGENT_PLATFORM=gcp_gce \
  CWAGENT_GCP_LOCATION=zone \
  CWAGENT_GCP_INSTANCE_NAME=instance-name \
  CWAGENT_AWS_ROLE_ARN=role-arn \
  CWAGENT_AWS_REGION=region \
  sh
```

2. On a machine with AWS credentials that have IAM write access to the target account (for example, AWS CloudShell), run the AWS trust step with the service account unique ID from the previous step. The script creates the role, attaches `CloudWatchAgentServerPolicy`, and adds the Google web-identity trust.

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/
scripts/aws/setup.sh | \
  CWAGENT_PLATFORM=gcp_gce \
  CWAGENT_GCP_SA_UNIQUE_ID=unique-id \
  CWAGENT_AWS_ROLE_ARN=role-arn \
  CWAGENT_AWS_REGION=region \
  sh
```

Manual setup

To find the instance's service account

Active Google Cloud project

The following `gcloud compute` commands act on the project that is active in the Google Cloud CLI. Confirm it with `gcloud config get-value project`, or add `--project`

project-id, before you run them. Don't scope `gcloud iam service-accounts describe` to a project. A service account email is globally unique, and the account can belong to a different project than the instance.

1. Retrieve the email of the service account attached to the instance. If the command returns nothing, the instance has no service account.

```
gcloud compute instances describe instance-name --zone zone --format
 'value(serviceAccounts[0].email)'
```

2. Retrieve the service account's unique ID to use in the next procedure. The trust policy matches on this value, not on the email address.

```
gcloud iam service-accounts describe service-account-email --format
 'value(uniqueId)'
```

To create the IAM role in your AWS account

1. Create a trust policy that allows the service account to assume the role. Save it to a file named `trust-policy.json`. Replace *unique-id* with the service account unique ID.

Reusing an existing IAM role (GCE)

If you reuse an existing role, merge this policy with the role's existing trust policy. Keep the `Sid` value. Every GCE statement uses the same `accounts.google.com` principal, so the `Sid` is what identifies the statement for this service account. A statement without one is replaced the next time you run the onboarding scripts.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GCEunique-id",
      "Effect": "Allow",
      "Principal": { "Federated": "accounts.google.com" },
      "Action": "sts:AssumeRoleWithWebIdentity",
```

```
      "Condition": { "StringEquals": { "accounts.google.com:aud": "unique-
id", "accounts.google.com:sub": "unique-id", "accounts.google.com:oaud":
 "sts.amazonaws.com" } }
    }
  ]
}
```

To onboard more than one service account to the same role, add a separate statement for each one, with its own `Sid` and unique ID.

On tokens that Google issues to a service account, IAM matches `sub` against the service account unique ID. It matches `aud` against the token's authorized party (`azp`), which Google also sets to the unique ID. It matches `oaud` against the audience that the agent requested the token for, which is `sts.amazonaws.com`.

2. Create the role and attach the CloudWatchAgentServerPolicy managed policy. Note the role ARN that the first command returns.

```
aws iam create-role --role-name role-name --assume-role-policy-document file://
trust-policy.json
aws iam attach-role-policy --role-name role-name --policy-arn
 arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

To install and start the agent

1. Download and install the agent on the instance, in the same way as on an on-premises server. See Install the CloudWatch agent on on-premises servers.
2. Set the AWS Region and the ARN of the role to assume, then start the agent with the default OpenTelemetry configuration (`default:otel`). The default OpenTelemetry configuration reads the role ARN from the `CWAGENT_ROLE_ARN` environment variable.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a set-env -e
 AWS_REGION=region
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a set-env -e
 CWAGENT_ROLE_ARN=role-arn
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m auto -c default:otel -s
```

Google Kubernetes Engine (GKE)

On GKE, you install the agent through the Amazon CloudWatch Observability Helm chart. The cluster authenticates to AWS with a projected service account token that is federated to an AWS IAM role.

Automated setup (recommended)

The onboarding scripts automate the setup. The scripts read the cluster, install the chart, and create the AWS IAM role and trust policy. The chart installs the agent with a default OpenTelemetry configuration. This configuration enables OTel Container Insights. It also starts an OTLP receiver for metrics, logs, and traces from applications in the cluster. The agent enriches all of this telemetry and forwards it to the CloudWatch OTLP endpoints.

Run the Google Cloud step first, then the AWS trust step. The AWS trust step needs the cluster's OIDC issuer URL, which the Google Cloud step prints. Provide the role ARN that the AWS trust step creates or updates (by default, `arn:aws:iam::`*`account-id`*`:role/CloudWatchAgentServerRole`).

> **Reusing an existing IAM role**
>
> Both scripts are safe to run even if the IAM role already exists. The AWS trust step merges the Google trust into the role's existing trust policy instead of replacing it, so other trust statements remain. It attaches `CloudWatchAgentServerPolicy` only if the role doesn't already have it, and leaves the role's other policies unchanged.

To set up the agent on GKE using the onboarding scripts

1. On a machine with the Google Cloud CLI signed in (for example, Cloud Shell), run the Google Cloud step with the role ARN and the AWS Region. The script installs the agent and prints the cluster's OIDC issuer URL.

   > **Tools the script needs to install the chart**
   >
   > The script installs the chart when `helm`, `kubectl`, and `gke-gcloud-auth-plugin` are all available. Otherwise it prints the commands for you to run from a shell that has them.

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/
scripts/gcp/setup.sh | \
  CWAGENT_PLATFORM=gcp_gke \
  CWAGENT_GCP_LOCATION=location \
  CWAGENT_K8S_CLUSTER_NAME=cluster-name \
  CWAGENT_AWS_ROLE_ARN=role-arn \
  CWAGENT_AWS_REGION=region \
  sh
```

2. On a machine with AWS credentials that have IAM write access to the target account (for example, AWS CloudShell), run the AWS trust step with the OIDC issuer URL from the previous step. The script creates the role, attaches `CloudWatchAgentServerPolicy`, and federates the cluster issuer.

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/
scripts/aws/setup.sh | \
  CWAGENT_PLATFORM=gcp_gke \
  CWAGENT_GCP_OIDC_ISSUER=issuer-url \
  CWAGENT_AWS_ROLE_ARN=role-arn \
  CWAGENT_AWS_REGION=region \
  sh
```

Manual setup

To find the cluster's OIDC issuer URL

> **Active Google Cloud project**
>
> The following `gcloud` commands act on the project that is active in the Google Cloud CLI. Confirm it with `gcloud config get-value project`, or add `--project` *`project-id`* to each command, before you run them.

> **GKE serves the issuer by default**
>
> Every GKE cluster serves its OIDC discovery document, so there is no setting to enable. You construct the issuer URL from the project, location, and cluster name.

1. Confirm that you can read the cluster, and note its project, location, and name.

```
gcloud container clusters describe cluster-name --location location --format
 'value(name)'
```

2. Build the issuer URL in the following form. Use `locations` for both zonal and regional clusters.

```
https://container.googleapis.com/v1/projects/project-id/locations/location/
clusters/cluster-name
```

To create the IAM role in your AWS account

1. Register the cluster's OIDC issuer as an IAM OIDC identity provider. The audience (`--client-id-list`) is `sts.amazonaws.com`.

```
aws iam create-open-id-connect-provider --url issuer-url --client-id-list
 sts.amazonaws.com
```

2. Create a trust policy that allows the agent's service account to assume the role. Save it to a file named `trust-policy.json`. Replace *account-id* with your AWS account ID and *issuer-host* with the issuer URL without the `https://` prefix.

> **Reusing an existing IAM role (GKE)**
>
> If you reuse an existing role, merge this policy with the role's existing trust policy. Each statement is identified by its cluster-specific OIDC provider principal and its `Condition` block, not by a `Sid`, so you don't need to set or preserve one.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": { "Federated": "arn:aws:iam::account-id:oidc-provider/issuer-
host" },
      "Action": "sts:AssumeRoleWithWebIdentity",
```

```
      "Condition": { "StringEquals": { "issuer-host:sub":
 "system:serviceaccount:amazon-cloudwatch:cloudwatch-agent", "issuer-host:aud":
 "sts.amazonaws.com" } }
    }
  ]
}
```

3. Create the role and attach the CloudWatchAgentServerPolicy managed policy. Note the role ARN that the first command returns.

```
aws iam create-role --role-name role-name --assume-role-policy-document file://
trust-policy.json
aws iam attach-role-policy --role-name role-name --policy-arn
 arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

To install the agent

1. Configure `kubectl` to use the cluster. This command requires `gke-gcloud-auth-plugin`.

```
gcloud container clusters get-credentials cluster-name --location location
```

2. Add the Amazon CloudWatch Observability Helm chart repository and install the chart. Set `k8sMode`, `roleArn`, `region`, and `clusterName`. Enable OTel Container Insights and assign the default OpenTelemetry configuration to the node agent.

```
helm repo add aws-observability https://aws-observability.github.io/helm-charts
helm repo update

helm upgrade --install amazon-cloudwatch-observability aws-observability/amazon-
cloudwatch-observability \
  --set k8sMode=GKE \
  --set roleArn=role-arn \
  --set region=region \
  --set clusterName=cluster-name \
  --set containerInsights.enabled=false \
  --set containerLogs.enabled=false \
  --set otelContainerInsights.enabled=true \
  --set otelContainerInsights.logs.enabled=true \
  --set-string 'agents[0].name=cloudwatch-agent' \
  --set-string 'agents[0].config=default:otel' \
  --set-string 'agents[1].name=cloudwatch-agent-cluster-scraper' \
```

```
  --set-string 'agents[1].mode=deployment' \
  --set-string 'agents[1].config=default' \
  --namespace amazon-cloudwatch --create-namespace
```

3. List every `agents[]` entry as shown. The Helm `--set` flag replaces a whole list element, so if you omit the cluster-scraper entry, you remove it.

Install the CloudWatch agent on new instances using CloudFormation

This section describes how to install the CloudWatch agent on new Amazon EC2 instances using AWS CloudFormation.

> **Note**
>
> Amazon uploaded several CloudFormation templates to GitHub that can help you install and update the CloudWatch agent on new Amazon EC2 instances. For more information about using CloudFormation, see What is AWS CloudFormation?.

The template location is Deploy the Amazon CloudWatch agent to EC2 instances using CloudFormation. This location includes both `inline` and `ssm` directories. Each of these directories contains templates for both Linux and Windows instances.

- The templates in the `inline` directory have the CloudWatch agent configuration embedded into the CloudFormation template. By default, the Linux templates collect the metrics `mem_used_percent` and `swap_used_percent`, and the Windows templates collect `Memory % Committed Bytes In Use` and `Paging File % Usage`.

  To modify these templates to collect different metrics, modify the following section of the template. The following example is from the template for Linux servers. Follow the format and syntax of the agent configuration file to make these changes. For more information, see Manually create or edit the CloudWatch agent configuration file.

```
{
   "metrics":{
      "append_dimensions":{
         "AutoScalingGroupName":"${!aws:AutoScalingGroupName}",
         "ImageId":"${!aws:ImageId}",
         "InstanceId":"${!aws:InstanceId}",
```

```
            "InstanceType":"${!aws:InstanceType}"
         },
         "metrics_collected":{
            "mem":{
               "measurement":[
                  "mem_used_percent"
               ]
            },
            "swap":{
               "measurement":[
                  "swap_used_percent"
               ]
            }
         }
      }
   }
```

> **Note**
>
> In the inline templates, all placeholder variables must have an exclamation mark (!) before them as an escape character. You can see this in the example template. If you add other placeholder variables, be sure to add an exclamation mark before the name.

- The templates in the `ssm` directory load an agent configuration file from Parameter Store. To use these templates, you must first create a configuration file and upload it to Parameter Store. You then provide the Parameter Store name of the file in the template. You can create the configuration file manually or by using the wizard. For more information, see Create the CloudWatch agent configuration file.

You can use both types of templates for installing the CloudWatch agent and for updating the agent configuration.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

Tutorial: Install and configure the CloudWatch agent using an CloudFormation inline template

This tutorial walks you through using CloudFormation to install the CloudWatch agent on a new Amazon EC2 instance. This tutorial installs on a new instance running Amazon Linux 2 using the inline templates, which don't require the use of the JSON configuration file or Parameter Store.

The inline template includes the agent configuration in the template. In this tutorial, you use the default agent configuration contained in the template.

After the procedure for installing the agent, the tutorial continues with how to update the agent.

To use CloudFormation to install the CloudWatch agent on a new instance

1. Download the template from GitHub. In this tutorial, download the inline template for Amazon Linux 2 as follows:

   ```
   curl -O https://raw.githubusercontent.com/aws-cloudformation/aws-cloudformation-templates/main/Solutions/AmazonCloudWatchAgent/inline/amazon_linux.yaml
   ```

2. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. Choose **Create stack**.
4. For **Choose a template**, select **Upload a template to Amazon S3**, choose the downloaded template, and choose **Next**.
5. On the **Specify Details** page, fill out the following parameters and choose **Next**:

   - **Stack name**: Choose a stack name for your CloudFormation stack.
   - **IAMRole**: Choose an IAM role that has permissions to write CloudWatch metrics, logs, and traces. For more information, see Prerequisites.
   - **InstanceAMI**: Choose an AMI that is valid in the Region where you're going to launch your stack.
   - **InstanceType**: Choose a valid instance type.
   - **KeyName**: To enable SSH access to the new instance, choose an existing Amazon EC2 key pair. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 Key Pairs in the *Amazon EC2 User Guide*.
   - **SSHLocation**: Specifies the IP address range that can be used to connect to the instance using SSH. The default allows access from any IP address.

6. On the **Options** page, you can choose to tag your stack resources. Choose **Next**.
7. On the **Review** page, review your information, acknowledge that the stack might create IAM resources, and then choose **Create**.

   If you refresh the console, you see that the new stack has the `CREATE_IN_PROGRESS` status.

8. When the instance is created, you can see it in the Amazon EC2 console. Optionally, you can connect to the host and check the progress.

   Use the following command to confirm that the agent is installed:

   ```
   rpm -qa amazon-cloudwatch-agent
   ```

   Use the following command to confirm that the agent is running:

   ```
   ps aux | grep amazon-cloudwatch-agent
   ```

The next procedure demonstrates using CloudFormation to update the CloudWatch agent using an inline template. The default inline template collects the `mem_used_percent` metric. In this tutorial, you change the agent configuration to stop collecting that metric.

To use CloudFormation to update the CloudWatch agent

1. In the template that you downloaded in the previous procedure, remove the following lines and then save the template:

   ```
   "mem": {

        "measurement": [
            "mem_used_percent"
          ]
    },
   ```

2. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. On the CloudFormation dashboard, select the stack that you created and choose **Update Stack**.
4. For **Select Template**, select **Upload a template to Amazon S3**, choose the template that you modified, and choose **Next**.
5. On the **Options** page, choose **Next** and then **Next**.
6. On the **Review** page, review your information and choose **Update**.

   After some time, you see `UPDATE_COMPLETE`.

Tutorial: Install the CloudWatch agent using CloudFormation and Parameter Store

This tutorial walks you through using CloudFormation to install the CloudWatch agent on a new Amazon EC2 instance. This tutorial installs on a new instance running Amazon Linux 2 using an agent configuration file that you create and save in Parameter Store.

After the procedure for installing the agent, the tutorial continues with how to update the agent.

To use CloudFormation to install the CloudWatch agent on a new instance using a configuration from Parameter Store

1. If you haven't done so already, download the CloudWatch agent package to one of your computers so that you can create the agent configuration file. For more information and downloading the agent using Parameter Store, see Download the CloudWatch agent package.
2. Create the agent configuration file and save it in Parameter Store. For more information, see Create the CloudWatch agent configuration file.
3. Download the template from GitHub as follows:

   ```
   curl -O https://raw.githubusercontent.com/awslabs/aws-cloudformation-templates/
   master/aws/solutions/AmazonCloudWatchAgent/ssm/amazon_linux.template
   ```

4. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
5. Choose **Create stack**.
6. For **Choose a template**, select **Upload a template to Amazon S3**, choose the template that you downloaded, and choose **Next**.
7. On the **Specify Details** page, fill out the following parameters accordingly and choose **Next**:

   - **Stack name**: Choose a stack name for your CloudFormation stack.
   - **IAMRole**: Choose an IAM role that has permissions to write CloudWatch metrics, logs, and traces. For more information, see Prerequisites.
   - **InstanceAMI**: Choose an AMI that is valid in the Region where you're going to launch your stack.
   - **InstanceType**: Choose a valid instance type.
   - **KeyName**: To enable SSH access to the new instance, choose an existing Amazon EC2 key pair. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 Key Pairs in the *Amazon EC2 User Guide*.

- **SSHLocation**: Specifies the IP address range that can be used to connect to the instance using SSH. The default allows access from any IP address.
- **SSMKey**: Specifies the agent configuration file that you created and saved in Parameter Store.

8. On the **Options** page, you can choose to tag your stack resources. Choose **Next**.
9. On the **Review** page, review your information, acknowledge that the stack might create IAM resources, and then choose **Create**.

   If you refresh the console, you see that the new stack has the `CREATE_IN_PROGRESS` status.
10. When the instance is created, you can see it in the Amazon EC2 console. Optionally, you can connect to the host and check the progress.

    Use the following command to confirm that the agent is installed:

    ```
    rpm -qa amazon-cloudwatch-agent
    ```

    Use the following command to confirm that the agent is running:

    ```
    ps aux | grep amazon-cloudwatch-agent
    ```

The next procedure demonstrates using CloudFormation to update the CloudWatch agent, using an agent configuration that you saved in Parameter Store.

To use CloudFormation to update the CloudWatch agent using a configuration in Parameter Store

1. Change the agent configuration file stored in Parameter Store to the new configuration that you want.
2. In the CloudFormation template that you downloaded in the the section called “Tutorial: Install the CloudWatch agent using CloudFormation and Parameter Store” topic, change the version number. For example, you might change `VERSION=1.0` to `VERSION=2.0`.
3. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
4. On the CloudFormation dashboard, select the stack that you created and choose **Update Stack**.

5. For **Select Template**, select **Upload a template to Amazon S3**, select the template that you just modified, and choose **Next**.
6. On the **Options** page, choose **Next** and then **Next**.
7. On the **Review** page, review your information and choose **Update**.

   After some time, you see `UPDATE_COMPLETE`.

Troubleshooting installation of the CloudWatch agent with CloudFormation

This section helps you troubleshoot issues with installing and updating the CloudWatch agent using CloudFormation.

Detecting when an update fails

If you use CloudFormation to update your CloudWatch agent configuration, and use an invalid configuration, the agent stops sending any metrics to CloudWatch. A quick way to check whether an agent configuration update succeeded is to look at the `cfn-init-cmd.log` file. On a Linux server, the file is located at `/var/log/cfn-init-cmd.log`. On a Windows instance, the file is located at `C:\cfn\log\cfn-init-cmd.log`.

Metrics are missing

If you don't see metrics that you expect to see after installing or updating the agent, confirm that the agent is configured to collect that metric. To do this, check the `amazon-cloudwatch-agent.json` file to make sure that the metric is listed, and check that you are looking in the correct metric namespace. For more information, see CloudWatch agent files and locations.

Set up the CloudWatch agent with security-enhanced Linux (SELinux)

If your system has security-enhanced Linux (SELinux) enabled, you must apply the appropriate security policies to ensure that the CloudWatch agent runs in a confined domain.

Prerequisites

Before you can configure SELinux for the agent, check the following **prerequisites**:

To complete the prerequisites for using the CloudWatch agent with SELinux

1. If you haven't done so, install the following SELinux policy development packages:

   ```
   sudo yum update
   ```

```
sudo yum install -y selinux-policy-devel policycoreutils-devel rpm-build git
```

2. Run the following command to check your system's SELinux status:

```
sestatus
```

Example output:

```
SELinux status:                 enabled
SELinuxfs mount:                /sys/fs/selinux
SELinux root directory:         /etc/selinux
Loaded policy name:             targeted
Current mode:                   permissive
Mode from config file:          permissive
Policy MLS status:              enabled
Policy deny_unknown status:     allowed
Memory protection checking:     actual (secure)
Max kernel policy version:      33
```

If you find that SELinux is currently disabled, do the following:

a. Open the SELinux file by entering the following command:

```
sudo vi /etc/selinux/config
```

b. Set the `SELINUX` parameter to either `permissive` or `enforcing`. For example:

```
SELINUX=enforcing
```

c. Save the file and reboot the system to apply the changes.

```
sudo reboot
```

3. Ensure that the CloudWatch agent is running as a `systemd` service. This is required to use it within a confined SELinux domain.

```
sudo systemctl status amazon-cloudwatch-agent
```

If the agent is correctly configured, the output should indicate that it is `active (running)` and `enabled` at startup.

Configure SELinux for the agent

After you complete the prerequisites, you can configure SELinux.

To configure SELinux for the CloudWatch agent

1. Clone the SELinux policy for the CloudWatch agent by entering the following command:

```
git clone https://github.com/aws/amazon-cloudwatch-agent-selinux.git
```

2. Navigate to the cloned repository and then update the script permissions by entering the following commands:

```
cd amazon-cloudwatch-agent-selinux
chmod +x amazon_cloudwatch_agent.sh
```

3. Use sudo to run the SELinux policy installation script by entering the following command. During execution, the script prompts you to enter y or n to allow automatic restart. This restart ensures that the agent transitions into the correct SELinux domain.

```
sudo ./amazon_cloudwatch_agent.sh
```

4. If the CloudWatch agent hasn't been restarted yet, restart it to ensure that it transitions to the correct SELinux domain:

```
sudo systemctl restart amazon-cloudwatch-agent
```

5. Verify that CloudWatch Agent is running in the confined domain by entering the following command:

```
ps -efZ | grep amazon-cloudwatch-agent
```

   If the agent is correctly confined, the output should indicate a SELinux-confined domain instead of `unconfined_service_t`.

   The following is an example of output when the agent is correctly confined.

```
system_u:system_r:confined_t:s0 root 1234 1 0 12:00 ? 00:00:10 /opt/aws/amazon-
cloudwatch-agent/bin/amazon-cloudwatch-agent
```

After SELinux is configured, you can proceed to configure the agent to collect metrics, logs, and traces. For more information, see Manually create or edit the CloudWatch agent configuration file.

Create the CloudWatch agent configuration file

Before running the CloudWatch agent on any servers, you must create one or more CloudWatch agent configuration files.

The agent configuration file is a JSON file that specifies the metrics, logs, and traces that the agent is to collect, including custom metrics. You can create it by using the wizard or by creating it yourself from scratch. You could also use the wizard to initially create the configuration file and then modify it manually. If you create or modify the file manually, the process is more complex, but you have more control over the metrics collected and can specify metrics not available through the wizard.

Any time you change the agent configuration file, you must then restart the agent to have the changes take effect. To restart the agent, follow the instructions in (Optional) Modify the common configuration and named profile for CloudWatch agent.

After you have created a configuration file, you can save it manually as a JSON file and then use this file when installing the agent on your servers. Alternatively, you can store it in Systems Manager Parameter Store if you're going to use Systems Manager when you install the agent on servers.

The CloudWatch agent supports using multiple configuration files. For more information, see Creating multiple CloudWatch agent configuration files.

Metrics, logs, and traces collected by the CloudWatch agent incur charges. For more information about pricing, see Amazon CloudWatch Pricing.

Contents

- Create the CloudWatch agent configuration file with the wizard
- Creating multiple CloudWatch agent configuration files
- Manually create or edit the CloudWatch agent configuration file

Create the CloudWatch agent configuration file with the wizard

The agent configuration file wizard, `amazon-cloudwatch-agent-config-wizard`, asks a series of questions to help you configure the CloudWatch agent for your needs. This section describes

the credentials required for the configuration file. It describes how to run the CloudWatch agent configuration wizard. It also describes the metrics that are predefined in the wizard.

Required credentials

The wizard can autodetect the credentials and AWS Region to use if you have the AWS credentials and configuration files in place before you start the wizard. For more information about these files, see Configuration and Credential Files in the *AWS Systems Manager User Guide*.

In the AWS credentials file, the wizard checks for default credentials and also looks for an `AmazonCloudWatchAgent` section such as the following:

```
[AmazonCloudWatchAgent]
aws_access_key_id = my_access_key
aws_secret_access_key = my_secret_key
```

The wizard displays the default credentials, the credentials from the `AmazonCloudWatchAgent`, and an `Others` option. You can select which credentials to use. If you choose `Others`, you can input credentials.

For *my_access_key* and *my_secret_key*, use the keys from the IAM user that has the permissions to write to Systems Manager Parameter Store.

In the AWS configuration file, you can specify the Region that the agent sends metrics to if it's different than the `[default]` section. The default is to publish the metrics to the Region where the Amazon EC2 instance is located. If the metrics should be published to a different Region, specify the Region here. In the following example, the metrics are published to the `us-west-1` Region.

```
[AmazonCloudWatchAgent]
region = us-west-1
```

Run the CloudWatch agent configuration wizard

To create the CloudWatch agent configuration file

1. Start the CloudWatch agent configuration wizard by entering the following:

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-config-wizard
   ```

On a server running Windows Server, run the following commands to launch the wizard:

```
cd "C:\Program Files\Amazon\AmazonCloudWatchAgent"
```

```
.\amazon-cloudwatch-agent-config-wizard.exe
```

2. Answer the questions to customize the configuration file for your server.
3. If you're storing the configuration file locally, the configuration file `config.json` is stored in `/opt/aws/amazon-cloudwatch-agent/bin/` on Linux servers, and is stored in `C:\Program Files\Amazon\AmazonCloudWatchAgent` on Windows Server. You can then copy this file to other servers where you want to install the agent.

   If you're going to use Systems Manager to install and configure the agent, be sure to answer **Yes** when prompted whether to store the file in Systems Manager Parameter Store. You can also choose to store the file in Parameter Store even if you aren't using the SSM Agent to install the CloudWatch agent. To be able to store the file in Parameter Store, you must use an IAM role with sufficient permissions.

CloudWatch agent predefined metric sets

The wizard is configured with predefined sets of metrics, with different detail levels. These sets of metrics are shown in the following tables. For more information about these metrics, see Metrics collected by the CloudWatch agent.

> **Note**
>
> Parameter Store supports parameters in Standard and Advanced tiers. These parameter tiers are not related to the Basic, Standard, and Advanced levels of metric details that are described in these tables.

Amazon EC2 instances running Linux

Detail level	Metrics included
Basic	**Mem:** mem_used_percent

Detail level	Metrics included
	Disk: disk_used_percent The `disk` metrics such as `disk_used_percent` have a dimension for `Partition`, which means that the number of custom metrics generated is dependent on the number of partitions associated with your instance. The number of disk partitions you have depends on which AMI you are using and the number of Amazon EBS volumes you attach to the server.
Standard	**CPU:** `cpu_usage_idle`, `cpu_usage_iowait`, `cpu_usage_user`, `cpu_usage_system` **Disk:** `disk_used_percent`, `disk_inodes_free` **Diskio:** `diskio_io_time` **Mem:** `mem_used_percent` **Swap:** `swap_used_percent`
Advanced	**CPU:** `cpu_usage_idle`, `cpu_usage_iowait`, `cpu_usage_user`, `cpu_usage_system` **Disk:** `disk_used_percent`, `disk_inodes_free` **Diskio:** `diskio_io_time`, `diskio_write_bytes`, `diskio_read_bytes`, `diskio_writes`, `diskio_reads` **Mem:** `mem_used_percent` **Netstat:** `netstat_tcp_established`, `netstat_tcp_time_wait` **Swap:** `swap_used_percent`

On-premises servers running Linux

Detail level	Metrics included
Basic	**Disk:** `disk_used_percent`

Detail level	Metrics included
	Diskio: diskio_write_bytes ,diskio_read_bytes ,diskio_writes ,diskio_reads **Mem:** mem_used_percent **Net:** net_bytes_sent ,net_bytes_recv ,net_packets_sent ,net_packets_recv **Swap:** swap_used_percent
Standard	**CPU:** cpu_usage_idle ,cpu_usage_iowait **Disk:** disk_used_percent ,disk_inodes_free **Diskio:** diskio_io_time ,diskio_write_bytes ,diskio_read_bytes ,diskio_writes ,diskio_reads **Mem:** mem_used_percent **Net:** net_bytes_sent ,net_bytes_recv ,net_packets_sent ,net_packets_recv **Swap:** swap_used_percent

Detail level	Metrics included
Advanced	**CPU:** `cpu_usage_guest` , `cpu_usage_idle` , `cpu_usage_iowait` , `cpu_usage_steal` , `cpu_usage_user` , `cpu_usage_system` **Disk:** `disk_used_percent` , `disk_inodes_free` **Diskio:** `diskio_io_time` , `diskio_write_bytes` , `diskio_read_bytes` , `diskio_writes` , `diskio_reads` **Mem:** `mem_used_percent` **Net:** `net_bytes_sent` , `net_bytes_recv` , `net_packets_sent` , `net_packets_recv` **Netstat:** `netstat_tcp_established` , `netstat_tcp_time_wait` **Swap:** `swap_used_percent`

Amazon EC2 instances running Windows Server

> **Note**
>
> The metric names listed in this table display how the metric appears when viewed in the console. The actual metric name might not include the first word. For example, the actual metric name for `LogicalDisk % Free Space` is just `% Free Space`.

Detail level	Metrics included
Basic	**Memory:** `Memory % Committed Bytes In Use` **LogicalDisk:** `LogicalDisk % Free Space`
Standard	**Memory:** `Memory % Committed Bytes In Use` **Paging:** `Paging File % Usage`

Detail level	Metrics included
	Processor: `Processor % Idle Time`, `Processor % Interrupt Time`, `Processor % User Time` **PhysicalDisk:** `PhysicalDisk % Disk Time` **LogicalDisk:** `LogicalDisk % Free Space`
Advanced	**Memory:** `Memory % Committed Bytes In Use` **Paging:** `Paging File % Usage` **Processor:** `Processor % Idle Time`, `Processor % Interrupt Time`, `Processor % User Time` **LogicalDisk:** `LogicalDisk % Free Space` **PhysicalDisk:** `PhysicalDisk % Disk Time` , `PhysicalDisk Disk Write Bytes/sec` , `PhysicalDisk Disk Read Bytes/sec` , `PhysicalDisk Disk Writes/sec` , `PhysicalDisk Disk Reads/sec` **TCP:** `TCPv4 Connections Established` , `TCPv6 Connections Established`

On-premises server running Windows Server

> **Note**
>
> The metric names listed in this table display how the metric appears when viewed in the console. The actual metric name might not include the first word. For example, the actual metric name for `LogicalDisk % Free Space` is just `% Free Space`.

Detail level	Metrics included
Basic	**Paging:** `Paging File % Usage`

Detail level	Metrics included
	Processor: Processor % Processor Time **LogicalDisk:**LogicalDisk % Free Space **PhysicalDisk:** PhysicalDisk Disk Write Bytes/sec ,PhysicalDisk Disk Read Bytes/sec ,PhysicalDisk Disk Writes/sec , PhysicalDisk Disk Reads/sec **Memory:** Memory % Committed Bytes In Use **Network Interface:** Network Interface Bytes Sent/sec, Network Interface Bytes Received/sec ,Network Interface Packets Sent/sec, Network Interface Packets Received/sec
Standard	**Paging:** Paging File % Usage **Processor:** Processor % Processor Time, Processor % Idle Time, Processor % Interrupt Time **LogicalDisk:** LogicalDisk % Free Space **PhysicalDisk:** PhysicalDisk % Disk Time ,PhysicalDisk Disk Write Bytes/sec ,PhysicalDisk Disk Read Bytes/sec , PhysicalDisk Disk Writes/sec ,PhysicalDisk Disk Reads/sec **Memory:** Memory % Committed Bytes In Use **Network Interface:** Network Interface Bytes Sent/sec, Network Interface Bytes Received/sec ,Network Interface Packets Sent/sec, Network Interface Packets Received/sec

Detail level	Metrics included
Advanced	**Paging:**`Paging File % Usage` **Processor:** `Processor % Processor Time`, `Processor % Idle Time`, `Processor % Interrupt Time`, `Processor % User Time` **LogicalDisk:** `LogicalDisk % Free Space` **PhysicalDisk:** `PhysicalDisk % Disk Time` , `PhysicalDisk Disk Write Bytes/sec` , `PhysicalDisk Disk Read Bytes/sec` , `PhysicalDisk Disk Writes/sec` , `PhysicalDisk Disk Reads/sec` **Memory:** `Memory % Committed Bytes In Use` **Network Interface:** `Network Interface Bytes Sent/sec`, `Network Interface Bytes Received/sec` , `Network Interface Packets Sent/sec`, `Network Interface Packets Received/sec` **TCP:** `TCPv4 Connections Established` , `TCPv6 Connections Established`

Examples of configuration files

Basic system metrics configuration

```
{
  "agent": {
    "metrics_collection_interval": 60,
    "region": "us-east-1"
  },
  "metrics": {
    "namespace": "MySystem",
    "metrics_collected": {
      "cpu": {
        "resources": ["*"],
        "measurement": ["usage_active", "usage_system", "usage_user"]
      },
      "mem": {
```

```
        "measurement": ["used_percent"]
      },
      "disk": {
        "resources": ["/"],
        "measurement": ["used_percent"]
      }
    },
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    }
  }
}
```

Web server monitoring configuration

```
{
  "agent": {
    "metrics_collection_interval": 60,
    "region": "us-east-1"
  },
  "metrics": {
    "namespace": "WebServer",
    "metrics_collected": {
      "cpu": {
        "resources": ["*"],
        "measurement": ["usage_active"]
      },
      "mem": {
        "measurement": ["used_percent"]
      },
      "net": {
        "resources": ["eth0"],
        "measurement": ["bytes_sent", "bytes_recv"]
      }
    }
  },
  "logs": {
    "logs_collected": {
      "files": {
        "collect_list": [
          {
            "file_path": "/var/log/apache2/access.log",
            "log_group_name": "apache-access-logs",
```

```
            "log_stream_name": "{instance_id}-access"
          },
          {
            "file_path": "/var/log/apache2/error.log",
            "log_group_name": "apache-error-logs",
            "log_stream_name": "{instance_id}-error"
          }
        ]
      }
    }
  }
}
```

Database server configuration

```
{
  "agent": {

Creating multiple CloudWatch agent configuration files

On both Linux servers and Windows servers, you can set up the CloudWatch agent to use multiple configuration files. For example, you can use a common configuration file that collects a set of metrics, logs, and traces that you always want to collect from all servers in your infrastructure. You can then use additional configuration files that collect metrics from certain applications or in certain situations.

To set this up, first create the configuration files that you want to use. Any configuration files that will be used together on the same server must have different file names. You can store the configuration files on servers or in Parameter Store.

Start the CloudWatch agent using the `fetch-config` option and specify the first configuration file. To append the second configuration file to the running agent, use the same command but with the `append-config` option. All metrics, logs, and traces listed in either configuration file are collected. The following example commands illustrate this scenario using configurations stores as files. The first line starts the agent using the `infrastructure.json` configuration file, and the second line appends the `app.json` configuration file.

The following example commands are for Linux.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2
 -s -c file:/tmp/infrastructure.json
```

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -m
 ec2 -s -c file:/tmp/app.json
```

The following example commands are for Windows Server.

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
 -a fetch-config -m ec2 -s -c file:"C:\Program Files\Amazon\AmazonCloudWatchAgent
\infrastructure.json"
```

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
 -a append-config -m ec2 -s -c file:"C:\Program Files\Amazon\AmazonCloudWatchAgent
\app.json"
```

The following example configuration files illustrate a use for this feature. The first configuration file is used for all servers in the infrastructure, and the second collects only logs from a certain application and is appended to servers running that application.

infrastructure.json

```
{
  "metrics": {
    "metrics_collected": {
      "cpu": {
        "resources": [
          "*"
        ],
        "measurement": [
          "usage_active"
        ],
        "totalcpu": true
      },
      "mem": {
         "measurement": [
           "used_percent"
        ]
      }
    }
  },
  "logs": {
    "logs_collected": {
      "files": {
        "collect_list": [
          {
            "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-
agent.log",
            "log_group_name": "amazon-cloudwatch-agent.log"
          },
          {
            "file_path": "/var/log/messages",
            "log_group_name": "/var/log/messages"
          }
        ]
```

```
      }
    }
  }
}
```

app.json

```
{
    "logs": {
        "logs_collected": {
            "files": {
                "collect_list": [
                    {
                        "file_path": "/app/app.log*",
                        "log_group_name": "/app/app.log"
                    }
                ]
            }
        }
    }
}
```

Any configuration files appended to the configuration must have different file names from each other and from the initial configuration file. If you use `append-config` with a configuration file with the same file name as a configuration file that the agent is already using, the append command overwrites the information from the first configuration file instead of appending to it. This is true even if the two configuration files with the same file name are on different file paths.

The preceding example shows the use of two configuration files, but there is no limit to the number of configuration files that you can append to the agent configuration. You can also mix the use of configuration files located on servers and configurations located in Parameter Store.

Manually create or edit the CloudWatch agent configuration file

The CloudWatch agent configuration file is a JSON file with five sections: `agent`, `metrics`, `logs`, `traces`, and `opentelemetry`.

- The `agent` section includes fields for the overall configuration of the agent.
- The `metrics` section specifies the custom metrics for collection and publishing to CloudWatch. If you're using the agent only to collect logs, you can omit the `metrics` section from the file.

- The `logs` section specifies what log files are published to CloudWatch Logs. This can include events from the Windows Event Log if the server runs Windows Server.
- The `traces` section specifies the sources for traces that are collected and sent to AWS X-Ray.
- The `opentelemetry` section specifies the sources of metrics, logs, and traces for the agent to collect and send to the CloudWatch OpenTelemetry Protocol (OTLP) endpoints. For more information, see OTLP Endpoints.

This section explains the structure and fields of the CloudWatch agent configuration file. You can view the schema definition for this configuration file. The schema definition is located at *`installation-directory`*`/doc/amazon-cloudwatch-agent-schema.json` on Linux servers and at *`installation-directory`*`/amazon-cloudwatch-agent-schema.json` on servers running Windows Server.

If you create or edit the agent configuration file manually, you can give it any name. For simplicity in troubleshooting, we recommend that you name it `/opt/aws/amazon-cloudwatch-agent/etc/cloudwatch-agent.json` on a Linux server and `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json` on servers running Windows Server. After you have created the file, you can copy it to other servers where you want to install the agent.

When the agent is started, it creates a copy of each configuration file in `/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.d` directory, with the filename prefixed with either `file_` (for local file sources) or `ssm_` (for Systems Manager parameter store sources) to indicate the configuration origin.

> **Note**
>
> Metrics, logs, and traces collected by the CloudWatch agent incur charges. For more information about pricing, see Amazon CloudWatch Pricing.

CloudWatch agent configuration file: Agent section

The `agent` section can include the following fields. The wizard doesn't create an `agent` section. Instead, the wizard omits it and uses the default values for all fields in this section.

- `metrics_collection_interval` – Optional. Specifies how often all metrics specified in this configuration file are to be collected. You can override this value for specific types of metrics.

This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

The default value is 60.

- `region` – Specifies the Region to use for the CloudWatch endpoint when an Amazon EC2 instance is being monitored. The metrics collected are sent to this Region, such as `us-west-1`. If you omit this field, the agent sends metrics to the Region where the Amazon EC2 instance is located.

  If you are monitoring an on-premises server, this field isn't used, and the agent reads the Region from the `AmazonCloudWatchAgent` profile of the AWS configuration file.

- `credentials` – Specifies an IAM role to use when sending metrics, logs, and traces to a different AWS account. If specified, this field contains one parameter, `role_arn`.
  - `role_arn` – Specifies the Amazon Resource Name (ARN) of an IAM role to use for authentication when sending metrics, logs, and traces to a different AWS account. For more information, see Sending metrics, logs, and traces to a different account.
- debug – Optional. Specifies running the CloudWatch agent with debug log messages. The default value is `false`.
- `aws_sdk_log_level` – Optional. Supported only in versions 1.247350.0 and later of the CloudWatch agent.

  You can specify this field to have the agent perform logging for AWS SDK endpoints. The value for this field can include one or more of the following options. Separate multiple options with the `|` character.
  - `LogDebug`
  - `LogDebugWithSigning`
  - `LogDebugWithHTTPBody`
  - `LogDebugRequestRetries`
  - `LogDebugWithEventStreamBody`

  For more information about these options, see LogLevelType.

- `logfile` – Specifies the location where the CloudWatch agent writes log messages. If you specify an empty string, the log goes to stderr. If you don't specify this option, the default locations are the following:
  - Linux: `/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log`
  - Windows Server: `c:\\ProgramData\\Amazon\\CloudWatchAgent\\Logs\\amazon-cloudwatch-agent.log`

  The CloudWatch agent automatically rotates the log file that it creates. A log file is rotated out when it reaches 100 MB in size. The agent keeps the rotated log files for up to seven days, and it keeps as many as five backup log files that have been rotated out. Backup log files have a timestamp appended to their filename. The timestamp shows the date and time that the file was rotated out: for example, `amazon-cloudwatch-agent-2018-06-08T21-01-50.247.log.gz`.
- `omit_hostname` – Optional. By default, the hostname is published as a dimension of metrics that are collected by the agent, unless you are using the `append_dimensions` field in the `metrics` section. Set `omit_hostname` to `true` to prevent the hostname from being published as a dimension even if you are not using `append_dimensions`. The default value is `false`.
- `run_as_user` – Optional. Specifies a user to use to run the CloudWatch agent. If you don't specify this parameter, the root user is used. This option is valid only on Linux servers.

  If you specify this option, the user must exist before you start the CloudWatch agent. For more information, see Running the CloudWatch agent as a different user.
- `user_agent` – Optional. Specifies the `user-agent` string that is used by the CloudWatch agent when it makes API calls to the CloudWatch backend. The default value is a string consisting of the agent version, the version of the Go programming language that was used to compile the agent, the runtime operating system and architecture, the build time, and the plugins enabled.
- `usage_data` – Optional. By default, the CloudWatch agent sends health and performance data about itself to CloudWatch whenever it publishes metrics or logs to CloudWatch. This data incurs no costs to you. You can prevent the agent from sending this data by specifying `false` for `usage_data`. If you omit this parameter, the default of `true` is used and the agent sends the health and performance data.

  If you set this value to `false`, you must stop and restart the agent for it to take effect.
- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.

- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.
- `use_dualstack_endpoint` – Optional. If this is `true`, the CloudWatch agent will use dual stack endpoints for all API calls.

The following is an example of an `agent` section.

```
"agent": {
   "metrics_collection_interval": 60,
   "region": "us-west-1",
   "logfile": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log",
   "debug": false,
   "run_as_user": "cwagent"
  }
```

CloudWatch agent configuration file: Metrics section

Fields common to Linux and Windows

On servers running either Linux or Windows Server, the `metrics` section includes the following fields:

- `namespace` – Optional. The namespace to use for the metrics collected by the agent. The default value is `CWAgent`. The maximum length is 255 characters. The following is an example:

  ```
  {
    "metrics": {
      "namespace": "Development/Product1Metrics",
     ......
     },
  }
  ```

- `append_dimensions` – Optional. Adds Amazon EC2 metric dimensions to all metrics collected by the agent. This also causes the agent to not publish the hostname as a dimension.

  The only supported key-value pairs for `append_dimensions` are shown in the following list. Any other key-value pairs are ignored. The agent supports these key-value pairs exactly as they are shown in the following list. You can't change the key values to publish different dimension names for them.

- `"ImageId":"${aws:ImageId}"` sets the instance's AMI ID as the value of the `ImageId` dimension.
- `"InstanceId":"${aws:InstanceId}"` sets the instance's instance ID as the value of the `InstanceId` dimension.
- `"InstanceType":"${aws:InstanceType}"` sets the instance's instance type as the value of the `InstanceType` dimension.
- `"AutoScalingGroupName":"${aws:AutoScalingGroupName}"` sets the instance's Auto Scaling group name as the value of the `AutoScalingGroupName` dimension.

If you want to append dimensions to metrics with arbitrary key-value pairs, use the `append_dimensions` parameter in the field for that particular type of metric.

If you specify a value that depends on Amazon EC2 metadata and you use proxies, you must make sure that the server can access the endpoint for Amazon EC2. For more information about these endpoints, see Amazon Elastic Compute Cloud (Amazon EC2) in the *Amazon Web Services General Reference*.

- `aggregation_dimensions` – Optional. Specifies the dimensions that collected metrics are to be aggregated on. For example, if you roll up metrics on the `AutoScalingGroupName` dimension, the metrics from all instances in each Auto Scaling group are aggregated and can be viewed as a whole.

  You can roll up metrics along single or multiple dimensions. For example, specifying `[["InstanceId"], ["InstanceType"], ["InstanceId","InstanceType"]]` aggregates metrics for instance ID singly, instance type singly, and for the combination of the two dimensions.

  You can also specify `[]` to roll up all metrics into one collection, disregarding all dimensions.

- `endpoint_override` – Specifies a FIPS endpoint or private link to use as the endpoint where the agent sends metrics. Specifying this and setting a private link enables you to send the metrics to an Amazon VPC endpoint. For more information, see What Is Amazon VPC?.

  The value of `endpoint_override` must be a string that is a URL.

  For example, the following part of the metrics section of the configuration file sets the agent to use a VPC Endpoint when sending metrics.

```
{
```

```
  "metrics": {
    "endpoint_override": "vpce-XXXXXXXXXXXXXXXXXXXXXXXX.monitoring.us-
east-1.vpce.amazonaws.com",
   ......
   },
}
```

- `metrics_collected` – Required. Specifies which metrics are to be collected, including custom metrics collected through `StatsD` or `collectd`. This section includes several subsections.

  The contents of the `metrics_collected` section depend on whether this configuration file is for a server running Linux or Windows Server.

- `metrics_destinations` – Optional. Specifies one or more destinations for all metrics defined in `metrics_collected`. If specified here, it overrides the default destination of `cloudwatch`.
  - `cloudwatch` – Amazon CloudWatch.
  - amp – Amazon Managed Service for Prometheus.
    - `workspace_id` – The ID corresponding to the Amazon Managed Service for Prometheus workspace.

```
{
  "metrics": {
    "metrics_destinations": {
      "cloudwatch": {},
      "amp": {
        "workspace_id": "ws-abcd1234-ef56-7890-ab12-example"
      }
    }
  }
}
```

- `force_flush_interval` – Specifies in seconds the maximum amount of time that metrics remain in the memory buffer before being sent to the server. No matter the setting for this, if the size of the metrics in the buffer reaches 1 MB or 1000 different metrics, the metrics are immediately sent to the server.

  The default value is 60.

- `credentials` – Specifies an IAM role to use when sending metrics to a different account. If specified, this field contains one parameter, `role_arn`.

- `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending metrics to a different account. For more information, see Sending metrics, logs, and traces to a different account. If specified here, this value overrides the `role_arn` specified in the `agent` section of the configuration file, if any.
- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.

Linux section

On servers running Linux, the `metrics_collected` section of the configuration file can also contain the following fields.

Many of these fields can include a `measurement` sections that lists the metrics you want to collect for that resource. These `measurement` sections can either specify the complete metric name such as `swap_used`, or just the part of the metric name that will be appended to the type of resource. For example, specifying `reads` in the `measurement` section of the `diskio` section causes the `diskio_reads` metric to be collected.

- `collectd` – Optional. Specifies that you want to retrieve custom metrics using the `collectd` protocol. You use `collectd` software to send the metrics to the CloudWatch agent. For more information about the configuration options available for collectd, see Retrieve custom metrics with collectd.
- `cpu` – Optional. Specifies that CPU metrics are to be collected. This section is valid only for Linux instances. You must include at least one of the `resources` and `totalcpu` fields for any CPU metrics to be collected. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `resources` – Optional. Specify this field with a value of `*` to cause per-cpu metrics to be collected. The only allowed value is `*`.
- `totalcpu` – Optional. Specifies whether to report cpu metrics aggregated across all cpu cores. The default is true.
- `measurement` – Specifies the array of cpu metrics to be collected. Possible values are `time_active`, `time_guest`, `time_guest_nice`, `time_idle`, `time_iowait`, `time_irq`, `time_nice`, `time_softirq`, `time_steal`, `time_system`, `time_user`, `usage_active`, `usage_guest`, `usage_guest_nice`, `usage_idle`, `usage_iowait`, `usage_irq`, `usage_nice`, `usage_softirq`, `usage_steal`, `usage_system`, and `usage_user`. This field is required if you include `cpu`.

  By default, the unit for `cpu_usage_*` metrics is `Percent`, and `cpu_time_*` metrics don't have a unit.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the cpu metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the cpu metrics. If you specify this field, it's used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics that the agent collects.

- `disk` – Optional. Specifies that disk metrics are to be collected. Collects metrics only for mounted volumes. This section is valid only for Linux instances. This section can include the following fields:

- `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
- `resources` – Optional. Specifies an array of disk mount points. This field limits CloudWatch to collect metrics from only the listed mount points. You can specify `*` as the value to collect metrics from all mount points. The default value is to collect metrics from all mount points.
- `measurement` – Specifies the array of disk metrics to be collected. Possible values are `free`, `total`, `used`, `used_percent`, `inodes_free`, `inodes_used`, and `inodes_total`. This field is required if you include `disk`.

  > **Note**
  >
  > The `disk` metrics have a dimension for `Partition`, which means that the number of custom metrics generated is dependent on the number of partitions associated with your instance. The number of disk partitions you have depends on which AMI you are using and the number of Amazon EBS volumes you attach to the server.

  To see the default units for each `disk` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `ignore_file_system_types` – Specifies file system types to exclude when collecting disk metrics. Valid values include `sysfs`, `devtmpfs`, and so on.
- `drop_device` – Setting this to `true` causes `Device` to not be included as a dimension for disk metrics.

Preventing `Device` from being used as a dimension can be useful on instances that use the Nitro system because on those instances the device names change for each disk mount when the instance is rebooted. This can cause inconsistent data in your metrics and cause alarms based on these metrics to go to `INSUFFICIENT DATA` state.

The default is `false`.

- `metrics_collection_interval` – Optional. Specifies how often to collect the disk metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.

- `append_dimensions` – Optional. Specify key-value pairs to use as additional dimensions for only the disk metrics. If you specify this field, it is used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

  One key-value pair that you can use is the following. You can also specify other custom key-value pairs.

  - `"VolumeId":"${aws:VolumeId}"` adds a `VolumeId` dimension to your block device disk metrics. For Amazon EBS volumes, this will be the Amazon EBS Volume ID. For EC2 instance store, this will be the device serial. Using this requires the `drop_device` parameter to be set to `false`.

- `diskio` – Optional. Specifies that disk i/o metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `resources` – Optional. If you specify an array of devices, CloudWatch collects metrics from only those devices. Otherwise, metrics for all devices are collected. You can also specify * as the value to collect metrics from all devices.
- `measurement` – Specifies the array of diskio and AWS NVMe driver metrics to be collected for Amazon EBS volumes and instance store volumes attached to Amazon EC2 instances. Possible diskio values are `reads`, `writes`, `read_bytes`, `write_bytes`, `read_time`, `write_time`, `io_time`, and `iops_in_progress`. For a list of the NVMe driver metrics for Amazon EBS volumes and Amazon EC2 instance store volumes, see Collect Amazon EBS NVMe driver metrics and Collect Amazon EC2 instance store volume NVMe driver metrics. This field is required if you include `diskio`.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

  For information on default units and description of the metrics, see Collect Amazon EBS NVMe driver metrics.
- `metrics_collection_interval` – Optional. Specifies how often to collect the diskio metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the diskio metrics. If you specify this field, it is used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `swap` – Optional. Specifies that swap memory metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value

of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of swap metrics to be collected. Possible values are `free`, `used`, and `used_percent`. This field is required if you include `swap`.

  To see the default units for each `swap` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `metrics_collection_interval` – Optional. Specifies how often to collect the swap metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

- `append_dimensions` – Optional. Additional dimensions to use for only the swap metrics. If you specify this field, it is used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics collected by the agent. It's collected as a high-resolution metric.

- `mem` – Optional. Specifies that memory metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter

don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of memory metrics to be collected. Possible values are `active`, `available`, `available_percent`, `buffered`, `cached`, `free`, `inactive`, `shared`, `total`, `used`, and `used_percent`. This field is required if you include `mem`.

  To see the default units for each `mem` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `metrics_collection_interval` – Optional. Specifies how often to collect the mem metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

- `append_dimensions` – Optional. Additional dimensions to use for only the mem metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics that the agent collects.

- `net` – Optional. Specifies that networking metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated

metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `resources` – Optional. If you specify an array of network interfaces, CloudWatch collects metrics from only those interfaces. Otherwise, metrics for all devices are collected. You can also specify `*` as the value to collect metrics from all interfaces.
- `measurement` – Specifies the array of networking metrics to be collected. Possible values are `bytes_sent`, `bytes_recv`, `drop_in`, `drop_out`, `err_in`, `err_out`, `packets_sent`, and `packets_recv`. This field is required if you include `net`.

  To see the default units for each `net` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the net metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the net metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `netstat` – Optional. Specifies that TCP connection state and UDP connection metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value

of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of netstat metrics to be collected. Possible values are `tcp_close`, `tcp_close_wait`, `tcp_closing`, `tcp_established`, `tcp_fin_wait1`, `tcp_fin_wait2`, `tcp_last_ack`, `tcp_listen`, `tcp_none`, `tcp_syn_sent`, `tcp_syn_recv`, `tcp_time_wait`, and `udp_socket`. This field is required if you include `netstat`.

  To see the default units for each `netstat` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the netstat metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the netstat metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `processes` – Optional. Specifies that process metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can

specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of processes metrics to be collected. Possible values are `blocked`, `dead`, `idle`, `paging`, `running`, `sleeping`, `stopped`, `total`, `total_threads`, `wait`, and `zombies`. This field is required if you include `processes`.

  For all `processes` metrics, the default unit is None.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of None for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the processes metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the process metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `nvidia_gpu` – Optional. Specifies that NVIDIA GPU metrics are to be collected. This section is valid only for Linux instances on hosts that are configured with a NVIDIA GPU accelerator and have the NVIDIA System Management Interface (nvidia-smi) installed.

  The NVIDIA GPU metrics that are collected are prefixed with the string `nvidia_smi_` to distinguish them from the metrics collected for other accelerator types. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent

sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of NVIDIA GPU metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect NVIDIA GPU metrics.

  Within the entry for each individual metric, you can optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the NVIDIA GPU metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

- `jmx` – Optional. Specifies that you want to retrieve Java Management Extensions (JMX) metrics from the instance. For more information about the parameters that you can use in this section and the metrics that you can collect, see Collect Java Management Extensions (JMX) metrics.
- `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.
- `procstat` – Optional. Specifies that you want to retrieve metrics from individual processes. For more information about the configuration options available for procstat, see Collect process metrics with the procstat plugin.
- `statsd` – Optional. Specifies that you want to retrieve custom metrics using the `StatsD` protocol. The CloudWatch agent acts as a daemon for the protocol. You use any standard `StatsD` client to send the metrics to the CloudWatch agent. For more information about the configuration options available for StatsD, see Retrieve custom metrics with StatsD.
- `ethtool` – Optional. Specifies that you want to retrieve network metrics using the `ethtool` plugin. This plugin can import both the metrics collected by the standard ethtool utility, as well as network performance metrics from Amazon EC2 instances. For more information about the configuration options available for ethtool, see Collect network performance metrics.

- `efa` – Optional. Specifies that Elastic Fabric Adapter (EFA) metrics are to be collected. This section is valid only for Linux instances that have EFA devices attached. The agent collects EFA metrics from the `/sys/class/infiniband/` sysfs interface.

  This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
  - `measurement` – Specifies the array of EFA metrics to be collected. This field is required. If you don't specify this field, the agent returns an error. You can specify metric names with or without the `efa_` prefix. For example, both `efa_tx_bytes` and `tx_bytes` are valid.

    For a list of the possible values to use here, see the **Metric** column in the table in Collect EFA metrics.
  - `metrics_collection_interval` – Optional. Specifies how often to collect the EFA metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file. The default value is 60 seconds.

  Each EFA metric is emitted with `device`, `port`, and `eniId` dimensions. To append the `InstanceId` dimension, use the `append_dimensions` field in the `metrics` section.

The following is an example of a `metrics` section for a Linux server. In this example, three CPU metrics, three netstat metrics, three process metrics, and one disk metric are collected, and the agent is set up to receive additional metrics from a `collectd` client.

```
"metrics": {
    "aggregation_dimensions" : [["AutoScalingGroupName"], ["InstanceId",
 "InstanceType"],[]],
    "metrics_collected": {
      "collectd": {},
      "cpu": {
        "resources": [
          "*"
```

```
        ],
        "measurement": [
          {"name": "cpu_usage_idle", "rename": "CPU_USAGE_IDLE", "unit": "Percent"},
          {"name": "cpu_usage_nice", "unit": "Percent"},
          "cpu_usage_guest"
        ],
        "totalcpu": false,
        "drop_original_metrics": [ "cpu_usage_guest" ],
        "metrics_collection_interval": 10,
        "append_dimensions": {
          "test": "test1",
          "date": "2017-10-01"
        }
      },
      "netstat": {
        "measurement": [
          "tcp_established",
          "tcp_syn_sent",
          "tcp_close"
        ],
        "metrics_collection_interval": 60
      },
       "disk": {
        "measurement": [
          "used_percent"
        ],
        "resources": [
          "*"
        ],
        "drop_device": true
      },
      "processes": {
        "measurement": [
          "running",
          "sleeping",
          "dead"
        ]
      }
    },
    "append_dimensions": {
      "ImageId": "${aws:ImageId}",
      "InstanceId": "${aws:InstanceId}",
      "InstanceType": "${aws:InstanceType}",
      "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
```

```
    }
  }
```

Windows Server

In the `metrics_collected` section for Windows Server, you can have subsections for each Windows performance object, such as `Memory`, `Processor`, and `LogicalDisk`. For information about what objects and counters are available, see Performance Counters in the Microsoft Windows documentation.

Within the subsection for each object, you specify a `measurement` array of the counters to collect. The `measurement` array is required for each object that you specify in the configuration file. You can also specify a `resources` field to name the instances to collect metrics from. You can also specify `*` for `resources` to collect separate metrics for every instance, excluding the `_Total` instance. To collect a single value aggregated across all instances, specify `_Total` for `resources`. If you omit `resources` for counters that have instances, such as `Processor`, the counters are not collected by the CloudWatch agent. If you omit `resources` for counters that don't have instances, such as `Memory`, the counters are collected. To determine whether counters have instances, you can use one of the following commands.

Powershell:

```
Get-Counter -ListSet *
```

Command line (not Powershell):

```
TypePerf.exe -q
```

Within each object section, you can also specify the following optional fields:

- `metrics_collection_interval` – Optional. Specifies how often to collect the metrics for this object, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.

- `append_dimensions` – Optional. Specifies additional dimensions to use for only the metrics for this object. If you specify this field, it's used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics collected by the agent.
- `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

Within each counter section, you can also specify the following optional fields:

- `rename` – Specifies a different name to be used in CloudWatch for this metric.
- `unit` – Specifies the unit to use for this metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

There are other optional sections that you can include in `metrics_collected`:

- `statsd` – Enables you to retrieve custom metrics using the `StatsD` protocol. The CloudWatch agent acts as a daemon for the protocol. You use any standard `StatsD` client to send the metrics to the CloudWatch agent. For more information, see Retrieve custom metrics with StatsD.
- `procstat` – Enables you to retrieve metrics from individual processes. For more information, see Collect process metrics with the procstat plugin.
- `jmx` – Optional. Specifies that you want to retrieve Java Management Extensions (JMX) metrics from the instance. For more information about the fields that you can use in this section and the metrics that you can collect, see Collect Java Management Extensions (JMX) metrics.
- `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.

The following is an example `metrics` section for use on Windows Server. In this example, many Windows metrics are collected, and the computer is also set to receive additional metrics from a `StatsD` client.

```
"metrics": {
    "metrics_collected": {
      "statsd": {},
      "Processor": {
        "measurement": [
          {"name": "% Idle Time", "rename": "CPU_IDLE", "unit": "Percent"},
          "% Interrupt Time",
          "% User Time",
          "% Processor Time"
        ],
        "resources": [
          "*"
        ],
        "append_dimensions": {
          "d1": "win_foo",
          "d2": "win_bar"
        }
      },
      "LogicalDisk": {
        "measurement": [
          {"name": "% Idle Time", "unit": "Percent"},
          {"name": "% Disk Read Time", "rename": "DISK_READ"},
          "% Disk Write Time"
        ],
        "resources": [
          "*"
        ]
      },
      "Memory": {
        "metrics_collection_interval": 5,
        "measurement": [
          "Available Bytes",
          "Cache Faults/sec",
          "Page Faults/sec",
          "Pages/sec"
        ],
        "append_dimensions": {
          "d3": "win_bo"
        }
      },
      "Network Interface": {
        "metrics_collection_interval": 5,
        "measurement": [
```

```
          "Bytes Received/sec",
          "Bytes Sent/sec",
          "Packets Received/sec",
          "Packets Sent/sec"
        ],
        "resources": [
          "*"
        ],
        "append_dimensions": {
          "d3": "win_bo"
        }
      },
      "System": {
        "measurement": [
          "Context Switches/sec",
          "System Calls/sec",
          "Processor Queue Length"
        ],
        "append_dimensions": {
          "d1": "win_foo",
          "d2": "win_bar"
        }
      }
    },
    "append_dimensions": {
      "ImageId": "${aws:ImageId}",
      "InstanceId": "${aws:InstanceId}",
      "InstanceType": "${aws:InstanceType}",
      "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
    },
    "aggregation_dimensions" : [["ImageId"], ["InstanceId", "InstanceType"], ["d1"],[]]
    }
  }
```

CloudWatch agent configuration file: Logs section

The `logs` section includes the following fields:

- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.

- `backpressure_mode` – Optional. Specifies the behavior when the CloudWatch agent is ingesting logs faster than it can send to CloudWatch Logs, resulting in backpressure. Backpressure can happen from network issues, API throttling, or high log volume.

  The agent supports the following values:

  - `fd_release` – Releases file descriptors for deleted files during backpressure conditions. This option can help prevent disk space exhaustion when external log rotation or cleanup processes remove files while the agent maintains open file descriptors. The `auto_removal` option takes precedence over the `backpressure_mode` option being set to `fd_release`. When `auto_removal` is enabled, the CloudWatch agent processes the file to completion without releasing the file descriptor.

    > **Important**
    >
    > Using `fd_release` can result in the CloudWatch agent being unable to read log files to completion, causing log loss.

- `concurrency` – Optional. Specifies the number of shared log publishers used to concurrently publish log files to CloudWatch Logs.

  If you omit this field, each log file destination (log group, stream combination) has a single shared log publisher, which can lead to bottlenecks for large files or when writing multiple files to the same destination. Enabling concurrency can help with throughput.

- `logs_collected` – Required if the `logs` section is included. Specifies which log files, Windows event logs, and journald logs the agent collects from the server. It can include the following fields: `files`, `windows_events` (Windows only), and `journald` (Linux only).
  - `files` – Specifies which regular log files the CloudWatch agent is to collect. It contains one field, `collect_list`, which further defines these files.
    - `collect_list` – Required if `files` is included. Contains an array of entries, each of which specifies one log file to collect. Each of these entries can include the following fields:
      - `file_path` – Specifies the path of the log file to upload to CloudWatch Logs. Standard Unix glob matching rules are accepted, with the addition of `**` as a *super asterisk*. For example, specifying `/var/log/**.log` causes all `.log` files in the `/var/log` directory tree to be collected. For more examples, see Glob Library.

You can also use the standard asterisk as a standard wildcard. For example, `/var/log/system.log*` matches files such as `system.log_1111`, `system.log_2222`, and so on in `/var/log`.

Only the latest file is pushed to CloudWatch Logs based on file modification time. We recommend that you use wildcards to specify a series of files of the same type, such as `access_log.2018-06-01-01` and `access_log.2018-06-01-02`, but not multiple kinds of files, such as `access_log_80` and `access_log_443`. To specify multiple kinds of files, add another log stream entry to the agent configuration file so that each kind of log file goes to a different log stream.

- `auto_removal` – Optional. If this is `true`, the CloudWatch agent automatically deletes this log file after reading it and it has been rotated. Usually the log files are deleted after their entire contents are uploaded to CloudWatch Logs. However, if the agent reaches the EOF (end of file) and also detects another newer log file that matches the same `file_path`, the agent deletes the OLD file, so you must make sure that you are done writing to the OLD file before creating the NEW file. The RUST tracing library has a known incompatibility because it will potentially create a NEW log file and then still attempt to write to the OLD log file.

  The agent only removes complete files from logs that create multiple files, such as logs that create separate files for each date. If a log continuously writes to a single file, it is not removed.

  If you already have a log file rotation or removal method in place, we recommend that you omit this field or set it to `false`.

  If you omit this field, the default value of `false` is used.

- `log_group_name` – Optional. Specifies what to use as the log group name in CloudWatch Logs.

  We recommend that you use this field to specify a log group name to prevent confusion. If you omit `log_group_name`, the value of `file_path` up to the final dot is used as the log group name. For example, if the file path is `/tmp/TestLogFile.log.2017-07-11-14`, the log group name is `/tmp/TestLogFile.log`.

  If you specify a log group name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}`

retrieves the hostname from the EC2 metadata, and {local_hostname} uses the hostname from the network configuration file.

If you use these variables to create many different log groups, keep in mind the limit of 1,000,000 log groups per Region per account.

Allowed characters include a–z, A–Z, 0–9, '_' (underscore), '-' (hyphen), '/' (forward slash), and '.' (period).

- log_group_class – Optional. Specifies which log group class to use for the new log group. For more information about log group classes, see Log classes.

  Valid values are STANDARD and INFREQUENT_ACCESS. If you omit this field, the default of STANDARD is used.

  > **Important**
  >
  > After a log group is created, its class can't be changed.

- log_stream_name – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use {instance_id}, {hostname}, {local_hostname}, and {ip_address} as variables within the name. {hostname} retrieves the hostname from the EC2 metadata, and {local_hostname} uses the hostname from the network configuration file.

  If you omit this field, the value of the log_stream_name parameter in the global logs section is used. If that is also omitted, the default value of {instance_id} is used.

  If a log stream doesn't already exist, it's created automatically.

- retention_in_days – Optional. Specifies the number of days to retain the log events in the specified log group.
  - If the agent is creating this log group now, and you omit this field, the retention of this new log group is set to never expire.
  - If this log group already exists and you specify this field, the new retention that you specify is used. If you omit this field for a log group that already exists, the log group's retention is not changed.

    The CloudWatch agent wizard uses -1 as the default value for this field when it is used to create the agent configuration file and you don't specify a value for log retention.

This `-1` value set by the wizard specifies that the events in the log group will never expire. However, manually editing this value to `-1` has no effect.

Valid values are 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400, 545, 731, 1827, 2192, 2557, 2922, 3288, and 3653.

If you configure the agent to write multiple log streams to the same log group, specifying the `retention_in_days` in one place will set the log retention for the entire log group. If you specify `retention_in_days` for the same log group in multiple places, the retention is set if all of those values are equal. However, if different `retention_in_days` values are specified for the same log group in multiple places, the log retention will not be set and the agent will stop, returning an error.

> **Note**
>
> The agent's IAM role or IAM user must have the `logs:PutRetentionPolicy` for it to be able to set retention policies.

> **Warning**
>
> If you set `retention_in_days` for a log group that already exists, all logs in that log group that were published before the number of days that you specify are deleted. For example, setting it to 3 would cause all logs from 3 days ago and before to be deleted.

- `filters` – Optional. Can contain an array of entries, each of which specifies a regular expression and a filter type to specify whether to publish or drop log entries that match the filter. If you omit this field, all logs in the log file are published to CloudWatch Logs. If you include this field, the agent processes each log message with all of the filters that you specify, and only the log events that pass all of the filters are published to CloudWatch Logs. The log entries that don't pass all of the filters will still remain in the host's log file, but will not be sent to CloudWatch Logs.

  Each entry in the filters array can include the following fields:

  - `type`– Denotes the type of filter. Valid values are `include` and `exclude`. With `include`, the log entry must match the expression to be published to CloudWatch Logs. With `exclude`, each log entry that matches the filter is not sent to CloudWatch Logs.

- `expression`– A regular expression string that follows the RE2 Syntax.

> **Note**
>
> The CloudWatch agent doesn't check the performance of any regular expression that you supply, or restrict the run time of the evaluation of the regular expressions. We recommend that you are careful not to write an expression that is expensive to evaluate. For more information about possible issues, see Regular expression Denial of Service - ReDoS

For example, the following excerpt of the CloudWatch agent configuration file publishes logs that are PUT and POST requests to CloudWatch Logs, but excluding logs that come from Firefox.

```
"collect_list": [
  {
    "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/test.log",
    "log_group_name": "test.log",
    "log_stream_name": "test.log",
    "filters": [
      {
        "type": "exclude",
        "expression": "Firefox"
      },
      {
        "type": "include",
        "expression": "P(UT|OST)"
      }
    ]
  },
  .....
]
```

> **Note**
>
> The order of the filters in the configuration file matters for performance. In the preceding example, the agent drops all the logs that match `Firefox` before it starts evaluating the second filter. To cause fewer log entries to be evaluated by

more than one filter, put the filter that you expect to rule out more logs first in the configuration file.

- `timezone` – Optional. Specifies the time zone to use when putting timestamps on log events. The valid values are `UTC` and `Local`. The default value is `Local`.

  This parameter is ignored if you don't specify a value for `timestamp_format`.

- `timestamp_format` – Optional. Specifies the timestamp format, using plaintext and special symbols that start with %. If you omit this field, the current time is used. If you use this field, you can use the symbols in the following list as part of the format.

  Note

  This parameter is not considered when the `file_path` is set to `amazon-cloudwatch-agent.log`

  If a single log entry contains two time stamps that match the format, the first time stamp is used.

  This list of symbols is different than the list used by the older CloudWatch Logs agent. For a summary of these differences, see Timestamp differences between the CloudWatch agent and the earlier CloudWatch Logs agent

  %y

  Year without century as a zero-padded decimal number. For example, 19 to represent 2019.

  %Y

  Year with century as a decimal number. For example, 2019.

  %b

  Month as the locale's abbreviated name

  %B

  Month as the locale's full name

`%m`

Month as a zero-padded decimal number

`%-m`

Month as a decimal number (not zero-padded)

`%d`

Day of the month as a zero-padded decimal number

`%-d`

Day of the month as a decimal number (not zero-padded)

`%A`

Full name of weekday, such as `Monday`

`%a`

Abbreviation of weekday, such as `Mon`

`%H`

Hour (in a 24-hour clock) as a zero-padded decimal number

`%I`

Hour (in a 12-hour clock) as a zero-padded decimal number

`%-I`

Hour (in a 12-hour clock) as a decimal number (not zero-padded)

`%p`

AM or PM

`%M`

Minutes as a zero-padded decimal number

`%-M`

Minutes as a decimal number (not zero-padded)

`%S`

Seconds as a zero-padded decimal number

`%-S`

Seconds as a decimal number (not zero padded)

`%f`

Fractional seconds as a decimal number (1-9 digits), zero-padded on the left.

`%Z`

Time zone, for example PST

`%z`

Time zone, expressed as the offset between the local time zone and UTC. For example, `-0700`. Only this format is supported. For example, `-07:00` isn't a valid format.

- `multi_line_start_pattern` – Specifies the pattern for identifying the start of a log message. A log message is made of a line that matches the pattern and any subsequent lines that don't match the pattern.

  If you omit this field, multi-line mode is disabled, and any line that begins with a non-whitespace character closes the previous log message and starts a new log message.

  If you include this field, you can specify `{timestamp_format}` to use the same regular expression as your timestamp format. Otherwise, you can specify a different regular expression for CloudWatch Logs to use to determine the start lines of multi-line entries.
- `encoding` – Specified the encoding of the log file so that it can be read correctly. If you specify an incorrect coding, there might be data loss because characters that can't be decoded are replaced with other characters.

  The default value is `utf-8`. The following are all possible values:

  ```
  ascii, big5, euc-jp, euc-kr, gbk, gb18030, ibm866, iso2022-jp,
  iso8859-2, iso8859-3, iso8859-4, iso8859-5, iso8859-6, iso8859-7,
  iso8859-8, iso8859-8-i, iso8859-10, iso8859-13, iso8859-14,
  iso8859-15, iso8859-16, koi8-r, koi8-u, macintosh, shift_jis, utf-8,
  utf-16, utf-16le, UTF-16, UTF-16LE, windows-874, windows-1250,
  ```

`windows-1251, windows-1252, windows-1253, windows-1254, windows-1255, windows-1256, windows-1257, windows-1258, x-mac-cyrillic`

- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.
- `trim_timestamp` – Optional. If this is true, the CloudWatch agent will remove the timestamp matched by `timestamp_format` from the line before sending it to CloudWatch Logs. The LogEvent will still contain the `timestamp` field.

  If you omit this field, the default value of `false` is used.

- The `windows_events` section specifies the type of Windows events to collect from servers running Windows Server. It includes the following fields:
  - `collect_list` – Required if `windows_events` is included. Specifies the types and levels of Windows events to be collected. Each log to be collected has an entry in this section, which can include the following fields:
    - `event_name` – Specifies the type of Windows events to log. This is equivalent to the Windows event log channel name: for example, `System`, `Security`, `Application`, and so on. This field is required for each type of Windows event to log.

      > **Note**
      >
      > When CloudWatch retrieves messages from a Windows log channel, it looks up the log channel based on its `Full Name` property. Meanwhile, the Windows Event Viewer navigation pane displays the `Log Name` property of log channels. The `Full Name` and `Log Name` do not always match. To confirm the `Full Name` of a channel, right-click on it in the Windows Event viewer and open **Properties**.

    - `event_levels` – Optional. Specifies the levels of event to log. You must specify each level to log. Possible values include `INFORMATION`, `WARNING`, `ERROR`, `CRITICAL`, and `VERBOSE`. This field is optional for each type of Windows event to log. and can be used with other filtering option like `event_ids` and `filters`.
    - `event_ids` – Optional. Contains an array of Windows Event IDs to specify which events to collect from the Windows Event Log. When this field is excluded, all events from the

specified event log are collected. When this field is included, the agent only collects events that match the specified Event IDs.

Each entry in the `event_ids` array should be a numeric Event ID value and can be used with other filtering options. See the third entry in the config sample below.

> **Note**
>
> Using `event_ids` for filtering is recommended over regex expressions when you need to filter by Event ID, as it provides better performance.

- `filters` – Optional. Contains an array of entries. Each entry specifies a regular expression and a filter type to specify whether to publish or drop the log entries that match the filter. When the field is included, the agent processes each log message with all of the filters that you specify, and only the log events that pass all filters are published to CloudWatch Logs. The windows event logs that doesn't pass all of the filters will be dropped and not sent to CloudWatch Logs. The filters section can also be used with other filtering mechanisms like event ids [4624, 4625] and system levels (Information, Error, or Critical) to effectively filter logs and push to CloudWatch.

  Each entry in the filters array can include the following fields:

  - `type` – Specifies the type of filter. Valid values are `include` and `exclude`. With include, the windows events entry must match the expression to be published to CloudWatch Logs. With exclude, each windows event log entry that matches the filter is not sent to CloudWatch Logs.
  - `expression` – A regular expression string that follows the RE2 Syntax.

  > **Note**
  >
  > The CloudWatch agent does not validate regular expressions that you provide. It also does not limit their evaluation time. Write your expressions carefully to avoid performance issues. For more information about security risks, see Regular expression Denial of Service - ReDoS .

  In the example agent configuration below:

For the first entry, the agent pushes logs that contain database failure messages, any authentication related activities, and all login events (both successful and failed attempts) to CloudWatch. Any log that doesn't match this pattern is dropped.

In the second entry, initial filtering is done based on event ids for windows event subscription. The agent collects all logs that contain the string user, discarding logs that don't match these patterns. The agent then drops logs containing `successful` before sending the remaining logs to CloudWatch Logs. Every filter type is applied to each windows event log before sending to CloudWatch.

```
"collect_list": [
  {
        "event_name": "Application",
        "log_group_name": "ApplicationEvents",
        "log_stream_name": "ApplicationEvents",
        "filters": [
            {
                "type": "include",
                "expression": "Database.*failed|Authentication.*|login.*"
            }
        ]
    },
    {
        "event_name": "System",
        "log_group_name": "SystemEvents",
        "log_stream_name": "Logon-events",
        "event_ids": [
            4624,
            4625
         ],
        "filters": [
            {
                "type": "include",
                "expression": ".*user.*"
            },
            {
                "type": "exclude",
                "expression": ".*successful.*"
            }
         ]
     }
```

```
  .....
]
```

> **Note**
>
> The order of the filters in the configuration will impact the performance. In the second entry, the agent drops all the logs that does not match the user before it starts evaluating the second filter expression. For optimal performance, order filters from highest to lowest exclusion rate.

While you can filter out logs on event ids and system levels in the filter expression, it is recommended to use the `event_ids` and `log_level` as shown in the second entry for improved performance.

> **Warning**
>
> Even though all filtering mechanisms (event_levels, event_ids, filters) are optional, at least one is required during agent configuration to filter logs.

- `log_group_name` – Required. Specifies what to use as the log group name in CloudWatch Logs.
- `log_stream_name` – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}` retrieves the hostname from the EC2 metadata, and `{local_hostname}` uses the hostname from the network configuration file.

  If you omit this field, the value of the `log_stream_name` parameter in the global `logs` section is used. If that is also omitted, the default value of `{instance_id}` is used.

  If a log stream doesn't already exist, it's created automatically.
- `event_format` – Optional. Specifies the format to use when storing Windows events in CloudWatch Logs. `xml` uses the XML format as in Windows Event Viewer. `text` uses the legacy CloudWatch Logs agent format.
- `retention_in_days` – Optional. Specifies the number of days to retain the Windows events in the specified log group.

- If the agent is creating this log group now, and you omit this field, the retention of this new log group is set to never expire.
- If this log group already exists and you specify this field, the new retention that you specify is used. If you omit this field for a log group that already exists, the log group's retention is not changed.

  The CloudWatch agent wizard uses `-1` as the default value for this field when it is used to create the agent configuration file and you don't specify a value for log retention. This `-1` value set by the wizard specifies that the events in the log group don't expire. However, manually editing this value to `-1` has no effect.

Valid values are 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400, 545, 731, 1827, 2192, 2557, 2922, 3288, and 3653.

If you configure the agent to write multiple log streams to the same log group, specifying the `retention_in_days` in one place will set the log retention for the entire log group. If you specify `retention_in_days` for the same log group in multiple places, the retention is set if all of those values are equal. However, if different `retention_in_days` values are specified for the same log group in multiple places, the log retention will not be set and the agent will stop, returning an error.

> **Note**
>
> The agent's IAM role or IAM user must have the `logs:PutRetentionPolicy` for it to be able to set retention policies.

> **Warning**
>
> If you set `retention_in_days` for a log group that already exists, all logs in that log group that were published before the number of days that you specify are deleted. For example, setting it to 3 would cause all logs from 3 days ago and before to be deleted.

- Use the `journald` section to specify which systemd journal logs to collect from Linux servers. Use this section only for Linux instances. It includes the following fields:

- `collect_list` – Required if `journald` is included. Specifies which journal log entries the agent collects. Each entry in this section defines a set of journal logs to collect and can include the following fields:
  - `units` – Optional. Specifies an array of systemd unit names to filter journal entries. If you include this field, the agent collects only journal entries from the specified systemd units. If you omit this field, the agent collects journal entries from all units. The agent accepts wildcards for pattern matching. For example, `["sshd*"]` matches `sshd.service`, `sshd@1.service`, and any other unit starting with `sshd`. You can specify multiple units such as `["sshd", "nginx", "cloudwatch-agent"]` to collect logs from several services.
  - `priority` – Optional. Specifies the minimum journal priority level to collect. If you include this field, the agent collects journal entries at the specified priority level and all levels more severe. If you omit this field, the default is `info`, collecting `info` and above and excluding debug. Set `"priority": "debug"` to collect all levels. Valid values are `emerg`, `alert`, `crit`, `err`, `warning`, `notice`, `info`, and debug. For example, setting `"priority": "err"` collects entries at `emerg` (0), `alert` (1), `crit` (2), and `err` (3) levels, excluding `warning`, `notice`, `info`, and debug.

    The following table shows the journal priority levels and their numeric values.

Priority	Numeric Value	Description
`emerg`	0	System is unusable
`alert`	1	Action must be taken immediately
`crit`	2	Critical conditions
`err`	3	Error conditions
`warning`	4	Warning conditions
`notice`	5	Normal but significant conditions
`info`	6	Informational messages
`debug`	7	Debug-level messages

- `matches` – Optional. Specifies an array of journal field match objects to filter journal entries by metadata fields. Each object in the array represents a set of conditions. Fields within a single object are AND'd together, while separate objects in the array are OR'd against each other. If you include this field, the agent collects journal entries that match any one of the specified objects. If you omit this field, the agent applies no field-level filtering.

  For example, specifying `[{"_UID": "0"}]` collects only journal entries from the root user. Specifying `[{"_SYSTEMD_UNIT": "sshd.service"}, {"_SYSTEMD_UNIT": "kubelet.service", "_UID": "1000"}]` collects entries from the SSH daemon OR entries from kubelet that are also from UID 1000. You can combine `matches` with `units` and `priority` for compound filtering.

  > **Note**
  >
  > Journal field names are case-sensitive and typically use uppercase with an underscore prefix for trusted fields set by the journal (for example, `_UID`, `_PID`, `_SYSTEMD_UNIT`). User-defined fields do not have the underscore prefix.

- `filters` – Optional. Contains an array of entries. Each entry specifies a regular expression and a filter type to specify whether to publish or drop the log entries that match the filter. If you include this field, the agent processes each log message with all filters you specify, and only the log events that pass all filters are published to CloudWatch Logs. The journald logs that don't pass all of the filters are dropped and not sent to CloudWatch Logs. The filters section can also be used with other filtering mechanisms like `units` and `priority` to effectively filter logs and push to CloudWatch.

  Each entry in the filters array can include the following fields:

  - `type` – Specifies the type of filter. Valid values are `include` and `exclude`. With `include`, the journald entry must match the expression to be published to CloudWatch Logs. With `exclude`, each journald log entry that matches the filter is not sent to CloudWatch Logs.
  - `expression` – A regular expression string that follows the RE2 Syntax.

> **Note**
>
> The CloudWatch agent does not validate regular expressions that you provide. It also does not limit their evaluation time. Write your expressions carefully to avoid performance issues. For more information about security risks, see Regular expression Denial of Service - ReDoS.

> **Note**
>
> The order of the filters in the configuration will impact the performance. For optimal performance, order filters from highest to lowest exclusion rate.

- `retention_in_days` – Optional. Specifies the number of days to retain the log events in the specified log group. If the agent is creating this log group now, and you omit this field, the retention of this new log group is set to never expire. If this log group already exists and you specify this field, the new retention that you specify is used. If you omit this field for a log group that already exists, the log group's retention is not changed.

  Valid values are 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400, 545, 731, 1827, 2192, 2557, 2922, 3288, and 3653.

  > **Note**
  >
  > The agent's IAM role or IAM user must have the `logs:PutRetentionPolicy` for it to be able to set retention policies.

  > **Warning**
  >
  > If you set `retention_in_days` for a log group that already exists, all logs in that log group that were published before the number of days that you specify are deleted. For example, setting it to 3 would cause all logs from 3 days ago and before to be deleted.

- `log_group_name` – Required. Specifies what to use as the log group name in CloudWatch Logs. You can use `{instance_id}`, `{hostname}`, `{local_hostname}`,

and {ip_address} as variables within the name. {hostname} retrieves the hostname from the EC2 metadata, and {local_hostname} uses the hostname from the network configuration file.

- log_stream_name – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use {instance_id}, {hostname}, {local_hostname}, and {ip_address} as variables within the name. If you omit this field, the value of the log_stream_name parameter in the global logs section is used. If that is also omitted, the default value of {instance_id} is used.

> **Note**
>
> SELinux support requires the amazon-cloudwatch-agent-selinux policy version 1.1.0 or newer.

> **Note**
>
> Running the agent as any user other than root requires the user to be added to the systemd-journal group to read the journal. On restart, the agent resumes from the last collected journal entry and does not collect historical data.

In the following example agent configuration:

- For the first entry, the agent collects all journal logs without any filtering and sends them to the journald-all-logs log group.
- In the second entry, the agent collects only logs from the sshd systemd unit.
- In the third entry, the agent collects journal entries at err priority and above.
- In the fourth entry, the agent uses compound filtering to collect logs from the systemd-logind unit that are also from the root user (_UID of 0).
- For the last entry, the agent collects journald logs from the sshd service and applies layered regex filtering.

```
"journald": {
    "collect_list": [
        {
            "log_group_name": "journald-all-logs",
```

```
            "log_stream_name": "{instance_id}",
            "retention_in_days": 7
        },
        {
            "log_group_name": "journald-sshd",
            "log_stream_name": "{instance_id}",
            "units": ["sshd"],
            "retention_in_days": 7
        },
        {
            "log_group_name": "journald-errors",
            "log_stream_name": "{instance_id}",
            "priority": "err",
            "retention_in_days": 7
        },
        {
            "log_group_name": "journald-root-logind",
            "log_stream_name": "{instance_id}",
            "units": ["systemd-logind"],
            "matches": [{"_UID": "0"}],
            "retention_in_days": 7
        },
        {
            "log_group_name": "journald-filters",
            "log_stream_name": "{instance_id}",
            "units": ["sshd"],
            "filters": [
                {
                    "type": "include",
                    "expression": ".*user.*"
                },
                {
                    "type": "exclude",
                    "expression": ".*successful.*"
                }
            ],
            "retention_in_days": 7
        }
    ]
}
```

> **Note**
>
> When you combine `units`, `priority`, and `matches` filters in a single entry, all filters are applied together. A journal entry must satisfy all specified filters to be collected and sent to CloudWatch Logs.

- `log_stream_name` – Optional. Specifies the default log stream name to be used for any logs or Windows events that don't have individual log stream names defined in the `log_stream_name` parameter within their entry in `collect_list`.
- `endpoint_override` – Specifies a FIPS endpoint or private link to use as the endpoint where the agent sends logs. Specifying this field and setting a private link enables you to send the logs to an Amazon VPC endpoint. For more information, see What Is Amazon VPC?.

  The value of `endpoint_override` must be a string that is a URL.

  For example, the following part of the logs section of the configuration file sets the agent to use a VPC Endpoint when sending logs.

```
{
  "logs": {
    "endpoint_override": "vpce-XXXXXXXXXXXXXXXXXXXXXXXX.logs.us-
east-1.vpce.amazonaws.com",
   ......
   },
}
```

- `force_flush_interval` – Specifies in seconds the maximum amount of time that logs remain in the memory buffer before being sent to the server. No matter the setting for this field, if the size of the logs in the buffer reaches 1 MB, the logs are immediately sent to the server. The default value is 5.

  If you are using the agent to report high-resolution metrics in embedded metric format, and you are setting alarms on those metrics, keep this parameter set to the default value of 5. Otherwise, the metrics are reported with a delay that can cause alarming on partial or incomplete data.
- `credentials` – Specifies an IAM role to use when sending logs to a different AWS account. If specified, this field contains one parameter, `role_arn`.
  - `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending logs to a different AWS account. For more information, see Sending metrics, logs, and traces to a

different account. If specified here, this overrides the `role_arn` specified in the `agent` section of the configuration file, if any.

- `metrics_collected` – This field can contain sections to specify that the agent is to collect logs to enable use cases such as CloudWatch Application Signals and Container Insights with enhanced observability for Amazon EKS.
  - `application_signals` (Optional) Specifies that you want to enable CloudWatch Application Signals For more information about this configuration, see Enable CloudWatch Application Signals.
  - `kubernetes` – This field can contain an `enhanced_container_insights` parameter, which you can use to enable Container Insights with enhanced observability for Amazon EKS.
    - `enhanced_container_insights` – Set this to `true` to enable Container Insights with enhanced observability for Amazon EKS. For more information, see Amazon EKS.
    - `accelerated_compute_metrics` – Set this to `false` to opt out of collecting Nvidia GPU metrics on Amazon EKS clusters. For more information, see NVIDIA GPU metrics.
  - `emf` – To collect metrics embedded in logs, it is no longer necessary to add this `emf` field. This is a legacy field that specified that the agent is to collect logs that are in embedded metric format. You can generate metric data from these logs. For more information, see Embedding metrics within logs.
  - `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.

The following is an example of a `logs` section.

```
"logs":{
    "logs_collected": {
    "files": {
            "collect_list": [
                   {
                        "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\Logs\\amazon-cloudwatch-agent.log",
                       "log_group_name": "amazon-cloudwatch-agent.log",
                       "log_stream_name": "my_log_stream_name_1"
                   },
                   {
                       "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\Logs\\test.log",
```

```
                    "log_group_name": "test.log",
                    "log_stream_name": "my_log_stream_name_2"
                }
            ]
        },
    "windows_events": {
             "collect_list": [
                            {

```
        "enhanced_container_insights": true
      }
    }
  }
```

CloudWatch agent configuration file: Traces section

By adding a `traces` section to the CloudWatch agent configuration file, you can enable CloudWatch Application Signals or collect traces from X-Ray and from the OpenTelemetry instrumentation SDK and send them to X-Ray.

> **Important**
>
> The agent's IAM role or IAM user must have the **AWSXrayWriteOnlyAccess** policy to send trace data to X-Ray.

For a quick start for collecting traces, you can add just the following to the CloudWatch agent configuration file.

```
"traces_collected": {
        "xray": {
        },
        "otlp": {
        }
      }
```

If you add the previous section to the CloudWatch agent configuration file and restart the agent, this causes the agent to start collecting traces using the following default options and values. For more information about these parameters, see the parameter definitions later in this section.

```
"traces_collected": {
        "xray": {
            "bind_address": "127.0.0.1:2000",
            "tcp_proxy": {
              "bind_address": "127.0.0.1:2000"
            }
        },
        "otlp": {
            "grpc_endpoint": "127.0.0.1:4317",
            "http_endpoint": "127.0.0.1:4318"
```

```
        }
      }
```

The `traces` section can include the following fields:

- `traces_collected` – Required if the `traces` section is included. Specifies which SDKs to collect traces from. It can include the following fields:
  - `application_signals` – Optional. Specifies that you want to enable CloudWatch Application Signals For more information about this configuration, see Enable CloudWatch Application Signals.
  - `xray` – Optional. Specifies that you want to collect traces from the X-Ray SDK. This section can include the following fields:
    - `bind_address` – Optional. Specifies the UDP address for the CloudWatch agent to use to listen for X-Ray traces. The format is `ip:port`. This address must match the address set in the X-Ray SDK.

      If you omit this field, the default of `127.0.0.1:2000` is used.
    - `tcp_proxy` – Optional. Configures the address for a proxy used to support X-Ray remote sampling. For more information, see Configuring sampling rules in the X-Ray documentation.

      This section can contain the following field.
      - `bind_address` – Optional. Specifies the TCP address to which the CloudWatch agent should set up the proxy. The format is `ip:port`. This address must match the address set in the X-Ray SDK.

        If you omit this field, the default of `127.0.0.1:2000` is used.
  - `otlp` – Optional. Specifies that you want to collect traces from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry). For more information about the AWS Distro for OpenTelemetry, see AWS Distro for OpenTelemetry. For more information about the AWS Distro for OpenTelemetry SDKs, see Introduction.

    This section can include the following fields:
    - `grpc_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry traces sent using gRPC Remote Procedure Calls. The format is `ip:port`. This address must match the address set for the gRPC exporter in the OpenTelemetry SDK.

If you omit this field, the default of `127.0.0.1:4317` is used.

- `http_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OTLP traces sent over HTTP. The format is `ip:port`. This address must match the address set for the HTTP exporter in the OpenTelemetry SDK.

  If you omit this field, the default of `127.0.0.1:4318` is used.

- `concurrency` – Optional. Specifies the maximum number of concurrent calls to X-Ray that can be used to upload traces. The default value is 8
- `local_mode` – Optional. If `true`, the agent doesn't collect Amazon EC2 instance metadata. The default is `false`
- `endpoint_override` – Optional. Specifies a FIPS endpoint or private link to use as the endpoint where the CloudWatch agent sends traces. Specifying this field and setting a private link enables you to send the traces to an Amazon VPC endpoint. For more information, see What is Amazon VPC

  The value of `endpoint_override` must be a string that is a URL.
- `region_override` – Optional. Specifies the Region to use for the X-Ray endpoint. The CloudWatch agent sends the traces to X-Ray in the specified Region. If you omit this field, the agent sends the traces to the Region where the Amazon EC2 instance is located.

  If you specify a Region here, it takes precedence over the setting of the `region` parameter in the `agent` section of the configuration file.
- `proxy_override` – Optional. Specifies the proxy server address for the CloudWatch agent to use when sending requests to X-Ray. The proxy server's protocol must be specified as part of this address.
- `credentials` – Specifies an IAM role to use when sending traces to a different AWS account. If specified, this field contains one parameter, `role_arn`.
  - `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending traces to a different AWS account. For more information, see Sending metrics, logs, and traces to a different account. If specified here, this overrides the `role_arn` specified in the `agent` section of the configuration file, if any.
- `transit_spans_in_otlp_format` – Optional. If `true`, sends traces to X-Ray in the OpenTelemetry Protocol format, which supports span events in Transaction Search. For more information, see Adding custom attributes. The default is `false`.

CloudWatch agent configuration file: OpenTelemetry section

The `opentelemetry` section depends on the agent's OTLP receiver, which was introduced in CloudWatch agent version 1.300070.0. Earlier versions do not support it. To check the installed version, read `/opt/aws/amazon-cloudwatch-agent/bin/CWAGENT_VERSION`.

> **Note**
>
> On Amazon Linux 2023, the `yum install amazon-cloudwatch-agent` and `dnf install amazon-cloudwatch-agent` commands install a version that meets this minimum. If your package repository offers a version earlier than 1.300070.0, install the agent from the CloudWatch agent download instead. For more information, see Collect metrics, logs, and traces using the CloudWatch agent.

The `opentelemetry` section can include the following fields:

- `cluster_name` – Optional. Specifies the name of the Kubernetes cluster. The agent applies this value to all telemetry collected under the `opentelemetry` section.
- `resource_attributes` – Optional. Specifies additional resource attributes to add to every metric, log, and trace collected under the `opentelemetry` section. This field is an object of string key-value pairs. You can specify up to 30 attributes. The maximum length of each value is 1024 characters. For attributes that the agent detects automatically, such as `cloud.region`, `host.id`, and `cloud.provider`, the detected value takes precedence. Use this field for attributes that the agent does not detect on its own.
- `collect` – Required. Specifies which telemetry sources the agent collects. You must include at least one of the following fields:
  - `otlp` – Optional. Specifies that the agent receives metrics, traces, and logs sent to it over the OpenTelemetry Protocol (OTLP). This section can include the following fields:
    - `grpc_endpoint` – Optional. Specifies the address the agent uses to listen for OTLP data sent using gRPC. The format is `ip:port`. This address must match the address set for the gRPC exporter in the OpenTelemetry SDK. If you omit this field, the agent uses the default `127.0.0.1:4317`. In a containerized deployment, set this to `0.0.0.0:4317` so the agent accepts traffic from other pods.
    - `http_endpoint` – Optional. Specifies the address the agent uses to listen for OTLP data sent over HTTP. The format is `ip:port`. This address must match the address set for the HTTP exporter in the OpenTelemetry SDK. If you omit this field, the agent uses the default

`127.0.0.1:4318`. In a containerized deployment, set this to `0.0.0.0:4318` so the agent accepts traffic from other pods.

- `span_metrics_enabled` – Optional. If `true`, the agent derives request, error, and duration metrics from received traces. The default value is `false`.

- `files` – Optional. Specifies that the agent collects log files from the host. It contains one field, `collect_list`.
  - `collect_list` – Required if `files` is included. Contains an array of entries, each of which specifies one set of log files to collect. The array must contain at least one entry. Each entry can include the following fields:
    - `file_path` – Required. Specifies the path or glob pattern of the log files to collect. The maximum length is 4096 characters.
    - `log_group_name` – Optional. Specifies the log group name to use in CloudWatch Logs. The maximum length is 512 characters. You can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. If you omit this field, the agent uses `/aws/cwagent/files`. On Kubernetes, the agent includes the cluster name, as in `/aws/cwagent/{cluster_name}/files`.
    - `log_stream_name` – Optional. Specifies the log stream name to use in CloudWatch Logs. The maximum length is 512 characters. This field supports the same variables as `log_group_name`. If you omit this field, the agent uses the host identifier and the log file name, separated by a slash (for example, `i-0123456789abcdef0/app.log`).
    - `multi_line_start_pattern` – Optional. Specifies a regular expression that marks the start of a new log entry. The agent appends lines that don't match the pattern to the previous entry. Specify the value `{timestamp_format}` to derive the pattern from `timestamp_format`.
    - `timestamp_format` – Optional. Specifies the format used to parse timestamps from log lines. For example, `%Y-%m-%d %H:%M:%S`.
    - `timezone` – Optional. Specifies the time zone to use when parsing timestamps. Valid values are UTC and `Local`. The default value is `Local`.
    - `encoding` – Optional. Specifies the encoding of the log files. If you omit this field, the agent uses the default `utf-8`.

- `windows_events` – Optional. Specifies that the agent collects events from the Windows Event Log. This source is available only on servers running Windows Server. It contains one field, `collect_list`.

- `collect_list` – Required if `windows_events` is included. Contains an array of entries, each of which specifies one Windows Event Log channel to collect. The array must contain at least one entry. Each entry can include the following fields:
  - `event_name` – Required. Specifies the Windows Event Log channel to collect from, such as `System` or `Application`. The maximum length is 255 characters.
  - `event_levels` – Optional. Specifies the event severity levels to collect. Valid values are `CRITICAL`, `ERROR`, `WARNING`, `INFORMATION`, and `VERBOSE`. If you omit this field, the agent collects events of all levels.
  - `event_ids` – Optional. Specifies a list of specific event IDs to collect. Each ID must be between 0 and 65535.
  - `event_format` – Optional. Specifies the output format. Valid values are `xml`, which sends the raw XML of the event, and `text`, which sends a structured representation. If you omit this field, the agent uses `text`.
  - `log_group_name` – Optional. Specifies the log group name to use in CloudWatch Logs. The maximum length is 512 characters. If you omit this field, the agent uses `/aws/cwagent/windows_events`.
  - `log_stream_name` – Optional. Specifies the log stream name to use in CloudWatch Logs. The maximum length is 512 characters. If you omit this field, the agent uses the host identifier and the event channel name, separated by a slash.
- `host_metrics` – Optional. Specifies that the agent collects host-level system metrics. This section can include the following field:
  - `collection_interval` – Optional. Specifies how often the agent collects the metrics, in seconds. If you omit this field, the agent uses the `metrics_collection_interval` value from the `agent` section, or 30 seconds if that is also omitted.
- `prometheus` – Optional. Specifies that the agent scrapes metrics from Prometheus targets. This section can include the following field:
  - `config_path` – Required. Specifies the path to the Prometheus scrape configuration file.

> **Note**
>
> Make sure Transaction Search is enabled before you send traces to the OTLP traces endpoint.

The following is an example of an `opentelemetry` section that collects OTLP telemetry and a log file.

```
"opentelemetry": {
  "collect": {
    "otlp": {
      "grpc_endpoint": "0.0.0.0:4317",
      "http_endpoint": "0.0.0.0:4318",
      "span_metrics_enabled": true
    },
    "files": {
      "collect_list": [
        {
          "file_path": "/var/log/app/*.log",
          "log_group_name": "/app/{instance_id}",
          "log_stream_name": "{hostname}",
          "timestamp_format": "%Y-%m-%d %H:%M:%S",
          "timezone": "UTC"
        }
      ]
    }
  }
}
```

CloudWatch agent configuration file: Complete examples

The following is an example of a complete CloudWatch agent configuration file for a Linux server.

The items listed in the `measurement` sections for the metrics you want to collect can either specify the complete metric name such or just the part of the metric name that will be appended to the type of resource. For example, specifying either `reads` or `diskio_reads` in the `measurement` section of the `diskio` section will cause the `diskio_reads` metric to be collected.

This example includes both ways of specifying metrics in the `measurement` section.

```
    {
      "agent": {
        "metrics_collection_interval": 10,
        "logfile": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log"
      },
      "metrics": {
        "namespace": "MyCustomNamespace",
        "metrics_collected": {
```

```
          "cpu": {
            "resources": [
              "*"
            ],
            "measurement": [
              {"name": "cpu_usage_idle", "rename": "CPU_USAGE_IDLE", "unit":
 "Percent"},
              {"name": "cpu_usage_nice", "unit": "Percent"},
              "cpu_usage_guest"
            ],
            "totalcpu": false,
            "metrics_collection_interval": 10,
            "append_dimensions": {
              "customized_dimension_key_1": "customized_dimension_value_1",
              "customized_dimension_key_2": "customized_dimension_value_2"
            }
          },
          "disk": {
            "resources": [
              "/",
              "/tmp"
            ],
            "measurement": [
              {"name": "free", "rename": "DISK_FREE", "unit": "Gigabytes"},
              "total",
              "used"
            ],
             "ignore_file_system_types": [
              "sysfs", "devtmpfs"
            ],
            "metrics_collection_interval": 60,
            "append_dimensions": {
              "customized_dimension_key_3": "customized_dimension_value_3",
              "customized_dimension_key_4": "customized_dimension_value_4"
            }
          },
          "diskio": {
            "resources": [
              "*"
            ],
            "measurement": [
              "reads",
              "writes",
              "read_time",

```
            "write_time",
            "io_time"
          ],
          "metrics_collection_interval": 60
        },
        "swap": {
          "measurement": [
            "swap_used",
            "swap_free",
            "swap_used_percent"
          ]
        },
        "mem": {
          "measurement": [
            "mem_used",
            "mem_cached",
            "mem_total"
          ],
          "metrics_collection_interval": 1
        },
        "net": {
          "resources": [
            "eth0"
          ],
          "measurement": [
            "bytes_sent",
            "bytes_recv",
            "drop_in",
            "drop_out"
          ]
        },
        "netstat": {
          "measurement": [
            "tcp_established",
            "tcp_syn_sent",
            "tcp_close"
          ],
          "metrics_collection_interval": 60
        },
        "processes": {
          "measurement": [
            "running",
            "sleeping",
            "dead"
```

```
            ]
          }
        },
        "append_dimensions": {
          "ImageId": "${aws:ImageId}",
          "InstanceId": "${aws:InstanceId}",
          "InstanceType": "${aws:InstanceType}",
          "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
        },
        "aggregation_dimensions" : [["ImageId"], ["InstanceId", "InstanceType"],
 ["d1"],[]],
        "force_flush_interval" : 30
      },
      "logs": {
        "logs_collected": {
          "files": {
            "collect_list": [
              {
                "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-
agent.log",
                "log_group_name": "amazon-cloudwatch-agent.log",
                "log_stream_name": "amazon-cloudwatch-agent.log",
                "timezone": "UTC"
              },
              {
                "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/test.log",
                "log_group_name": "test.log",
                "log_stream_name": "test.log",
                "timezone": "Local"
              }
            ]
          }
        },
        "log_stream_name": "my_log_stream_name",
        "force_flush_interval" : 15,
        "metrics_collected": {
           "kubernetes": {
                "enhanced_container_insights": true
      }
    }
  }
}
```

The following is an example of a complete CloudWatch agent configuration file for a server running Windows Server.

```
{
      "agent": {
        "metrics_collection_interval": 60,
        "logfile": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\Logs\\amazon-
cloudwatch-agent.log"
      },
      "metrics": {
        "namespace": "MyCustomNamespace",
        "metrics_collected": {
          "Processor": {
            "measurement": [
              {"name": "% Idle Time", "rename": "CPU_IDLE", "unit": "Percent"},
              "% Interrupt Time",
              "% User Time",
              "% Processor Time"
            ],
            "resources": [
              "*"
            ],
            "append_dimensions": {
              "customized_dimension_key_1": "customized_dimension_value_1",
              "customized_dimension_key_2": "customized_dimension_value_2"
            }
          },
          "LogicalDisk": {
            "measurement": [
              {"name": "% Idle Time", "unit": "Percent"},
              {"name": "% Disk Read Time", "rename": "DISK_READ"},
              "% Disk Write Time"
            ],
            "resources": [
              "*"
            ]
          },
          "customizedObjectName": {
            "metrics_collection_interval": 60,

```

Save the CloudWatch agent configuration file manually

If you create or edit the CloudWatch agent configuration file manually, you can give it any name. After you have created the file, you can copy it to other servers where you want to run the agent.

Update the CloudWatch agent configuration file manually

Creating or naming a configuration file does not apply it to the agent. When you apply a configuration, the agent stores it and generates the files that it uses at runtime. On a Linux server, these files are in the `/opt/aws/amazon-cloudwatch-agent/etc` directory, as shown in the following structure.

```
/opt/aws/amazon-cloudwatch-agent/etc/
    cloudwatch-agent.json         (your source configuration file; you can give it any
 name)
    amazon-cloudwatch-agent.d/    (agent-managed directory of active configuration
 fragments)
        file_name              (a fragment copied from a local file source)
        ssm_name               (a fragment copied from a Systems Manager Parameter
 Store source)
    amazon-cloudwatch-agent.toml  (generated file that the systemd or upstart service
 uses to run the agent)
```

The `amazon-cloudwatch-agent.d` directory holds the active configuration that the agent manages. Keep your source configuration file in a location that you choose, and do not use the `amazon-cloudwatch-agent.d` directory to store source files.

To apply or update the configuration, use the following commands. For the full command syntax and the behavior when configuration file names match, see Creating multiple CloudWatch agent configuration files.

- To apply a source configuration file, run `amazon-cloudwatch-agent-ctl -a fetch-config -c file:`*`configuration-file-path`*. This command applies the initial configuration or replaces the active configuration set.
- To add another configuration to a running agent without replacing the current one, use the `append-config` option. The `append-config` option preserves the existing configuration fragments, unless a configuration file name matches one that the agent is already using.

> **Note**
>
> The systemd and upstart services use the generated `amazon-cloudwatch-agent.toml` file to run the agent. If this file is absent, starting the agent can apply the default configuration. The default configuration can replace the active configuration in the `amazon-cloudwatch-agent.d` directory. Apply your configuration with `fetch-config` or `append-config` before you start the agent.

Uploading the CloudWatch agent configuration file to Systems Manager Parameter Store

If you plan to use the SSM Agent to install the CloudWatch agent on servers, after you manually edit the CloudWatch agent configuration file, you can upload it to Systems Manager Parameter Store. To do so, use the Systems Manager `put-parameter` command.

To be able to store the file in Parameter Store, you must use an IAM role with sufficient permissions.

Use the following command, where *`parameter name`* is the name to be used for this file in Parameter Store and *`configuration_file_pathname`* is the path and file name of the configuration file that you edited.

```
aws ssm put-parameter --name "parameter name" --type "String" --value
 file://configuration_file_pathname
```

Enable CloudWatch Application Signals

Use CloudWatch Application Signals to automatically instrument your applications on AWS so that you can track application performance against your business objectives. Application Signals provides you a unified, application-centric view of your Java applications, their dependencies, and their edges. For more information, see Application Signals.

CloudWatch Application Signals leverages the CloudWatch agent to receive metrics and traces from your auto-instrumented applications, optionally apply rules to reduce high cardinality, and then publish the processed telemetry to CloudWatch. You can provide custom configuration to the CloudWatch agent specifically for Application Signals using the agent configuration file. To start with, the presence of an `application_signals` section under the `metrics_collected` section within the `logs` section of the agent configuration file specifies that the CloudWatch

agent will receive metrics from your auto-instrumented applications. Similarly, the presence of an `application_signals` section under the `traces_collected` section within the `traces` section of the agent configuration file specifies that the CloudWatch agent is enabled to receive traces from your auto-instrumented applications. In addition, you can optionally pass in custom configuration rules to reduce publishing high-cardinality telemetry as outlined in this section.

- For Amazon EKS clusters, when you install the Amazon CloudWatch Observability EKS add-on, the CloudWatch agent is by default enabled to receive both metrics and traces from your auto-instrumented applications. If you would like to optionally pass in custom configuration rules, you can do so by passing in a custom agent configuration to the Amazon EKS add-on when you create or update it by using additional configuration, as outlined in (Optional) Additional configuration.
- For RedHat for OpenShift on AWS (ROSA), when you install the CloudWatch agent operator using helm charts, the CloudWatch agent is by default enabled to receive both metrics and traces from your auto-instrumented applications. If you would like to optionally pass in custom configuration rules, you can do so by passing in a custom agent configuration by using the Helm chart, as outlined in (Optional) Additional configuration.
- For other supported platforms including Amazon EC2, you must start the CloudWatch agent with an agent configuration that enables Application Signals by specifying the `application_signals` sections and optionally any custom configuration rules as outlined later in this section.

The following is an overview of the fields in the CloudWatch agent configuration file that are related to CloudWatch Application Signals.

- `logs`
  - `metrics_collected` – This field can contain sections to specify that the agent is to collect logs to enable use cases such as CloudWatch Application Signals and Container Insights with enhanced observability for Amazon EKS.

> **Note**
>
> Previously this section was also used to specify that the agent is to collect logs that are in embedded metric format. Those settings are no longer needed.

- `application_signals` (Optional) Specifies that you want to enable CloudWatch Application Signals to receive metrics from your auto-instrumented applications to facilitate CloudWatch Application Signals.
  - `rules` (Optional) An array of rules to conditionally select metrics and traces and apply actions to handle high-cardinality scenarios. Each rule can contain the following fields:
    - `rule_name` (Optional) The name of the rule.
    - `selectors` (Optional) An array of metrics and traces dimension matchers. Each selector must provide the following fields:
      - `dimension` Required if `selectors` is not empty. This specifies the dimension of metrics and traces to use as a filter.
      - `match` Required if `selectors` is not empty. A wildcard pattern used for matching values of the specified dimension.
    - `action` (Optional) The action to be applied to metrics and traces that match the specified selectors. The value of `action` must be one of the following keywords:
      - `keep` Specifies to send only the metrics and traces to CloudWatch if matched by the `selectors`.
      - `drop` Specifies to drop the metric and traces that match the `selectors`.
      - `replace` Specifies to replace the dimensions of the metrics and traces that match `selectors`. They are replaced according to the `replacements` section.
    - `replacements` Required if `action` is `replace`. An array of dimension and value pairs that will be applied to metrics and traces that match the specified `selectors` when the `action` is `replace`. Each replacement must provide the following fields:
      - `target_dimension` Required if `replacements` is not empty. Specifies the dimension that needs to be replace.
      - `value` Required if `replacements` is not empty. The value to replace the original value of `target_dimension` with.
  - `limiter` (Optional) Use this section to limit how many metrics and dimensions Application Signals sends to CloudWatch, to optimize your costs.
    - `disabled` (Optional) If `true`, the metric limiting feature is disabled. The default is `false`
    - `drop_threshold` (Optional) The maximum number of distinct metrics per service in one rotation interval that can be exported by one CloudWatch agent. The default is 500.

- `rotation_interval` (Optional) The interval at which the limiter resets the metric records for distinction counting. This is expressed as a string with a sequence of numbers and a unit suffix. Fractions are supported. The supported unit suffixes are `s`, `m`, `h`, `ms`, `us`, and `ns`. The default is `1h` for one hour.
- `log_dropped_metrics` (Optional) Specifies whether the agent should write logs to the CloudWatch agent logs when Application Signals metrics are dropped. The default is `false`.

> **Note**
>
> To activate this logging, the `debug` parameter in the `agent` section must also be set to `true`.

- `traces`
  - `traces_collected`
    - `application_signals` Optional. Specify this to enable the CloudWatch agent to receive traces from your auto-instrumented applications for facilitating CloudWatch Application Signals.

> **Note**
>
> Even though the custom `application_signals` rules are specified under the `metrics_collected` section that is contained in the `logs` section, they also implicitly apply to the `traces_collected` section as well. The same set of rules will apply to both metrics and traces.

When there are multiple rules with different actions, they apply in the following sequence: `keep`, then `drop`, then `replace`.

The following is an example of a full CloudWatch agent configuration file that applies custom rules.

```
{
  "logs": {
    "metrics_collected": {
      "application_signals": {
```

```
        "rules": [
          {
            "rule_name": "keep01",
            "selectors": [
              {
                "dimension": "Service",
                "match": "pet-clinic-frontend"
              },
              {
                "dimension": "RemoteService",
                "match": "customers-service"
              }
            ],
            "action": "keep"
          },
          {
            "rule_name": "drop01",
            "selectors": [
              {
                "dimension": "Operation",
                "match": "GET /api/customer/owners/*"
              }
            ],
            "action": "drop"
          },
          {
            "rule_name": "replace01",
            "selectors": [
              {
                "dimension": "Operation",
                "match": "PUT /api/customer/owners/*/pets/*"
              },
              {
                "dimension": "RemoteOperation",
                "match": "PUT /owners"
              }
            ],
            "replacements": [
              {
                "target_dimension": "Operation",
                "value": "PUT /api/customer/owners/{ownerId}/pets{petId}"
              }
            ],
            "action": "replace"
```

```
          }
        ]
      }
    }
  },
  "traces": {
    "traces_collected": {
      "application_signals": {}
    }
  }
}
```

For the previous example configuration file, the `rules` are processed as follows:

1. Rule `keep01` ensures that any metrics and traces with the dimension `Service` as `pet-clinic-frontend` and the dimension `RemoteService` as `customers-service` are kept.
2. For the processed metrics and traces after applying `keep01`, the `drop01` rule ensures that metrics and traces with the dimension `Operation` as `GET /api/customer/owners/*` are dropped.
3. For the processed metrics and traces after applying `drop01`, the `replace01` rule updates metrics and traces that have the dimension `Operation` as `PUT /api/customer/owners/*/pets/*` and the dimension `RemoteOperation` as `PUT /owners` such that their `Operation` dimension is now replaced to be `PUT /api/customer/owners/{ownerId}/pets{petId}`.

The following is a complete example of a CloudWatch configuration file that manages cardinality in Application Signals by changing the metric limit to 100, enabling the logging of dropped metrics, and setting the rotation interval to two hours.

```
{
    "logs": {
        "metrics_collected": {
            "application_signals": {
                "limiter": {
                    "disabled": false,
                    "drop_threshold": 100,
                    "rotation_interval": "2h",
                    "log_dropped_metrics": true
                }
            }
        },
```

```
        "traces": {
            "traces_collected": {
                "application_signals": {}
            }
        }
    }
}
```

Collect network performance metrics

EC2 instances running on Linux that use the Elastic Network Adapter (ENA) publish network performance metrics. Version 1.246396.0 and later of the CloudWatch agent enable you to import these network performance metrics into CloudWatch. When you import these network performance metrics into CloudWatch, they are charged as CloudWatch custom metrics.

For more information about the ENA driver, see Enabling enhanced networking with the Elastic Network Adapter (ENA) on Linux instances and Enabling enhanced networking with the Elastic Network Adapter (ENA) on Windows instances.

How you set up the collection of network performance metrics differs on Linux servers and Windows servers.

The following table lists these network performance metrics enabled by the ENA adapter. When the CloudWatch agent imports these metrics into CloudWatch from Linux instances, it prepends `ethtool_` at the beginning of each of these metric names.

Metric	Description
Name on Linux servers: **`bw_in_allowance_exceeded`** Name on Windows servers: **`Aggregate inbound BW allowance exceeded`**	The number of packets queued and/or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
Name on Linux servers: **bw_out_allowance_exceeded** Name on Windows servers: **Aggregate outbound BW allowance exceeded**	The number of packets queued and/or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers:**conntrack_allowance_available** Name on Windows servers: **Available connection tracking allowance**	Reports the number of tracked connections that can be established by the instance before hitting the Connections Tracked allowance of that instance type. This metric is available only on Nitro-based EC2 instances using the Linux driver for Elastic Network Adapter (ENA) starting from version 2.8.1, and on computers using the Windows driver for Elastic Network Adapter (ENA) starting from version 2.6.0. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
Name on Linux servers:**ena_srd_mode** Name on Windows servers: **ena srd mode**	Describes which ENA Express features are enabled. For more information about ENA Express, see Improve network performance with ENA Express on Linux instances Values are as follows: • 0 = ENA Express off, UDP off • 1 = ENA Express on, UDP off • 2 = ENA Express off, UDP on **Note** This happens only when ENA Express was originally enabled, and UDP was configure d to use it. The prior value is retained for UDP traffic. • 3 = ENA Express on, UDP on
Name on Linux servers:**ena_srd_e ligible_tx_pkts** Name on Windows servers: **ena srd eligible tx pkts**	The number of network packets sent within a given time period that meet AWS Scalable Reliable Datagram (SRD) requirements for eligibility, as follows: • Both sending and receiving instance types are supported. • Both sending and receiving instances must have ENA Express configured. • The sending and receiving instances must be on the same subnet. • The network path between the instances must not include middleware boxes. ENA Express doesn't currently support middleware boxes.

Metric	Description
Name on Linux servers:**ena_srd_tx_pkts** Name on Windows servers: **ena srd tx pkts**	The number of SRD packets transmitted within a given time period.
Name on Linux servers:**ena_srd_rx_pkts** Name on Windows servers: **ena srd rx pkts**	The number of SRD packets received within a given time period.
Name on Linux servers:**ena_srd_resource_utilization** Name on Windows servers: **ena srd resource utilization**	The percentage of the maximum allowed memory utilization for concurrent SRD connections that the instance has consumed.
Name on Linux servers: **linklocal_allowance_exceeded** Name on Windows servers: **Link local packet rate allowance exceeded**	The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service, but does not impact traffic to custom DNS resolvers. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
Name on Linux servers: **pps_allowance_exceeded** Name on Windows servers: **PPS allowance exceeded**	The number of packets queued and/or dropped because the bidirectional PPS exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Linux setup

On Linux servers, the *ethtool plugin* enables you to import the network performance metrics into CloudWatch.

ethtool is a standard Linux utility that can collect statistics about Ethernet devices on Linux servers. The statistics it collects depend on the network device and driver. Examples of these statistics include `tx_cnt`, `rx_bytes`, `tx_errors`, and `align_errors`. When you use the ethtool plugin with the CloudWatch agent, you can also import these statistics into CloudWatch, along with the EC2 network performance metrics listed earlier in this section.

> **Tip**
>
> To find the statistics available on our operating system and network device, use the `ethtool -S` command.

When the CloudWatch agent imports metrics into CloudWatch, it adds an `ethtool_` prefix to the names of all imported metrics. So the standard ethtool statistic `rx_bytes` is called `ethtool_rx_bytes` in CloudWatch, and the EC2 network performance metric `bw_in_allowance_exceeded` is called `ethtool_bw_in_allowance_exceeded` in CloudWatch.

On Linux servers, to import ethtool metrics, add an `ethtool` section to the `metrics_collected` section of the CloudWatch agent configuration file. The `ethtool` section can include the following subsections:

- **interface_include**— Including this section causes the agent to collect metrics from only the interfaces that have names listed in this section. If you omit this section, metrics are collected from all Ethernet interfaces that aren't listed in `interface_exclude`.

  The default ethernet interface is `eth0`.
- **interface_exclude**— If you include this section, list the Ethernet interfaces that you don't want to collect metrics from.

  The ethtool plugin always ignores loopback interfaces.
- **metrics_include**— This section lists the metrics to import into CloudWatch. It can include both standard statistics collected by ethtool and Amazon EC2 high-resolution network metrics.

The following example displays part of the CloudWatch agent configuration file. This configuration collects the standard ethtool metrics `rx_packets` and `tx_packets`, and the Amazon EC2 network performance metrics from only the `eth1` interface.

For more information about the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

```
{
"metrics": {
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "ethtool": {
        "interface_include": [
          "eth1"
        ],
        "metrics_include": [
          "bw_in_allowance_exceeded",
          "bw_out_allowance_exceeded",
          "conntrack_allowance_exceeded",
          "linklocal_allowance_exceeded",
          "pps_allowance_exceeded"
         ]
```

```
      }
   }
}
}
```

Windows setup

On Windows servers, the network performance metrics are available through Windows Performance Counters, which the CloudWatch agent already collects metrics from. So you do not need a plugin to collect these metrics from Windows servers.

The following is a sample configuration file to collect network performance metrics from Windows. For more information about editing the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

```
{
    "metrics": {
        "append_dimensions": {
            "InstanceId": "${aws:InstanceId}"
        },
        "metrics_collected": {
            "ENA Packets Shaping": {
                "measurement": [
                    "Aggregate inbound BW allowance exceeded",
                    "Aggregate outbound BW allowance exceeded",
                    "Connection tracking allowance exceeded",
                    "Link local packet rate allowance exceeded",
                    "PPS allowance exceeded"
                ],
                "metrics_collection_interval": 60,
                "resources": [
                    "*"
                ]
            }
        }
    }
}
```

Viewing network performance metrics

After importing network performance metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a

threshold that you specify. The following procedure shows how to view ethtool metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

Because all of these metrics are aggregate counters, you can use CloudWatch metric math functions such as `RATE(METRICS())` to calculate the rate for these metrics in graphs or use them to set alarms. For more information about metric math functions, see Math expressions with metrics.

To view network performance metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:
    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.
    b. To sort the table, use the column heading.
    c. To filter by resource, choose the resource ID, and then choose **Add to search**.
    d. To filter by metric, choose the metric name, and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, and then choose **Add to dashboard**.

Collect Amazon EBS NVMe driver metrics

For CloudWatch agent to collect AWS NVMe driver metrics for Amazon EBS volumes attached to an Amazon EC2 instance, add the `diskio` section inside the `metrics_collected` section of the CloudWatch agent configuration file.

Additionally, the CloudWatch agent binary requires `ioctl` permissions for NVMe driver devices to collect metrics from attached Amazon EBS volumes.

The following metrics can be collected.

Metric	Metric name in CloudWatch	Description
ebs_total_read_ops	diskio_ebs_total_read_ops	The total number of completed read operations.
ebs_total_write_ops	diskio_ebs_total_write_ops	The total number of completed write operations.
ebs_total_read_bytes	diskio_ebs_total_read_bytes	The total number of read bytes transferred.
ebs_total_write_bytes	diskio_ebs_total_write_bytes	The total number of write bytes transferred.
ebs_total_read_time	diskio_ebs_total_read_time	The total time spent, in microseconds, by all completed read operations.
ebs_total_write_time	diskio_ebs_total_write_time	The total time spent, in microseconds, by all completed write operations.
ebs_volume_performance_exceeded_iops	diskio_ebs_volume_performance_exceeded_iops	The total time, in microseconds, that IOPS demand exceeded the volume's provisioned IOPS performance.
ebs_volume_performance_exceeded_tp	diskio_ebs_volume_performance_exceeded_tp	The total time, in microseconds, that throughput demand exceeded the volume's provisioned throughput performance.
ebs_ec2_instance_performanc	diskio_ebs_ec2_instance_performance_exceeded_iops	The total time, in microseconds, that the EBS volume exceeded the attached Amazon EC2 instance's maximum IOPS performance.

Metric	Metric name in CloudWatch	Description
e_exceeded_iops		
ebs_ec2_instance_performance_exceeded_tp	diskio_ebs_ec2_instance_performance_exceeded_tp	The total time, in microseconds, that the EBS volume exceeded the attached Amazon EC2 instance's maximum throughput performance.
ebs_volume_queue_length	diskio_ebs_volume_queue_length	The number of read and write operations waiting to be completed.

Collect Amazon EC2 instance store volume NVMe driver metrics

For CloudWatch agent to collect AWS NVMe driver metrics for instance store volumes attached to an Amazon EC2 instance, add the `diskio` section inside the `metrics_collected` section of the CloudWatch agent configuration file.

Additionally, the CloudWatch agent binary requires `ioctl` permissions for NVMe driver devices to collect metrics from attached instance store volumes.

The following metrics can be collected.

Metric	Metric name in CloudWatch	Description
instance_store_total_read_ops	diskio_instance_store_total_read_ops	The total number of completed read operations.
instance_store_total_write_ops	diskio_instance_store_total_write_ops	The total number of completed write operations.

Metric	Metric name in CloudWatch	Description
instance_store_total_read_bytes	diskio_instance_store_total_read_bytes	The total number of read bytes transferred.
instance_store_total_write_bytes	diskio_instance_store_total_write_bytes	The total number of write bytes transferred.
instance_store_total_read_time	diskio_instance_store_total_read_time	The total time spent, in microseconds, by all completed read operations.
instance_store_total_write_time	diskio_instance_store_total_write_time	The total time spent, in microseconds, by all completed write operations.
instance_store_performance_exceeded_iops	diskio_instance_store_performance_exceeded_iops	The total time, in microseconds, that IOPS demand exceeded the volume's IOPS maximum performance.
instance_store_performance_exceeded_tp	diskio_instance_store_performance_exceeded_tp	The total time, in microseconds, that throughput demand exceeded the volume's maximum throughput performance.
instance_store_volume_queue_length	diskio_instance_store_volume_queue_length	The number of read and write operations waiting to be completed.

Collect NVIDIA GPU metrics

You can use the CloudWatch agent to collect NVIDIA GPU metrics from Linux servers. To set this up, add a `nvidia_gpu` section inside the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Linux section.

Additionally, the instance must have an NVIDIA driver installed. NVIDIA drivers on pre-installed on some Amazon Machine Images (AMIs). Otherwise, you can manually install the driver. For more information, see Install NVIDIA drivers on Linux instances.

The following metrics can be collected. All of these metrics are collected with no CloudWatch `Unit`, but you can specify a unit for each metric by adding a parameter to the CloudWatch agent configuration file. For more information, see Linux section.

Metric	Metric name in CloudWatch	Description
`utilization_gpu`	`nvidia_smi_utilization_gpu`	The percentage of time over the past sample period during which one or more kernels on the GPU was running.
`temperature_gpu`	`nvidia_smi_temperature_gpu`	The core GPU temperature in degrees Celsius.
`power_draw`	`nvidia_smi_power_draw`	The last measured power draw for the entire board, in watts.
`utilization_memory`	`nvidia_smi_utilization_memory`	The percentage of time over the past sample period during which global (device) memory was being read or written.
`fan_speed`	`nvidia_smi_fan_speed`	The percentage of maximum fan speed that the device's fan is currently intended to run at.
`memory_total`	`nvidia_smi_memory_total`	Reported total memory, in MB.
`memory_used`	`nvidia_smi_memory_used`	Memory used, in MB.

Metric	Metric name in CloudWatch	Description
memory_free	nvidia_smi_memory_free	Memory free, in MB.
pcie_link_gen_current	nvidia_smi_pcie_link_gen_current	The current link generation.
pcie_link_width_current	nvidia_smi_pcie_link_width_current	The current link width.
encoder_stats_session_count	nvidia_smi_encoder_stats_session_count	Current number of encoder sessions.
encoder_stats_average_fps	nvidia_smi_encoder_stats_average_fps	The moving average of the encode frames per second.
encoder_stats_average_latency	nvidia_smi_encoder_stats_average_latency	The moving average of the encode latency in microseconds.
clocks_current_graphics	nvidia_smi_clocks_current_graphics	The current frequency of the graphics (shader) clock.
clocks_current_sm	nvidia_smi_clocks_current_sm	The current frequency of the Streaming Multiprocessor (SM) clock.
clocks_current_memory	nvidia_smi_clocks_current_memory	The current frequency of the memory clock.

Metric	Metric name in CloudWatch	Description
clocks_current_video	nvidia_smi_clocks_current_video	The current frequency of the video (encoder plus decoder) clocks.

All of these metrics are collected with the following dimensions:

Dimension	Description
index	A unique identifier for the GPU on this server. Represents the NVIDIA Management Library (NVML) index of the device.
name	The type of GPU. For example, NVIDIA Tesla A100
arch	The server architecture.

Collect EFA metrics

You can use the CloudWatch agent to collect Elastic Fabric Adapter (EFA) metrics from Linux servers that have EFA devices attached. To set this up, add an `efa` section inside the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Linux section.

> **Note**
>
> All EFA metrics are reported as delta values. The agent automatically applies cumulative-to-delta conversion.

The following metrics can be collected.

Metric	Description
`efa_tx_bytes`	Bytes transmitted on the EFA device.
`efa_rx_bytes`	Bytes received on the EFA device.
`efa_tx_pkts`	Packets transmitted on the EFA device.
`efa_rx_pkts`	Packets received on the EFA device.
`efa_rx_dropped`	Received packets dropped on the EFA device.
`efa_send_bytes`	Bytes sent through EFA send operations.
`efa_send_wrs`	Send work requests completed.
`efa_recv_bytes`	Bytes received through EFA receive operations.
`efa_recv_wrs`	Receive work requests completed.
`efa_rdma_read_bytes`	Bytes transferred through RDMA read operations.
`efa_rdma_read_resp_bytes`	Bytes received in RDMA read responses.
`efa_rdma_read_wrs`	RDMA read work requests completed.
`efa_rdma_read_wr_err`	RDMA read work request errors.
`efa_rdma_write_bytes`	Bytes transferred through RDMA write operations.

Metric	Description
efa_rdma_write_recv_bytes	Bytes received through RDMA write operations.
efa_rdma_write_wrs	RDMA write work requests completed.
efa_rdma_write_wr_err	RDMA write work request errors.
efa_retrans_bytes	Bytes retransmitted.
efa_retrans_pkts	Packets retransmitted.
efa_retrans_timeout_events	Retransmission timeout events.
efa_impaired_remote_conn_events	Impaired remote connection events.
efa_unresponsive_remote_events	Unresponsive remote endpoint events.

Dimensions

Each EFA metric is emitted with the following dimensions by default:

- `device` – The EFA device name.
- `port` – The EFA port number.
- `eniId` – The ENI ID of the EFA NIC.

To append additional dimensions such as `InstanceId`, use the `append_dimensions` field in the `metrics` section of the agent configuration file.

Example configuration

The following example configuration collects a subset of EFA metrics every 60 seconds and appends the `InstanceId` dimension to each metric.

```
{
  "metrics": {
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "efa": {
        "measurement": [
          "efa_tx_bytes",
          "efa_rx_bytes",
          "efa_tx_pkts",
          "efa_rx_pkts",
          "efa_rx_dropped",
          "efa_rdma_read_bytes",
          "efa_rdma_write_bytes"
        ],
        "metrics_collection_interval": 60
      }
    }
  }
}
```

Collect Java Management Extensions (JMX) metrics

You can use the CloudWatch agent to collect Java Management Extensions (JMX) metrics from your Java applications.

The CloudWatch agent supports collecting these metrics from the following versions:

- JVM 8 and later
- Kafka 0.8.2.x and later
- Tomcat 9, 10.1, and 11 (beta)

Amazon EC2

To enable JMX in your JVM instance

For the CloudWatch agent to be able to collect JMX metrics, your application's JVM must bind to a port using the `com.sun.management.jmxremote.port` system property.

```
java -Dcom.sun.management.jmxremote.port=port-number -jar example.jar
```

For more information and other configurations, see the JMX documentation.

Amazon EKS

To enable JMX on your Java application pods

When using the CloudWatch Observability EKS add-on, add the following annotations to the workload manifest file under the `PodTemplate` section to enable JMX metrics collection:

- `instrumentation.opentelemetry.io/inject-java: "true"`
- One or more of the following:
  - For JVM metrics: `cloudwatch.aws.amazon.com/inject-jmx-jvm: "true"`
  - For Kafka broker metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka: "true"`
  - For Kafka consumer metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka-consumer: "true"`
  - For Kafka producer metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka-producer: "true"`
  - For Tomcat metrics: `cloudwatch.aws.amazon.com/inject-jmx-tomcat: "true"`

You must also configure a `jmx` section in the CloudWatch agent configuration as described below. For more information about providing a custom agent configuration with the EKS add-on, see Use a custom CloudWatch agent configuration.

Fields common to Amazon EC2 and Amazon EKS

To start collecting JMX metrics, add a `jmx` section inside the `metrics_collected` section of the CloudWatch agent configuration file. The `jmx` section must include at least one of the following target subsections.

- `jvm` – Optional. Specifies that you want to retrieve Java Virtual Machine (JVM) metrics from the instance. For more information, see Collect JVM metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of JVM metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect JVM metrics.

Within the entry for each individual metric, you can optionally specify one or both of the following:

- `rename` – Specifies a different name for this metric.
- `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `kafka` – Optional. Specifies that you want to retrieve Apache Kafka broker metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka broker metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the first table in Collect Kafka metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `kafka-consumer` – Optional. Specifies that you want to retrieve Apache Kafka consumer metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka consumer metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the second metrics table in Collect Kafka metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `kafka-producer` – Optional. Specifies that you want to retrieve Apache Kafka producer metrics from the instance. For more information, see Collect Kafka metrics.

This section can include the following fields:

- `measurement` – Specifies the array of Kafka producer metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the third metrics table in Collect Kafka metrics.

  Within the entry for each individual metric, you can optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `tomcat` – Optional. Specifies that you want to retrieve Apache Tomcat metrics from the instance. For more information, see Collect Tomcat metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Tomcat metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect Tomcat metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

The `jmx` section can also include the optional `append_dimensions` field:

- `append_dimensions` – Optional. Additional dimensions to use for only the process metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

Fields only on Amazon EC2

The following fields apply only when running the CloudWatch agent on Amazon EC2 instances.

- `endpoint` – The address for the JMX client to connect to. The format is `ip:port`. If the endpoint is not localhost, both password authentication and SSL must be enabled.
- `metrics_collection_interval` – Optional. Specifies how often to collect the processes metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.

If JMX was enabled with password authentication or SSL for remote access, you can use the following fields.

- `password_file` – Optional. Specifies a Java properties file of keys to passwords. The file must be read-only and restricted to the user running the CloudWatch agent. If password authentication is enabled, this requires the same username and password pair as the entry in the JMX password file provided in the `com.sun.management.jmxremote.password.file` property. If SSL is enabled, it requires entries for `keystore` and `truststore` and corresponds to the `javax.net.ssl.keyStorePassword` and `javax.net.ssl.trustStorePassword` respectively.
- `username` – If password authentication is enabled, specify the username that matches the username in the provided password file.
- `keystore_path` – If SSL is enabled, specify the full path to the Java keystore, which consists of a private key and a certificate to the public key. Corresponds to the `javax.net.ssl.keyStore` property.
- `keystore_type` – If SSL is enabled, specify the type of keystore being used. Corresponds to the `javax.net.ssl.keyStoreType` property.
- `truststore_path` – If SSL is enabled, specify the full path to the Java truststore, which must contain the remote JMX server's public certificate. Corresponds to the `javax.net.ssl.trustStore` property.
- `truststore_type` – If SSL is enabled, specify the type of truststore being used. Corresponds to the `javax.net.ssl.trustStoreType` property.
- `remote_profile` – Optional. Supported JMX remote profiles are TLS in combination with SASL profiles: `SASL/PLAIN`, `SASL/DIGEST-MD5`, and `SASL/CRAM-MD5`. Should be one of:`SASL/`

PLAIN, SASL/DIGEST-MD5, SASL/CRAM-MD5, TLS SASL/PLAIN, TLS SASL/DIGEST-MD5, or TLS SASL/CRAM-MD5

- realm – Optional. The realm as required by the remote profile SASL/DIGEST-MD5.
- registry_ssl_enabled – If RMI registry authentication is enabled. Set to true if the JVM was configured with com.sun.management.jmxremote.registry.ssl=true.
- insecure – Optional. Set to true to opt out of the validation required if the agent is configured for a non-localhost endpoint.

The following is an example of the jmx section of the CloudWatch agent configuration file.

```
{
  "metrics": {
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "remotehost:1314",
          "jvm": {
            "measurement": [
              "jvm.memory.heap.init",
              "jvm.memory.nonheap.used"
            ]
          },
          "kafka": {
            "measurement": [
              "kafka.request.count",
              {
                "name": "kafka.message.count",
                "rename": "KAFKA_MESSAGE_COUNT",
                "unit": "Count"
              }
            ]
          },
          "username": "cwagent",
          "keystore_path": "/path/to/keystore",
          "keystore_type": "PKCS12",
          "truststore_path": "/path/to/truststore",
          "truststore_type": "PKCS12"
        },
        {
          "endpoint": "localhost:1315",
          "kafka-producer": {
```

```
            "measurement": [
              "kafka.producer.request-rate"
            ]
          },
          "append_dimensions": {
            "service.name": "kafka/1"
          }
        }
      ]
    }
  }
}
```

Collect JVM metrics

You can use the CloudWatch agent to collect Java Virtual Machine (JVM) metrics. To set this up, add a `jvm` section inside the `jmx`section of the CloudWatch agent configuration file.

The following metrics can be collected.

Metric	Dimensions	Description
`jvm.classes.loaded`	[DEFAULT]	The total number of loaded classes. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`jvm.gc.collections.count`	[DEFAULT], `name`	The total number of garbage collections that have occurred.

Metric	Dimensions	Description
		Unit: None **Meaningful statistics:** Minimum, Maximum, Average
`jvm.gc.collections.elapsed`	[DEFAULT], `name`	The approximate accumulated garbage collection elapsed time. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
jvm.memory.heap.init	[DEFAULT]	The initial amount of memory that the JVM requests from the operating system for the heap. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.heap.max	[DEFAULT]	The maximum amount of memory that can be used for the heap. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
jvm.memory.heap.used	[DEFAULT]	The current heap memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.heap.committed	[DEFAULT]	The amount of memory that is guaranteed to be available for the heap. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
jvm.memory.nonheap.init	[DEFAULT]	The initial amount of memory that the JVM requests from the operating system for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.nonheap.max	[DEFAULT]	The maximum amount of memory that can be used for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
jvm.memory.nonheap.used	[DEFAULT]	The current non-heap memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.nonheap.committed	[DEFAULT]	The amount of memory that is guaranteed to be available for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
jvm.memory.pool.init	[DEFAULT], name	The initial amount of memory that the JVM requests from the operating system for the memory pool. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.pool.max	[DEFAULT], name	The maximum amount of memory that can be used for the memory pool. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
jvm.memory.pool.used	[DEFAULT], name	The current memory pool memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.pool.committed	[DEFAULT], name	The amount of memory that is guaranteed to be available for the memory pool. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`jvm.threads.count`	[DEFAULT]	The current number of threads. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

The JVM metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information. On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name`, `k8s.deployment.name`, `k8s.namespace.name`, `k8s.node.name`, `k8s.pod.name`, and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.

Dimension	Description
name	For jvm.gc.collections metrics, the value is the garbage collector name. For jvm.memory.pool metrics, the value is the memory pool name.

Collect Kafka metrics

You can use the CloudWatch agent to collect Apache Kafka metrics. To set this up, add one or more of the following subsections inside the jmx section of the CloudWatch agent configuration file.

- Use a kafka section to collect Kafka broker metrics.
- Use a kafka-consumer section to collect Kafka consumer metrics.
- Use a kafka-producer section to collect Kafka producer metrics.

Kafka broker metrics

The following metrics can be collected for Kafka brokers.

Metric	Dimensions	Description
kafka.message.count	[DEFAULT]	The number of messages received by the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.request.count`	[DEFAULT], `type`	The number of requests received by the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.failed`	[DEFAULT], `type`	The number of requests to the Kafka broker that resulted in a failure. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.request.time.total`	[DEFAULT], `type`	The total time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.time.50p`	[DEFAULT], `type`	The 50th percentile time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.request.time.99p	[DEFAULT], type	The 99th percentile time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
kafka.request.time.avg	[DEFAULT], type	The average time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.network.io`	[DEFAULT], `state`	The number of bytes received by or sent by the Kafka broker. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`kafka.purgatory.size`	[DEFAULT], `type`	The number of requests waiting in purgatory. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.partition.count	[DEFAULT]	The number of partitions on the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.partition.offline	[DEFAULT]	The number of partitions that are offline. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.partition.under_replicated	[DEFAULT]	The number of under-replicated partitions. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.isr.operation.count	[DEFAULT], operation	The number of in-sync replica shrink and expand operations. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.max.lag	[DEFAULT]	The maximum lag in messages between follower and leader replicas. **Unit:** None **Meaningful statistics:** Maximum

Metric	Dimensions	Description
kafka.controller.active.count	[DEFAULT]	The number of active controllers on the broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.leader.election.rate	[DEFAULT]	Leader election rate. If this increases, it indicates broker failures. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.unclean.election.rate	[DEFAULT]	Unclean leader election rate. If this increases, it indicates broker failures. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.request.queue	[DEFAULT]	The size of the request queue. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.logs.flush.time.count	[DEFAULT]	The logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.logs.flush.time.median	[DEFAULT]	The 50th percentile value of the logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
kafka.logs.flush.time.99p	[DEFAULT]	The 99th percentile value of the logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

The Kafka broker metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are

Dimension	Description
	collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information. On Amazon EKS by default, k8s related context is also published as dimension s of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`type`	The request type. Possible values are `produce`, `fetch`, `fetchconsumer` , and `fetchfollower` .
`state`	The direction of network traffic. Possible values are `in` and `out`.
`operation`	The operation type for the in-sync replica. Possible values are `shrink` and `expand`.

Kafka consumer metrics

The following metrics can be collected for Kafka consumers.

Metric	Dimensions	Description
`kafka.consumer.fetch-rate`	[DEFAULT], `client-id`	The number of fetch requests

Metric	Dimensions	Description
		for all topics per second. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.records-lag-max`	[DEFAULT], `client-id`	The number of messages that the consumer lags behind the producer. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.total.bytes-consumed-rate`	[DEFAULT], `client-id`	The average number of bytes consumed for all topics per second. **Unit:** Bytes **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.consumer.total.fetch-size-avg	[DEFAULT], client-id	The number of bytes fetched per request for all topics. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
kafka.consumer.total.records-consumed-rate	[DEFAULT], client-id	The average number of records consumed for all topics per second. **Unit:** None **Meaningful statistics:** Average
kafka.consumer.bytes-consumed-rate	[DEFAULT], client-id , topic	The average number of bytes consumed per second. **Unit:** Bytes **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.consumer.fetch-size-avg`	[DEFAULT], `client-id` , `topic`	The number of bytes fetched per request. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.records-consumed-rate`	[DEFAULT], `client-id` , `topic`	The average number of records consumed per second. **Unit:** None **Meaningful statistics:** Average

The Kafka consumer metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information.

Dimension	Description
	On Amazon EKS by default, k8s related context is also published as dimension s of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`client-id`	The ID of the client.
`topic`	The Kafka topic.

Kafka producer metrics

The following metrics can be collected for Kafka producers.

Metric	Dimensions	Description
`kafka.producer.io-wait-time-ns-avg`	[DEFAULT], `client-id`	The average length of time the I/O thread spent waiting for a socket ready for reads or writes. **Unit:** None **Meaningful statistics:** Average
`kafka.producer.out`	[DEFAULT], `client-id`	The average number of

Metric	Dimensions	Description
`going-byte-rate`		outgoing bytes sent per second to all servers. **Unit:** Bytes **Meaningful statistics:** Average
`kafka.producer.request-latency-avg`	[DEFAULT], `client-id`	The average request latency. **Unit:** Milliseconds **Meaningful statistics:** Average
`kafka.producer.request-rate`	[DEFAULT], `client-id`	The average number of requests sent per second. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.producer.response-rate	[DEFAULT], client-id	The number of responses received per second. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.producer.byte-rate	[DEFAULT], client-id , topic	The average number of bytes sent per second for a topic. **Unit:** Bytes **Meaningful statistics:** Average
kafka.producer.compression-rate	[DEFAULT], client-id , topic	The average compression rate of record batches for a topic. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.producer.record-error-rate`	[DEFAULT], `client-id` , `topic`	The average per-second number of record sends that resulted in errors for a topic. **Unit:** None **Meaningful statistics:** Average
`kafka.producer.record-retry-rate`	[DEFAULT], `client-id` , `topic`	The average per-second number of retried record sends for a topic. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.producer.record-send-rate`	[DEFAULT], `client-id` , `topic`	The average number of records sent per second for a topic. **Unit:** None **Meaningful statistics:** Average

Kafka producer metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information. On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.

Dimension	Description
client-id	The ID of the client.
topic	The Kafka topic.

Collect Tomcat metrics

You can use the CloudWatch agent to collect Apache Tomcat metrics. To set this up, add a `tomcat` section inside the `jmx` section of the CloudWatch agent configuration file.

The following metrics can be collected.

Metric	Dimensions	Description
tomcat.sessions	[DEFAULT]	The number of active sessions. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
tomcat.errors	[DEFAULT], proto_handler	The number of errors encountered. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`tomcat.processing_time`	[DEFAULT], `proto_handler`	The total processing time. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`tomcat.traffic`	[DEFAULT], `proto_handler`	The number of bytes received and sent. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`tomcat.threads`	[DEFAULT], `proto_handler`	The number of threads. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`tomcat.max_time`	[DEFAULT], `proto_handler` , `direction`	Maximum time to process a request. **Unit:** Milliseconds **Meaningful statistics:** Maximum
`tomcat.request_count`	[DEFAULT], `proto_handler`	The total requests. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Tomcat metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information.

Dimension	Description
	On Amazon EKS by default, k8s related context is also published as dimension s of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`proto_handler`	The `proto_handler` is an identifier for a connector, which is provided in the `<protocol>-<type>-<port>` format (for example, `http-nio-8080`).
`direction`	The traffic direction. Possible values are `received` and `sent`.

Collect metrics and traces with OpenTelemetry

You can collect metrics and traces from your applications or services using the CloudWatch agent with the OpenTelemetry Protocol (OTLP), which is a popular open source solution. You can use any OpenTelemetry SDK to send metrics and traces to the CloudWatch agent. For more information about the available OpenTelemetry SDKs, see OpenTelemetry Supported Language APIs & SDKs..

To collect OpenTelemetry metrics and traces, add an `otlp` section to the CloudWatch agent configuration file. The section has the following fields:

- `grpc_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry metrics or traces sent using gRPC Remote Procedure Calls. The format is `ip:port`. This address must match the address set for the gRPC exporter in the OpenTelemetry SDK. If you omit this field, the default of `127.0.0.1:4317` is used.
- `http_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry metrics or traces sent over HTTP. The format is `ip:port`. This address must match the address set for the HTTP exporter in the OpenTelemetry SDK. If you omit this field, the default of `127.0.0.1:4318` is used.

- `tls` – Optional. Specifies that the server should be configured with TLS.
  - `cert_file` – Path to the TLS certificate to use for TLS required connections.
  - `key_file` – Path to the TLS key to use for TLS required connections.

The `otlp` section can be placed in multiple sections within the CloudWatch agent configuration file depending on how and where you want to send the metrics and traces.

Important

Each `otlp` section requires a unique endpoint and port. For detailed information about splitting the metrics and traces endpoints, see OTLP Exporter Configuration in the OpenTelemetry SDK documentation.

To send metrics to CloudWatch or Amazon Managed Service for Prometheus, add the `otlp` section under `metrics_collected` within the `metrics` section. For more information about sending metrics to different destinations, see Manually create or edit the CloudWatch agent configuration file. The following example shows a configuration that sends metrics to CloudWatch:

Note

If you are running the agent in containerized environments and sending telemetry from outside the agent container's network, make sure to specify the endpoint as `0.0.0.0` instead of the default endpoint `127.0.0.1`.

```
{
  "metrics": {
    "metrics_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

To send metrics to Amazon CloudWatch Logs using the Embedded metric format (EMF), add the `otlp` section under `metrics_collected` within the `logs` section. This sends the EMF logs by default to the `/aws/cwagent` log group and a generated log stream. The metrics are extracted into the `CWAgent` namespace by default. The following example shows a configuration that sends metrics as EMF logs to CloudWatch Logs:

```
{
  "logs": {
    "metrics_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

To send traces to AWS X-Ray, add the `otlp` section under `traces_collected` within the `traces` section. The following example shows a configuration that sends traces to X-Ray:

```
{
  "traces": {
    "traces_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

Collect process metrics with the procstat plugin

The *procstat* plugin enables you to collect metrics from individual processes. The plugin is supported on Linux servers and on servers running supported version of Windows Server. This section describes how to configure the CloudWatch agent for procstat and view metrics the CloudWatch agent imports. It also lists the metrics that procstat collects.

> **Note**
>
> The `procstat` plugin is not supported for the Fargate launch type in Amazon ECS environments.

Topics

- Configure the CloudWatch agent for procstat
- Metrics collected by procstat
- Viewing process metrics imported by the CloudWatch agent

Configure the CloudWatch agent for procstat

To use the procstat plugin, add a `procstat` section in the `metrics_collected` section of the CloudWatch agent configuration file. There are three ways to specify the processes to monitor. You can use only one of these methods, but you can use that method to specify one or more processes to monitor.

- `pid_file`: Selects processes by the names of the process identification number (PID) files they create.
- `exe`: Selects the processes that have process names that match the string that you specify, using regular expression matching rules. The match is a "contains" match, meaning that if you specify `agent` as the term to match, processes with names like `cloudwatchagent` match the term. For more information, see Syntax.
- `pattern`: Selects processes by the command lines used to start the processes. All processes are selected that have command lines matching the specified string using regular expression matching rules. The entire command line is checked, including parameters and options used with the command.

  The match is a "contains" match, meaning that if you specify `-c` as the term to match, processes with parameters like `-config` match the term.

The CloudWatch agent uses only one of these methods, even if you include more than one of the above sections. If you specify more than one section, the CloudWatch agent uses the `pid_file` section if it is present. If not, it uses the `exe` section.

On Linux servers, the strings that you specify in an `exe` or `pattern` section are evaluated as regular expressions. On servers running Windows Server, these strings are evaluated as WMI queries. An example would be `pattern: "%apache%"`. For more information, see LIKE Operator.

Whichever method you use, you can include an optional `metrics_collection_interval` parameter, which specifies how often in seconds to collect those metrics. If you omit this parameter, the default value of 60 seconds is used.

In the examples in the following sections, the `procstat` section is the only section included in the `metrics_collected` section of the agent configuration file. Actual configuration files can also include other sections in `metrics_collected`. For more information, see Manually create or edit the CloudWatch agent configuration file.

Configure with pid_file

The following example `procstat` section monitors the processes that create the PID files `example1.pid` and `example2.pid`. Different metrics are collected from each process. Metrics collected from the process that creates `example2.pid` are collected every 10 seconds, and the metrics collected from the `example1.pid` process are collected every 60 seconds, the default value.

```
{
    "metrics": {
        "metrics_collected": {
            "procstat": [
                {
                    "pid_file": "/var/run/example1.pid",
                    "measurement": [
                        "cpu_usage",
                        "memory_rss"
                    ]
                },
                {
                    "pid_file": "/var/run/example2.pid",
                    "measurement": [
                        "read_bytes",
                        "read_count",
                        "write_bytes"
                    ],
                    "metrics_collection_interval": 10
                }
            ]
```

```
        }
    }
}
```

Configuring with exe

The following example `procstat` section monitors all processes with names that match the strings `agent` or `plugin`. The same metrics are collected from each process.

```
{
    "metrics": {
        "metrics_collected": {
            "procstat": [
                {
                    "exe": "agent",
                    "measurement": [
                        "cpu_time",
                        "cpu_time_system",
                        "cpu_time_user"
                    ]
                },
                {
                    "exe": "plugin",
                    "measurement": [
                        "cpu_time",
                        "cpu_time_system",
                        "cpu_time_user"
                    ]
                }
            ]
        }
    }
}
```

Configuring with pattern

The following example `procstat` section monitors all processes with command lines that match the strings `config` or `-c`. The same metrics are collected from each process.

```
{
    "metrics": {
        "metrics_collected": {
```

```
            "procstat": [
                {
                    "pattern": "config",
                    "measurement": [
                        "rlimit_memory_data_hard",
                        "rlimit_memory_data_soft",
                        "rlimit_memory_stack_hard",
                        "rlimit_memory_stack_soft"
                    ]
                },
                {
                    "pattern": "-c",
                    "measurement": [
                        "rlimit_memory_data_hard",
                        "rlimit_memory_data_soft",
                        "rlimit_memory_stack_hard",
                        "rlimit_memory_stack_soft"
                    ]
                }
            ]
        }
    }
}
```

Metrics collected by procstat

The following table lists the metrics that you can collect with the `procstat` plugin.

The CloudWatch agent adds `procstat` to the beginning of the following metric names. There is a different syntax depending on whether it was collected from a Linux server or a server running Windows Server. For example, the `cpu_time` metric appears as `procstat_cpu_time` when collected from Linux and as `procstat cpu_time` when collected from Windows Server.

Metric name	Available on	Description
`cpu_time`	Linux	The amount of time that the process uses the CPU. This metric is measured in

Metric name	Available on	Description
		hundredths of a second. Unit: Count
cpu_time_guest	Linux	The amount of time that the process is in guest mode. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_guest_nice	Linux	The amount of time that the process is running in a nice guest. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_idle	Linux	The amount of time that the process is in idle mode. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_iowait	Linux	The amount of time that the process is waiting for I/O operations to complete. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_irq	Linux	The amount of time that the process is servicing interrupts. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_nice	Linux	The amount of time that the process is in nice mode. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_soft_irq	Linux	The amount of time that the process is servicing software interrupts. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_steal	Linux	The amount of time spent running in other operating systems when running in a virtualized environment. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_stolen	Linux, Windows Server	The amount of time that the process is in *stolen time*, which is time spent in other operating systems in a virtualized environment. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_system	Linux, Windows Server, macOS	The amount of time that the process is in system mode. This metric is measured in hundredths of a second. Type: Float Unit: Count

Metric name	Available on	Description
cpu_time_user	Linux, Windows Server, macOS	The amount of time that the process is in user mode. This metric is measured in hundredths of a second. Unit: Count
cpu_usage	Linux, Windows Server, macOS	The percentage of time that the process is active in any capacity. Unit: Percent
memory_data	Linux, macOS	The amount of memory that the process uses for data. Unit: Bytes
memory_locked	Linux, macOS	The amount of memory that the process has locked. Unit: Bytes

Metric name	Available on	Description
memory_rss	Linux, Windows Server, macOS	The amount of real memory (resident set) that the process is using. Unit: Bytes
memory_stack	Linux, macOS	The amount of stack memory that the process is using. Unit: Bytes
memory_swap	Linux, macOS	The amount of swap memory that the process is using. Unit: Bytes
memory_vms	Linux, Windows Server, macOS	The amount of virtual memory that the process is using. Unit: Bytes

Metric name	Available on	Description
num_fds	Linux	The number of file descriptors that this process has open. Unit: None
num_threads	Linux, Windows, macOS	The number of threads in this process. Unit: None
pid	Linux, Windows Server, macOS	Process identifier (ID). Unit: None

Metric name	Available on	Description
`pid_count`	Linux, Windows Server. macOS	The number of process IDs associated with the process. On Linux servers and macOS computers the full name of this metric is `procstat_lookup_pid_count` and on Windows Server it is `procstat_lookup pid_count` . Unit: None
`read_bytes`	Linux, Windows Server	The number of bytes that the process has read from disks. Unit: Bytes

Metric name	Available on	Description
write_bytes	Linux, Windows Server	The number of bytes that the process has written to disks. Unit: Bytes
read_count	Linux, Windows Server	The number of disk read operations that the process has executed. Unit: None
rlimit_realtime_priority_hard	Linux	The hard limit on the real-time priority that can be set for this process. Unit: None
rlimit_realtime_priority_soft	Linux	The soft limit on the real-time priority that can be set for this process. Unit: None

Metric name	Available on	Description
rlimit_signals_pending_hard	Linux	The hard limit on maximum number of signals that can be queued by this process. Unit: None
rlimit_signals_pending_soft	Linux	The soft limit on maximum number of signals that can be queued by this process. Unit: None
rlimit_nice_priority_hard	Linux	The hard limit on the maximum nice priority that can be set by this process. Unit: None

Metric name	Available on	Description
rlimit_nice_priority_soft	Linux	The soft limit on the maximum nice priority that can be set by this process. Unit: None
rlimit_num_fds_hard	Linux	The hard limit on the maximum number of file descriptors that this process can have open. Unit: None
rlimit_num_fds_soft	Linux	The soft limit on the maximum number of file descriptors that this process can have open. Unit: None

Metric name	Available on	Description
write_count	Linux, Windows Server	The number of disk write operations that the process has executed. Unit: None
involuntary_context_switches	Linux	The number of times that the process was involuntarily context-switched. Unit: None
voluntary_context_switches	Linux	The number of times that the process was context-switched voluntarily. Unit: None
realtime_priority	Linux	The current usage of real-time priority for the process. Unit: None

Metric name	Available on	Description
nice_priority	Linux	The current usage of nice priority for the process. Unit: None
signals_pending	Linux	The number of signals pending to be handled by the process. Unit: None
rlimit_cpu_time_hard	Linux	The hard CPU time resource limit for the process. Unit: None
rlimit_cpu_time_soft	Linux	The soft CPU time resource limit for the process. Unit: None
rlimit_file_locks_hard	Linux	The hard file locks resource limit for the process. Unit: None

Metric name	Available on	Description
rlimit_file_locks_soft	Linux	The soft file locks resource limit for the process. Unit: None
rlimit_memory_data_hard	Linux	The hard resource limit on the process for memory used for data. Unit: Bytes
rlimit_memory_data_soft	Linux	The soft resource limit on the process for memory used for data. Unit: Bytes
rlimit_memory_locked_hard	Linux	The hard resource limit on the process for locked memory. Unit: Bytes

Metric name	Available on	Description
rlimit_memory_locked_soft	Linux	The soft resource limit on the process for locked memory. Unit: Bytes
rlimit_memory_rss_hard	Linux	The hard resource limit on the process for physical memory. Unit: Bytes
rlimit_memory_rss_soft	Linux	The soft resource limit on the process for physical memory. Unit: Bytes
rlimit_memory_stack_hard	Linux	The hard resource limit on the process stack. Unit: Bytes
rlimit_memory_stack_soft	Linux	The soft resource limit on the process stack. Unit: Bytes

Metric name	Available on	Description
`rlimit_memory_vms_hard`	Linux	The hard resource limit on the process for virtual memory. Unit: Bytes
`rlimit_memory_vms_soft`	Linux	The soft resource limit on the process for virtual memory. Unit: Bytes

Viewing process metrics imported by the CloudWatch agent

After importing process metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view process metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view process metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

b. To sort the table, use the column heading.

c. To filter by resource, choose the resource ID and then choose **Add to search**.

d. To filter by metric, choose the metric name and then choose **Add to search**.

6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Retrieve custom metrics with StatsD

You can retrieve additional custom metrics from your applications or services using the CloudWatch agent with the `StatsD` protocol. StatsD is a popular open-source solution that can gather metrics from a wide variety of applications. StatsD is especially useful for instrumenting your own metrics. For an example of using the CloudWatch agent and StatsD together, see How to better monitor your custom application metrics using Amazon CloudWatch Agent.

`StatsD` is supported on both Linux servers and servers running Windows Server. CloudWatch supports the following `StatsD` format:

```
MetricName:value|type|@sample_rate|#tag1:
  value,tag1...
```

- `MetricName` – A string with no colons, bars, # characters, or @ characters.
- `value` – This can be either integer or float.
- `type` – Specify `c` for counter, `g` for gauge, `ms` for timer, `h` for histogram, or `s` for set.
- `sample_rate` – (Optional) A float between 0 and 1, inclusive. Use only for counter, histogram, and timer metrics. The default value is 1 (sampling 100% of the time).
- `tags` – (Optional) A comma-separated list of tags. `StatsD` tags are similar to dimensions in CloudWatch. Use colons for key/value tags, such as `env:prod`.

You can use any `StatsD` client that follows this format to send the metrics to the CloudWatch agent. For more information about some of the available `StatsD` clients, see the StatsD client page on GitHub.

To collect these custom metrics, add a `"statsd": {}` line to the `metrics_collected` section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it's done for you. For more information, see Create the CloudWatch agent configuration file.

The `StatsD` default configuration works for most users. There are optional fields that you can add to the **statsd** section of the agent configuration file as needed:

- `service_address` – The service address to which the CloudWatch agent should listen. The format is *`ip`*`:`*`port`*. If you omit the IP address, the agent listens on all available interfaces. Only the UDP format is supported, so you don't need to specify a UDP prefix.

  The default value is `:8125`.
- `metrics_collection_interval` – How often in seconds that the `StatsD` plugin runs and collects metrics. The default value is 10 seconds. The range is 1–172,000.
- `metrics_aggregation_interval` – How often in seconds CloudWatch aggregates metrics into single data points. The default value is 60 seconds.

  For example, if `metrics_collection_interval` is 10 and `metrics_aggregation_interval` is 60, CloudWatch collects data every 10 seconds. After each minute, the six data readings from that minute are aggregated into a single data point, which is sent to CloudWatch.

  The range is 0–172,000. Setting `metrics_aggregation_interval` to 0 disables the aggregation of `StatsD` metrics.
- `allowed_pending_messages` – The number of UDP messages that are allowed to queue up. When the queue is full, the StatsD server starts dropping packets. The default value is 10000.
- `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

The following is an example of the **statsd** section of the agent configuration file, using the default port and custom collection and aggregation intervals.

```
{
   "metrics":{
      "metrics_collected":{
         "statsd":{
```

```
            "service_address":":8125",
            "metrics_collection_interval":60,
            "metrics_aggregation_interval":300
         }
      }
   }
}
```

Viewing StatsD metrics imported by the CloudWatch agent

After importing StatsD metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view StatsD metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view StatsD metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

    b. To sort the table, use the column heading.

    c. To filter by resource, choose the resource ID and then choose **Add to search**.

    d. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Retrieve custom metrics with collectd

You can retrieve additional metrics from your applications or services using the CloudWatch agent with the collectd protocol, which is supported only on Linux servers. collectd is a popular open-source solution with plugins that can gather system statistics for a wide variety of applications. By combining the system metrics that the CloudWatch agent can already collect with the additional

metrics from collectd, you can better monitor, analyze, and troubleshoot your systems and applications. For more information about collectd, see collectd - The system statistics collection daemon.

You use the collectd software to send the metrics to the CloudWatch agent. For the collectd metrics, the CloudWatch agent acts as the server while the collectd plugin acts as the client.

The collectd software is not installed automatically on every server. On a server running Amazon Linux 2, follow these steps to install collectd

```
sudo amazon-linux-extras install collectd
```

For information about installing collectd on other systems, see the Download page for collectd.

To collect these custom metrics, add a **"collectd": {}** line to the **metrics_collected** section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it is done for you. For more information, see Create the CloudWatch agent configuration file.

Optional parameters are also available. If you are using collectd and you do not use `/etc/collectd/auth_file` as your **collectd_auth_file**, you must set some of these options.

- **service_address:** The service address to which the CloudWatch agent should listen. The format is `"udp://`*`ip`*`:`*`port`*. The default is `udp://127.0.0.1:25826`.
- **name_prefix:** A prefix to attach to the beginning of the name of each collectd metric. The default is `collectd_`. The maximum length is 255 characters.
- **collectd_security_level:** Sets the security level for network communication. The default is **encrypt**.

  encrypt specifies that only encrypted data is accepted. **sign** specifies that only signed and encrypted data is accepted. **none** specifies that all data is accepted. If you specify a value for **collectd_auth_file**, encrypted data is decrypted if possible.

  For more information, see Client setup and Possible interactions in the collectd Wiki.
- **collectd_auth_file** Sets a file in which user names are mapped to passwords. These passwords are used to verify signatures and to decrypt encrypted network packets. If given, signed data is verified and encrypted packets are decrypted. Otherwise, signed data is accepted without checking the signature and encrypted data cannot be decrypted.

The default is `/etc/collectd/auth_file`.

If **collectd_security_level** is set to **none**, this is optional. If you set **collectd_security_level** to `encrypt` or **sign**, you must specify **collectd_auth_file**.

For the format of the auth file, each line is a user name followed by a colon and any number of spaces followed by the password. For example:

```
user1: user1_password

user2: user2_password
```

- **collectd_typesdb:** A list of one or more files that contain the dataset descriptions. The list must be surrounded by brackets, even if there is just one entry in the list. Each entry in the list must be surrounded by double quotes. If there are multiple entries, separate them with commas. The default on Linux servers is `["/usr/share/collectd/types.db"]`. The default on macOs computers depends on the version of collectd. For example, `["/usr/local/Cellar/collectd/5.12.0/share/collectd/types.db"]`.

  For more information, see https://www.collectd.org/documentation/manpages/types.db.html.
- **metrics_aggregation_interval:** How often in seconds CloudWatch aggregates metrics into single data points. The default is 60 seconds. The range is 0 to 172,000. Setting it to 0 disables the aggregation of collectd metrics.

The following is an example of the collectd section of the agent configuration file.

```
{
   "metrics":{
      "metrics_collected":{
         "collectd":{
            "name_prefix":"My_collectd_metrics_",
            "metrics_aggregation_interval":120
         }
      }
   }
}
```

Viewing collected metrics imported by the CloudWatch agent

After importing collectd metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view collectd metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view collectd metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

    b. To sort the table, use the column heading.

    c. To filter by resource, choose the resource ID and then choose **Add to search**.

    d. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Set up and configure Prometheus metrics collection on Amazon EC2 instances

The following sections explain how to install the CloudWatch agent with Prometheus monitoring on EC2 instances, and how to configure the agent to scrape additional targets. It also provides tutorials for setting up sample workloads to use testing with Prometheus monitoring.

Both Linux and Windows instances are supported.

For information about the operating systems supported by the CloudWatch agent, see Collect metrics, logs, and traces using the CloudWatch agent

VPC security group requirements

If you are using a VPC, the following requirements apply.

- The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.
- The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

- Step 1: Install the CloudWatch agent
- Step 2: Scrape Prometheus sources and import metrics
- Example: Set up Java/JMX sample workloads for Prometheus metric testing

Step 1: Install the CloudWatch agent

The first step is to install the CloudWatch agent on the EC2 instance. For instructions, see Installing the CloudWatch agent.

Step 2: Scrape Prometheus sources and import metrics

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. One is for the standard Prometheus configurations as documented in <scrape_config>in the Prometheus documentation. The other is for the CloudWatch agent configuration.

Prometheus scrape configuration

The CloudWatch agent supports the standard Prometheus scrape configurations as documented in <scrape_config> in the Prometheus documentation. You can edit this section to update the configurations that are already in this file, and add additional Prometheus scraping targets. A sample configuration file contains the following global configuration lines:

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
- job_name: MY_JOB
  sample_limit: 10000
  file_sd_configs:
```

```
    - files: ["C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus_sd_1.yaml",
"C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus_sd_2.yaml"]
```

The `global` section specifies parameters that are valid in all configuration contexts. They also serve as defaults for other configuration sections. It contains the following parameters:

- `scrape_interval`— Defines how frequently to scrape targets.
- `scrape_timeout`— Defines how long to wait before a scrape request times out.

The `scrape_configs` section specifies a set of targets and parameters that define how to scrape them. It contains the following parameters:

- `job_name`— The job name assigned to scraped metrics by default.
- `sample_limit`— Per-scrape limit on the number of scraped samples that will be accepted.
- `file_sd_configs`— List of file service discovery configurations. It reads a set of files containing a list of zero or more static configs. The `file_sd_configs` section contains a `files` parameter which defines patterns for files from which target groups are extracted.

The CloudWatch agent supports the following service discovery configuration types.

`static_config` Allows specifying a list of targets and a common label set for them. It is the canonical way to specify static targets in a scrape configuration.

The following is a sample static config to scrape Prometheus metrics from a local host. Metrics can also be scraped from other servers if the Prometheus port is open to the server where the agent runs.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_sd_1.yaml
- targets:
    - 127.0.0.1:9404
  labels:
    key1: value1
    key2: value2
```

This example contains the following parameters:

- `targets`— The targets scraped by the static config.
- `labels`— Labels assigned to all metrics that are scraped from the targets.

`ec2_sd_config` Allows retrieving scrape targets from Amazon EC2 instances. The following is a sample `ec2_sd_config` to scrape Prometheus metrics from a list of EC2 instances. The Prometheus ports of these instances have to open to the server where the CloudWatch agent runs. The IAM role for the EC2 instance where the CloudWatch agent runs must include the `ec2:DescribeInstance` permission. For example, you could attach the managed policy **AmazonEC2ReadOnlyAccess** to the instance running the CloudWatch agent.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: MY_JOB
    sample_limit: 10000
    ec2_sd_configs:
      - region: us-east-1
        port: 9404
        filters:
          - name: instance-id
            values:
              - i-98765432109876543
              - i-12345678901234567
```

This example contains the following parameters:

- `region`— The AWS Region where the target EC2 instance is. If you leave this blank, the Region from the instance metadata is used.
- `port`— The port to scrape metrics from.
- `filters`— Optional filters to use to filter the instance list. This example filters based on EC2 instance IDs. For more criteria that you can filter on, see DescribeInstances.

CloudWatch agent configuration for Prometheus

The CloudWatch agent configuration file includes `prometheus` sections under both `logs` and `metrics_collected`. It includes the following parameters.

- **cluster_name**— specifies the cluster name to be added as a label in the log event. This field is optional.
- **log_group_name**— specifies the log group name for the scraped Prometheus metrics.

- **prometheus_config_path**— specifies the Prometheus scrape configuration file path.
- **emf_processor**— specifies the embedded metric format processor configuration. For more information about embedded metric format, see Embedding metrics within logs.

  The `emf_processor` section can contain the following parameters:

  - **metric_declaration_dedup**— It set to true, the de-duplication function for the embedded metric format metrics is enabled.
  - **metric_namespace**— Specifies the metric namespace for the emitted CloudWatch metrics.
  - **metric_unit**— Specifies the metric name:metric unit map. For information about supported metric units, see MetricDatum.
  - **metric_declaration**— are sections that specify the array of logs with embedded metric format to be generated. There are `metric_declaration` sections for each Prometheus source that the CloudWatch agent imports from by default. These sections each include the following fields:
    - `source_labels` specifies the value of the labels that are checked by the `label_matcher` line.
    - `label_matcher` is a regular expression that checks the value of the labels listed in `source_labels`. The metrics that match are enabled for inclusion in the embedded metric format sent to CloudWatch.
    - `metric_selectors` is a regular expression that specifies the metrics to be collected and sent to CloudWatch.
    - `dimensions` is the list of labels to be used as CloudWatch dimensions for each selected metric.

The following is an example CloudWatch agent configuration for Prometheus.

```
{
   "logs":{
      "metrics_collected":{
         "prometheus":{
            "cluster_name":"prometheus-cluster",
            "log_group_name":"Prometheus",
            "prometheus_config_path":"C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\prometheus.yaml",
            "emf_processor":{
               "metric_declaration_dedup":true,
               "metric_namespace":"CWAgent-Prometheus",
```

```
                "metric_unit":{
                   "jvm_threads_current": "Count",
                   "jvm_gc_collection_seconds_sum": "Milliseconds"
                },
                "metric_declaration":[
                   {
                      "source_labels":[
                         "job", "key2"
                      ],
                      "label_matcher":"MY_JOB;^value2",
                      "dimensions":[
                         [
                            "key1", "key2"
                         ],
                         [
                            "key2"
                         ]
                      ],
                      "metric_selectors":[
                         "^jvm_threads_current$",
                         "^jvm_gc_collection_seconds_sum$"
                      ]
                   }
                ]
             }
          }
       }
    }
}
```

The previous example configures an embedded metric format section to be sent as a log event if the following conditions are met:

- The value of the label `job` is `MY_JOB`
- The value of the label `key2` is `value2`
- The Prometheus metrics `jvm_threads_current` and `jvm_gc_collection_seconds_sum` contains both `job` and `key2` labels.

The log event that is sent includes the following highlighted section.

```
{
```

```
    "CloudWatchMetrics": [
        {
            "Metrics": [
                {
                    "Unit": "Count",
                    "Name": "jvm_threads_current"
                },
                {
                    "Unit": "Milliseconds",
                    "Name": "jvm_gc_collection_seconds_sum"
                }
            ],
            "Dimensions": [
                [
                    "key1",
                    "key2"
                ],
                [
                    "key2"
                ]
            ],
            "Namespace": "CWAgent-Prometheus"
        }
    ],
    "ClusterName": "prometheus-cluster",
    "InstanceId": "i-0e45bd06f196096c8",
    "Timestamp": "1607966368109",
    "Version": "0",
    "host": "EC2AMAZ-PDDOIUM",
    "instance": "127.0.0.1:9404",
    "jvm_threads_current": 2,
    "jvm_gc_collection_seconds_sum": 0.006000000000000002,
    "prom_metric_type": "gauge",
    ...
}
```

Example: Set up Java/JMX sample workloads for Prometheus metric testing

JMX Exporter is an official Prometheus exporter that can scrape and expose JMX mBeans as Prometheus metrics. For more information, see prometheus/jmx_exporter.

The CloudWatch agent can collect predefined Prometheus metrics from Java Virtual Machine (JVM), Hjava, and Tomcat (Catalina), from a JMX exporter on EC2 instances.

Step 1: Install the CloudWatch agent

The first step is to install the CloudWatch agent on the EC2 instance. For instructions, see Installing the CloudWatch agent.

Step 2: Start the Java/JMX workload

The next step is to start the Java/JMX workload.

First, download the latest JMX exporter jar file from the following location: prometheus/jmx_exporter.

Use the jar for your sample application

The example commands in the following sections use `SampleJavaApplication-1.0-SNAPSHOT.jar` as the jar file. Replace these parts of the commands with the jar for your application.

Prepare the JMX exporter configuration

The `config.yaml` file is the JMX exporter configuration file. For more information, see Configuration in the JMX exporter documentation.

Here is a sample configuration for Java and Tomcat.

```

```

Start the Java application with the Prometheus exporter

Start the sample application. This will emit Prometheus metrics to port 9404. Be sure to replace the entry point `com.gubupt.sample.app.App` with the correct information for your sample java application.

On Linux, enter the following command.

```
$ nohup java -javaagent:./jmx_prometheus_javaagent-0.14.0.jar=9404:./config.yaml -cp
  ./SampleJavaApplication-1.0-SNAPSHOT.jar com.gubupt.sample.app.App &
```

On Windows, enter the following command.

```
PS C:\> java -javaagent:.\jmx_prometheus_javaagent-0.14.0.jar=9404:.\config.yaml -cp  .
\SampleJavaApplication-1.0-SNAPSHOT.jar com.gubupt.sample.app.App
```

Verify the Prometheus metrics emission

Verify that Prometheus metrics are being emitted.

On Linux, enter the following command.

```
$ curl localhost:9404
```

On Windows, enter the following command.

```
PS C:\> curl  http://localhost:9404
```

Sample output on Linux:

```

Step 3: Configure the CloudWatch agent to scrape Prometheus metrics

Next, set up the Prometheus scrape configuration in the CloudWatch agent configuration file.

To set up the Prometheus scrape configuration for the Java/JMX example

1. Set up the configuration for `file_sd_config` and `static_config`.

   On Linux, enter the following command.

   ```
   $ cat /opt/aws/amazon-cloudwatch-agent/var/prometheus.yaml
   global:
     scrape_interval: 1m
     scrape_timeout: 10s
   scrape_configs:
     - job_name: jmx
       sample_limit: 10000
       file_sd_configs:
         - files: [ "/opt/aws/amazon-cloudwatch-agent/var/prometheus_file_sd.yaml" ]
   ```

   On Windows, enter the following command.

   ```
   PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
   global:
     scrape_interval: 1m
     scrape_timeout: 10s
   scrape_configs:
     - job_name: jmx
       sample_limit: 10000
       file_sd_configs:
         - files: [ "C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
   \prometheus_file_sd.yaml" ]
   ```

2. Set up the scrape targets configuration.

   On Linux, enter the following command.

   ```
   $ cat /opt/aws/amazon-cloudwatch-agent/var/prometheus_file_sd.yaml
   ```

```
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
    os: linux
```

On Windows, enter the following command.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_file_sd.yaml
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
    os: windows
```

3. Set up the Prometheus scrape configuration by `ec2_sc_config`. Replace *your-ec2-instance-id* with the correct EC2 instance ID.

   On Linux, enter the following command.

```
$ cat .\prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: jmx
    sample_limit: 10000
    ec2_sd_configs:
      - region: us-east-1
        port: 9404
        filters:
          - name: instance-id
            values:
              - your-ec2-instance-id
```

   On Windows, enter the following command.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_file_sd.yaml
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
```

```
    os: windows
```

4. Set up the CloudWatch agent configuration. First, navigate to the correct directory. On Linux, it is `/opt/aws/amazon-cloudwatch-agent/var/cwagent-config.json`. On Windows, it is `C:\ProgramData\Amazon\AmazonCloudWatchAgent\cwagent-config.json`.

   The following is a sample configuration with Java/JHX Prometheus metrics defined. Be sure to replace *`path-to-Prometheus-Scrape-Configuration-file`* with the correct path.

```
{
  "agent": {
    "region": "us-east-1"
  },
  "logs": {
    "metrics_collected": {
      "prometheus": {
        "cluster_name": "my-cluster",
        "log_group_name": "prometheus-test",
        "prometheus_config_path": "path-to-Prometheus-Scrape-Configuration-file",
        "emf_processor": {
          "metric_declaration_dedup": true,
          "metric_namespace": "PrometheusTest",
          "metric_unit":{
            "jvm_threads_current": "Count",
            "jvm_classes_loaded": "Count",
            "java_lang_operatingsystem_freephysicalmemorysize": "Bytes",
            "catalina_manager_activesessions": "Count",
            "jvm_gc_collection_seconds_sum": "Seconds",
            "catalina_globalrequestprocessor_bytesreceived": "Bytes",
            "jvm_memory_bytes_used": "Bytes",
            "jvm_memory_pool_bytes_used": "Bytes"
          },
          "metric_declaration": [
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["instance"]],
              "metric_selectors": [
                "^jvm_threads_current$",
                "^jvm_classes_loaded$",
                "^java_lang_operatingsystem_freephysicalmemorysize$",
                "^catalina_manager_activesessions$",
                "^jvm_gc_collection_seconds_sum$",
```

```
                "^catalina_globalrequestprocessor_bytesreceived$"
              ]
            },
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["area"]],
              "metric_selectors": [
                "^jvm_memory_bytes_used$"
              ]
            },
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["pool"]],
              "metric_selectors": [
                "^jvm_memory_pool_bytes_used$"
              ]
            }
          ]
        }
      }
    },
    "force_flush_interval": 5
  }
}
```

5. Restart the CloudWatch agent by entering one of the following commands.

   On Linux, enter the following command.

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
   config -m ec2 -s -c file:/opt/aws/amazon-cloudwatch-agent/var/cwagent-config.json
   ```

   On Windows, enter the following command.

   ```
   & "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
    -a fetch-config -m ec2 -s -c file:C:\ProgramData\Amazon\AmazonCloudWatchAgent
   \cwagent-config.json
   ```

Viewing the Prometheus metrics and logs

You can now view the Java/JMX metrics being collected.

To view the metrics for your sample Java/JMX workload

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the Region where your cluster is running, choose **Metrics** in the left navigation pane. Find the **PrometheusTest** namespace to see the metrics.
3. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group **prometheus-test**.

Configure CloudWatch agent service and environment names for related entities

The CloudWatch agent can send metrics and logs with entity data to support the Explore related pane in the CloudWatch console. The service name or environment name can be configured by the CloudWatch Agent JSON configuration.

> **Note**
>
> The agent configuration may be overridden. For details about how the agent decides what data to send for related entities, see Using the CloudWatch agent with related telemetry.

For metrics, it can be configured at the agent, metrics, or plugin level. For logs it can be configured at the agent, logs, or file level. The most specific configuration is always used. For example if the configuration exists at the agent level and metrics level, then metrics will use the metric configuration, and anything else (logs) will use the agent configuration. The following example shows different ways to configure the service name and environment name.

```
{
  "agent": {
    "service.name": "agent-level-service",
    "deployment.environment": "agent-level-environment"
  },

  "metrics": {
    "service.name": "metric-level-service",
     "deployment.environment": "metric-level-environment",
```

```
    "metrics_collected": {
      "statsd": {
        "service.name": "statsd-level-service",
        "deployment.environment": "statsd-level-environment",
      },
      "collectd": {
        "service.name": "collectdd-level-service",
        "deployment.environment": "collectd-level-environment",
      }
    }

  },

  "logs": {
    "service.name": "log-level-service",
    "deployment.environment": "log-level-environment",

    "logs_collected": {
      "files": {
        "collect_list": [
          {
            "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-
agent.log",
            "log_group_name": "amazon-cloudwatch-agent.log",
            "log_stream_name": "amazon-cloudwatch-agent.log",

            "service.name": "file-level-service",
            "deployment.environment": "file-level-environment"
          }
        ]
      }
    }

  }
}
```

Starting the CloudWatch agent

You can start the CloudWatch agent using either Systems Manager Run Command or the command line.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

Start the CloudWatch agent using the command line on Amazon EC2

Follow these steps to use the command line to start the CloudWatch agent on on Amazon EC2.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

To use the command line to start the CloudWatch agent on on Amazon EC2

1. Copy the agent configuration file that you want to use to the server where you're going to run the agent. Note the pathname where you copy it to.
2. In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

   Enter one of the following commands. Replace *`configuration-file-path`* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

   On an EC2 instance running Linux, enter the following command.

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
   config -m ec2 -s -c file:configuration-file-path
   ```

   On an on-premises server running Linux, enter the following:

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
   config -m onPremise -s -c file:configuration-file-path
   ```

   On an EC2 instance running Windows Server, enter the following from the PowerShell console:

   ```
   & "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
   a fetch-config -m ec2 -s -c file:configuration-file-path
   ```

   On an on-premises server running Windows Server, enter the following from the PowerShell console:

   ```
   & "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
   a fetch-config -m onPremise -s -c file:configuration-file-path
   ```

Start the CloudWatch agent on an on-premises server

Follow these steps to start the CloudWatch agent on an on-premises server.

To use SSM Agent to start the CloudWatch agent on an on-premises server

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, select the button next to **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, select the instance where you installed the agent.
6. In the **Action** list, choose **configure**.
7. In the **Mode** list, choose **onPremise**.
8. In the **Optional Configuration Location** box, enter the name of the agent configuration file that you created with the wizard and stored in the Parameter Store.
9. Choose **Run**.

   The agent starts with the configuration you specified in the configuration file.

To use the command line to start the CloudWatch agent on an on-premises server

- In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

  Linux: If you saved the configuration file in the Systems Manager Parameter Store, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m onPremise -s -c ssm:configuration-parameter-store-name
```

Linux: If you saved the configuration file on the local computer, enter the following command. Replace *configuration-file-path* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m onPremise -s -c file:configuration-file-path
```

Windows Server: If you saved the agent configuration file in Systems Manager Parameter Store, enter the following from the PowerShell console:

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
a fetch-config -m onPremise -s -c ssm:configuration-parameter-store-name
```

Windows Server: If you saved the agent configuration file on the local computer, enter the following from the PowerShell console. Replace *configuration-file-path* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
a fetch-config -m onPremise -s -c file:configuration-file-path
```

Metrics collected by the CloudWatch agent

You can collect metrics from servers by installing the CloudWatch agent on the server. You can install the agent on both Amazon EC2 instances and on-premises servers. You can also install the agent on computers running Linux, Windows Server, or macOS. If you install the agent on an Amazon EC2 instance, the metrics the agent collects are in addition to the metrics enabled by default on Amazon EC2 instances. For information about installing the CloudWatch agent on an instance, see Collect metrics, logs, and traces using the CloudWatch agent. You can use this section to learn about metrics the CloudWatch agent collects.

Metrics collected by the CloudWatch agent on Windows Server instances

On a server running Windows Server, installing the CloudWatch agent enables you to collect the metrics associated with the counters in Windows Performance Monitor. The CloudWatch metric names for these counters are created by putting a space between the object name and the counter

name. For example, the `% Interrupt Time` counter of the `Processor` object is given the metric name `Processor % Interrupt Time` in CloudWatch. For more information about Windows Performance Monitor counters, see the Microsoft Windows Server documentation.

The default namespace for metrics collected by the CloudWatch agent is `CWAgent`, although you can specify a different namespace when you configure the agent.

Metrics collected by the CloudWatch agent on Linux and macOS instances

The following table lists the metrics that you can collect with the CloudWatch agent on Linux servers and macOS computers.

Metric	Description
`cpu_time_active`	The amount of time that the CPU is active in any capacity. This metric is measured in hundredths of a second. Unit: None
`cpu_time_guest`	The amount of time that the CPU is running a virtual CPU for a guest operating system. This metric is measured in hundredths of a second. Unit: None
`cpu_time_guest_nice`	The amount of time that the CPU is running a virtual CPU for a guest operating system, which is low-priority and can be interrupted by other processes. This metric is measured in hundredths of a second. Unit: None
`cpu_time_idle`	The amount of time that the CPU is idle. This metric is measured in hundredths of a second. Unit: None

Metric	Description
cpu_time_iowait	The amount of time that the CPU is waiting for I/O operations to complete. This metric is measured in hundredths of a second. Unit: None
cpu_time_irq	The amount of time that the CPU is servicing interrupts. This metric is measured in hundredths of a second. Unit: None
cpu_time_nice	The amount of time that the CPU is in user mode with low-priority processes, which can easily be interrupted by higher-priority processes. This metric is measured in hundredths of a second. Unit: None
cpu_time_softirq	The amount of time that the CPU is servicing software interrupts. This metric is measured in hundredths of a second. Unit: None
cpu_time_steal	The amount of time that the CPU is in *stolen time*, which is time spent in other operating systems in a virtualized environment. This metric is measured in hundredths of a second. Unit: None
cpu_time_system	The amount of time that the CPU is in system mode. This metric is measured in hundredths of a second. Unit: None

Metric	Description
cpu_time_user	The amount of time that the CPU is in user mode. This metric is measured in hundredths of a second. Unit: None
cpu_usage_active	The percentage of time that the CPU is active in any capacity. Unit: Percent
cpu_usage_guest	The percentage of time that the CPU is running a virtual CPU for a guest operating system. Unit: Percent
cpu_usage_guest_nice	The percentage of time that the CPU is running a virtual CPU for a guest operating system, which is low-priority and can be interrupted by other processes. Unit: Percent
cpu_usage_idle	The percentage of time that the CPU is idle. Unit: Percent
cpu_usage_iowait	The percentage of time that the CPU is waiting for I/O operations to complete. Unit: Percent
cpu_usage_irq	The percentage of time that the CPU is servicing interrupts. Unit: Percent

Metric	Description
cpu_usage_nice	The percentage of time that the CPU is in user mode with low-priority processes, which higher-priority processes can easily interrupt. Unit: Percent
cpu_usage_softirq	The percentage of time that the CPU is servicing software interrupts. Unit: Percent
cpu_usage_steal	The percentage of time that the CPU is in *stolen time*, or time spent in other operating systems in a virtualized environment. Unit: Percent
cpu_usage_system	The percentage of time that the CPU is in system mode. Unit: Percent
cpu_usage_user	The percentage of time that the CPU is in user mode. Unit: Percent
disk_free	Free space on the disks. Unit: Bytes
disk_inodes_free	The number of available index nodes on the disk. Unit: Count
disk_inodes_total	The total number of index nodes reserved on the disk. Unit: Count

Metric	Description
`disk_inodes_used`	The number of used index nodes on the disk. Unit: Count
`disk_total`	Total space on the disks, including used and free. Unit: Bytes
`disk_used`	Used space on the disks. Unit: Bytes
`disk_used_percent`	The percentage of total disk space that is used. Unit: Percent
`diskio_iops_in_progress`	The number of I/O requests that have been issued to the device driver but have not yet completed. Unit: Count
`diskio_io_time`	The amount of time that the disk has had I/O requests queued. Unit: Milliseconds The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`diskio_reads`	The number of disk read operations. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.

Metric	Description
diskio_read_bytes	The number of bytes read from the disks. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.
diskio_read_time	The amount of time that read requests have waited on the disks. Multiple read requests waiting at the same time increase the number. For example, if 5 requests all wait for an average of 100 milliseconds, 500 is reported. Unit: Milliseconds The only statistic that should be used for this metric is Sum. Do not use Average.
diskio_writes	The number disk write operations. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
diskio_write_bytes	The number of bytes written to the disks. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
diskio_write_time	The amount of time that write requests have waited on the disks. Multiple write requests waiting at the same time increase the number. For example, if 8 requests all wait for an average of 1000 milliseconds, 8000 is reported. Unit: Milliseconds The only statistic that should be used for this metric is Sum. Do not use Average.
ethtool_bw_in_allowance_exceeded	The number of packets queued and/or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
ethtool_bw_out_allowance_exceeded	The number of packets queued and/or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
ethtool_conntrack_allowance_exceeded	The number of packets dropped because connection tracking exceeded the maximum for the instance and new connections could not be established. This can result in packet loss for traffic to or from the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
ethtool_linklocal_allowance_exceeded	The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
ethtool_pps_allowance_exceeded	The number of packets queued and/or dropped because the bidirectional PPS exceeded the maximum for the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics. Unit: None
mem_active	The amount of memory that has been used in some way during the last sample period. Unit: Bytes
mem_available	The amount of memory that is available and can be given instantly to processes. Unit: Bytes
mem_available_percent	The percentage of memory that is available and can be given instantly to processes. Unit: Percent
mem_buffered	The amount of memory that is being used for buffers. Unit: Bytes
mem_cached	The amount of memory that is being used for file caches. Unit: Bytes

Metric	Description
mem_free	The amount of memory that isn't being used. Unit: Bytes
mem_inactive	The amount of memory that hasn't been used in some way during the last sample period Unit: Bytes
mem_shared	The amount of memory that is being shared between processes. Unit: Bytes
mem_total	The total amount of memory. Unit: Bytes
mem_used	The amount of memory currently in use. Unit: Bytes
mem_used_percent	The percentage of memory currently in use. Unit: Percent
net_bytes_recv	The number of bytes received by the network interface. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.
net_bytes_sent	The number of bytes sent by the network interface. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
net_drop_in	The number of packets received by this network interface that were dropped. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_drop_out	The number of packets transmitted by this network interface that were dropped. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_err_in	The number of receive errors detected by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_err_out	The number of transmit errors detected by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_packets_sent	The number of packets sent by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
net_packets_recv	The number of packets received by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
netstat_tcp_close	The number of TCP connections with no state. Unit: Count
netstat_tcp_close_wait	The number of TCP connections waiting for a termination request from the client. Unit: Count
netstat_tcp_closing	The number of TCP connections that are waiting for a termination request with acknowledgment from the client. Unit: Count
netstat_tcp_established	The number of TCP connections established. Unit: Count
netstat_tcp_fin_wait1	The number of TCP connections in the FIN_WAIT1 state during the process of closing a connection. Unit: Count
netstat_tcp_fin_wait2	The number of TCP connections in the FIN_WAIT2 state during the process of closing a connection. Unit: Count

Metric	Description
netstat_tcp_last_ack	The number of TCP connections waiting for the client to send acknowledgment of the connectio n termination message. This is the last state right before the connection is closed down. Unit: Count
netstat_tcp_listen	The number of TCP ports currently listening for a connection request. Unit: Count
netstat_tcp_none	The number of TCP connections with inactive clients. Unit: Count
netstat_tcp_syn_sent	The number of TCP connections waiting for a matching connection request after having sent a connection request. Unit: Count
netstat_tcp_syn_recv	The number of TCP connections waiting for connection request acknowledgment after having sent and received a connection request. Unit: Count
netstat_tcp_time_wait	The number of TCP connections currently waiting to make sure that the client received the acknowled gment of its connection termination request. Unit: Count
netstat_udp_socket	The number of current UDP connections. Unit: Count

Metric	Description
processes_blocked	The number of processes that are blocked. Unit: Count
processes_dead	The number of processes that are dead, indicated by the X state code on Linux. This metric is not collected on macOS computers. Unit: Count
processes_idle	The number of processes that are idle (sleeping for more than 20 seconds). Available only on FreeBSD instances. Unit: Count
processes_paging	The number of processes that are paging, indicated by the W state code on Linux. This metric is not collected on macOS computers. Unit: Count
processes_running	The number of processes that are running, indicated by the R state code. Unit: Count
processes_sleeping	The number of processes that are sleeping, indicated by the S state code. Unit: Count
processes_stopped	The number of processes that are stopped, indicated by the T state code. Unit: Count

Metric	Description
processes_total	The total number of processes on the instance. Unit: Count
processes_total_threads	The total number of threads making up the processes. This metric is available only on Linux instances. This metric is not collected on macOS computers. Unit: Count
processes_wait	The number of processes that are paging, indicated by the W state code on FreeBSD instances. This metric is available only on FreeBSD instances, and is not available on Linux, Windows Server, or macOS instances. Unit: Count
processes_zombies	The number of zombie processes, indicated by the Z state code. Unit: Count
swap_free	The amount of swap space that isn't being used. Unit: Bytes
swap_used	The amount of swap space currently in use. Unit: Bytes
swap_used_percent	The percentage of swap space currently in use. Unit: Percent

Definitions of memory metrics collected by the CloudWatch agent

When the CloudWatch agent collects memory metrics, the source is the host's memory management subsystem. For example, the Linux kernel exposes OS-maintained data in `/proc`. For memory, the data is in `/proc/meminfo`.

Each different operating system and architecture has different calculations of the resources that are used by processes. For more information, see the following sections.

During each collection interval, the CloudWatch agent on each instance collects the instance resources and calculates the resources being used by all processes which are running in that instance. This information is reported back to CloudWatch metrics. You can configure the length of the collection interval in the CloudWatch agent configuration file. For more information, see CloudWatch agent configuration file: Agent section.

The following list explains how the memory metrics that the CloudWatch agent collects are defined.

- **Active Memory**– Memory that is being used by a process. In other words, the memory used by current running apps.
- **Available Memory**– The memory that can be instantly given to the processes without the system going into swap (also known as virtual memory).
- **Buffer Memory**– The data area shared by hardware devices or program processes that operate at different speeds and priorities.
- **Cached Memory**– Stores program instructions and data that are used repeatedly in the operation of programs that the CPU is likely to need next.
- **Free Memory**– Memory that is not being used at all and is readily available. It is completely free for the system to be used when needed.
- **Inactive Memory**– Pages that have not been accessed "recently".
- **Total Memory**– The size of the actual physical memory RAM.
- **Used Memory**– Memory that is currently in use by programs and processes.

Topics

- Linux: Metrics collected and calculations used
- macOS: Metrics collected and calculations used
- Windows: Metrics collected

- Example: Calculating memory metrics on Linux

Linux: Metrics collected and calculations used

Metrics collected and units:

- Active (Bytes)
- Available (Bytes)
- Available Percent (Percent)
- Buffered (Bytes)
- Cached (Bytes)
- Free (Bytes)
- Inactive (Bytes)
- Total (Bytes)
- Used (Bytes)
- Used Percent (Percent)

Used memory = Total Memory - Free Memory - Cached memory - Buffer memory

Total memory = Used Memory + Free Memory + Cached memory + Buffer memory

macOS: Metrics collected and calculations used

Metrics collected and units:

- Active (Bytes)
- Available (Bytes)
- Available Percent (Percent)
- Free (Bytes)
- Inactive (Bytes)
- Total (Bytes)
- Used (Bytes)
- Used Percent (Percent)

Available memory = Free Memory + Inactive memory

Used memory = Total Memory - Available memory

Total memory = Available Memory + Used Memory

Windows: Metrics collected

The metrics collected on Windows hosts are listed below. All of these metrics have `None` for `Unit`.

- Available bytes
- Cache Faults/sec
- Page Faults/sec
- Pages/sec

There are no calculations used for Windows metrics because the CloudWatch agent parses events from performance counters.

Example: Calculating memory metrics on Linux

As an example, suppose that entering the **`cat /proc/meminfo`** command on a Linux host shows the following results:

```
MemTotal:       3824388 kB
MemFree:         462704 kB
MemAvailable:   2157328 kB
Buffers:         126268 kB
Cached:         1560520 kB
SReclaimable:    289080 kB>
```

In this example, the CloudWatch agent will collect the following values. All the values that the CloudWatch agent collects and reports are in bytes.

- `mem_total`: 3916173312 bytes
- `mem_available`: 2209103872 bytes (MemFree + Cached)
- `mem_free`: 473808896 bytes
- `mem_cached`: 1893990400 bytes (`cached` + `SReclaimable`)
- `mem_used`: 1419075584 bytes (`MemTotal` – (`MemFree` + `Buffers` + (`Cached` + `SReclaimable`)))
- `mem_buffered`: 129667072 bytes

- `mem_available_percent`: 56.41%
- `mem_used_percent`: 36.24% (`mem_used` / `mem_total`) * 100

Using the CloudWatch agent with related telemetry

Metrics and logs that are sent to CloudWatch can include an optional entity to correlate telemetry. Entities are used in the Explore related pane. The CloudWatch agent sends entities with a service name and environment name included.

The agent chooses the service name and environment name from the following data.

Service name

The agent chooses the service name from the following options, in priority order:

- **Application Signals instrumentation** – The agent sends the service name used by Application Signals. This can be overwritten by changing the `OTEL_SERVICE_NAME` environment variable used by supported OpenTelemetry instrumentation libraries.
- **CloudWatch agent configuration** – You can configure the agent to use a specific service name. This can be configured at the agent, plugin, metrics, logs, or log file level.
- **Kubernetes workload name** – For Kubernetes workloads, the agent sends the name of the workload for the corresponding pod, in the following priority order.
  - Deployment name
  - ReplicaSet name
  - StatefulSet name
  - DaemonSet name
  - CronJob name
  - Job name
  - Pod name
  - Container name
- **Resource tags from instance metadata** – For Amazon EC2 workloads, the agent sends the a name from tags, in the following order.
  - service
  - application
  - app

You must setup instance metadata for the agent to be able to access tags.

- **Default** – If no other service name is found, the agent will send the name `Unknown`.

Environment name

The agent chooses the environment name from the following options, in priority order:

- **Application Signals instrumentation** – The agent sends the environment name used by Application Signals. This can be overwritten by setting a `deployment.environment` environment variable used by supported OpenTelemetry instrumentation libraries. For example, applications may set the environment variable `OTEL_RESOURCE_ATTRIBUTES=deployment.environment=MyEnvironment`.
- **CloudWatch agent configuration** – You can configure the agent to use a specific environment name. This can be configured at the agent, plugin, metrics, logs, or log file level.
- **Cluster name and workspace** – For Amazon EKS, `eks:`*`cluster-name`*`/`*`Namespace`*. For native Kubernetes running on Amazon EC2, `k8s:`*`cluster-name`*`/`*`Namespace`*.
- **Resource tags from instance metadata** – For Amazon EC2 workloads, the agent can will use the `AutoScalingGroup` tag.

  You must setup instance metadata for the agent to be able to access tags.
- By default, Amazon EC2 instances that aren't running Kubernetes will get the environment name `ec2:default`.

Common scenarios with the CloudWatch agent

This section provides you with different scenarios that outline how to complete common configuration and customization tasks for the CloudWatch agent.

Topics

- Running the CloudWatch agent as a different user
- How the CloudWatch agent handles sparse log files
- Adding custom dimensions to metrics collected by the CloudWatch agent
- Aggregating or rolling up metrics collected by the CloudWatch agent
- Collecting high-resolution metrics with the CloudWatch agent

- Sending metrics, logs, and traces to a different account
- Timestamp differences between the CloudWatch agent and the earlier CloudWatch Logs agent
- Appending OpenTelemetry collector configuration files

Running the CloudWatch agent as a different user

On Linux servers, the CloudWatch runs as the root user by default. To have the agent run as a different user, use the `run_as_user` parameter in the `agent` section in the CloudWatch agent configuration file. This option is available only on Linux servers.

If you're already running the agent with the root user and want to change to using a different user, use one of the following procedures.

To run the CloudWatch agent as a different user on an EC2 instance running Linux

1. Download and install a new CloudWatch agent package.
2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.
3. Provide credentials for this user in one of these ways:
   - If the file `.aws/credentials` exists in the home directory of the root user, you must create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be /home/*username*/`.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
   - If the file `.aws/credentials` does not exist in the home directory of the root user, you can do one of the following:
     - Create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be /home/*username*/`.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
     - Instead of creating a credentials file, attach an IAM role to the instance. The agent uses this role as the credential provider.
4. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch agent configuration file

5. Give the user the required permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.
6. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c file:configuration-file-path
```

To run the CloudWatch agent as a different user on an on-premises server running Linux

1. Download and install a new CloudWatch agent package.
2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.
3. Store the credentials of this user to a path that the user can access, such as `/home/username/.aws/credentials`.
4. Set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
5. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch agent configuration file

6. Give the user required permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.
7. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c file:configuration-file-path
```

How the CloudWatch agent handles sparse log files

Sparse files are files with both empty blocks and real contents. A sparse file uses disk space more efficiently by writing brief information representing the empty blocks to disk instead of the actual null bytes which makes up the block. This makes the actual size of a sparse file usually much smaller than its apparent size.

However, the CloudWatch agent doesn't treat sparse files differently than it treats normal files. When the agent reads a sparse file, the empty blocks are treated as "real" blocks filled with null bytes. Because of this, the CloudWatch agent publishes as many bytes as the apparent size of a sparse file to CloudWatch.

Configuring the CloudWatch agent to publish a sparse file can cause higher than expected CloudWatch costs, so we recommend not to do so. For example, `/var/logs/lastlog` in Linux is usually a very sparse file, and we recommend that you don't publish it to CloudWatch.

Adding custom dimensions to metrics collected by the CloudWatch agent

To add custom dimensions such as tags to metrics collected by the agent, add the `append_dimensions` field to the section of the agent configuration file that lists those metrics.

For example, the following example section of the configuration file adds a custom dimension named `stackName` with a value of `Prod` to the `cpu` and `disk` metrics collected by the agent.

```
"cpu":{
  "resources":[
    "*"
  ],
  "measurement":[
    "cpu_usage_guest",
    "cpu_usage_nice",
    "cpu_usage_idle"
  ],
  "totalcpu":false,
  "append_dimensions":{
    "stackName":"Prod"
  }
},
"disk":{
  "resources":[
    "/",
    "/tmp"
```

```
  ],
  "measurement":[
    "total",
    "used"
  ],
  "append_dimensions":{
    "stackName":"Prod"
  }
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Aggregating or rolling up metrics collected by the CloudWatch agent

To aggregate or roll up metrics collected by the agent, add an `aggregation_dimensions` field to the section for that metric in the agent configuration file.

For example, the following configuration file snippet rolls up metrics on the `AutoScalingGroupName` dimension. The metrics from all instances in each Auto Scaling group are aggregated and can be viewed as a whole.

```
"metrics": {
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [["AutoScalingGroupName"]]
}
```

To roll up along the combination of each `InstanceId` and `InstanceType` dimensions in addition to rolling up on the Auto Scaling group name, add the following.

```
"metrics": {
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [["AutoScalingGroupName"], ["InstanceId", "InstanceType"]]
}
```

To roll up metrics into one collection instead, use `[]`.

```
"metrics": {
  "cpu":{...}
```

```
  "disk":{...}
  "aggregation_dimensions" : [[]]
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Collecting high-resolution metrics with the CloudWatch agent

The `metrics_collection_interval` field specifies the time interval for the metrics collected, in seconds. By specifying a value of less than 60 for this field, the metrics are collected as high-resolution metrics.

For example, if your metrics should all be high-resolution and collected every 10 seconds, specify 10 as the value for `metrics_collection_interval` under the `agent` section as a global metrics collection interval.

```
"agent": {
  "metrics_collection_interval": 10
}
```

Alternatively, the following example sets the `cpu` metrics to be collected every second, and all other metrics are collected every minute.

```
"agent":{
  "metrics_collection_interval": 60
},
"metrics":{
  "metrics_collected":{
    "cpu":{
      "resources":[
        "*"
      ],
      "measurement":[
        "cpu_usage_guest"
      ],
      "totalcpu":false,
      "metrics_collection_interval": 1
    },
    "disk":{
      "resources":[
        "/",
```

```
        "/tmp"
      ],
      "measurement":[
        "total",
        "used"
      ]
    }
  }
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Sending metrics, logs, and traces to a different account

To have the CloudWatch agent send the metrics, logs, or traces to a different account, specify a `role_arn` parameter in the agent configuration file on the sending server. The `role_arn` value specifies an IAM role in the target account that the agent uses when sending data to the target account. This role enables the sending account to assume a corresponding role in the target account when delivering the metrics or logs to the target account.

You can also specify separate `role_arn` strings in the agent configuration file: one to use when sending metrics, another for sending logs, and another for sending traces.

The following example of part of the `agent` section of the configuration file sets the agent to use `CrossAccountAgentRole` when sending data to a different account.

```
{
  "agent": {
    "credentials": {
      "role_arn": "arn:aws:iam::123456789012:role/CrossAccountAgentRole"
    }
  },
  .....
}
```

Alternatively, the following example sets different roles for the sending account to use for sending metrics, logs, and traces:

```
"metrics": {
    "credentials": {
```

```
     "role_arn": "RoleToSendMetrics"
    },
    "metrics_collected": {....
```

```
"logs": {
    "credentials": {
    "role_arn": "RoleToSendLogs"
    },
    ....
```

Policies needed

When you specify a `role_arn` in the agent configuration file, you must also make sure the IAM roles of the sending and target accounts have certain policies. The roles in both the sending and target accounts should have `CloudWatchAgentServerPolicy`. For more information about assigning this policy to a role, see Prerequisites.

The role in the sending account also must include the following policy. You add this policy on the **Permissions** tab in the IAM console when you edit the role.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sts:AssumeRole"
            ],
            "Resource": [
                "arn:aws:iam::111122223333:role/agent-role-in-target-account"
            ]
        }
    ]
}
```

The role in the target account must include the following policy so that it recognizes the IAM role used by the sending account. You add this policy on the **Trust relationships** tab in the IAM console

when you edit the role. This role is the role specified in *agent-role-in-target-account* in the policy used by the sending account.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:role/role-in-sender-account"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Timestamp differences between the CloudWatch agent and the earlier CloudWatch Logs agent

The CloudWatch agent supports a different set of symbols for timestamp formats, compared to the earlier CloudWatch Logs agent. These differences are shown in the following table.

Symbols supported by both agents	Symbols supported only by CloudWatch agent	Symbols supported only by earlier CloudWatch Logs agent
%A, %a, %b, %B, %d, %f, %H, %l, %m, %M, %p, %S, %y, %Y, %Z, %z	%-d, %-l, %-m, %-M, %-S	%c,%j, %U, %W, %w

For more information about the meanings of the symbols supported by the new CloudWatch agent, see CloudWatch Agent Configuration File: Logs Section in the *Amazon CloudWatch User*

Guide. For information about symbols supported by the CloudWatch Logs agent, see Agent Configuration File in the *Amazon CloudWatch Logs User Guide*.

Appending OpenTelemetry collector configuration files

The CloudWatch agent supports supplemental OpenTelemetry collector configuration files alongside its own configuration files. This feature allows you to use CloudWatch agent features such as CloudWatch Application Signals or Container Insights through the CloudWatch agent configuration and bring in your existing OpenTelemetry collector configuration with a single agent.

To prevent merge conflicts with pipelines automatically created by CloudWatch agent, add a custom suffix to each of the components and pipelines in your OpenTelemetry collector configuration.

```
receivers:
  otlp/custom-suffix:
    protocols:
      http:

exporters:
  awscloudwatchlogs/custom-suffix:
    log_group_name: "test-group"
    log_stream_name: "test-stream"

service:
  pipelines:
    logs/custom-suffix:
      receivers: [otlp/custom-suffix]
      exporters: [awscloudwatchlogs/custom-suffix]
```

To configure the CloudWatch agent, start the CloudWatch agent using the `fetch-config` option and specify the CloudWatch agent's configuration file. CloudWatch agent requires at least one CloudWatch agent configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -c
 file:/tmp/agent.json -s
```

Next, use the `append-config` option while specifying the OpenTelemetry collector configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -c
 file:/tmp/otel.yaml -s
```

The agent merges the two configuration files on start up and logs the resolved configuration.

The following OpenTelemetry components are available for you to configure in your appended YAML configuration. Use the component type name shown here as the key in your YAML.

Component type	Available components
Receivers	`otlp`, `prometheus` , `statsd`, `collectd`, `jmx`, `hostmetrics` , `filelog`, `tcplog`, `udplog`, `jaeger`, `zipkin`, `kafka`, `kubeletstats`
Processors	`batch`, `memory_limiter` , `filter`, `attributes` , `resource`, `resourcedetection` , `metricstransform` , `transform` , `cumulativetodelta` , `deltatocumulative` , `deltatorate` , `groupbyattrs` , `groupbytrace` , `k8sattributes` , `metricsgeneration` , `metricstarttime` , `probabilistic_sampler` , `span`, `tail_sampling`
Exporters	`otlphttp`, `awsemf`, `awscloudwatchlogs` , `awsxray`, `prometheusremotewrite` , `debug`
Extensions	`sigv4auth` , `headers_setter` , `file_storage` , `health_check` , `pprof`, `zpages`

The CloudWatch agent only supports writing telemetry to AWS destinations.

For YAML examples that send each signal to the CloudWatch OpenTelemetry Protocol (OTLP) endpoints, see Configuration examples.

CloudWatch agent credentials preference

This section outlines the credentials provider chain the CloudWatch agent uses to obtain credentials when communicating with other AWS services and APIs. The ordering is as follows:

> **Note**
>
> The preferences listed in numbers two through five are the same preference order as defined in the AWS SDK. For more information, see Specifying Credentials in the SDK documentation.

1. Shared config and credentials files as defined in the CloudWatch agent's `common-config.toml` file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
2. AWS SDK environment variables

> **Important**
>
> On Linux, if you run the CloudWatch agent using the `amazon-cloudwatch-agent-ctl` script, the script starts the agent as a `systemd` service. In this case, environment variables such as `HOME`, `AWS_ACCESS_KEY_ID`, and `AWS_SECRET_ACCESS_KEY` are not accessible by the agent.

3. Shared configuration and credentials files found in `$HOME/%USERPROFILE%`

> **Note**
>
> The CloudWatch agent looks for `.aws/credentials` in `$HOME` on Linux and macOS and in `%USERPROFILE%` on Windows. These environment variables resolve to the home directory of the user the agent runs as: `root` on Linux and macOS (or the `run_as_user` if configured), and `LocalSystem` on Windows.
> Unlike the AWS SDK, the CloudWatch agent does not have fallback methods to determine the home directory if the environment variables are inaccessible. This difference in behavior is to maintain backwards compatibility with earlier implementations of the AWS SDK.
> Furthermore, unlike with the shared credentials found in `common-config.toml`, if the AWS SDK-derived shared credentials expire and are rotated, the renewed credentials are not automatically picked up by the CloudWatch agent and require a restart of the agent to do so.

4. An AWS Identity and Access Management role for tasks if an application is present that uses an Amazon Elastic Container Service task definition or a RunTask API operation.

5. An instance profile attached to an Amazon EC2 instance.

As a best practice, we recommend that you specify credentials in the following order when you use the CloudWatch agent.

1. Use IAM roles for tasks if your application uses an Amazon Elastic Container Service task definition or a RunTask API operation.
2. Use IAM roles if your application runs on an Amazon EC2 instance.
3. Use the CloudWatch agent `common-config.toml` file to specify the credentials file. This credentials file is the same one used by other AWS SDKs and the AWS CLI. If you're already using a shared credentials file, you can also use it for this purpose. If you provide it by using the CloudWatch agent's `common-config.toml` file, you ensure that the agent will consume rotated credentials when they expire and get replaced without requiring you to restart the agent.
4. Use environment variables. Setting environment variables is useful if you're doing development work on a computer other than an Amazon EC2 instance.

> **Note**
>
> If you send telemetry to a different account as explained in Sending metrics, logs, and traces to a different account, the CloudWatch agent uses the credentials provider chain described in this section to obtain the initial set of credentials. It then uses those credentials when assuming the IAM role specified by `role_arn` in the CloudWatch agent configuration file.

Troubleshooting the CloudWatch agent

You can use the information in this section to troubleshoot issues you might encounter with the CloudWatch agent.

When encountering issues with the CloudWatch agent, you can use the `AWSSupport-TroubleshootCloudWatchAgent` automation runbook. The AWS troubleshooting tool can:

- Verify IAM permissions and instance profiles
- Check agent status and analyze logs
- Test endpoint connectivity

- Automatically collect and upload relevant logs to Amazon S3

For detailed information on the AWS troubleshooting tool, see Support Automation Workflow (SAW) Runbook - Troubleshoot CloudWatch agent.

Topics

- CloudWatch agent command line parameters
- Install the CloudWatch agent using Run Command fails
- The CloudWatch agent won't start
- Verify that the CloudWatch agent is running
- The CloudWatch agent won't start, and the error mentions an Amazon EC2 Region
- The CloudWatch agent won't start on Windows Server
- Where are the metrics?
- The CloudWatch agent takes a long time to run in a container or logs a hop limit error
- I updated my agent configuration but don't see the new metrics or logs in the CloudWatch console
- The CloudWatch agent is using the wrong credentials
- CloudWatch agent files and locations
- Finding information about CloudWatch agent versions
- Logs generated by the CloudWatch agent
- Stopping and restarting the CloudWatch agent

CloudWatch agent command line parameters

To see the full list of parameters supported by the CloudWatch agent, enter the following at the command line at a computer where you have it installed:

```
amazon-cloudwatch-agent-ctl -help
```

Install the CloudWatch agent using Run Command fails

To install the CloudWatch agent using Systems Manager Run Command, the SSM Agent on the target server must be version 2.2.93.0 or later of the SSM Agent agent. If your SSM Agent isn't the correct version, you might see errors that include the following messages:

```
no latest version found for package AmazonCloudWatchAgent on platform linux
```

```
failed to download installation package reliably
```

For information about updating your SSM Agent version, see Installing and Configuring SSM Agent in the *AWS Systems Manager User Guide*.

The CloudWatch agent won't start

If the CloudWatch agent fails to start, there might be an issue in your configuration. Configuration information is logged in the `configuration-validation.log` file. This file is located in `/opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log` on Linux servers and in `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log` on servers running Windows Server.

Verify that the CloudWatch agent is running

You can query the CloudWatch agent to find whether it's running or stopped. You can use AWS Systems Manager to do this remotely. You can also use the command line, but only to check the local server.

To query the status of the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose the button next to **AmazonCloudWatch-ManageAgent**.
5. In the **Action** list, choose **status**.
6. For **Optional Configuration Source** choose **default** and keep **Optional Configuration Location** blank.
7. In the **Target** area, choose the instance to check.

8. Choose **Run**.

If the agent is running, the output resembles the following.

```
{
       "status": "running",
       "starttime": "2017-12-12T18:41:18",
       "version": "1.73.4"
}
```

If the agent is stopped, the `"status"` field displays `"stopped"`.

To query the status of the CloudWatch agent locally using the command line

- On a Linux server, enter the following:

  ```
  sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a
   status
  ```

  On a server running Windows Server, enter the following in PowerShell as an administrator:

  ```
  & $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m
   ec2 -a status
  ```

The CloudWatch agent won't start, and the error mentions an Amazon EC2 Region

If the agent doesn't start and the error message mentions an Amazon EC2 Region endpoint, you might have configured the agent to need access to the Amazon EC2 endpoint without granting that access.

For example, if you specify a value for the `append_dimensions` parameter in the agent configuration file that depends on Amazon EC2 metadata and you use proxies, you must make sure that the server can access the endpoint for Amazon EC2. For more information about these endpoints, see Amazon Elastic Compute Cloud (Amazon EC2) in the *Amazon Web Services General Reference*.

The CloudWatch agent won't start on Windows Server

On Windows Server, you might see the following error:

```
Start-Service : Service 'Amazon CloudWatch Agent (AmazonCloudWatchAgent)' cannot be
 started due to the following
error: Cannot start service AmazonCloudWatchAgent on computer '.'.
At C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1:113
 char:12
+     $svc | Start-Service
+            ~~~~~~~~~~~~~
    + CategoryInfo          : OpenError:
 (System.ServiceProcess.ServiceController:ServiceController) [Start-Service],
   ServiceCommandException
    + FullyQualifiedErrorId :
 CouldNotStartService,Microsoft.PowerShell.Commands.StartServiceCommand
```

To fix this, first make sure that the server service is running. This error can be seen if the agent tries to start when the server service isn't running.

If the server service is already running, the following may be the issue. On some Windows Server installations, the CloudWatch agent takes more than 30 seconds to start. Because Windows Server, by default, allows only 30 seconds for services to start, this causes the agent to fail with an error similar to the following:

To fix this issue, increase the service timeout value. For more information, see A service does not start, and events 7000 and 7011 are logged in the Windows event log.

Where are the metrics?

If the CloudWatch agent has been running but you can't find metrics collected by it in the AWS Management Console or the AWS CLI, confirm that you're using the correct namespace. By default, the namespace for metrics collected by the agent is `CWAgent`. You can customize this namespace using the `namespace` field in the `metrics` section of the agent configuration file. If you don't see the metrics that you expect, check the configuration file to confirm the namespace being used.

When you first download the CloudWatch agent package, the agent configuration file is `amazon-cloudwatch-agent.json`. This file is in the directory where you ran the configuration wizard, or you might have moved it to a different directory. If you use the configuration wizard, the agent configuration file output from the wizard is named `config.json`. For more information about the configuration file, including the `namespace` field, see CloudWatch agent configuration file: Metrics section.

The CloudWatch agent takes a long time to run in a container or logs a hop limit error

When you run the CloudWatch agent as a container service and want to add Amazon EC2 metric dimensions to all metrics collected by the agent, you might see the following errors in version v1.247354.0 of the agent:

```
2022-06-07T03:36:11Z E! [processors.ec2tagger] ec2tagger: Unable to retrieve Instance
 Metadata Tags. This plugin must only be used on an EC2 instance.
2022-06-07T03:36:11Z E! [processors.ec2tagger] ec2tagger: Please increase hop limit
 to 2 by following this document https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/
configuring-instance-metadata-options.html#configuring-IMDS-existing-instances.
2022-06-07T03:36:11Z E! [telegraf] Error running agent: could not initialize processor
 ec2tagger: EC2MetadataRequestError: failed to get EC2 instance identity document
caused by: EC2MetadataError: failed to make EC2Metadata request
        status code: 401, request id:
caused by:
```

You might see this error if the agent tries to get metadata from IMDSv2 inside a container without an appropriate hop limit. In versions of the agent earlier than v1.247354.0, you can experience this issue without seeing the log message.

To solve this, increase the hop limit to 2 by following the instructions in Configure the instance metadata options.

I updated my agent configuration but don't see the new metrics or logs in the CloudWatch console

If you update your CloudWatch agent configuration file, the next time that you start the agent, you need to use the **`fetch-config`** option. For example, if you stored the updated file on the local computer, enter the following command:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -
s -m ec2 -c file:configuration-file-path
```

The CloudWatch agent is using the wrong credentials

If the CloudWatch agent is using unexpected credentials, the agent may be resolving credentials from a different source than you expect. The agent follows a credentials provider chain that

differs from the AWS SDK in some cases. For more information, see CloudWatch agent credentials preference.

CloudWatch agent files and locations

The following table lists the files installed by and used with the CloudWatch agent, along with their locations on servers running Linux or Windows Server.

File	Linux location	Windows Server location
The control script that controls starting, stopping, and restarting the agent.	`/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl` or `/usr/bin/amazon-cloudwatch-agent-ctl`	`$Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1`
The log file the agent writes to. You might need to attach this when contacting AWS Support.	`/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log` or `/var/log/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.log`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\amazon-cloudwatch-agent.log`
Agent configuration validation file.	`/opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log` or `/var/log/amazon/amazon-cloudwatch-agent/configuration-validation.log`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log`
The JSON file used to configure the agent immediately after the wizard	`/opt/aws/amazon-cloudwatch-agent/bin/config.json`	`$Env:ProgramFiles\Amazon\AmazonCloud`

File	Linux location	Windows Server location
creates it. For more information, see Create the CloudWatch agent configuration file.		WatchAgent\config.json
The JSON file used to configure the agent if this configuration file has been downloaded from Parameter Store.	/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json or /etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.json	$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json
The TOML file used to specify Region and credential information to be used by the agent, overriding system defaults.	/opt/aws/amazon-cloudwatch-agent/etc/common-config.toml or /etc/amazon/amazon-cloudwatch-agent/common-config.toml	$Env:ProgramData\Amazon\AmazonCloudWatchAgent\common-config.toml
The TOML file that contains the converted contents of the JSON configuration file. The amazon-cloudwatch-agent-ctl script generates this file. Users should not directly modify this file. It can be useful for verifying that JSON to TOML translation was successful.	/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.toml or /etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.toml	$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.toml

File	Linux location	Windows Server location
The YAML file that contains the converted contents of the JSON configuration file. The `amazon-cloudwatch-agent-ctl` script generates this file. You should not directly modify this file. This file can be useful for verifying that the JSON to YAML translation was successful.	`/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.yaml or /etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.yaml`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.yaml`

Finding information about CloudWatch agent versions

To find the version number of the CloudWatch agent on a Linux server, enter the following command:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a status
```

To find the version number of the CloudWatch agent on Windows Server, enter the following command:

```
& $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m ec2
 -a status
```

> **Note**
>
> Using this command is the correct way to find the version of the CloudWatch agent. If you use **Programs and Features** in the Control Panel, you will see an incorrect version number.

You can also download a README file about the latest changes to the agent, and a file that indicates the version number that is currently available for download. These files are in the following locations:

- https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/RELEASE_NOTES or https://amazoncloudwatch-agent-*us-east-1*.s3.*us-east-1*.amazonaws.com/info/latest/RELEASE_NOTES
- https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/CWAGENT_VERSION or https://amazoncloudwatch-agent-*us-east-1*.s3.*us-east-1*.amazonaws.com/info/latest/CWAGENT_VERSION

Logs generated by the CloudWatch agent

The agent generates a log while it runs. This log includes troubleshooting information. This log is the amazon-cloudwatch-agent.log file. This file is located in /opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log on Linux servers and in $Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\amazon-cloudwatch-agent.log on servers running Windows Server.

You can configure the agent to log additional details in the amazon-cloudwatch-agent.log file. In the agent configuration file, in the agent section, set the debug field to true, then reconfigure and restart the CloudWatch agent. To disable the logging of this extra information, set the debug field to false. Then, reconfigure and restart the agent. For more information, see Manually create or edit the CloudWatch agent configuration file.

In versions 1.247350.0 and later of the CloudWatch agent, you can optionally set the aws_sdk_log_level field in the agent section of the agent configuration file to one or more of the following options. Separate multiple options with the | character.

- LogDebug
- LogDebugWithSigning
- LogDebugWithHTTPBody
- LogDebugRequestRetries
- LogDebugWithEventStreamBody

For more information about these options, see LogLevelType.

Stopping and restarting the CloudWatch agent

You can manually stop the CloudWatch agent using either AWS Systems Manager or the command line.

To stop the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, choose the instance where you installed the CloudWatch agent.
6. In the **Action** list, choose **stop**.
7. Keep **Optional Configuration Source** and **Optional Configuration Location** blank.
8. Choose **Run**.

To stop the CloudWatch agent locally using the command line

- On a Linux server, enter the following:

  ```
  sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a
   stop
  ```

  On a server running Windows Server, enter the following in PowerShell as an administrator:

  ```
  & $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m
   ec2 -a stop
  ```

To restart the agent, follow the instructions in (Optional) Modify the common configuration and named profile for CloudWatch agent.

Embedding metrics within logs

The CloudWatch embedded metric format allows you to generate custom metrics asynchronously in the form of logs written to CloudWatch Logs. You can embed custom metrics alongside detailed log event data, and CloudWatch automatically extracts the custom metrics so that you can

visualize and alarm on them, for real-time incident detection. Additionally, the detailed log events associated with the extracted metrics can be queried using CloudWatch Logs Insights to provide deep insights into the root causes of operational events.

Embedded metric format helps you generate actionable custom metrics from ephemeral resources such as Lambda functions and containers. By using the embedded metric format to send logs from these ephemeral resources, you can now easily create custom metrics without having to instrument or maintain separate code, while gaining powerful analytical capabilities on your log data.

No setup is required to use the embedded metric format. Either structure your logs by following the Embedded metric format specification, or generate them using our client libraries and send them to CloudWatch Logs using the PutLogEvents API or the CloudWatch agent.

To generate metrics from logs with embedded metric format, you need the `logs:PutLogEvents` permission but you don't need to also have the `cloudwatch:PutMetricData` permission.

Charges are incurred for logs ingestion and archival, and custom metrics that are generated. For more information, see Amazon CloudWatch Pricing.

> **Note**
>
> Be careful when configuring your metric extraction as it impacts your custom metric usage and corresponding bill. If you unintentionally create metrics based on high-cardinality dimensions (such as `requestId`), the embedded metric format will by design create a custom metric corresponding to each unique dimension combination. For more information, see Dimensions.

> **Note**
>
> Embedded metric format ensures at least one time delivery of metrics extracted from log events, while duplicate metric values may occasionally occur.

The following topics describe how to publish logs using the embedded metric format, view your metrics and logs in the console, and set alarms on metrics created with the embedded metric format.

Topics

- Publishing logs with the embedded metric format
- Viewing your metrics and logs in the console
- Setting alarms on metrics created with the embedded metric format

Publishing logs with the embedded metric format

You can generate embedded metric format logs using the following methods:

- Generate and send the logs by using the open-sourced client libraries.
- Manually generate the logs using the embedded metric format specification, and then use the CloudWatch agent or the PutLogEvents API to send the logs.

The following topics provide more information about embedded metrics.

Topics

- Creating logs in embedded metric format using the client libraries
- Specification: Embedded metric format
- Using the PutLogEvents API to send manually-created embedded metric format logs
- Using the CloudWatch agent to send embedded metric format logs
- Using the embedded metric format with AWS Distro for OpenTelemetry

Creating logs in embedded metric format using the client libraries

You can use the open-sourced client libraries that Amazon provides to create embedded metric format logs. Full examples for different setups can be found in our client libraries under **/ examples**. The libraries and the instructions for how to use them are located on Github.

- Node.Js

> **Note**
>
> For Node.js, versions 4.1.1+, 3.0.2+, 2.0.7+ are required for use with the Lambda JSON log format. Using previous versions in such Lambda environments will lead to metric loss. For more information, see Accessing Amazon CloudWatch logs for AWS Lambda.

- Python
- Java
- C#

Client libraries are meant to work out of the box with the CloudWatch agent. Generated embedded metric format logs are sent to the CloudWatch agent, which then aggregates and publishes them to CloudWatch Logs for you.

> **Note**
>
> When using Lambda, no agent is required to send the logs to CloudWatch. Anything logged to STDOUT is sent to CloudWatch Logs through the Lambda Logging Agent.

Specification: Embedded metric format

The CloudWatch embedded metric format is a JSON specification used to instruct CloudWatch Logs to automatically extract metric values embedded in structured log events. You can use CloudWatch to graph and create alarms on the extracted metric values. This section describes embedded metric format specification conventions and the embedded metric format document structure.

> **Note**
>
> Embedded metric format ensures at least one time delivery of metrics extracted from log events, while duplicate metric values may occasionally occur.

Embedded metric format specification conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this format specification are to be interpreted as described in Key Words RFC2119.

The terms "JSON", "JSON text", "JSON value", "member", "element", "object", "array", "number", "string", "boolean", "true", "false", and "null" in this format specification are to be interpreted as defined in JavaScript Object Notation RFC8259.

> **Note**
>
> If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

Embedded metric format document structure

This section describes the structure of an embedded metric format document. Embedded metric format documents are defined in JavaScript Object Notation RFC8259.

Unless otherwise noted, objects defined by this specification MUST NOT contain any additional members. Members not recognized by this specification MUST be ignored. Members defined in this specification are case-sensitive.

The embedded metric format is subject to the same limits as standard CloudWatch Logs events and are limited to a maximum size of 1 MB.

With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the `AWS/Logs` namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Root node

The LogEvent message MUST be a valid JSON object with no additional data at the beginning or end of the LogEvent message string. For more information about the LogEvent structure, see InputLogEvent.

Embedded metric format documents MUST contain the following top-level member on the root node. This is a Metadata object object.

```
{
 "_aws": {
    "CloudWatchMetrics": [ ... ]
  }
}
```

The root node MUST contain all Target members members defined by the references in the MetricDirective object.

The root node MAY contain any other members that are not included in the above requirements. The values of these members MUST be valid JSON types.

Metadata object

The `_aws` member can be used to represent metadata about the payload that informs downstream services how they should process the LogEvent. The value MUST be an object and MUST contain the following members:

- **CloudWatchMetrics**— An array of MetricDirective object used to instruct CloudWatch to extract metrics from the root node of the LogEvent.

```
{
  "_aws": {
    "CloudWatchMetrics": [ ... ]
  }
}
```

- **Timestamp**— A number representing the time stamp used for metrics extracted from the event. Values MUST be expressed as the number of milliseconds after Jan 1, 1970 00:00:00 UTC. The time stamp MUST be no more than 14 days in the past and no more than 2 hours in the future. CloudWatch does not publish metrics that have a time stamp outside this range.

```
{
  "_aws": {
    "Timestamp": 1559748430481
  }
}
```

MetricDirective object

The MetricDirective object instructs downstream services that the LogEvent contains metrics that will be extracted and published to CloudWatch. MetricDirectives MUST contain the following members:

- **Namespace**— A string representing the CloudWatch namespace for the metric. The namespace MUST contain 1 to 255 printable ASCII characters (0x20 through 0x7E) and MUST NOT contain only whitespace. If the namespace is not valid, CloudWatch does not publish any metrics in that namespace.
- **Dimensions**— A DimensionSet array.

- **Metrics**— An array of MetricDefinition objects. A log event MUST NOT contain more than 100 MetricDefinition objects in total, counted across all of its MetricDirectives. If a log event exceeds this limit, CloudWatch does not extract any metrics from it.

DimensionSet array

A DimensionSet is an array of strings containing the dimension keys that will be applied to all metrics in the document. The values within this array MUST also be members on the root-node—referred to as the Target members

A DimensionSet MUST NOT contain more than 30 dimension keys. A DimensionSet MAY be empty.

Each dimension key has the following constraints:

- It MUST contain 1 to 250 printable ASCII characters.
- It MUST NOT contain only whitespace.
- It MUST NOT start with a colon (`:`).

The target member MUST have a string value. This value MUST contain 1 to 1024 printable ASCII characters and MUST NOT contain only whitespace. The target member defines a dimension that will be published as part of the metric identity. Every DimensionSet used creates a new metric in CloudWatch. For more information about dimensions, see Dimension and Dimensions.

If a DimensionSet or a dimension it references doesn't meet these requirements, CloudWatch doesn't publish the metrics for that DimensionSet. The other DimensionSets in the MetricDirective are not affected.

```
{
 "_aws": {
   "CloudWatchMetrics": [
     {
       "Dimensions": [ [ "functionVersion" ] ],
       ...
     }
   ]
 },
 "functionVersion": "$LATEST"
}
```

> **Note**
>
> Be careful when configuring your metric extraction as it impacts your custom metric usage and corresponding bill. If you unintentionally create metrics based on high-cardinality dimensions (such as `requestId`), the embedded metric format will by design create a custom metric corresponding to each unique dimension combination. For more information, see Dimensions.

MetricDefinition object

A MetricDefinition is an object that MUST contain the following member:

- **Name**— A string Reference values to a metric Target members. Metric targets MUST be either a numeric value or an array of numeric values. The name MUST contain 1 to 255 printable ASCII characters and MUST NOT contain only whitespace. If the name is not valid, CloudWatch does not publish that metric.

A MetricDefinition object MAY contain the following members:

- **Unit**— An OPTIONAL string value representing the unit of measure for the corresponding metric. Values SHOULD be valid CloudWatch metric units. For information about valid units, see MetricDatum. If a value is not provided, then a default value of NONE is assumed.
- **StorageResolution**— An OPTIONAL integer value representing the storage resolution for the corresponding metric. Setting this to 1 specifies this metric as a high-resolution metric, so that CloudWatch stores the metric with sub-minute resolution down to one second. Setting this to 60 specifies this metric as standard-resolution, which CloudWatch stores at 1-minute resolution. Values SHOULD be valid CloudWatch supported resolutions, 1 or 60. If a value is not provided, then a default value of 60 is assumed. CloudWatch stores the metric at high resolution only when the value is 1. For example, CloudWatch treats `1.0` as 60.

  For more information about high-resolution metrics, see High-resolution metrics.

> **Note**
>
> If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

```
{
  "_aws": {
    "CloudWatchMetrics": [
      {
        "Metrics": [
          {
            "Name": "Time",
            "Unit": "Milliseconds",
            "StorageResolution": 60
          }
        ],
        ...
      }
    ]
  },
  "Time": 1
}
```

Reference values

Reference values are string values that reference Target members members on the root node. These references should NOT be confused with the JSON Pointers described in RFC6901. Target values cannot be nested.

Target members

Valid targets MUST be members on the root node and cannot be nested objects. For example, a _reference_ value of `"A.a"` MUST match the following member:

```
{ "A.a" }
```

It MUST NOT match the nested member:

```
{ "A": { "a" } }
```

Valid values of target members depend on what is referencing them. A metric target MUST be a numeric value or an array of numeric values. Numeric values MUST be in the range -2^{360} to 2^{360}. If a value is outside this range, CloudWatch does not publish that metric. Numeric array metric targets MUST NOT have more than 100 members. If a numeric array exceeds this limit, CloudWatch does not extract any metrics from the log event. A dimension target MUST have a string value.

Embedded metric format example and JSON schema

The following is a valid example of embedded metric format.

```
{
  "_aws": {
    "Timestamp": 1574109732004,
    "CloudWatchMetrics": [
      {
        "Namespace": "lambda-function-metrics",
        "Dimensions": [["functionVersion"]],
        "Metrics": [
          {
            "Name": "time",
            "Unit": "Milliseconds",
            "StorageResolution": 60
          }
        ]
      }
    ]
  },
  "functionVersion": "$LATEST",
  "time": 100,
  "requestId": "989ffbf8-9ace-4817-a57c-e4dd734019ee"
}
```

You can use the following schema to validate embedded metric format documents. The schema checks the MetricDefinition limit for each MetricDirective only. It does not check the total across all MetricDirectives in a log event.

```
{
    "type": "object",
    "title": "Root Node",
    "required": [
        "_aws"
    ],
    "properties": {
        "_aws": {
            "$id": "#/properties/_aws",
            "type": "object",
            "title": "Metadata",
            "required": [
                "Timestamp",
```

```
                "CloudWatchMetrics"
            ],
            "properties": {
                "Timestamp": {
                    "$id": "#/properties/_aws/properties/Timestamp",
                    "type": "integer",
                    "title": "The Timestamp Schema",
                    "examples": [
                        1565375354953
                    ]
                },
                "CloudWatchMetrics": {
                    "$id": "#/properties/_aws/properties/CloudWatchMetrics",
                    "type": "array",
                    "title": "MetricDirectives",
                    "items": {
                        "$id": "#/properties/_aws/properties/CloudWatchMetrics/items",
                        "type": "object",
                        "title": "MetricDirective",
                        "required": [
                            "Namespace",
                            "Dimensions",
                            "Metrics"
                        ],
                        "properties": {
                            "Namespace": {
                                "$id": "#/properties/_aws/properties/CloudWatchMetrics/
items/properties/Namespace",
                                "type": "string",
                                "title": "CloudWatch Metrics Namespace",
                                "examples": [
                                    "MyApp"
                                ],
                                "pattern": "^[ -~]*[!-~][ -~]*$",
                                "minLength": 1,
                                "maxLength": 255
                            },
                            "Dimensions": {
                                "$id": "#/properties/_aws/properties/CloudWatchMetrics/
items/properties/Dimensions",
                                "type": "array",
                                "title": "The Dimensions Schema",
                                "minItems": 1,
                                "items": {
```

```
                                    "$id": "#/properties/_aws/properties/

                                            "examples": [
                                                60
                                            ]
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
    }
}
```

Entity information in EMF format

When you publish logs to Amazon CloudWatch using Embedded Metric Format (EMF), you can include entity information in the log event. This section describes how to specify entity information and how CloudWatch processes this information.

Entity types

When no Entity is specified with the `PutLogEvents` request, CloudWatch will look for entity information in the EMF log content:

- **Service-type entities**

  Required fields: `Service` and `Environment`
- **Resource-type entities**

  Required fields: `ResourceType` and `Identifier`

Platform attributes

CloudWatch automatically determines the platform type based on these attributes:

- **Kubernetes (K8s):**

  Required: `K8s.Cluster`

  Optional: `K8s.Namespace`, `K8s.Workload`, `K8s.Node`, `K8s.Pod`, `EC2.InstanceId`, `EC2.AutoScalingGroup`
- **Amazon EKS**

  Required: `EKS.Cluster`

  Optional: `K8s.Namespace`, `K8s.Workload`, `K8s.Node`, `K8s.Pod`, `EC2.InstanceId`
- **Amazon ECS:**

  Required: `ECS.Cluster`

  Optional: `ECS.Service`, `ECS.Task`
- **Amazon EC2**

  Required: `EC2.InstanceId`

  Optional: `EC2.AutoScalingGroup`
- **Lambda:**

  Required: `Lambda.Function`

- **Generic hosts:**

  Required: `Host`

Example EMF log format

```
{
    "_aws": {
        "CloudWatchMetrics": [
            {
                "Metrics": [
                    {"Name": "RequestLatency", "Unit": "Milliseconds"}
                ],
                "Namespace": "MyApplication"
            }
        ]
    },
    "Service": "PaymentService",
    "Environment": "Production",
    "K8s.Cluster": "main-cluster",
    "K8s.Namespace": "payment-ns",
    "K8s.Pod": "payment-pod-123",
    "K8s.Node": "worker-node-1",
    "K8s.Workload": "payment-deployment",
    "RequestLatency": 135.5,
    "timestamp": 1622163600000
}
```

Generated Entity

The above EMF log will generate the following Entity:

```
{
    "KeyAttributes": {
        "Type": "Service",
        "Name": "PaymentService",
        "Environment": "Production"
    },
    "Attributes": {
        "PlatformType": "K8s",
        "K8s.Cluster": "main-cluster",
        "K8s.Namespace": "payment-ns",
```

```
        "K8s.Pod": "payment-pod-123",
        "K8s.Node": "worker-node-1",
        "K8s.Workload": "payment-deployment"
    }
}
```

Entity processing

CloudWatch processes the entity information as follows:

- **KeyAttributes:**
  - Determines entity type based on required fields
  - For Service-type, extracts Service name and Environment
  - These become the primary identifiers for the entity
- **Attributes:**
  - Sets PlatformType based on included platform attributes
  - Includes all relevant platform-specific information
  - Maintains relationship context for the telemetry data

CloudWatch uses this entity information to establish relationships between different pieces of telemetry data, enabling enhanced observability and contextual analysis of your applications and infrastructure. For more information, see How to add related information to custom telemetry sent to CloudWatch .

> **Note**
>
> Entity information helps CloudWatch create a complete picture of your application's telemetry data and its relationships within your infrastructure.

Using the PutLogEvents API to send manually-created embedded metric format logs

You can send embedded metric format logs to CloudWatch Logs using the CloudWatch Logs PutLogEvents API. When calling PutLogEvents, you have the option to include the following HTTP header, which tells CloudWatch Logs the metrics should be extracted, but it's not required.

```
x-amzn-logs-format: json/emf
```

The following is a full example using the AWS SDK for Java 2.x:

```
package org.example.basicapp;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatchlogs.CloudWatchLogsClient;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeLogStreamsRequest;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeLogStreamsResponse;
import software.amazon.awssdk.services.cloudwatchlogs.model.InputLogEvent;
import software.amazon.awssdk.services.cloudwatchlogs.model.PutLogEventsRequest;

import java.util.Collections;

public class EmbeddedMetricsExample {
        public static void main(String[] args) {

                final String usage = "To run this example, supply a Region code (eg.
 us-east-1), log group, and stream name as command line arguments"
                                + "Ex: PutLogEvents <region-id> <log-group-name>
 <stream-name>";

                if (args.length != 3) {
                        System.out.println(usage);
                        System.exit(1);
                }

                String regionId = args[0];
                String logGroupName = args[1];
                String logStreamName = args[2];

                CloudWatchLogsClient logsClient =
 CloudWatchLogsClient.builder().region(Region.of(regionId)).build();

                // Build a JSON log using the EmbeddedMetricFormat.
                long timestamp = System.currentTimeMillis();
                String message = "{" +
                                "  \"_aws\": {" +
                                "    \"Timestamp\": " + timestamp  + "," +
                                "    \"CloudWatchMetrics\": [" +
                                "      {" +
                                "        \"Namespace\": \"MyApp\"," +
```

```
                                "       \"Dimensions\": [[\"Operation\"], [\"Operation
\", \"Cell\"]]," +
                                "       \"Metrics\": [{ \"Name\": \"ProcessingLatency
\", \"Unit\": \"Milliseconds\", \"StorageResolution\": 60 }]" +
                                "      }" +
                                "    ]" +
                                "  }," +
                                "  \"Operation\": \"Aggregator\"," +
                                "  \"Cell\": \"001\"," +
                                "  \"ProcessingLatency\": 100" +
                                "}";
                InputLogEvent inputLogEvent = InputLogEvent.builder()
                        .message(message)
                        .timestamp(timestamp)
                        .build();

                // Specify the request parameters.
                PutLogEventsRequest putLogEventsRequest = PutLogEventsRequest.builder()
                        .logEvents(Collections.singletonList(inputLogEvent))
                        .logGroupName(logGroupName)
                        .logStreamName(logStreamName)
                        .build();

                logsClient.putLogEvents(putLogEventsRequest);

                System.out.println("Successfully put CloudWatch log event");
        }

}
```

Note

With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the `AWS/Logs` namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Using the CloudWatch agent to send embedded metric format logs

This section describes how to install and use the CloudWatch agent. The first part of this section describes how to install the CloudWatch agent. The second part of this section describes how to

use the CloudWatch agent to send embedded metric format logs. If you want to use this method, you must install the CloudWatch agent for the AWS services you want to send embedded metric format logs from. Then you can begin sending the events. The CloudWatch agent must be version 1.230621.0 or later.

> **Note**
>
> You do not need to install the CloudWatch agent to send logs from Lambda functions. Lambda function timeouts are not handled automatically. This means that if your function times out before the metrics get flushed, then the metrics for that invocation will not be captured.

Installing the CloudWatch agent

Install the CloudWatch agent for each service which is to send embedded metric format logs.

Installing the CloudWatch agent on EC2

First, install the CloudWatch agent on the instance. For more information, see Installing the CloudWatch agent.

After you have installed the agent, configure the agent to listen on a UDP or TCP port for the embedded metric format logs. The following is an example of this configuration that listens on the default socket `tcp:25888`. For more information about agent configuration, see Manually create or edit the CloudWatch agent configuration file.

```
{
  "logs": {
    "metrics_collected": {
      "emf": { }
    }
  }
}
```

Installing the CloudWatch agent on Amazon ECS

The easiest way to deploy the CloudWatch agent on Amazon ECS is to run it as a sidecar, defining it in the same task definition as your application.

Create agent configuration file

Create your CloudWatch agent configuration file locally. In this example, the relative file path will be `amazon-cloudwatch-agent.json`.

For more information about agent configuration, see Manually create or edit the CloudWatch agent configuration file.

```
{
  "logs": {
    "metrics_collected": {
      "emf": { }
    }
  }
}
```

Push configuration to SSM Parameter Store

Enter the following command to push the CloudWatch agent configuration file to the AWS Systems Manager (SSM) Parameter Store.

```
aws ssm put-parameter \
    --name "cwagentconfig" \
    --type "String" \
    --value "`cat amazon-cloudwatch-agent.json`" \
    --region "{{region}}"
```

Configure the task definition

Configure your task definition to use the CloudWatch Agent and expose the TCP or UDP port. The sample task definition that you should use depends on your networking mode.

Notice that the `webapp` specifies the `AWS_EMF_AGENT_ENDPOINT` environment variable. This is used by the library and should point to the endpoint that the agent is listening on. Additionally, the `cwagent` specifies the `CW_CONFIG_CONTENT` as a "valueFrom" parameter that points to the SSM configuration that you created in the previous step.

This section contains one example for bridge mode and one example for host or awsvpc mode. For more examples of how you can configure the CloudWatch agent on Amazon ECS, see the Github samples repository

The following is an example for bridge mode. When bridge mode networking is enabled, the agent needs to be linked to your application using the `links` parameter and must be addressed using the container name.

```
{
  "containerDefinitions": [
          {
              "name": "webapp",
              "links": [ "cwagent" ],
              "image": "my-org/web-app:latest",
              "memory": 256,
              "cpu": 256,
              "environment": [{
                "name": "AWS_EMF_AGENT_ENDPOINT",
                "value": "tcp://cwagent:25888"
              }],
          },
          {
              "name": "cwagent",
              "mountPoints": [],
              "image": "public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest",
              "essential": false,
              "memory": 256,
              "cpu": 256,
              "portMappings": [{
                  "protocol": "tcp",
                  "containerPort": 25888
              }],
              "environment": [{
                "name": "CW_CONFIG_CONTENT",
                "valueFrom": "cwagentconfig"
              }],
          }
      ],
}
```

The following is an example for host mode or awsvpc mode. When running on these network modes, the agent can be addressed over `localhost`.

```
{
  "containerDefinitions": [
          {
```

```
            "name": "webapp",
            "image": "my-org/web-app:latest",
            "memory": 256,
            "cpu": 256,
            "environment": [{
              "name": "AWS_EMF_AGENT_ENDPOINT",
              "value": "tcp://127.0.0.1:25888"
            }],
        },
        {
            "name": "cwagent",
            "mountPoints": [],
            "image": "public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest",
            "essential": false,
            "memory": 256,
            "cpu": 256,
            "portMappings": [{
                "protocol": "tcp",
                "containerPort": 25888
            }],
            "environment": [{
              "name": "CW_CONFIG_CONTENT",
              "valueFrom": "cwagentconfig"
            }],
        }
    ],
}
```

Note

In awsvpc mode, you must either give a public IP address to the VPC (Fargate only), set up a NAT gateway, or set up a CloudWatch Logs VPC endpoint. For more information about setting up a NAT, see NAT Gateways. For more information about setting up a CloudWatch Logs VPC endpoint, see Using CloudWatch Logs with Interface VPC Endpoints.
The following is an example of how to assign a public IP address to a task that uses the Fargate launch type.

```
aws ecs run-task \
--cluster {{cluster-name}} \
--task-definition cwagent-fargate \
--region {{region}} \
--launch-type FARGATE \
```

```
--network-configuration
 "awsvpcConfiguration={subnets=[{{subnetId}}],securityGroups=[{{sgId}}],assignPublicIp=ENA
```

Required permissions

Make sure the IAM role executing your tasks has permission to read from the SSM Parameter Store. You can add this permission by attaching the **AmazonSSMReadOnlyAccess** policy. To do so, enter the following command.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonSSMReadOnlyAccess
 \
--role-name CWAgentECSExecutionRole
```

Installing the CloudWatch agent on Amazon EKS

Parts of this process can be skipped if you have already installed CloudWatch Container Insights on this cluster.

Permissions

If you have not already installed Container Insights, then first make sure that your Amazon EKS nodes have the appropriate IAM permissions. They should have the **CloudWatchAgentServerPolicy** attached. For more information, see Setup guide (AWS CLI).

Create ConfigMap

Create a ConfigMap for the agent. The ConfigMap also tells the agent to listen on a TCP or UDP port. Use the following ConfigMap.

```
# cwagent-emf-configmap.yaml
apiVersion: v1
data:
  # Any changes here must not break the JSON format
  cwagentconfig.json: |
    {
      "agent": {
        "omit_hostname": true
      },
      "logs": {
        "metrics_collected": {
          "emf": { }
```

```
        }
      }
    }
kind: ConfigMap
metadata:
  name: cwagentemfconfig
  namespace: default
```

If you have already installed Container Insights, add the following `"emf": { }` line to your existing ConfigMap.

Apply the ConfigMap

Enter the following command to apply the ConfigMap.

```
kubectl apply -f cwagent-emf-configmap.yaml
```

Deploy the agent

To deploy the CloudWatch agent as a sidecar, add the agent to your pod definition, as in the following example.

```
apiVersion: v1
kind: Pod
metadata:
  name: myapp
  namespace: default
spec:
  containers:
    # Your container definitions go here
    - name: web-app
      image: my-org/web-app:latest
    # CloudWatch Agent configuration
    - name: cloudwatch-agent
      image: public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest
      imagePullPolicy: Always
      resources:
        limits:
          cpu: 200m
          memory: 100Mi
        requests:
          cpu: 200m
          memory: 100Mi
```

```
      volumeMounts:
        - name: cwagentconfig
          mountPath: /etc/cwagentconfig
      ports:
  # this should match the port configured in the ConfigMap
        - protocol: TCP
          hostPort: 25888
          containerPort: 25888
  volumes:
    - name: cwagentconfig
      configMap:
        name: cwagentemfconfig
```

Using the CloudWatch agent to send embedded metric format logs

When you have the CloudWatch agent installed and running, you can send the embedded metric format logs over TCP or UDP. There are two requirements when sending the logs over the agent:

- The logs must contain a `LogGroupName` key that tells the agent which log group to use.
- Each log event must be on a single line. In other words, a log event cannot contain the newline (\n) character.

The log events must also follow the embedded metric format specification. For more information, see Specification: Embedded metric format.

If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

The following is an example of sending log events manually from a Linux bash shell. You can instead use the UDP socket interfaces provided by your programming language of choice.

```
echo '{"_aws":{"Timestamp":1574109732004,"LogGroupName":"Foo","CloudWatchMetrics":
[{"Namespace":"MyApp","Dimensions":[["Operation"]],"Metrics":
[{"Name":"ProcessingLatency","Unit":"Milliseconds","StorageResolution":60}]}]},"Operation":"Agg
 \
> /dev/udp/0.0.0.0/25888
```

Note

With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the `AWS/Logs` namespace of your account. These can be

used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Using the embedded metric format with AWS Distro for OpenTelemetry

OpenTelemetry is an open-source initiative that removes boundaries and restrictions between vendor-specific formats for tracing, logs, and metrics by offering a single set of specifications and APIs. For more information, see OpenTelemetry. You can use the embedded metric format as a part of the OpenTelemetry project. Using the embedded metric format with OpenTelemetry requires two components: an OpenTelemetry-compliant data source and the AWS Distro for OpenTelemetry Collector enabled for use with CloudWatch embedded metric format logs.

We have preconfigured redistributions of the OpenTelemetry components, which AWS maintains, to make onboarding as easy as possible. For more information about using OpenTelemetry with the embedded metric format, in addition to other AWS services, see AWS Distro for OpenTelemetry. For additional information regarding language support and usage, see AWS Observability on Github.

Viewing your metrics and logs in the console

After you generate embedded metric format logs that extract metrics, you can use the CloudWatch console to view the metrics. Embedded metrics have the dimensions that you specified when you generated the logs. Also, the embedded metrics that you generated using the client libraries have the following default dimensions:

- ServiceType
- ServiceName
- LogGroup

This section describes how to view these metrics in the CloudWatch console and query your extracted metrics using CloudWatch Logs Insights.

To view metrics that were generated from embedded metric format logs

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.

3. Select a namespace that you specified for your embedded metrics when you generated them. If you used the client libraries to generate the metrics and did not specify a namespace, then select **aws-embedded-metrics**. This is the default namespace for embedded metrics generated using the client libraries.
4. Select a metric dimension (for example, **ServiceName**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To sort the table, use the column heading.

    b. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

    c. To filter by resource, choose the resource ID and then choose **Add to search**.

    d. To filter by metric, choose the metric name and then choose **Add to search**.

Querying logs using CloudWatch Logs Insights

You can query the detailed log events associated with the extracted metrics by using CloudWatch Logs Insights to provide deep insights into the root causes of operational events. One of the benefits of extracting metrics from your logs is that you can filter your logs later by the unique metric (metric name plus unique dimension set) and metric values, to get context on the events that contributed to the aggregated metric value

For example, to get an impacted request id or x-ray trace id, you could run the following query in CloudWatch Logs Insights.

```
filter Latency > 1000 and Operation = "Aggregator"
| fields RequestId, TraceId
```

You can also perform query-time aggregation on high-cardinality keys, such as finding the customers impacted by an event. The following example illustrates this.

```
filter Latency > 1000 and Operation = "Aggregator"
| stats count() by CustomerId
```

For more information, see Analyzing Log Data with CloudWatch Logs Insights

Setting alarms on metrics created with the embedded metric format

In general, creating alarms on metrics generated by the embedded metric format follows the same pattern as creating alarms on any other metrics. For more information, see Using Amazon CloudWatch alarms. Embedded metric format metric generation depends on your log publishing flow because CloudWatch Logs needs to process logs so they can be transformed into metrics. It's important to publish logs in a timely manner, so that metric datapoints are created within the period of time that alarms are evaluated.

If you plan on using the embedded metric format to send high-resolution metrics and create alarms on these metrics, we recommended that you flush logs to CloudWatch Logs at an interval of 5 seconds or less to avoid introducing an additional delay, which can cause alarming on partial or missing data. If you are using the CloudWatch agent, you can adjust the flush interval by setting the `force_flush_interval` parameter in the CloudWatch agent configuration file. This value defaults to 5 seconds. If you are using Lambda on other platforms where you can't control the log flush interval, consider using "M out of N" alarms to control the number of datapoints used to alarm. For more information, see Alarm evaluation.

CloudWatch pipelines

CloudWatch pipelines is a fully managed data collector that ingests, transforms, and routes telemetry data—including logs and metrics—from AWS services, third-party applications, and custom sources to CloudWatch. Built-in processors let you enrich, filter, and standardize logs into formats like OCSF—without managing infrastructure or third-party tools. For metrics, CloudWatch pipelines processes and enriches OpenTelemetry (OTel) metrics inline during ingestion into CloudWatch.

CloudWatch pipelines is fully integrated with the logs management experience, enabling you to consistently process and enrich log data across related log groups through data-source and data-type specification. This unlocks use cases such as:

- **Automatic log categorization** – Logs processed through pipelines are automatically tagged with data source information, enabling service-centric discovery and querying across your infrastructure
- **Expanding third-party support** – Aggregate and normalize logs from a growing library of third-party sources for unified analytics and compliance

For metrics, CloudWatch pipelines enables the following use cases:

- **Enrichment** – Add business context such as team, cost center, or environment to metrics from sources you cannot modify
- **Cost optimization** – Strip high-cardinality attributes to reduce storage costs
- **Standardization** – Rename metrics and attributes to enforce naming conventions

Output from pipelines is fully compatible with CloudWatch Logs features including Logs Insights queries, Logs Anomaly Detection, and Live Tail. CloudWatch pipelines works with both Standard and Infrequent Access log classes and is backwards compatible with Log Transformers.

For metrics pipelines, processed metrics are fully queryable through PromQL in Query Studio and compatible with CloudWatch Alarms and Anomaly Detection.

To get started with CloudWatch pipelines, visit pipelines within the CloudWatch ingestion page in the CloudWatch console.

> **Note**
>
> Be aware of the following limits that apply to CloudWatch pipelines
>
> - Logs pipelines per account: 330
> - Up to 300 pipelines for collecting data from CloudWatch Logs
> - Up to 30 pipelines for collecting data from other sources
> - Metrics pipelines per account: up to 300
> - Up to 20 processors per pipeline (logs and metrics)
> - Metrics pipelines supported ingestion path: OTLP only

Pipeline components

Each pipeline consists of the following components:

- **Source** – Defines where data originates from (Amazon S3 buckets, CloudWatch Logs, CloudWatch Metrics (OTel), third-party integration). Each pipeline must have exactly one source. Metrics pipelines process OTel metrics on the OTLP ingestion path.

- **Processors** (optional) – Transform, parse, and enrich telemetry data as it flows through the pipeline. Processors are applied sequentially in the order they are defined. Metrics pipelines support a distinct set of processors optimized for OTel metric attributes.
- **Sink** – Defines the destination where processed data is sent. Supported sink types include `cloudwatch_logs` and `cloudwatch_metrics`. A logs pipeline can use up to 10 ordered `cloudwatch_logs` sinks for conditional routing. A metrics pipeline must have exactly one sink.
- **Extensions** (optional) – Provide additional functionality such as AWS Secrets Manager integration for credential management.

Throughout the entire pipeline, your data remains protected with transport layer encryption so that your data meets security and compliance requirements.

> **Note**
>
> Pipeline definitions are not encrypted with customer-provided keys and must never include sensitive data, such as passwords, API keys, or personally identifiable information (PII).

> **Note**
>
> Adding processors leads to mutation of the log events and original (raw) logs are not retained.

Pricing

CloudWatch pipelines is included with CloudWatch Logs at no additional cost. Standard log ingestion rates based on log class (vended or custom) and storage class (Standard or Infrequent Access) still apply. Metering occurs at time of first ingestion into CloudWatch. CloudWatch Logs sources are metered before pipeline processing. Third-party and S3 bucket sources are classified as Custom logs and metered after processing. For pricing details, see CloudWatch Pricing.

For metrics pipelines, standard CloudWatch OTel metrics ingestion and storage charges apply. There is no additional charge for pipeline processing.

Region availability

CloudWatch pipelines is available in the following AWS Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Asia Pacific (Malaysia)
- Asia Pacific (Melbourne)
- Asia Pacific (Mumbai)
- Asia Pacific (New Zealand)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Taipei)
- Asia Pacific (Thailand)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Milan)
- Europe (Paris)
- Europe (Spain)
- Europe (Stockholm)

- Europe (Zurich)
- AWS European Sovereign Cloud (Germany)
- Israel (Tel Aviv)
- Mexico (Central)
- South America (São Paulo)

> **Note**
>
> Third-party data source collection is available in regions where OpenSearch Ingestion has API endpoints.

For more details, see Amazon CloudWatch endpoints and quotas in the *AWS General Reference*.

Creating pipelines

CloudWatch pipelines supports creating pipelines for both logs and metrics data. The following sections describe how to create each type of pipeline.

Creating a logs pipeline

The pipeline configuration wizard guides you through creating your logs data pipeline.

1. Under **General settings**, provide the data source details including source name and type. You can also specify pipeline tags and the name of your pipeline.
2. Under **Destination**, specify the destination details. For logs pipelines, CloudWatch Logs is the only supported destination. For metrics pipelines, CloudWatch Metrics is the only supported destination.
3. Under **Processor**, add the desired processors and parsers. A parser is a required first step for certain data types. You can perform custom parsing using processors like Grok or CSV. You can use the lookup processor to enrich log events with data from an Amazon CloudWatch Logs lookup table. Processors that are not supported by the data type are disabled.

   To configure processors using natural language, enable the **AI-assisted** toggle. Enter a description of the log transformations you need, and CloudWatch pipelines generates the processor configuration automatically. For AWS vended logs, a sample log event is also

generated so you can verify the output before deploying. You can review and edit the generated configuration before creating the pipeline.

> **Important**
>
> To use AI-assisted processor configuration, you must have the `logs:GeneratePipeline` IAM permission. For more information, see the section called "AI-assisted processor configuration permissions".

You can also add conditional processing rules to supported processors using the `when` parameter. Conditional processing lets you control which log entries a processor acts on. For the expression syntax and supported processors, see the section called "Expression syntax for conditional processing".

To preserve unmodified copies of your log data for audit or compliance purposes, enable the **Keep original log** toggle. When enabled, CloudWatch pipelines automatically stores a copy of each raw log event before any transformation takes place in the `@original_message` system field of the event. This ensures that original data is always available for audits or investigations, even after processors modify the log events. The **Keep original log** toggle is only available for pipelines with a CloudWatch vended log source.

4. Under **Review and create**, review the pipeline configuration. If you're satisfied with the configuration, choose **Create pipeline** to start deployment and creation of pipeline resources. Pipeline creation completion takes up to 5 minutes depending on the source type. Upon completion, you'll be taken to the Pipelines tab in the Ingestion Console.

> **Important**
>
> Pipeline processor configurations are logged in AWS CloudTrail events for auditing and compliance purposes. To protect sensitive information, do not include passwords, API keys, or other sensitive information in processor configurations.

Creating a metrics pipeline

You can create a metrics pipeline by using the CloudWatch console or the AWS CLI. With a metrics pipeline, you can process CloudWatch metrics data, apply transformations, and forward the processed metrics to CloudWatch.

To create a metrics pipeline (console)

Use the following procedure to create a metrics pipeline in the CloudWatch console.

1. Open the CloudWatch console and in the navigation pane, choose **Ingestion**, **Pipelines**.
2. Choose **Create pipeline**.
3. For the source type, select **CloudWatch Metrics (OTel)**.
4. Configure the selection criteria to specify which metrics the pipeline processes. Selection criteria use OTel attribute paths such as `resource.attributes`, `metric.name`, and `datapoint.attributes`. All criteria use AND semantics (all must match).
5. Under **Processor**, add up to 20 processors to transform your metrics data.
6. Under **Review and create**, review the pipeline configuration and choose **Create pipeline**.

To create a metrics pipeline (AWS CLI)

Use the `create-telemetry-pipeline` command to create a metrics pipeline from the AWS CLI.

```
aws observabilityadmin create-telemetry-pipeline \
    --pipeline-configuration-body file://config.yaml
```

The following example shows a YAML configuration file that defines a metrics pipeline with a source, processor, and sink.

```
pipeline:
  source:
    cloudwatch_metrics:
      format: otlp
      selection_criteria:
        - match_all:
            - 'resource.attributes["service.name"] == "payment-service"'
            - 'metric.name == "http.server.request.duration"'
  processor:
```

```
    - add_attributes:
        attributes:
          - key: resource.attributes["team"]
            value: "platform-engineering"
  sink:
    - cloudwatch_metrics: {}
```

When the pipeline is created, it returns an ARN in the following format:

```
arn:aws:observabilityadmin:region:accountId:telemetry-pipeline/pipelineID
```

> **Note**
>
> CloudWatch Metrics is the only supported destination for metrics pipelines.

Supported API operations

The following table lists the API operations that you can use to manage metrics pipelines.

Operation	Description
`CreateTelemetryPipeline`	Creates a new metrics pipeline.
`GetTelemetryPipeline`	Retrieves details about a specific metrics pipeline.
`ListTelemetryPipelines`	Lists all metrics pipelines in your account.
`DeleteTelemetryPipeline`	Deletes a metrics pipeline.
`ValidateTelemetryPipelineConfiguration`	Validates a pipeline configuration before creation.
`UpdateTelemetryPipeline`	Updates an existing metrics pipeline configuration.

Managing pipelines

After creating pipelines, you can monitor their performance and manage their configuration through the Pipelines tab.

Pipeline status monitoring

Each pipeline displays real-time status information including:

- Pipeline status: Active, Creating, Updating, Deleting, Create Failed, Update Failed, or Delete Failed.
- Data throughput metrics
- Error rates and failure details

Pipeline operations

You can perform the following operations on existing pipelines:

- **View details** – Review pipeline configuration and status
- **Edit pipeline** – Edit pipeline configuration including processors, parsing, and source selection criteria
- **Delete pipeline** – Remove pipelines that are no longer needed

> **Note**
>
> To programmatically manage metrics pipelines, use the Observability Admin APIs including `CreateTelemetryPipeline`, `UpdateTelemetryPipeline`, and `DeleteTelemetryPipeline`.

Supported data sources for CloudWatch

CloudWatch collects and processes telemetry data from a wide range of sources to provide unified observability and security insights. Data sources fall into four categories: AWS native services, third-party platforms, custom sources, and CloudWatch Metrics (OTel).

You can automate the enablement of AWS data sources using telemetry configuration. For more information, see Telemetry discovery and enablement.

AWS service data sources

CloudWatch provides native integration with 90+ AWS services for automatic data collection. When an AWS service source is selected, CloudWatch pipelines intercepts logs ingested into CloudWatch Logs for processing. To get started, enable logging for the supported AWS services using the service's console, then select the data source and type in the CloudWatch pipelines creation wizard.

The following table highlights key AWS service data sources. For the complete list of 90+ supported services, see Supported AWS services for data sources.

AWS service	Data type	Description
Amazon Amazon VPC	Flow Logs	Network traffic metadata for Amazon VPCs, subnets, and network interfaces
Amazon Amazon EKS	Control Plane Logs	Kubernetes API server, audit, authenticator, controller manager, and scheduler logs
AWS WAF	Web ACL Logs	Web request inspection logs including rule match details and actions taken
Amazon Route 53	Resolver Query Logs	DNS query logs for Amazon VPC resources routed through Route 53 Resolver
CloudTrail	Management and Data Events	API activity and resource-level operations across AWS services
Amazon Amazon EC2	Detailed Metrics	Instance-level performance metrics at 1-minute granularity
AWS Security Hub	CSPM Findings	Cloud security posture managemen t findings from AWS and third-party providers

AWS service	Data type	Description
Amazon Bedrock AgentCore	Runtime, Browser, CodeInterpreter, Gateway, Memory	Agent runtime execution, browser interaction, code execution, gateway, and memory operation logs
Amazon CloudFront	Distribution Logs	CDN access logs for content delivery distributions
Network Load Balancer	Access Logs	Network Load Balancer connection and TLS negotiation logs
Amazon RDS	Aurora MySQL and Aurora PostgreSQL Logs	Audit, error, general, slow query, IAM DB authentication error, proxy, and enhanced monitoring logs

For more information about CloudWatch Logs data sources, see Data source discovery and management.

Third-party data sources

CloudWatch extends monitoring capabilities beyond AWS with direct integrations for 38 third-party security, identity, and endpoint platforms. These integrations consolidate security events, audit logs, and telemetry data from external sources into CloudWatch Logs for unified analysis.

The following table lists the supported direct third-party integrations:

Source	Integration pattern	Category
Akamai DataStream 2	S3 Delivery	CDN and edge security
Check Point NGFW	S3 Delivery	Network security
Cisco Duo	API	Identity and access management
Cisco Meraki	API	Network security
Cisco Umbrella	S3 Delivery	DNS and network security

Source	Integration pattern	Category
CrowdStrike Falcon	S3 Delivery	Endpoint security
Drupal Core	API	Content management
Entrust IDaaS	API	Identity and access management
F5 BIG-IP	S3 Delivery	Network security
GitHub	API	Source code and audit logs
GitLab	API	DevSecOps and source code
HashiCorp Vault	S3 Delivery	Secrets management
Jamf Protect	S3 Delivery	Endpoint security
Microsoft Entra ID	API	Identity and access management
Microsoft Office 365	API	Productivity and audit logs
Microsoft Windows Event Logs	API	Operating system events
Netskope	API	Network security and CASB
Okta Auth0	API	Identity and access management
Okta SSO	API	Identity and access management
OneLogin Identity	API	Identity and access management
Palo Alto Networks NGFW	API	Network security
Palo Alto Prisma Cloud	API	Cloud security
PingIdentity PingAccess	S3 Delivery	Access management
PingIdentity PingFederate	S3 Delivery	Identity federation
PingIdentity PingOne	API	Identity and access management

Source	Integration pattern	Category
Proofpoint TAP	API	Email security
Slack Audit Log	API	Collaboration and audit logs
SentinelOne	S3 Delivery	Endpoint security
ServiceNow CMDB	API	IT service management
Tanium Endpoint Management	S3 Delivery	Endpoint security and management
Tenable Vulnerability Management	API	Vulnerability management
Wazuh Platform	API	Security monitoring and threat detection
Box	API	Content management and file sharing
Jamf Pro	API	Device management (Apple)
Broadcom Carbon Black	S3 Delivery	Endpoint detection and response
Wiz CNAPP	API	Cloud security
Zeek	S3 Delivery	Network security monitoring
Zscaler ZIA/ZPA	S3 Delivery	Network security

For detailed setup procedures, prerequisites, and configuration steps for each integration, see Third-party data sources integration.

Additional third-party sources through Security Hub CSPM

Beyond the 34 direct integrations, 49+ additional third-party sources are available through AWS Security Hub CSPM integration. Security Hub CSPM partner providers that send

findings to Security Hub are automatically available as data sources. For the full list of supported partners, see the Security Hub CSPM partner providers documentation.

Additional third-party sources through Security Hub

AWS Security Hub (distinct from Security Hub CSPM) provides its own set of third-party integrations. These integrations that send findings to Security Hub are automatically available as data sources. For the full list of supported integrations, see the Security Hub third-party integrations documentation.

Custom data sources

For logs that are not covered by AWS service or third-party integrations, CloudWatch pipelines can process custom logs stored in CloudWatch Logs or Amazon S3 buckets. Custom sources accommodate unique organizational requirements:

- **Syslog data** – Messages ingested through the CloudWatch Logs Syslog service
- **Application-specific logs** – Custom application telemetry from Amazon EC2 instances with specialized logging formats
- **File-based ingestion** – Amazon S3-based log files from legacy systems or batch processing workflows
- **Serverless integration** – Lambda function logs and custom serverless application telemetry

For more details, see Custom log data from CloudWatch Logs or an Amazon S3 bucket.

CloudWatch Metrics (OTel) source

The CloudWatch Metrics (OTel) source processes OpenTelemetry (OTel) metrics on the OTLP ingestion path based on selection criteria. This source enables you to transform metrics data through CloudWatch pipelines before the metrics are persisted in CloudWatch Metrics.

The following metric types are supported:

- **Custom OTel metrics** – Metrics that your applications emit through OpenTelemetry instrumentation and send to the OTLP endpoint
- **AWS vended OTel metrics** – Metrics that AWS services emit through OTLP

> **Note**
>
> The CloudWatch Metrics (OTel) source only supports metrics ingested through the OTLP endpoint. Metrics sent through other ingestion paths, such as the `PutMetricData` API, are not processed by this source.

You define which metrics to process by configuring metrics pipeline selection criteria. Selection criteria let you target specific metrics based on OTel attributes such as resource attributes, metric name, and datapoint attributes. For more information, see the section called “CloudWatch Metrics (OTel)”.

For information about sending OTel metrics to CloudWatch, see Using OpenTelemetry with CloudWatch.

Topics

- CloudWatch Metrics (OTel)
- Third-party data sources integration
- Custom log data from CloudWatch Logs or an Amazon S3 bucket
- AWS service logs from CloudWatch Logs

CloudWatch Metrics (OTel)

Selection criteria determine which OTel metrics enter a pipeline for processing. Each criterion is an expression of the form `<path> == "<value>"` that matches against a specific attribute of the incoming metric. At least one selection criterion is required.

Criteria are grouped inside a `match_all` block with AND semantics — a metric must match every expression in the group to enter the pipeline.

Supported paths

The following OTTL paths are supported in selection criteria:

Path	Description
`resource.attributes["key"]`	Resource-level attribute

Path	Description
`instrumentation_scope.name`	Instrumentation scope name
`instrumentation_scope.version`	Instrumentation scope version
`instrumentation_scope.attributes["key"]`	Instrumentation scope attribute
`metric.name`	Metric name
`datapoint.attributes["key"]`	Datapoint-level attribute
`attributes["key"]`	Short form for `datapoint.attributes["key"]`

Configuration

Selection criteria are defined in the `source` section of the pipeline configuration:

```
pipeline:
  source:
    cloudwatch_metrics:
      format: otlp
      selection_criteria:
        - match_all:
            - 'resource.attributes["service.name"] == "my-service"'
            - 'metric.name == "http.server.request.duration"'
  processor:
    - add_attributes:
        attributes:
          - key: resource.attributes["team"]
            value: "platform-engineering"
  sink:
    - cloudwatch_metrics: {}
```

The following example uses all supported path types:

```
pipeline:
  source:
    cloudwatch_metrics:
```

```
      format: otlp
      selection_criteria:
        - match_all:
            - 'resource.attributes["service.name"] == "my-service"'
            - 'instrumentation_scope.name == "my-scope"'
            - 'instrumentation_scope.version == "1.0.0"'
            - 'instrumentation_scope.attributes["library"] == "otel-java"'
            - 'metric.name == "http.server.request.duration"'
            - 'datapoint.attributes["status_code"] == "200"'
            - 'attributes["environment"] == "production"'
  processor:
    - add_attributes:
        attributes:
          - key: resource.attributes["team"]
            value: "observability"
  sink:
    - cloudwatch_metrics: {}
```

Verifying with PromQL

CloudWatch maps OTLP attribute scopes to PromQL labels using the @ prefix convention. Use this mapping to verify that your pipeline is processing metrics as expected in Query Studio:

Pipeline OTTL path	PromQL label prefix	Example
`resource.attributes["key"]`	`@resource.`	`@resource.service.name`
`instrumentation_scope.name`	`@instrumentation.@name`	`@instrumentation.@name`
`instrumentation_scope.attributes["key"]`	`@instrumentation.`	`@instrumentation.library`
`datapoint.attributes["key"]` / `attributes["key"]`	`@datapoint.` or bare	`status_code`

For example, if your pipeline adds `resource.attributes["team"]` with value `"platform-engineering"`, you can confirm it was applied:

```
{"CPUUtilization", "@resource.team"="platform-engineering"}
```

Requirements and limitations

Single `match_all` group

Each pipeline supports exactly one `match_all` group in `selection_criteria`. You cannot define multiple `match_all` groups in a single pipeline.

Minimum criteria

At least one expression is required in the `match_all` group.

Maximum criteria

A `match_all` group can contain at most 20 expressions.

AND semantics

All expressions in the `match_all` group must match for a metric to enter the pipeline.

Exact string matching

Values must be static strings. Wildcards, regular expressions, and partial matches are not supported. Each expression must use the == operator.

No overlapping criteria across pipelines

Each metric datapoint must match at most one pipeline. If a datapoint matches both new and existing pipeline criteria, pipeline creation fails. To prevent overlap, include at least one attribute path with distinct values in each pipeline's selection criteria.

For example, the following two selection criteria overlap because Pipeline A selects all metrics from `payment-service`, which includes the specific metric that Pipeline B targets:

```
# Pipeline A — selects ALL metrics from payment-service
selection_criteria:
  - match_all:
      - 'resource.attributes["service.name"] == "payment-service"'

# Pipeline B — FAILS: a datapoint with service.name="payment-service"
# and metric.name="http.server.request.duration" matches both pipelines
selection_criteria:
```

```
  - match_all:
      - 'metric.name == "http.server.request.duration"'
```

Third-party data sources integration

Integrating CloudWatch pipelines with your third-party data source let you connect external security tools, identity providers, and monitoring platforms to CloudWatch pipelines for centralized data analysis. This integration consolidates security events, audit logs, and telemetry data from multiple sources.

> **Note**
>
> Data collected from third-party sources is mutated to adhere to the required schema when it is collected by CloudWatch pipelines. The original data source is not retained by CloudWatch.

Third-party data can be collected using two methods:

1. **Direct API Integration** – Some sources offer Event Stream APIs where you only need to provide API credentials to configure the connector
2. **S3 Bucket Integration** – Data from sources can be ingested into a customer-managed S3 bucket for CloudWatch pipelines to collect

The following table identified the integrations methods used by the supported third-party data platforms:

Source	Integration pattern	Requires S3 bucket	Requires SQS queue	Uses Secrets Manager extension	Required IAM policies
Akamai DataStream 2	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Check Point NGFW	S3 Delivery	Yes	Yes	No	Source-specific IAM policies

Source	Integration pattern	Requires S3 bucket	Requires SQS queue	Uses Secrets Manager extension	Required IAM policies
Cisco Duo	API	No	No	Yes	API caller permissions
Cisco Meraki	API	No	No	Yes	API caller permissions
Cisco Umbrella	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
CrowdStrike Falcon	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Drupal Core	API	No	No	Yes	API caller permissions
Entrust IDaaS	API	No	No	Yes	API caller permissions
F5 BIG-IP	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
GitHub	API	No	No	Yes (optional)	API caller permissions
GitLab	API	No	No	Yes	API caller permissions
HashiCorp Vault	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Jamf Protect	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Microsoft Entra ID	API	No	No	Yes	API caller permissions

Source	Integration pattern	Requires S3 bucket	Requires SQS queue	Uses Secrets Manager extension	Required IAM policies
Microsoft Office 365	API	No	No	Yes	API caller permissions
Microsoft Windows Event Logs	API	No	No	Yes	API caller permissions
Netskope	API	No	No	Yes	API caller permissions
Okta Auth0	API	No	No	Yes	API caller permissions
Okta SSO	API	No	No	Yes	API caller permissions
OneLogin Identity	API	No	No	Yes	API caller permissions
Palo Alto Networks NGFW	API	No	No	Yes	API caller permissions
Palo Alto Prisma Cloud	API	No	No	Yes	API caller permissions
PingIdentity PingAccess	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
PingIdentity PingFederate	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
PingIdentity PingOne	API	No	No	Yes	API caller permissions

Source	Integration pattern	Requires S3 bucket	Requires SQS queue	Uses Secrets Manager extension	Required IAM policies
Proofpoint TAP	API	No	No	Yes	API caller permissions
Slack Audit Log	API	No	No	Yes	API caller permissions
SentinelOne	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
ServiceNow CMDB	API	No	No	Yes	API caller permissions
Tanium Endpoint Management	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Tenable Vulnerability Management	API	No	No	Yes	API caller permissions
Wiz CNAPP	API	No	No	Yes	API caller permissions
Zeek	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Zscaler ZIA/ZPA	S3 Delivery	Yes	Yes	No	Source-specific IAM policies

Third-party integration sent through Security Hub CSPM is also supported. For comprehensive information about Security Hub's third-party integrations, including supported partners and integration configurations with "Sends findings" direction, refer to the Security Hub Third-Party Integration documentation.

AWS Security Hub (distinct from Security Hub CSPM) also supports third-party integrations as data sources. For the full list of supported integrations, refer to the Security Hub third-party integrations documentation.

Data transformation and standardization

Third-party integrations support data transformation to standardized formats for consistent analysis:

- **Open Cybersecurity Schema Framework (OCSF)** – Converts security events from different vendors into a common schema for unified threat detection and analysis. Because OCSF is only for certain event classes, not all raw events are mapped to OCSF.
- **Custom transformations** – Pipeline processors that normalize data formats, enrich events with additional context, and filter relevant information.
- **Field mapping** – Automatic mapping of vendor-specific fields to standardized field names for consistent querying and analysis.

> **Note**
>
> Storing telemetry data from third-party sources in OCSF is an optional feature that might not be available for all data sources.

Log group

Third-party data is ingested into a CloudWatch log group. If you are using the AWS Management Console to configure CloudWatch pipelines if the log group does not exist, it is created automatically through the wizard process.

Authentication and security

Third-party integrations use secure authentication methods to protect data in transit:

- **OAuth 2.0 and application registration** – Secure token-based authentication for cloud platforms like Microsoft and Okta.
- **API keys and certificates** – Encrypted authentication credentials for direct API access.
- **IAM roles and policies** – AWS Identity and Access Management integration for secure S3 bucket access and cross-account data sharing.

> **Note**
>
> Data collected from third-party sources is mutated to adhere to the required schema when it is collected by CloudWatch pipelines. The original data source is not retained by CloudWatch.

Each integration requires platform-specific configuration to establish secure data delivery to your AWS environment.

The following sections provide detailed setup procedures for supported third-party integrations. Each integration includes prerequisites, configuration steps, and validation procedures to make sure proper data flow.

Akamai DataStream 2 integration configuration

Akamai DataStream 2 is a near real-time log streaming service that delivers detailed performance and security metrics from the Akamai edge platform to various third-party destinations. It enables proactive monitoring, troubleshooting, and, through its support for DataStream 2.1, includes Edge DNS, Global Traffic Management (GTM), and EdgeWorkers log data.

Topics

- Source configuration for Akamai DataStream 2
- CloudWatch pipelines configuration for Akamai DataStream 2

Source configuration for Akamai DataStream 2

Integrating with Akamai DataStream 2

To integrate Akamai DataStream 2 Data Replicator with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your Akamai DataStream 2 source by configuring Amazon S3 and Amazon SQS to receive data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Log forwarding setup

Akamai DataStream 2 supports real-time log delivery through DataStream 2 to forward logs to Amazon S3.

Instructions to setup Amazon S3 and Amazon SQS

Configuring Akamai DataStream 2 to send logs to an Amazon S3 bucket involves several steps. These steps focus on setting up the Amazon S3 bucket, Amazon SQS queue, and IAM roles, and then configuring the CloudWatch pipeline.

- Create an Amazon S3 bucket that stores Akamai logs and create separate folders for each log type (for example, DNS, CDN, EdgeWorkers). Create an IAM user and grant S3 write permission, then create an access key and secret key for this account.
- Make sure the Akamai DataStream 2 log exporter is configured to send logs to Amazon S3. DataStream 2 uploads logs to Amazon S3 over TLS, so you need to enable server-side encryption for Amazon S3. Refer to the Akamai S3 streaming setup guide for detailed instructions.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Akamai DataStream 2, choose Akamai DataStream 2 as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Akamai DataStream 2 events that map to DNS Activity (4003), HTTP Activity (4002), and Base Event (0). Any events that don't conform to the mentioned OCSF schema are passed through.

DNS Activity (4003) contains the following event logs:

- DNS Logs
- GTM Logs

HTTP Activity (4002) contains the following event logs:

- CDN Logs

Base Event (0) contains the following event logs:

- EdgeWorkers Logs

> **Note**
>
> DNS and Global Traffic Management (GTM) logs share the same format. No separate OCSF mappings are required.

Events that do not match any OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

CloudWatch pipelines configuration for Akamai DataStream 2

The Akamai DataStream 2 setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Akamai DataStream 2 source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "akamai_datastream_2"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "akamai_datastream_2".

`aws.region` (required)

The AWS Region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

Box integration configuration

Box is a cloud content management and collaboration platform that enables secure file sharing, storage, and workflow automation across organizations. With CloudWatch Pipelines, you can use the Box REST API to retrieve enterprise events, user inventories, group structures, group memberships, and group collaborations from your Box enterprise. The pipeline authenticates using OAuth2 Client Credentials Grant and polls the API at configurable intervals to collect security and administrative data for monitoring and analysis.

Topics

- Source configuration for Box
- CloudWatch pipelines configuration for Box

Source configuration for Box

Prerequisites

Before you begin, make sure you have the following:

- A Box Enterprise account with **admin** privileges. **Two-factor authentication (2FA)** must be enabled.
- A Box App configured with OAuth2 **Client Credentials Grant** (Server Authentication) in the Box Developer Console.
- A Box App authorized for authentication in the Box Admin Console
- An AWS account with permissions to create and manage CloudWatch Pipelines.
- An AWS account with required permissions to create, retrieve, and update secrets in AWS Secrets Manager.
- An AWS account with permissions to create and manage CloudWatch Logs log groups.

Integrating with Box

To integrate Box with CloudWatch Pipelines, complete the following high-level steps:

- Create and configure a Custom App with Client Credentials Grant in the Box Developer Console.
- Verify 2FA and authorize the Custom App.
- Note the Client ID, Client Secret, and Enterprise ID.
- Store the client credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Box as the data source.
- Verify data is flowing into the configured CloudWatch Logs log group.

Authenticating with Box

To read the data, the pipeline needs to authenticate with your Box enterprise. Box uses OAuth2 Client Credentials Grant, which issues a short-lived access token (60 minutes) for server-to-server API access without user interaction.

Configure Authentication for Box

To configure authentication credentials for the pipeline:

1. Log in to the Box Developer Console and create a **New App**.
2. Enter the App Name, choose **Client Credentials Grant** as the App Type, and choose **Create App**.
3. Navigate to **App Details > Access** panel, choose **Fetch Secret** and complete the 2FA verification.
4. Choose **Fetch Secret** again, and then copy the `Client ID` and `Client Secret` for later use.
5. Under App Access Level, select **App + Enterprise Access**. Keep the default selections for Application Scopes.
6. Navigate to **App Details > Status**, choose **Authorize**, and make sure the application is marked as Authorized.
7. Choose your profile icon and select **Copy Enterprise ID** for later use. Alternatively, you can find it in **Admin Console** > **Account & Billing** > **Enterprise ID**.
8. In AWS Secrets Manager, create a secret and store:
   - Client ID under the key `client_id`
   - Client Secret under the key `client_secret`

Configuring the CloudWatch Pipeline

To configure the pipeline to read data, choose Box as the data source. Provide the required information such as the Enterprise ID (`enterprise_id`), Client ID (`client_id`), and Client Secret (`client_secret`). After you create and activate the pipeline, enterprise events and inventory data from Box will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Box events that map to the following OCSF event classes.

> **Note**
>
> Events that do not match any OCSF event classes listed below are automatically passed through and sent directly to the configured sink in their original format without additional processing.

Entity Management (3004)

Enterprise Events – Contains enterprise-wide administrative and security events including file operations, sharing changes, user management actions, Shield alerts, and application events.

Account Change (3001)

Users – Provides user account inventory including profile information, status, storage usage, and role assignments.

Group Management (3006)

- **Groups** – Contains group inventory with group type, membership visibility, and invitability settings.
- **Group Memberships** – Records user-to-group membership associations including role assignments (member, admin).
- **Group Collaborations** – Provides shared access grants (collaborations) between groups and content items including role and status.

Base Event (0)

Events that do not map to a specific OCSF class are mapped to the Base Event class.

CloudWatch pipelines configuration for Box

Collects enterprise events, user inventory, group inventory, group memberships, and group collaborations from Box using OAuth2 Client Credentials authentication.

Configure the Box source with the following parameters:

```
source:
  box:
    enterprise_id: "123456789"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:my-box-secret:client_id}}"
        client_secret: "${{aws_secrets:my-box-secret:client_secret}}"
```

Parameters

`enterprise_id` (required)

The Box Enterprise ID (numeric). Found in the Box Admin Console under Account & Billing > Enterprise ID.

`authentication.oauth2.client_id` (required)

The OAuth2 Client ID from the Box Custom App. Stored in AWS Secrets Manager.

`authentication.oauth2.client_secret` (required)

The OAuth2 Client Secret from the Box Custom App. Stored in AWS Secrets Manager.

> **Note**
>
> The `client_id` and `client_secret` values are retrieved from AWS Secrets Manager. These credentials can be found in the Box Developer Console under your Custom App's Configuration tab.

Broadcom Carbon Black integration configuration

Broadcom Carbon Black is a cloud-native endpoint protection platform (EPP) that combines next-generation antivirus (NGAV), behavioral detection, and endpoint detection and response (EDR). It provides continuous monitoring of endpoints and workloads from a single console to detect and stop ransomware, malware, and fileless attacks.

The Carbon Black Data Forwarder is a high-volume data streaming service designed to send alerts, endpoint events, watchlist hits, authentication events, auditlog events, and livequery results to Amazon S3.

Data Forwarder can be configured to forward events for one of the following types:

- alert 2.1.0
- auth.event 1.0.0
- endpoint.event 1.2.0
- watchlist.hit 1.0.0
- auditlog 1.0.0

- livequery 1.0.0

Topics

- Source configuration for Broadcom Carbon Black
- CloudWatch pipelines configuration for Broadcom Carbon Black

Source configuration for Broadcom Carbon Black

Integrating with Broadcom Carbon Black

CloudWatch Pipeline ingests Broadcom Carbon Black event data from Amazon S3. You configure Carbon Black Cloud to export event data to an Amazon S3 bucket using the Data Forwarder, then create a pipeline that reads from that bucket using Amazon SQS notifications.

To integrate CloudWatch Pipelines with Broadcom Carbon Black, complete the following high-level steps:

- Configure Carbon Black Cloud Data Forwarder to export events to an Amazon S3 bucket.
- Set up Amazon SQS notifications on the Amazon S3 bucket for new object creation.
- Create the required IAM role for pipeline access.
- Create a CloudWatch pipeline with Broadcom Carbon Black as the data source.
- Verify that data is flowing into the pipeline.

Instructions to set up Amazon S3 and Amazon SQS

Setting up the Carbon Black Data Forwarder to send logs to an Amazon S3 bucket involves several steps to create the required AWS resources (Amazon S3 bucket, Amazon SQS queue, IAM roles) and configure the Carbon Black Data Forwarder to send the desired log events.

1. Create an Amazon S3 bucket to store Carbon Black logs.

> **Important**
>
> You must select the same region as your Broadcom Carbon Black instance. See the Carbon Black documentation on the Broadcom developer website to determine which AWS region your Carbon Black product URL maps to.

> **Important**
>
> CloudWatch Pipelines will not be able to apply OCSF transformations or other processing to KMS encrypted logs. If processing is needed, do not set up KMS encryption.

For detailed instructions, see Configure the Destination: Use Amazon S3 in the Carbon Black Data Forwarder documentation on the Broadcom developer website.

2. Attach an IAM policy to the Amazon S3 bucket to grant the Forwarder permissions to write to your bucket (see *Example IAM policy for Amazon S3 bucket* below).

> **Note**
>
> The Principal ID ARN to use in the policy is based on the AWS region the Amazon S3 bucket is in. See the *Principal ID to allow by AWS Region* table below.

3. Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket. For more information, see Create an Amazon SQS queue.
4. Attach an IAM policy to the Amazon SQS queue to allow Amazon S3 to write event notifications to the Amazon SQS queue (see *Example IAM policy for Amazon SQS queue* below).
5. Configure the Amazon S3 bucket to generate "Object Create" event notifications to be sent to the Amazon SQS queue. For more information, see Enable event notifications on the S3 bucket with the SQS queue as a destination.
6. Create and configure the Carbon Black Data Forwarder, through the Carbon Black Console or API, by following the Carbon Black Create a Forwarder documentation. For complete documentation, see Carbon Black Data Forwarders on the Broadcom website.

Example IAM policy for Amazon S3 bucket

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Sid": "AllowCarbonBlackForwarderWriteAccess",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::132308400445:role/mcs-psc-prod-event-forwarder-
<aws-region>-event-forwarder"
            },
            "Action": [
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": "arn:aws:s3:::<bucket-name>[/<prefix>]/*"
        }
    ]
}
```

Principal ID to allow by AWS Region

AWS Region	Principal ID
US East (N. Virginia) us-east-1	`arn:aws:iam::132308400445:role/mcs-psc-prod-event-forwarder-us-east-1-event-forwarder`
Europe (Frankfurt) eu-central-1	`arn:aws:iam::132308400445:role/mcs-psc-prod-event-forwarder-eu-central-1-event-forwarder`
Asia Pacific (Tokyo) ap-northeast-1	`arn:aws:iam::132308400445:role/mcs-psc-prod-event-forwarder-ap-northeast-1-event-forwarder`
Asia Pacific (Sydney) ap-southeast-2	`arn:aws:iam::132308400445:role/mcs-psc-prod-event-forwarder-ap-southeast-2-event-forwarder`

Example IAM policy for Amazon SQS queue

```
{
    "Version": "2012-10-17",
    "Id": "PolicyForS3SendMessage",
    "Statement": [
        {
            "Sid": "AllowS3SendMessage",
            "Effect": "Allow",
            "Principal": {
```

```
                "Service": "s3.amazonaws.com"
            },
            "Action": "sqs:SendMessage",
            "Resource": "arn:aws:sqs:<aws-region>:<aws-account-number>:<queue-name>",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:::<bucket-name>"
                },
                "StringEquals": {
                    "aws:SourceAccount": "<aws-account-number>"
                }
            }
        }
    ]
}
```

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Broadcom Carbon Black, choose Broadcom Carbon Black as the data source. After you create the pipeline, data will be available in the selected CloudWatch Logs log group. The log group will require a resource policy. The policy is automatically added if the pipeline is created through the console.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the Broadcom Carbon Black log events (Endpoint Events v1.2.0, Alerts v2.1.0, Watchlist Hits v1.0.0, Auth Events v1.0.0, Audit Logs v1.0.0) that map to the following OCSF event classes.

When parseOCSF is enabled, if any log events aren't one of the supported log event types, the logs will be ingested in their raw form with a `@transformationError` field added and a `TransformationErrors` metric emitted.

File System Activity (1001)

Contains the following events:

- endpoint.event.filemod

Module Activity (1005)

Contains the following events:

- endpoint.event.moduleload
- endpoint.event.scriptload

Process Activity (1007)

Contains the following events:

- endpoint.event.procstart
- endpoint.event.procend
- endpoint.event.crossproc
- endpoint.event.apicall

Script Activity (1009)

Contains the following events:

- endpoint.event.fileless_scriptload

Detection Finding (2004)

Contains the following events:

- alert CB_ANALYTICS
- alert WATCHLIST
- alert INTRUSION_DETECTION_SYSTEM
- alert HOST_BASED_FIREWALL
- alert DEVICE_CONTROL
- alert CONTAINER_RUNTIME

Authentication (3002)

Contains the following events:

- auth.event.logonop

Network Activity (4001)

Contains the following events:

- endpoint.event.netconn
- endpoint.event.netconn_proxy

Registry Key Activity (win ext) (201001)

Contains the following events:

- endpoint.event.regmod (action ends in "_KEY" or action == "ACTION_SET_SECURITY")

Registry Value Activity (win ext) (201002)

Contains the following events:

- endpoint.event.regmod (action ends in "_VALUE")

CloudWatch pipelines configuration for Broadcom Carbon Black

The Broadcom Carbon Black setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Broadcom Carbon Black source with the following parameters:

```
source:
  s3:
    aws:
      region: "<aws_region>"
      sts_role_arn: "arn:aws:iam::<account_id>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "broadcom_carbonblack"
    default_bucket_owner: "<account_id>"
    bucket_owners:
      my-bucket: "<account_id>"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
```

```
      queue_url: "https://sqs.<aws_region>.amazonaws.com/<account_id>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be `sqs` to use Amazon SQS for Amazon S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: `broadcom_carbonblack`.

`aws.region` (required)

The AWS Region where the Amazon S3 bucket and Amazon SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing Amazon S3 and Amazon SQS resources.

`codec` (required)

Codec configuration for parsing Amazon S3 objects. Supports `csv`, `json`, `ndjson` codecs.

`compression` (optional)

Compression type of the Amazon S3 objects. Valid values are `none`, `gzip`, `automatic`. Defaults to `none`.

`sqs.queue_url` (required)

The complete Amazon SQS queue URL that receives Amazon S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either `retain_messages` or `delete_messages`. Default is `retain_messages`.

Check Point NGFW integration configuration

Check Point Next-Generation Firewall (NGFW), also known as Check Point Quantum, is an advanced on-premises firewall that combines traditional filtering with modern threat-prevention

technologies such as intrusion prevention, antivirus, and application control. CloudWatch pipelines allow ingestion of Check Point NGFW log data into CloudWatch Logs, providing scalable collection, processing, normalization, and integration with downstream AWS security and monitoring services.

Topics

- Source configuration for Check Point NGFW
- CloudWatch pipelines configuration for Check Point NGFW

Source configuration for Check Point NGFW

Integrating with Check Point NGFW

Check Point NGFW integration uses Amazon S3 and Amazon SQS to ingest log data into CloudWatch pipelines. Log data is forwarded from the Check Point appliance using the `cp_log_export` utility to a syslog receiver, then collected by Fluent Bit and delivered to an Amazon S3 bucket. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles
- A Check Point NGFW appliance with access to the `cp_log_export` utility
- A Linux host with Fluent Bit installed (for log collection and delivery to Amazon S3)
- Network connectivity between the Check Point appliance, syslog receiver, and AWS

Log forwarding setup

Check Point NGFW exports logs using the `cp_log_export` utility, which forwards log data in syslog format to a designated receiver. Fluent Bit running on the syslog receiver host collects these logs and delivers them to Amazon S3 in NDJSON format.

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for Check Point NGFW log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store Check Point NGFW logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        "StringEquals": {
          "aws:SourceAccount": "<account-id>"
        }
      }
    }
  ]
}
```

Step 5: Configure Check Point log export and Fluent Bit

On the Check Point appliance, configure `cp_log_export` to forward logs to your syslog receiver:

```
cp_log_export add name my_export target-server <syslog-host> target-port 514 protocol
 udp format syslog
```

On the syslog receiver host, install Fluent Bit and configure it to tail the Check Point NGFW log files and upload them to Amazon S3. Use the following example configuration:

```
########################################
# SERVICE SECTION
########################################
[SERVICE]
    Flush                     5
    Daemon                    Off
    Log_Level                 info
    storage.path              /etc/fluent-bit/db/storage
    storage.sync              normal
    storage.checksum          off
    storage.backlog.mem_limit 10M

########################################
# INPUT SECTION
########################################
[INPUT]
    Name                      tail
    Path                      /var/logs/<checkpoint_ip_address>/*.log
    Tag                       checkpoint.*
    Read_from_Head            True
    DB                        /etc/fluent-bit/db/checkpoint.db
    DB.Sync                   Normal
    storage.type              filesystem
    Rotate_Wait               30
    Refresh_Interval          60

########################################
# OUTPUT SECTION
########################################
[OUTPUT]
    Name                      s3
    Match                     checkpoint.*
    Bucket                    <<Bucket name>>
```

```
    Region                      <region>
    S3_Key_Format               /checkpoint-ngfw/%Y/%m/%d/%H/%M/%S.log.gz
    compression                 gzip
    use_put_object              On
    store_dir                   /etc/fluent-bit/db/s3
    total_file_size             1M
    log_key                     log
    upload_timeout              60
```

Note

- Logs from `cp_log_export` arrive in JSON format through syslog to the receiver host.
- `log_key log` sends only the value of the `log` key to Amazon S3.
- `storage.path` and `store_dir` provide local buffering.
- The DB parameter tracks file read positions to prevent duplicate ingestion.
- Replace `<checkpoint_ip_address>` with the actual IP address.
- Replace `<<Bucket name>>` with your actual Amazon S3 bucket name.

Step 6: IAM permissions

Create an IAM policy with the following permissions for the Fluent Bit host to write objects to the Amazon S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FluentBitS3Write",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetBucketLocation",
        "s3:ListBucket",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
```

```
        "arn:aws:s3:::amzn-s3-demo-bucket/checkpoint-ngfw/*"
      ]
    }
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose Check Point NGFW as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between Check Point NGFW event types and OCSF event classes.

Event name	OCSF event class
Firewall	Network Activity [4001]
URL Filtering	Network Activity [4001]
HTTPS Inspection	Network Activity [4001]
Application Control	Network Activity [4001]
Identity Awareness	Network Activity [4001]
Anti Virus	Detection Finding [2004]
Anti Spam	Detection Finding [2004]

Event name	OCSF event class
IPS	Detection Finding [2004]
Anti Bot	Detection Finding [2004]
Threat Emulation	Detection Finding [2004]
Audit	Entity Management [3004]
DLP	Data Security Finding [2006]

CloudWatch pipelines configuration for Check Point NGFW

The Check Point NGFW setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "checkpoint_nextgenerationfirewall"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Must be "checkpoint_nextgenerationfirewall".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

Cisco Duo integration configuration

Cisco Duo is a cloud-based identity and access management (IAM) platform that provides secure access through multi-factor authentication (MFA), device trust, and adaptive authentication policies. CloudWatch Pipelines use the Duo Admin API to retrieve audit logs, authentication activity, administrator actions, and policy-related events from your Cisco Duo environment.

Topics

- Source configuration for Cisco Duo
- CloudWatch pipelines configuration for Cisco Duo

Source configuration for Cisco Duo

Integrating with Cisco Duo

CloudWatch Pipeline uses the Cisco Duo Admin API to retrieve audit logs, authentication activity, administrator actions, and policy-related events from your Cisco Duo environment. The Admin API

exposes REST endpoints that allow fetching time-filtered event data for security monitoring and analysis.

To integrate CloudWatch Pipelines with Cisco Duo, complete the following high-level steps:

- Create an Admin API integration in the Duo Admin Panel.
- Note the Integration Key, Secret Key, and API Hostname.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Cisco Duo as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, make sure you have the following:

- An active Cisco Duo account with Admin API access
- A Cisco Duo auth credential with Admin API access
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with Cisco Duo

Cisco Duo uses HMAC Authentication with an integration key and secret key, combined with request signing. The pipeline uses these credentials to authenticate each API request to the Duo Admin API.

Configure Authentication for Cisco Duo

To configure authentication credentials for the pipeline:

1. Log in to the Duo Admin Panel and navigate to Applications > Protect an Application.
2. Search for "Admin API" and create a new integration.
3. Note the Integration Key, Secret Key, and API Hostname provided by Duo.
4. Grant the "Grant read log" permission to the integration.
5. Store the `integration_key` and `secret_key` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Cisco Duo as the data source. Provide the `api_host`, `integration_key`, and `secret_key`. After you create and activate the pipeline, log data from Cisco Duo will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Page sizes** – Default is 100 for all streams. Valid ranges vary by stream.
- **Polling intervals** – Default is `P1D` (one day). Valid range is `PT30M` to `P15D`.
- **Backfill durations** – Default is `P180D` (180 days). Valid range is `PT1H` to `P180D`.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Base Event [0]** – Telephony Logs
- **Authentication [3002]** – Authentication Logs
- **Entity Management [3004]** – Activity Logs
- **Device Inventory Info [5001]** – Registered Devices, Phones
- **User Inventory Info [5003]** – Users

CloudWatch pipelines configuration for Cisco Duo

Collects log data from Cisco Duo using HMAC authentication through the Duo Admin API.

Configure the Cisco Duo source with the following parameters:

```
source:
  cisco_duo:
    api_host: "api-XXXXXXXX.duosecurity.com"
    authentication:
      hmac:
        integration_key: "${{aws_secrets:<secret-name>:integration_key}}"
        secret_key: "${{aws_secrets:<secret-name>:secret_key}}"
    range: "P30D"
```

Parameters

`api_host` (required)

The Duo API hostname for your organization (for example, `api-XXXXXXXX.duosecurity.com`).

`authentication.hmac.integration_key` (required)

The Duo Admin API integration key, stored in AWS Secrets Manager.

`authentication.hmac.secret_key` (required)

The Duo Admin API secret key, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `PT1H`, maximum is `P180D`. Default is `P180D`.

Cisco FTD integration configuration

Cisco Firepower Threat Defense (FTD) is a next-generation firewall platform that provides advanced threat protection, intrusion prevention, and deep visibility into network traffic. It generates security logs including connection events, intrusion detections, file and malware activity, and system events, which can be exported for centralized monitoring and analysis.

Topics

- Source configuration for Cisco FTD
- CloudWatch pipelines configuration for Cisco FTD

Source configuration for Cisco FTD

Integrating with Cisco FTD

Cisco FTD exports logs using the syslog protocol. These logs are collected by a syslog server, processed using Fluent Bit, and delivered to a customer-managed Amazon S3 bucket. CloudWatch pipelines read from this bucket using Amazon SQS notifications for new object events.

To integrate Cisco FTD with CloudWatch Logs, you must configure both the source and the pipeline. First, set up the syslog server, Fluent Bit, Amazon S3, and Amazon SQS to receive and

store data from Cisco FTD. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Prerequisites

Before you begin, make sure you have the following:

- Access to Cisco FTD with permissions to configure syslog export (through Firepower Management Center or CLI)
- A Linux-based syslog server (Amazon Linux 2 or Amazon Linux 2023 recommended) with network connectivity to your Cisco FTD appliance
- An AWS account with permissions to create and manage CloudWatch pipelines
- An AWS account with permissions to create and manage Amazon S3 buckets, Amazon SQS queues, and IAM roles

Instructions to set up Syslog Server, Fluent Bit, Amazon S3 and Amazon SQS

1. **Create an Amazon S3 Bucket**

   Create an Amazon S3 bucket in the same AWS region where you plan to run the pipeline. Enable server-side encryption and block public access. Reference: Creating a general purpose bucket

2. **Create an IAM User with Programmatic Access for Fluent Bit**

   In IAM, create a user with programmatic (CLI) access for Fluent Bit to write logs to Amazon S3. Attach a policy scoped to the target bucket:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:AbortMultipartUpload",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket-name>",
                "arn:aws:s3:::<bucket-name>/*"
            ]
```

```
        }
    ]
}
```

3. **Create an Amazon SQS Queue**

   Create a standard Amazon SQS queue in the same AWS region as the Amazon S3 bucket. Note the Queue URL and Queue ARN. Reference: Creating an Amazon SQS queue

4. **Configure Amazon SQS Queue Policy**

   Add a resource policy to the Amazon SQS queue allowing Amazon S3 to send event notifications:

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Principal": {"Service": "s3.amazonaws.com"},
        "Action": "sqs:SendMessage",
        "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
        "Condition": {
            "ArnEquals": {"aws:SourceArn": "arn:aws:s3:::<bucket-name>"},
            "StringEquals": {"aws:SourceAccount": "<account-id>"}
        }
    }]
}
```

5. **Enable Amazon S3 Event Notifications**

   Navigate to the Amazon S3 bucket > Properties > Event notifications. Create a notification for `s3:ObjectCreated:*` events. Select the Amazon SQS queue created in Step 3 as the destination. Reference: Enabling event notifications

6. **Configure Cisco FTD, the Syslog Server, and Fluent Bit**

   Configure Cisco FTD to forward logs over syslog (UDP 514/5514) to the syslog server, set up the syslog server (for example, rsyslog on Amazon Linux) to receive them, and install Fluent Bit to compress (gzip) and upload the logs to the Amazon S3 bucket created in Step 1.

   Use the following Fluent Bit configuration as a reference:

```
[SERVICE]
```

```
    Flush             1
    Daemon            Off
    Log_Level         info
    Parsers_File      /etc/fluent-bit/parsers.conf
    storage.path      /tmp/fluent-bit/storage

[INPUT]
    Name              tail
    Path              /var/log/cisco-ftd.log,/var/log/messages
    Tag               cisco.ftd
    Read_from_Head    True
    Refresh_Interval  5
    Mem_Buf_Limit     50MB
    Skip_Long_Lines   On
    DB                /tmp/fluent-bit/flb.db

[OUTPUT]
    Name              s3
    Match             cisco.ftd
    bucket            <bucket-name>
    region            <region>
    total_file_size   5M
    upload_timeout    1m
    store_dir         /tmp/fluent-bit/s3
    s3_key_format     /cisco-ftd/%Y/%m/%d/%H/%M/%S-$UUID.gz
    compression       gzip
    log_key           log
```

Replace <bucket-name> and <region> with the values from Step 1. Ensure Fluent Bit has AWS credentials (the IAM user from Step 2, or an instance role) with permission to write to the bucket.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Cisco FTD, choose Cisco FTD as the data source. Provide the Amazon SQS queue URL and IAM role ARN. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms the following events that map to Authentication (3002), Tunnel Activity (4014), Network Activity (4001), Detection Finding

(2004), and Authorize Session (3003). Events that are not listed but pulled are not mapped to OCSF and will be forwarded to the sink as raw logs.

Authentication contains the following Syslog IDs:

109011, 109012, 109013, 109026, 109027, 109039, 109201, 109202, 109203, 109204, 109205, 109206, 109207, 109208, 109209, 109210, 109211, 109212, 109213, 113001, 113004, 113005, 113006, 113007, 113008, 113009, 113010, 113012, 113013, 113014, 113016, 113017, 113019, 113020, 113021, 113022, 113023, 113024, 113025, 113026, 113027, 113028, 113029, 113033, 113035, 113037, 113038, 113039, 113040, 214001, 308001, 320001, 324302, 324303, 333001, 333002, 333003, 333004, 333005, 333006, 333007, 333008, 333009, 333010, 334001, 334002, 334003, 334004, 334005, 334006, 334007, 334008, 334009, 611101, 611102, 611103, 611104, 611316, 611317, 611318, 611319, 716036, 716038, 716039, 716040, 716160, 717001, 717009, 717010, 717012, 717013, 717014, 717015, 717016, 717017, 717018, 717021, 717022, 717024, 717025, 717026, 717027, 717028, 717029, 717030, 717031, 717032, 717033, 717034, 717035, 717036, 717037, 717038, 717053, 772002, 772003, 772004, 772005, 772006

Tunnel Activity contains the following Syslog IDs:

316001, 316002, 602303, 602304, 602305, 602306, 603110, 611309, 611315, 702307, 713041, 713049, 713050, 713056, 713060, 713061, 713073, 713074, 713075, 713076, 713092, 713099, 713113, 713120, 713123, 713136, 713169, 713187, 713194, 713195, 713196, 713206, 713207, 713218, 713227, 713239, 713259, 713262, 713276, 715009, 715013, 715080, 716001, 716002, 716006, 716007, 716009, 716023, 716057, 716058, 716059, 716060, 716166, 718048, 718049, 718050, 718051, 722020, 722029, 722030, 722031, 722032, 722033, 722034, 722037, 722038, 722041, 722045, 722046, 722047, 722048, 722049, 722050, 722054, 724001, 724002, 750001, 750002, 750003, 750004, 750005, 750006, 750007, 750008, 750009, 750010, 750011, 750012, 750013, 750014, 751001, 751002, 751003, 751004, 751005, 751006, 751007, 751008, 751009, 751010, 751011, 751012, 751013, 751014, 751015, 751016, 751017, 751018, 751019, 751020, 751021, 751022, 751023, 751024, 751025, 751026, 751027, 751031, 752002, 752012, 752015, 752016, 752017, 840001

Network Activity contains the following Syslog IDs:

430002, 430003, 106029, 302003, 302004, 302012, 302013, 302015, 302017, 302020, 302022, 302024, 302026, 302033, 302037, 302303, 305009, 305011, 609001, 302014, 302016, 302018, 302021, 302023, 302025, 302027, 302038, 302304, 305010, 305012, 419006, 507001, 609002, 500005, 110002, 110003, 201005, 201006, 302034, 302311, 305006, 305016, 305021, 305023, 106001, 106002, 106006, 106007, 106010, 106011, 106012, 106013, 106014, 106015, 106016,

106017, 106018, 106020, 106021, 106022, 106023, 106027, 106103, 201002, 201003, 201004, 201008, 201009, 201010, 201011, 201012, 201013, 209003, 209004, 209005, 209006, 302302, 313001, 313004, 313005, 313008, 313009, 322001, 407001, 407002, 407003, 418001, 419001, 421001, 424001, 424002, 446003, 448001, 500003, 500004, 509001, 710003, 710004, 710005, 710006, 767001, 815002, 106100, 106102, 302010, 302310, 305013, 419002, 419003, 419004, 419005, 421007, 507003, 775002, 805001, 805002, 805003, 815004, 852001, 852002

Detection Finding contains the following Syslog IDs:

430001, 430004, 430005

Authorize Session contains the following Syslog IDs:

109100, 109101, 109102, 109103, 109104, 113003, 113011, 113034, 113036, 501101, 634001, 734001, 734003, 113015, 113018, 113030, 113031, 113032, 113041, 113042, 730002, 734002, 109016, 109018, 109019, 109020, 109029, 109030, 109032, 109033, 109034, 109035, 109036, 109037, 109038, 610101, 734004

CloudWatch pipelines configuration for Cisco FTD

The Cisco FTD setup reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Cisco FTD source with the following parameters:

```
source:
  s3:
    aws:
      region: "<region>"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      newline:
    data_source_name: "cisco_ftd"
    default_bucket_owner: "<account-id>"
    bucket_owners:
      <bucket-name>: "<account-id>"
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.<region>.amazonaws.com/<account>/<queue-name>"
```

Parameters

`sqs.queue_url` (required)

Amazon SQS queue receiving Amazon S3 event notifications.

`data_source_name` (required)

Set to `cisco_ftd`.

`aws.region` (required)

Region of Amazon S3 and Amazon SQS.

`aws.sts_role_arn` (required)

IAM role to assume for Amazon S3/Amazon SQS access.

`notification_type` (required)

Set to `sqs`.

`codec` (required)

Codec for parsing Amazon S3 objects. Cisco FTD uses `newline`.

`bucket_owners` (optional)

Mapping of Amazon S3 bucket to AWS account ID.

`default_bucket_owner` (optional)

Default AWS account ID.

`compression` (optional)

Default none.

Note

The `sts_role_arn` role must have permissions to read from Amazon S3 and receive/delete Amazon SQS messages. See the pipeline IAM reference for the required trust policy and permissions policy.

Cisco ISE integration configuration

Cisco Identity Services Engine (ISE) is the Cisco enterprise Network Access Control (NAC) and identity policy engine, providing AAA services (Authentication, Authorization, Accounting) using RADIUS and TACACS+ across wired, wireless, and VPN connections. ISE enforces who and what can connect to the network, under what conditions, and with what privileges, while providing rich session context including user identity, device type, posture, and location to other security tools.

Use this connector to collect Passed Authentications, Failed Attempts, Authentication Flow Diagnostics, Identity Store Diagnostics, Policy Diagnostics, RADIUS Accounting, Guest, and Administrative and Operational Audit events. Use CloudWatch pipelines to ingest Cisco ISE log data into CloudWatch Logs for scalable collection, processing, normalization, and integration with downstream AWS security and monitoring services.

Topics

- Source configuration for Cisco ISE
- CloudWatch pipelines configuration for Cisco ISE

Source configuration for Cisco ISE

Integrating with Cisco ISE

CloudWatch Pipeline ingests Cisco ISE log data from Amazon S3. You configure ISE to forward syslog to a Fluent Bit host, which compresses and uploads the logs to Amazon S3. The pipeline then reads from Amazon S3 using Amazon SQS notifications.

To integrate CloudWatch Pipelines with Cisco ISE, complete the following high-level steps:

- Configure ISE Remote Logging Target to forward syslog to a Fluent Bit host.
- Assign the Remote Target to the desired Logging Categories.
- Install and configure Fluent Bit to receive syslog and upload to Amazon S3.
- Create an Amazon S3 bucket and Amazon SQS queue with event notifications.
- Create a CloudWatch pipeline with Cisco ISE as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, make sure you have the following:

- Active Cisco ISE deployment (version 2.x or 3.x) with administrative access to configure Remote Logging Targets and Logging Categories
- Network connectivity from ISE nodes to the Fluent Bit host (TCP port configurable, default 1514)
- Fluent Bit installed on a host reachable from all ISE nodes generating logs
- AWS credentials configured for Fluent Bit to write to Amazon S3
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create and manage CloudWatch Logs log groups

Instructions to set up Cisco ISE, Fluent Bit, Amazon S3 and Amazon SQS

1. **Configure ISE Remote Logging Target**

   In the ISE Admin Console, navigate to **Administration > System > Logging > Remote Logging Targets > Add**. Configure the following settings:

   - **Name:** Descriptive name (for example, `FluentBit_S3_Collector`)
   - **Target Type:** `TCP Syslog` or `Secure Syslog` (TCP+TLS) recommended for reliability
   - **Status:** Enabled
   - **Host/IP Address:** Fluent Bit host IP or FQDN
   - **Port:** Must match Fluent Bit listener port (for example, 1514)
   - **Maximum Length:** Set to **8192** (default 1024 will truncate messages)
   - **Comply to RFC 3164:** Check this box
2. **Assign Remote Target to Logging Categories**

   Navigate to **Administration > System > Logging > Logging Categories**. For each desired category, move the remote target from "Available" to "Selected".

   - **Categories from PSN nodes only:** AAA Audit, AAA Diagnostics, Accounting, Profiler, Posture, External MDM, Passive ID
   - **Categories from all nodes:** Administrative and Operational Audit, System Diagnostics, System Statistics

   Ensure Fluent Bit is reachable from all ISE nodes that generate the selected categories.
3. **Install and configure Fluent Bit**

   Install Fluent Bit on the designated log collection host. Configure Fluent Bit with a TCP input to receive syslog from ISE and an Amazon S3 output plugin:

```
[SERVICE]
    Flush        5
    Log_Level    info

[INPUT]
    Name         tcp
    Tag          cisco.ise
    Listen       0.0.0.0
    Port         1514
    Format       none
    Separator    \n

[OUTPUT]
    Name         s3
    Match        cisco.ise
    bucket       <your-bucket-name>
    region       <your-region>
    s3_key_format /cisco-ise-logs/$TAG/%Y/%m/%d/%H/%M/$UUID.gz
    total_file_size 5M
    upload_timeout 60s
    use_put_object On
    compression  gzip
    content_type application/gzip
    store_dir    /tmp/fluent-bit-s3
    log_key      log
```

> **Note**
>
> Maximum message length in ISE MUST be set to 8192 to avoid truncation of verbose ISE syslog messages. Fluent Bit uses TCP input (not the built-in syslog input) because ISE's syslog format is not fully RFC 3164 compliant. The `log_key` parameter ensures only the raw log line is written to Amazon S3 (without Fluent Bit metadata).

4. **Create Amazon S3 bucket and Amazon SQS queue**

   Create an Amazon S3 bucket in your desired AWS region to receive Cisco ISE logs. Create an Amazon SQS queue in the same region and configure the Amazon S3 bucket to send "Object Create" event notifications to the Amazon SQS queue.

5. **Verify log delivery**

Use ISE TCP Dump (**Operations > Troubleshoot > TCP Dump**) filtered by Fluent Bit IP to confirm log delivery from ISE. Verify objects appear in the Amazon S3 bucket under the configured prefix.

Configuring the CloudWatch Pipeline

When configuring the pipeline, choose **Cisco ISE** as the data source. Configure the Amazon S3 bucket and Amazon SQS queue details and select the destination log group. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Data flow

```
Cisco ISE -> Fluent Bit (TCP Syslog) -> Amazon S3 -> Amazon SQS Notification ->
 CloudWatch Pipeline -> CloudWatch Logs
```

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports **OCSF schema version v1.5.0**. Cisco ISE syslog events are parsed using a custom ISE syslog parser and mapped to OCSF classes based on the ISE logging category and message code.

ISE Event Type	OCSF Event Class	Description
Failed Attempts	Authentication (3002)	Failed RADIUS authentication and authorization attempts
Passed Authentication	Authentication (3002)	Successful RADIUS authentication and authorization events
Radius Accounting	Network Activity (4001), Tunnel Activity (4014)	RADIUS accounting start, stop, and interim update events (codes 3000-3004). RADIUS tunnel-related accounting events (codes 3005-3010).
Policy Diagnostics	Authentication (3002)	Policy evaluation and matching diagnostic events

ISE Event Type	OCSF Event Class	Description
Identity Store Diagnostics	Authentication (3002)	Identity store lookup and validation diagnostic events
Authentication Flow Diagnostics	Authentication (3002)	Authentication flow processing diagnostic events
Administrative and Operational Audit	Authentication (3002), Account Change (3001), Entity Management (3004), Application Lifecycle (6002), Application Error (6008), API Activity (6003), Network Activity (4001), Detection Finding (2004)	Administrative actions, system operations, and configuration changes mapped by message code
Guest	Web Resources Activity (6004)	Guest portal access and lifecycle events (codes 86001, 86005, 86012, 86021-86023, 86030-86031)

The following event types are ingested but not currently mapped to OCSF classes (forwarded as raw logs):

- Radius Diagnostics
- Administrator Authentication and Authorization
- Posture and Client Provisioning Audit
- Posture and Client Provisioning Diagnostics
- Profiler
- System Diagnostics
- Distributed Management
- Internal Operations Diagnostics
- System Statistics

Events that do not match any OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

CloudWatch pipelines configuration for Cisco ISE

The Cisco ISE setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Cisco ISE source with the following parameters:

```
source:
  s3:
    aws:
      region: "<region>"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      multiline:
        continuation_line_end_pattern: "\\\\$"
        omit_matched_section: true
        line_separator: ""
    data_source_name: "cisco_ise"
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.<region>.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be `sqs` to use Amazon SQS for Amazon S3 event notifications.

`data_source_name` (required)

Identifies the data source. Value: `cisco_ise`.

`aws.region` (required)

The AWS Region where the Amazon S3 bucket and Amazon SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing Amazon S3 and Amazon SQS resources.

`codec` (required)

Codec configuration for parsing Amazon S3 objects. Must be `multiline` for ISE syslog format.

`compression` (optional)

Compression type of Amazon S3 objects. Valid values: `gzip`, none. Default: none.

`sqs.queue_url` (required)

The complete Amazon SQS queue URL that receives Amazon S3 bucket notifications.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Valid values: `retain_messages`, `delete_messages`. Default: `retain_messages`.

Cisco Meraki integration configuration

Cisco Meraki is a cloud-managed IT platform by Cisco that provides centralized management of enterprise networking infrastructure — including security appliances (MX), wireless access points (MR), switches (MS), cameras (MV), sensors (MT), and mobile device management (SM) — through a single dashboard. CloudWatch pipelines uses the Meraki Dashboard REST API v1 to retrieve security events, configuration changes, assurance alerts, and network events from your Meraki organization.

Topics

- Source configuration for Cisco Meraki
- CloudWatch pipelines configuration for Cisco Meraki

Source configuration for Cisco Meraki

Integrating with Cisco Meraki

To integrate Cisco Meraki with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your Cisco Meraki source by configuring API access to the Meraki Dashboard API to retrieve data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Authenticating with the Meraki Dashboard API

To retrieve events from Cisco Meraki, CloudWatch pipelines needs to authenticate with your Meraki organization. Cisco Meraki supports API key access.

API key

- Generate an API key from the Meraki Dashboard. Navigate to your profile and select **API access** to generate a new API key.
- In AWS Secrets Manager, create a secret and store the API key under the key `api_key`.
- API keys are permanent and can be scoped down if needed. Make sure the API key has at least read-only access to the specific organization and the APIs.

For more information on Meraki API authorization, see Meraki API Authorization.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Cisco Meraki, choose Cisco Meraki as the data source. Fill in the required information including the Organization ID and the secret where your credentials are stored. You can find your organization ID in the Meraki Dashboard under **Organization > Settings**, or by calling `GET /organizations` through the Cisco Meraki API. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Cisco Meraki Dashboard API events that map to Network Activity (4001), API Activity (6003), and Detection Finding (2004).

Network Activity (4001)

Network Activity maps to Meraki Security Events — IDS/IPS alerts (Snort-based), malware detections through Advanced Malware Protection (AMP), and file scan results from MX security appliances.

API endpoint: `GET /organizations/{organizationId}/appliance/security/events`

API Activity (6003)

API Activity maps to Meraki Configuration Changes — an audit log of all administrative actions capturing who changed what configuration, when, and the before/after values. Covers changes made through the Dashboard UI and API.

API endpoint: `GET /organizations/{organizationId}/configurationChanges`

Detection Finding (2004)

Detection Finding maps to Meraki Assurance Alerts — alerts produced by Meraki's monitoring engine that analyze device telemetry and produce discrete alerts with IDs, severity, and a lifecycle status.

API endpoint: `GET /organizations/{organizationId}/assurance/alerts`

CloudWatch pipelines configuration for Cisco Meraki

Collects log data from the Cisco Meraki Dashboard REST API v1 using API key authentication.

Configure the Cisco Meraki source with the following parameters:

```
source:
  cisco_meraki:
    organization_id: "<meraki-organization-ID>"
    range: "P7D"
    authentication:
      api_key: "${{aws_secrets:<secret-name>:api_key}}"
```

Parameters

`organization_id` (required)

The Cisco Meraki organization ID. Each pipeline collects data from a single organization. You can find your organization ID in the Meraki Dashboard under **Organization > Settings**, or by calling `GET /organizations`.

`authentication.api_key` (required)

Cisco Meraki API key, stored as a key/value pair. From the preceding example, the name of the key will be `api_key`.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

> **Note**
>
> Store sensitive credentials like API keys in AWS Secrets Manager and reference them using the `${{aws_secrets:secret-name:key}}` syntax in your configuration.

Cisco Umbrella

To integrate Cisco Umbrella Data Replicator with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your Cisco Umbrella source by configuring Amazon S3 and Amazon SQS to receive data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Topics

- Source configuration for Cisco Umbrella
- Pipeline configuration for Cisco Umbrella

Source configuration for Cisco Umbrella

Integrating with Cisco Umbrella

Cisco Umbrella is a cloud-delivered security platform that provides secure internet access and threat protection across all devices, locations, and users. It uses DNS-layer security, web filtering, and cloud-delivered firewall features to block malicious domains and prevent cyberattacks before they reach your network. CloudWatch pipelines enables you to collect this data in CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring Cisco Umbrella to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, and IAM roles, then configuring the CloudWatch pipeline.

- Make sure Cisco Umbrella logs environment exporter is configured with S3. This is typically found under Admin → Logs Management in the Cisco Umbrella console.
- Amazon S3 bucket that stores the Cisco Umbrella logs should reside in the same AWS region as your CloudWatch pipeline.

- Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to the Amazon SQS queue you created in the previous step.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Cisco Umbrella, choose Cisco Umbrella as the data source. After filling in the required information and creating the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Cisco Umbrella events that map to DNS Activity (4003), Network Activity (4001), Data Security Finding (2006), and Entity Management (3004). Each event comes from a source as mentioned below.

DNS Activity contains the following actions:

- DNS Logs

Network Activity contains the following actions:

- Cloud Firewall Logs
- Secure Gateway logs
- IPS logs

Data Security Finding contains the following actions:

- DLP (Data Loss Prevention) logs

Entity Management contains the following actions:

- Admin Audit logs

Pipeline configuration for Cisco Umbrella

The Cisco Umbrella setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Cisco Umbrella source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      csv:
    data_source_name: "cisco_umbrella"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "cisco_umbrella".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

CrowdStrike integration configuration

To integrate CrowdStrike Falcon Data Replicator with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your CrowdStrike source by configuring Amazon S3 and Amazon SQS to receive FDR data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Topics

- Source configuration for CrowdStrike
- CloudWatch pipelines configuration for CrowdStrike

Source configuration for CrowdStrike

Integrating with CrowdStrike Falcon

CrowdStrike Falcon Data Replicator (FDR) delivers and enriches endpoint, cloud workload and identity data with the CrowdStrike Security Cloud and world-class artificial intelligence (AI), enabling your team to derive actionable insights to improve security operations center (SOC) performance. Amazon CloudWatch Logs enables you to collect this data in CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring CrowdStrike FDR to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, IAM roles, and then configuring the Amazon Telemetry Pipeline.

- Make sure CrowdStrike FDR is enabled within your CrowdStrike Falcon environment. This typically requires a specific license and may involve working with CrowdStrike support.
- Amazon S3 bucket that stores the CrowdStrike logs should reside in the same AWS region where the FDR is enabled.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from CrowdStrike FDR, choose CrowdStrike as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the CrowdStrike FDR actions that maps to Detection Findings (2004) and Process Activity (1007).

Detection Findings

Detection Findings contains the following actions:

- CloudAssociateTreeIdWithRoot
- CustomIOADomainNameDetectionInfoEvent
- TemplateDetectAnalysis

Process Activity

Process Activity contains the following actions:

CloudWatch pipelines configuration for CrowdStrike

The CrowdStrike setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "crowdstrike_falcon"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "crowdstrike_falcon".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

Drupal Core integration configuration

Drupal Core is the foundational open-source web application framework built on PHP that provides the base platform for building websites, applications, and digital experiences.

Topics

- Source configuration for Drupal Core

- CloudWatch pipelines configuration for Drupal Core

Source configuration for Drupal Core

Integrating with Drupal Core

Drupal Core is the foundational open-source web application framework built on PHP that provides the base platform for building websites, applications, and digital experiences. CloudWatch Pipeline uses the custom View-based REST API to retrieve audit log data — including content changes, user authentication events, and administrative actions — from your Drupal Core site. The API enables access to time-filtered log data through REST endpoints, allowing retrieval of activity records scoped to a configurable time window.

Authenticating with Drupal Core

To read the logs, the pipeline needs to authenticate with your Drupal Core site. The plugin supports Basic Authentication (HTTP Basic Auth using a username and password).

Configure Basic Authentication for Drupal Core

- Log in to your Drupal Core admin interface and navigate to Administration → Extend (`/admin/modules`).
- Enable the following modules: RESTful Web Services, Serialization, HTTP Basic Authentication, and Views. Choose Install.
- Install and enable the Admin Audit Trail module by using Composer (`composer require drupal/admin_audit_trail`) and run `drush en admin_audit_trail -y && drush cr` to activate it.
- Navigate to Structure → Views and create a new View named `Audit Logs API`. Set Show to `Log entries`, enable Provide a REST export, and set the REST export path to `/api/v1/audit-logs`.
- In the View editor, add two exposed Watchdog: Timestamp filters — one with operator `is greater than or equal to` and filter identifier `starttime`, and another with operator `is less than` and filter identifier `endtime`.
- In the REST EXPORT SETTINGS section of the View, choose Authentication and enable `basic_auth`.
- Navigate to People → Permissions and grant the roles that need API access the Access admin audit trail and Administer REST resource configuration permissions. Save the View.

- In AWS Secrets Manager, create a secret and store the Drupal Core username under the key `username` and the account password under the key `password`.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose Drupal Core as the data source. Fill in the required information:

- **Domain** — The base URL of your Drupal Core site (for example, `https://your-drupal-site.example.com`).
- **API Endpoint** — The path to the View REST export endpoint (for example, `/api/v1/audit-logs`). Must start with `/`.
- **Range** — Specify the lookback duration in ISO 8601 format (for example, `PT21H` for the last 21 hours, `P7D` for the last 7 days). The default is 0 hours, and the maximum is 90 days.

After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms events that map to Authentication (3002), Entity Management (3004), HTTP Activity (4002), and Application Lifecycle (6002). Events that are not listed are not mapped to OCSF and will be forwarded to the sink as raw logs.

Authentication contains the following event types:

- user — Login and authentication related events

Entity Management contains the following event types:

- user — User creation and deletion
- content
- comment

HTTP Activity contains the following event types:

- access denied

- page not found
- php
- new custom types

Application Lifecycle contains the following event types:

- system
- cron

CloudWatch pipelines configuration for Drupal Core

Collects audit logs from Drupal Core using basic authentication.

Configure the Drupal source with the following parameters:

```
source:
  drupal_core:
    range: "P7D"
    domain: "<drupal-site-domain>"
    api_endpoint: "<drupal-api-endpoint>"
    authentication:
      basic:
        username: "${{aws_secrets:<secret-name>:username}}"
        password: "${{aws_secrets:<secret-name>:password}}"
```

Parameters

`range` (optional)

For pulling historical logs. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for the last 21 hours). The default is 0 hours, and the maximum is 90 days.

`domain` (required)

The domain name of the Drupal Core site.

`api_endpoint` (required)

The path of the Drupal Core audit logs API endpoint. Must start with `/` (for example, `/api/v1/audit-logs`).

`authentication.basic.username` (required)

The username for Basic Authentication.

`authentication.basic.password` (required)

The password for Basic Authentication.

Entrust IDaaS integration configuration

Entrust Identity as a Service (IDaaS) is a cloud-based Identity and Access Management (IAM) platform that provides multi-factor authentication (MFA), single sign-on (SSO), adaptive risk-based authentication, and comprehensive audit logging across workforce, consumer, and citizen use cases.

Topics

- Source configuration for Entrust IDaaS
- CloudWatch pipelines configuration for Entrust IDaaS

Source configuration for Entrust IDaaS

Integrating with Entrust IDaaS

Entrust Identity as a Service (IDaaS) is a cloud-based Identity and Access Management (IAM) platform that provides multi-factor authentication (MFA), single sign-on (SSO), adaptive risk-based authentication, and comprehensive audit logging across workforce, consumer, and citizen use cases. CloudWatch pipeline uses the Entrust IDaaS Administration REST API to retrieve identity and access events from your IDaaS tenant.

The Administration REST API provides access to two primary log categories. Authentication Logs capture user authentication events across multiple event types, including MFA, SSO, SAML, OIDC, and passwordless authentication methods. Management Logs track administrative actions and changes performed across various entity types such as users, groups, applications, tokens, and policies.

Authenticating with Entrust IDaaS

To read the logs, the pipeline needs to authenticate with your Entrust IDaaS tenant. The plugin supports Administration API authentication using an `applicationId` and `sharedSecret`.

Create an Administration API application

- Go to your IDaaS Admin portal and navigate to Security → Applications.
- Choose + and select Administration API from the list of available applications.
- In the General tab, enter a name and description for your application, then choose Next.
- In the Setup tab, assign the role with the permissions required by your application, then choose Submit. The Entrust IDaaS Administration API requires the Super Administrator role to access audit log endpoints.
- In the Complete tab, choose Copy to copy your `applicationId` and `sharedSecret`, or download the JSON file.
- In AWS Secrets Manager, create a secret and store the `applicationId` under the key `client_id` and the `sharedSecret` under the key `client_secret`.
- Your IDaaS API base URL is `https://<hostname>` where `hostname` is taken from the credentials (for example, `https://entrust.us.trustedauth.com`).

Configuring the CloudWatch Pipeline

To configure the pipeline to read audit logs from Entrust IDaaS, choose `entrust_idaas` as the data source. Fill in the required information such as your tenant `hostname` and the AWS Secrets Manager secret ARN for your credentials where `client_id` and `client_secret` are stored. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Authentication (3002) and Entity Management (3004).

Authentication contains the following events:

- AuthenticationAdminApiSuccessEvent
- AuthenticationDeniedEvent
- AuthenticationExternalSecondFactorBypassEvent
- AuthenticationExternalSuccessEvent
- AuthenticationFaceSuccessEvent
- AuthenticationFidoSuccessEvent
- AuthenticationFirstFactorExternalSuccessEvent

- AuthenticationFirstFactorIdpSuccessEvent

CloudWatch pipelines configuration for Entrust IDaaS

Collects identity and access management audit logs from Entrust IDaaS using OAuth2 authentication.

Configure the Entrust IDaaS source with the following parameters:

```
source:
  entrust_idaas:
    hostname: "<hostname>"
    range: "P7D"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`hostname` (required)

Entrust IDaaS tenant hostname (for example, `entrust.us.trustedauth.com`). Do not include the `https://` prefix.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Entrust IDaaS Administration API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Entrust IDaaS Administration API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

> **Note**
>
> The parameter information should correspond to values received in the Authenticating with Entrust IDaaS section.

F5 BIG-IP integration configuration

F5 Telemetry Streaming is a real-time log streaming solution that delivers detailed traffic and security logs from F5 BIG-IP to external destinations such as Amazon S3 and CloudWatch. It

enables monitoring, troubleshooting, and analysis of logs generated by modules like AFM, LTM, APM, ASM, and Advanced WAF.

Topics

- Source configuration for F5 BIG-IP
- CloudWatch pipelines configuration for F5 BIG-IP

Source configuration for F5 BIG-IP

Integrating with F5 BIG-IP

To integrate F5 BIG-IP with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your F5 BIG-IP source by configuring Amazon S3 and Amazon SQS to receive data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Setup log forwarding

F5 BIG-IP supports real-time log delivery through Telemetry Streaming to forward logs to Amazon S3.

Instructions to setup Amazon S3 and Amazon SQS

Configuring F5 BIG-IP to send logs to an Amazon S3 bucket involves several steps. These steps focus on setting up the Amazon S3 bucket, Amazon SQS queue, and IAM credentials, and then configuring Telemetry Streaming and the CloudWatch pipeline.

- Make sure F5 BIG-IP Telemetry Streaming is installed and configured. Create an Amazon S3 bucket to store logs. It is recommended to enable server-side encryption for security.
- Amazon S3 bucket that stores the F5 BIG-IP logs should reside in the same AWS Region.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring F5 BIG-IP log forwarding

- Install and verify the Telemetry Streaming (TS) extension.

- Create a log destination (Amazon S3, CloudWatch, or other supported destination).
- Create a log publisher and map the destination.
- Create a logging profile specific to each module (for example, ASM, Advanced WAF).
- Apply the logging profile to the virtual server.
- Configure Telemetry Streaming (JSON declaration).
- Define the destination S3 bucket and log types.

Configuring Telemetry Streaming

- Configure Telemetry Streaming using the declarative API endpoint: `/mgmt/shared/telemetry/declare`.
- Define the Telemetry configuration with class `Telemetry`.
- Define a Telemetry Listener to receive logs (for example, port 6514).
- Define a Telemetry Consumer of type Amazon S3: configure the bucket name and Region, and provide IAM access key and secret key for authentication.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from F5 BIG-IP, choose F5 BIG-IP as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and F5 BIG-IP events that map to Network Activity (4001) and HTTP Activity (4002). The following lists show the source for each event.

Network Activity (4001) contains the following log formats:

- AFM
- APM

HTTP Activity (4002) contains the following log formats:

- ASM

- LTM
- Advanced WAF

Events that do not match any OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

CloudWatch pipelines configuration for F5 BIG-IP

The F5 BIG-IP setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the F5 BIG-IP source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "f5_bigip"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "f5_bigip".

`aws.region` (required)

The AWS Region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

GitHub Audit Log integration configuration

Amazon Telemetry Pipelines enables you to collect audit logs from GitHub Enterprise Cloud. GitHub Enterprise is an enterprise-grade software development platform designed for the complex workflows of modern development.

Topics

- Source configuration for GitHub Audit Log
- CloudWatch pipelines configuration for GitHub Audit Log

Source configuration for GitHub Audit Log

> **Note**
>
> Important: GitHub Enterprise accounts are required to use this connector. GitHub Personal or Organization accounts are not supported.

Integrating with GitHub

Amazon Telemetry Pipelines enables you to collect audit logs from GitHub Enterprise Cloud. GitHub Enterprise is an enterprise-grade software development platform designed for the complex workflows of modern development. GitHub Enterprise Cloud is the cloud-based solution of GitHub Enterprise, hosted on GitHub's servers.

Authenticating with GitHub

To read the audit logs, pipeline needs to authenticate with your GitHub account. For Enterprise scope , you can use Personal Access Token and for Organization scope , you can either use Personal Access Token or GitHub App.

Generate the token to authenticate as Personal Access Token:

- Sign in to GitHub using credentials for the GitHub account
- The authenticated user must be an enterprise admin to use this endpoint
- Open the GitHub Personal access tokens (classic) page, locate the Generate new token (classic) and then follow the GitHub procedure to generate a token with `read:audit_log` scope and No expiration
- Store this new token in a secret in the AWS Secrets Manager under the key `personal_access_token`

Generate the private key to authenticate as GitHub App:

- Sign in to GitHub using credentials for the GitHub account
- Make sure the GitHub App has the "Administration" organization permissions (read) permission
- Follow the instructions in Managing private keys for GitHub Apps and generate the private key
- Store this private key in a secret in the AWS Secrets Manager under the key `private_key` and the GitHub App name under the key `app_id`

Configuring the CloudWatch Pipeline

When configuring the pipeline to read audit logs from GitHub Enterprise Cloud, choose GitHub Audit Logs as the data source. Select the Source Type as Enterprise or Organization based on the scope of your integration and fill in the required information like Enterprise or Organization name

according to the selected scope. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the GitHub actions that maps to Account Change (3001), API Activity (6003) and Entity Management (3004).

Account Change contains the following actions:

- org.enable_two_factor_requirement
- org.disable_two_factor_requirement
- two_factor_authentication.add_factor
- two_factor_authentication.enabled
- two_factor_authentication.disabled
- two_factor_authentication.remove_factor
- org.disable_saml
- org.enable_saml
- personal_access_token.access_restriction_disabled
- personal_access_token.access_restriction_enabled
- personal_access_token.expiration_limit_set
- personal_access_token.expiration_limit_unset

API Activity contains the following actions:

- repository_secret_scanning_custom_pa....create
- repository_secret_scanning_custom_pa....update
- repository_secret_scanning_custom_pa....delete
- repository_secret_scanning_custom_pa....publish
- repository_secret_scanning_custom_p....enabled

- business_secret_scanning_push_prote....update
- business_secret_scanning_push_prote....disable

CloudWatch pipelines configuration for GitHub Audit Log

> **Note**
>
> Important: GitHub Enterprise accounts are required to use this connector. GitHub Personal or Organization accounts are not supported.

Collects audit log data from GitHub organizations or enterprises using personal access tokens or GitHub App authentication.

Configure the GitHub Audit Log source with the following parameters:

```
source:
  github_auditlog:
    scope: "ORGANIZATION"
    organization: "<example-org-name>"
    range: "P7D"
    authentication:
      personal_access_token: "${{aws_secrets:<secret-name>:token}}"
```

Parameters

`scope` (required)

Scope of audit logs to collect. Must be "ORGANIZATION" or "ENTERPRISE".

`organization` (required when scope is ORGANIZATION)

GitHub organization name.

`enterprise` (required when scope is ENTERPRISE)

GitHub enterprise name.

`authentication.personal_access_token` (required for PAT auth)

Personal access token for GitHub API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

GitLab integration configuration

GitLab is a DevSecOps platform that provides source code management, CI/CD pipelines, project planning, and security scanning capabilities. CloudWatch Pipelines use the GitLab REST API and GraphQL API to retrieve audit events, project activity, merge request data, group membership information, and vulnerability findings from your GitLab environment.

Topics

- Source configuration for GitLab
- CloudWatch pipelines configuration for GitLab

Source configuration for GitLab

Integrating with GitLab

CloudWatch Pipeline uses the GitLab REST API and GraphQL API to retrieve audit events, project activity, merge request data, group membership information, and vulnerability findings from your GitLab environment. The REST API exposes endpoints for fetching time-filtered event data for security monitoring and compliance analysis, while the GraphQL API is used to retrieve project vulnerability data.

To integrate CloudWatch Pipelines with GitLab, complete the following high-level steps:

- Generate a Personal Access Token (PAT) in the GitLab Console.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with GitLab as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, make sure you have the following:

- An active GitLab (SaaS) account with Owner or Admin access
- A GitLab Personal Access Token (PAT) with the `read_api` scope
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with GitLab

GitLab uses a Personal Access Token (PAT) for authentication. The pipeline passes the token through the `PRIVATE-TOKEN` header to authenticate each API request.

Configure Authentication for GitLab

To configure authentication credentials for the pipeline:

1. In the upper-right corner of GitLab, select your avatar.
2. Select **Edit profile**.
3. In the left sidebar, select **Access** > **Personal access tokens**.
4. From the **Generate token** dropdown, select **Legacy token**.
5. Enter a token name.
6. (Optional) Enter a token description.
7. Set an expiration date for the token.
8. Select `read_api` as the scope.
9. Select **Generate token**.
10. Save the token value.

11Store the `pat_token` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose GitLab as the data source. Provide the Personal Access Token. After you create and activate the pipeline, audit and activity data from GitLab will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Polling intervals** – `members_polling_interval` (default `P1D`), `vulnerabilities_polling_interval` (default `P1D`)
- **Backfill durations** – `projects_backfill` (default `P180D`), `merge_requests_backfill` (default `P180D`), `group_audit_events_backfill` (default `P180D`), `project_audit_events_backfill` (default `P180D`)

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Vulnerability Finding [2002]** – Vulnerability Finding Activity
- **Group Management [3006]** – Group Audit Event Activity
- **User Inventory Info [5003]** – Member Activity
- **Software Inventory Info [5020]** – Project Activity
- **Web Resources Activity [6001]** – Merge Request Activity

CloudWatch pipelines configuration for GitLab

Collects log data from GitLab using Personal Access Token authentication through the GitLab REST API and GraphQL API.

Configure the GitLab source with the following parameters:

```
source:
  gitlab:
    authentication:
      personal_access_token: "${{aws_secrets:gitlab-account-credentials:pat_token}}"
    range: "P30D"
```

Parameters

`authentication.personal_access_token` (required)

The GitLab Personal Access Token with `read_api` scope, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `PT1H`, maximum is `P180D`. Default is `P180D`.

Google Workspace integration configuration

Google Workspace, formerly G Suite, is Google's cloud-native productivity and collaboration suite. It includes Gmail, Drive, Docs, Sheets, Slides, Calendar, Meet, and Chat, along with identity and security services. CloudWatch pipelines use the Google Workspace Admin SDK Reports API and Alert Center API. These APIs retrieve audit logs, authentication activity, account and access changes, drive operations, and security alerts. The data comes from your Google Workspace environment. Both APIs expose REST endpoints that fetch time-filtered event data for security monitoring and analysis.

Topics

- Source configuration for Google Workspace
- CloudWatch pipelines configuration for Google Workspace

Source configuration for Google Workspace

Supported API and platform versions

Component	Version	Notes
Admin SDK Reports API	v1	Activity reports for all supported applications
Alert Center API	v1beta1	Security alerts and investigation data
OCSF Schema	v1.5.0	Open Cybersecurity Schema Framework mapping
OAuth 2.0	2	Service account authentication with a JSON Web Token (JWT)

Prerequisites

Before you begin, make sure you have the following:

- An active Google Workspace subscription. Individual applications and reports can require specific Google Workspace editions. For more information, see the section called “Known platform limitations”.
- A Google Cloud project.
- A Google Cloud service account with domain-wide delegation enabled.
- An administrator email address available for impersonation.
- The Admin SDK Reports API enabled in the Google Cloud console.
- The Alert Center API enabled in the Google Cloud console.
- Super-admin access to the Google Admin console for domain-wide delegation authorization.
- An AWS account with permissions to create and manage CloudWatch pipelines. For more information, see the section called “API caller permissions”.
- An AWS account with permissions to create and update secrets in AWS Secrets Manager, and a source role that can retrieve the stored credentials. For more information, see the section called “Third-party sources (API Pull)”.
- An AWS account with permissions to create and manage CloudWatch Logs log groups. For more information, see the section called “CloudWatch Logs API operations and required permissions for actions”.
- The service account JSON key file that you create during Google Workspace configuration.

Configure Google Workspace

1. Navigate to the Google Cloud console, log in to your Google account, and choose your organization name in the navigation bar.
2. In the **Select a resource** window, choose **New Project**.
3. In the **New Project** window, enter your project name, and choose **Create**.
4. In the Google Cloud console, open the menu in the upper-left corner.
5. Navigate to **APIs & Services** > **Library**.
6. Choose the search bar.
7. Search for and select **Admin SDK API**. Repeat this step for **Google Workspace Alert Center API**.

8. For both the Admin SDK API and Google Workspace Alert Center API, choose **Enable**.
9. Navigate to **IAM & Admin** > **Service Accounts**.
10. Choose **Create Service Account**.
11. Name your service account, choose **Create and Continue**, and then choose **Done**.
12. On the **Service Accounts** page, choose your new service account.
13. On the service account details page, create a JSON key:
    a. Choose the **Keys** tab, and then choose **Add Key**.
    b. Choose **Create new key**.
    c. Select **JSON**, and then choose **Create**.
    d. Save the JSON key file to a secure directory. You use the credentials from this file when you configure the pipeline.
14. Navigate to the Google Admin console, and then navigate to **Security** > **Access and data control** > **API controls**.
15. Under **Domain wide delegation**, choose **Manage Domain Wide Delegation**.
16. Choose **Add new** to add a new client ID.
17. In the **Add a new client ID** window, complete the following steps:
    a. For **Client ID**, enter the value of the `client_id` key from the service account JSON key file.
    b. For **OAuth scopes**, add the following comma-delimited scopes:
       - Admin Audit Read Only
       - Alerts
    c. Choose **Authorize**.

Integrating with Google Workspace

1. **Store credentials in AWS Secrets Manager**
    a. Open the AWS Secrets Manager console.
    b. Choose **Store a new secret** > **Other type of secret**.
    c. Add the following key-value pairs:
       - `private_key` – The `private_key` value from the service account JSON key file.
       - `client_email` – The `client_email` value from the service account JSON key file.
       - `subject` – The administrator email address to impersonate.

d. Name the secret, for example, `google-workspace/pipeline-credentials`.

2. **Create the destination CloudWatch Logs log group**

   a. Open the CloudWatch console.

   b. Navigate to **Logs** > **Log groups** > **Create log group**.

   c. Choose a descriptive name, for example, `/aws/cloudwatch/pipelines/google-workspace`.

3. **Create the source IAM role**

   Create an IAM role with the required permissions. For information about the required policies and permissions, see the section called “CloudWatch pipelines IAM policies and permissions”.

4. **Create the CloudWatch pipeline**

   a. Open the CloudWatch console, and navigate to **Pipelines**.

   b. Choose **Google Workspace** as the data source.

   c. Configure authentication with `client_email`, `private_key` from AWS Secrets Manager, and `subject`, which is the administrator email address to impersonate.

   d. Select the destination log group.

   For the complete pipeline YAML configuration and parameter reference, see the section called “Pipeline configuration”.

5. **Add the CloudWatch Logs resource policy**

   The resource policy behavior depends on whether the log group is new or already exists:

   - **New log group (first-time use)** – The resource policy is created automatically. No action is required.
   - **Existing log group (reusing)** – If the selected log group already has a resource policy, the console displays the following warning:

     Resource Policy Detected: The log group you selected already has a resource policy. Please verify that this policy includes permissions for pipelines to write to the destination log group. You may need to modify the existing resource policy to add the necessary permissions.

     In this case, add the CloudWatch Logs resource policy within 5 minutes of pipeline creation, before the pipeline becomes active. Review and update the existing resource policy to make sure that it includes the required pipeline write permissions.

> **Note**
>
> If you create the pipeline using the AWS CLI or API, a resource policy is never created automatically, regardless of whether the log group is new or existing. You must create the CloudWatch Logs resource policy manually before the pipeline becomes active.

6. **Verify data flow**
   a. Wait a few minutes for the initial data pull.
   b. Check the destination log group for incoming events.
   c. Monitor pipeline metrics for successful ingestion.

Authenticating with Google Workspace

Google Workspace uses OAuth 2.0 with service account authentication and domain-wide delegation. The pipeline performs the following actions:

1. Signs a JWT with the service account private key.
2. Exchanges the JWT for an access token through Google's OAuth endpoint.
3. Impersonates the specified administrator account to access organization-wide data.

Supported Open Cybersecurity Schema Framework event classes

This integration supports OCSF schema version v1.5.0. Each application maps to one or more OCSF event classes.

Event type	Application ID	OCSF class	Description
Login Activity	`login`	Authentication (3002), Account Change (3001), Detection Finding (2004), Base Event (0)	User authentication attempts, MFA challenges, login success or failure, suspicious login flags, and password changes
SAML Activity	`saml`	Authentication (3002)	SAML-based SSO authentication attempts for federated applicati ons

Event type	Application ID	OCSF class	Description
Token Activity	`token`	API Activity (6003), User Access Management (3005)	OAuth token grants, revocations, and third-party application access
Drive Activity	`drive`	File Hosting Activity (6006)	File sharing, downloads, deletions, and permission changes
Gmail Activity	`gmail`	Email Activity (4009)	Message delivery events, including messages sent and received
Context-Aware Access	`context_aware_access`	Detection Finding (2004)	Zero-trust policy enforcement events, including access denials, warn-mode events, and policy evaluation errors
Rules Activity	`rules`	Detection Finding (2004), Data Security Finding (2006)	DLP and activity rules triggered by Google's built-in rule engine
Access Transparency	`access_transparency`	API Activity (6003)	Google employee access to customer data, available with the Frontline Plus, Enterprise Plus, Education Standard, Education Plus, and Enterprise Essentials Plus editions
User Accounts Activity	`user_accounts`	Account Change (3001)	2-step verification enrollment or disablement and recovery information changes
LDAP Activity	`ldap`	API Activity (6003), Authentication (3002)	LDAP authentication operations against Secure LDAP
Takeout Activity	`takeout`	Web Resources Activity (6001)	Bulk data export and download operations through Google Takeout

Event type	Application ID	OCSF class	Description
Vault Activity	`vault`	Entity Management (3004)	eDiscovery and retention operations for compliance monitoring
Directory Sync Activity	`directory_sync`	Entity Management (3004)	Active Directory and LDAP directory synchronization operations
Alert Center	Not applicable	Detection Finding (2004)	Security alerts, including phishing reclassifications, government-backed attack warnings, leaked passwords, and suspicious sharing

Ingestion-only event types

The following event types are ingested for completeness but do not have OCSF class mappings:

Event type	Application ID	Description
Calendar Activity	`calendar`	Calendar ACL changes and event modifications
Chat Activity	`chat`	Space management, uploads, and message operations
Meet Activity	`meet`	Video call events and abuse reports
Chrome Activity	`chrome`	ChromeOS logins, unsafe browsing events, and device management

CloudWatch pipelines configuration for Google Workspace

Collects audit logs from Google Workspace using OAuth 2.0 service account authentication with domain-wide delegation.

YAML configuration

```
extension:
  aws:
    secrets:
      google_workspace:
        secret_id: <<arn:aws:secretsmanager:<region>:<account-id>:secret:<secret-
name>>>
        region: <<region>>
        sts_role_arn: <<arn:aws:iam::<account-id>:role/<role-name>>>
pipeline:
  source:
    google_workspace:
      user_key: all
      range: P30D
      authentication:
        jwt_key_pair:
          private_key: ${{aws_secrets:google_workspace:private_key}}
          client_email: ${{aws_secrets:google_workspace:client_email}}
          subject: ${{aws_secrets:google_workspace:subject}}
  sink:
    - cloudwatch_logs:
        log_group: <<google-workspace-log-group>>
  processor:
    - ocsf:
        schema:
          google_workspace: null
        version: "1.5"
        mapping_version: 1.5.0
```

AWS extension parameters

The AWS extension configures AWS Secrets Manager access for securely retrieving credentials at runtime. Define a named secret block, such as `google_workspace`, with `secret_id` set to the ARN of your AWS Secrets Manager secret, `region` set to the AWS Region where the secret is stored, and `sts_role_arn` set to the IAM role ARN to assume when accessing the secret. Credentials are then referenced in the pipeline by using `${{aws_secrets:<name>:<key>}}`. For the complete configuration reference, see the AWS Secrets Manager extension.

Source parameters

Parameters

`user_key` (optional)

String that provides the profile ID or user email for which the data is filtered. The default value, `all`, fetches all information.

`range` (optional)

Lookback duration for activity logs in ISO 8601 format. The minimum value is `P1D`, the maximum value is `P180D`, and the default value is `P180D`.

`authentication.jwt_key_pair.private_key` (required)

The private key from the Google Cloud service account JSON key file. Store the value in AWS Secrets Manager and reference it using `${{aws_secrets:google_workspace:private_key}}`.

`authentication.jwt_key_pair.client_email` (required)

The service account email address. Store the value in AWS Secrets Manager and reference it using `${{aws_secrets:google_workspace:client_email}}`.

`authentication.jwt_key_pair.subject` (required)

The administrator email address to impersonate through domain-wide delegation. This value must be a delegated administrator account, not the service account email. Store the value in AWS Secrets Manager and reference it using `${{aws_secrets:google_workspace:subject}}`.

Note

Store all three authentication values, `private_key`, `client_email`, and `subject`, in AWS Secrets Manager. Reference them through the `google_workspace` secret block. The service account credentials, `private_key` and `client_email`, are available in the Google Cloud console under **IAM & Admin** > **Service Accounts**. The `subject`, or delegated administrator email, must be an administrator in your Google Workspace organization with domain-wide delegation authorized for the service account.

> **Note**
>
> For Gmail activity, if `range` is set to more than `P30D`, only the last 30 days of logs are fetched because of API constraints.

Sink parameters

The sink delivers processed events to a CloudWatch Logs log group. Set `log_group` to the name of your destination log group, for example, `google-workspace-log-group`. For complete configuration options, see the CloudWatch Logs sink.

Processor parameters

The processor transforms ingested events into OCSF format using the `google_workspace` schema key. Set `schema.google_workspace` to `null`. The presence of the key activates the Google Workspace schema mapping. Set `version` to `"1.5"` and `mapping_version` to `1.5.0`. For the full parameter reference, see the OCSF processor.

Known platform limitations

Limitation	Details	Impact
Gmail query window	The Reports API requires a start time and an end time for every Gmail request, and the difference between them cannot be greater than 30 days.	`range` values exceeding `P30D` fetch only the most recent 30 days of Gmail data.
Activity data availability delay	The delay before events become available in the Reports API depends on the application, and ranges from near real time to several days.	For the slower applications, recent events might not appear in the destination log group immediately.
Alert Center availability	The Alert Center API is in beta, version v1beta1.	API behavior can change without notice.

Limitation	Details	Impact
Access Transparency edition requirements	Access Transparency logs are available only with the Frontline Plus, Enterprise Plus, Education Standard, Education Plus, and Enterprise Essentials Plus editions.	If your organization uses an edition that is not listed, you do not receive these events.
Domain-wide delegation	Domain-wide delegation requires super-admin privileges to configure.	If you are not a super-admin, you cannot configure the integration.
API rate limits	The Reports API allows 2,400 queries per minute for each user in a Google Cloud project. The Alert Center API allows 1,000 requests per second for each project and 150 requests per second for each user.	High-volume environments might experience throttling.

Troubleshooting

Error	Likely cause	Resolution or connector behavior
`401 Unauthorized`	Invalid or expired service account credentials	Verify that the `private_key` stored in AWS Secrets Manager matches the current service account key. If necessary, regenerate the key in the Google Cloud console.
`403 Forbidden – Not Authorized to access this resource/ api`	Domain-wide delegation is not configured or scopes are not authorized.	Verify that the service account client ID is added in the Google Admin console with the correct OAuth scopes. Make sure that the `subject` is an administrator account.

Error	Likely cause	Resolution or connector behavior
`403 Forbidden – Access Not Configured`	A required API is not enabled.	Enable the Admin SDK API and Alert Center API in the Google Cloud console.
`429 Too Many Requests`	An API rate limit is exceeded.	The connector automatically backs off and retries. If the error persists, verify that other workloads are not consuming the same Google Workspace API quota.
`400 Bad Request – Invalid subject`	The subject email is not a valid administrator account.	Verify that the `subject` value is an administrator email address in your Google Workspace organization.
No data appears in the log group.	The pipeline resource policy was not added within 5 minutes of pipeline creation, before the pipeline became active.	Delete and recreate the pipeline, and then immediately add the CloudWatch Logs resource policy.
Some applications are missing from the data.	Service account scopes are too restrictive.	Verify that all required OAuth scopes are authorized in the Google Admin console domain-wide delegation settings.

Gmail activity shows fewer events than expected

- The Reports API limits each Gmail request to a window of 30 days, so only the most recent 30 days of Gmail activity are fetched regardless of the configured `range` value.
- Gmail activity reports message delivery events, such as messages sent and received.

Alert Center returns empty results

- The current version of the Alert Center API, v1beta1, is available to all Google Workspace customers. Access depends on a privilege rather than on an edition. Verify that the impersonated `subject` account holds the Alert center administrator privilege.
- Alerts can take up to 24 hours to appear after the triggering event.
- Verify that the `https://www.googleapis.com/auth/apps.alerts` scope is authorized.

Access Transparency logs do not appear

- This feature requires the Frontline Plus, Enterprise Plus, Education Standard, Education Plus, or Enterprise Essentials Plus edition.
- Verify that your organization opted in to Access Transparency in the Google Admin console.

HashiCorp Vault integration configuration

HashiCorp Vault is the industry-leading secrets management and encryption-as-a-service platform that enables organizations to centrally store, access, and distribute digital secrets. CloudWatch Pipelines allow ingestion of HashiCorp Vault audit log and operational log data into CloudWatch Logs.

Topics

- Source configuration for HashiCorp Vault
- CloudWatch pipelines configuration for HashiCorp Vault

Source configuration for HashiCorp Vault

Integrating with HashiCorp Vault

HashiCorp Vault integration uses Amazon S3 and Amazon SQS to ingest log data into CloudWatch pipelines. Vault produces two log types: audit logs (detailed JSON records of all API requests and responses) and operational logs (server health and performance). Fluent Bit collects both log types from the Vault host and delivers them to an Amazon S3 bucket. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles
- A HashiCorp Vault server (self-managed) with administrative access
- A Linux host with Fluent Bit installed (can be the same host as Vault)
- Network connectivity between the Vault host and AWS

Log forwarding setup

HashiCorp Vault audit logs can be forwarded to Amazon S3 using the Vault file audit device combined with Fluent Bit. Vault supports three audit device types: **file**, **socket**, and **syslog**. We recommend the **file** audit device for highest reliability.

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for HashiCorp Vault log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store HashiCorp Vault logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
```

```
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        "StringEquals": {
          "aws:SourceAccount": "<account-id>"
        }
      }
    }
  ]
}
```

Step 5: Configure Vault log export and Fluent Bit

Enable the Vault file audit device to write audit logs:

```
vault audit enable file file_path=/var/log/vault/audit.log
```

Configure JSON operational logs in the Vault server configuration file (`vault.hcl`):

```
log_level = "info"
log_format = "json"
```

Configure Fluent Bit to collect both audit and operational logs and deliver them to Amazon S3:

```
########################################
# SERVICE SECTION
########################################
[SERVICE]
    Flush        5
    Daemon       Off
    Log_Level    info
    storage.path /etc/fluent-bit/db/storage
    storage.sync normal
```

```
    storage.checksum off
    storage.backlog.mem_limit 10M

########################################
# INPUT SECTION
########################################
[INPUT]
    Name             tail
    Path             /var/log/vault/audit.log
    Tag              vault.audit
    Parser           json
    Read_from_Head   False
    DB               /etc/fluent-bit/db/vault-audit.db
    DB.Sync          Normal
    storage.type     filesystem
    Rotate_Wait      30
    Refresh_Interval 60

[INPUT]
    Name             tail
    Path             /var/log/vault/vault.log
    Tag              vault.operational
    Parser           json
    Read_from_Head   False
    DB               /etc/fluent-bit/db/vault-operational.db
    DB.Sync          Normal
    storage.type     filesystem
    Rotate_Wait      30
    Refresh_Interval 60

########################################
# OUTPUT SECTION
########################################
[OUTPUT]
    Name                s3
    Match               vault.*
    bucket              amzn-s3-demo-bucket
    region              <region>
    s3_key_format       /hashicorp-vault/%Y/%m/%d/%H/%M/%S.log.gz
    compression         gzip
    use_put_object      On
    store_dir           /etc/fluent-bit/db/s3
    total_file_size     1M
    log_key             log
```

```
    upload_timeout       60
```

Step 6: IAM permissions

Create an IAM policy with the following permissions for the Fluent Bit host to write objects to the Amazon S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FluentBitS3Write",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetBucketLocation",
        "s3:ListBucket",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/hashicorp-vault/*"
      ]
    }
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose HashiCorp Vault as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between HashiCorp Vault log types and OCSF event classes. Events that are not mapped are forwarded as raw logs.

Event name	OCSF event class
Audit	API Activity [6003]
Operational	N/A (raw pass-through)

CloudWatch pipelines configuration for HashiCorp Vault

The HashiCorp Vault setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "hashicorp_vault"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Must be "hashicorp_vault".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

Jamf Pro integration configuration

Jamf Pro is the flagship enterprise Mobile Device Management (MDM) and Enterprise Mobility Management (EMM) platform providing centralized lifecycle management for Apple devices across macOS, iOS, iPadOS, and tvOS. It provides structured per-device inventory records including hardware specifications, OS versions, security posture (FileVault, SIP, Gatekeeper), installed software, and user assignments. With CloudWatch Pipelines, you can use the Jamf Pro REST API to retrieve computer inventory data from your Jamf Pro tenant. The API exposes paginated REST endpoints with OAuth2 authentication that allow fetching device inventory records for monitoring and analysis.

Topics

- Source configuration for Jamf Pro
- CloudWatch pipelines configuration for Jamf Pro

Source configuration for Jamf Pro

Prerequisites

Before you begin, make sure you have the following:

- An active Jamf Pro tenant (Jamf Cloud or on-premises) with API access enabled.
- A Jamf Pro user account with API role permissions to access the Computer Inventory endpoint, or an API Client configured with the required OAuth2 scopes.
- An AWS account with permissions to create and manage CloudWatch Pipelines.
- An AWS account with required permissions to create, retrieve, and update secrets in AWS Secrets Manager.
- An AWS account with permissions to create and manage CloudWatch Logs log groups.

Integrating with Jamf Pro

To integrate Jamf Pro with CloudWatch Pipelines, complete the following high-level steps:

- Create an API Client (OAuth2) in the Jamf Pro Console with the required scopes.
- Note the Client ID and Client Secret.
- Identify your Jamf Pro instance URL.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Jamf Pro as the data source.
- Verify data is flowing into the configured CloudWatch Logs log group.

Authenticating with Jamf Pro

To read the data, the pipeline needs to authenticate with your Jamf Pro tenant. Jamf Pro uses OAuth2 Client Credentials flow, which exchanges a Client ID and Client Secret for a short-lived bearer token (valid for 20 minutes) used for all subsequent API calls.

Configure Authentication for Jamf Pro

To configure authentication credentials for the pipeline:

1. Log in to the Jamf Pro Console and navigate to **Settings > System > API Roles and Clients**.
2. Choose **New API Role** and create a role with the following privileges:

- Read Computers
- Read Computer Inventory Collection

3. Choose **API Clients** > **New API Client**.
4. Assign the API Role created above to the client.
5. Enable the client and note the following credentials:
   - **Client ID**
   - **Client Secret**
6. Identify your **Jamf Pro instance URL** based on your deployment:
   - Jamf Cloud: `https://<instance_name>.jamfcloud.com`
   - On-premises: `https://<your-jamf-server-url>`
7. In AWS Secrets Manager, create a secret and store:
   - Client ID under the key `client_id`
   - Client Secret under the key `client_secret`

For more information, see Jamf Pro API Overview on the Jamf developer website.

Configuring the CloudWatch Pipeline

To configure the pipeline to read data, choose Jamf Pro as the data source. Provide the required information such as the Jamf Pro hostname (`hostname`), Client ID (`client_id`), and Client Secret (`client_secret`). After you create and activate the pipeline, computer inventory data from Jamf Pro will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Jamf Pro events that map to Device Inventory Info (5001).

Device Inventory Info (5001)

Computer Inventory – Contains structured per-device records for managed Macs including hardware specifications, OS version, security posture (FileVault/SIP/Gatekeeper status), installed software, last contact time, and assigned user information.

> **Note**
>
> Events that do not match any OCSF event classes listed above – such as custom or newly introduced Jamf Pro event types that have not yet been mapped – are automatically passed through and sent directly to the configured sink in their original format without additional processing.

CloudWatch pipelines configuration for Jamf Pro

Collects computer inventory data from Jamf Pro using OAuth2 Client Credentials authentication.

Configure the Jamf Pro source with the following parameters:

```
source:
  jamf_pro:
    hostname: "<<your-instance>>.jamfcloud.com"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:jamf-pro-credentials:client_id}}"
        client_secret: "${{aws_secrets:jamf-pro-credentials:client_secret}}"
```

Parameters

`hostname` (required)

The Jamf Pro instance hostname for your tenant. For Jamf Cloud deployments, this follows the format `<instance_name>.jamfcloud.com`. For on-premises deployments, use your self-hosted Jamf Pro server hostname. Do not include `https://`.

`authentication.oauth2.client_id` (required)

The OAuth2 Client ID generated in the Jamf Pro Console. Stored in AWS Secrets Manager.

`authentication.oauth2.client_secret` (required)

The OAuth2 Client Secret generated in the Jamf Pro Console. Stored in AWS Secrets Manager.

> **Note**
>
> The `client_id` and `client_secret` values are retrieved from AWS Secrets Manager. These credentials can be generated in the Jamf Pro Console under Settings > System > API

Roles and Clients. The OAuth2 token is valid for 20 minutes and is automatically refreshed by the pipeline.

Jamf Protect integration configuration

Jamf Protect is an endpoint security solution purpose-built for macOS and iOS environments, providing real-time threat detection, behavioral analytics, and compliance monitoring across Apple device fleets. CloudWatch pipelines allow ingestion of Jamf Protect data into CloudWatch Logs.

Topics

- Source configuration for Jamf Protect
- CloudWatch pipelines configuration for Jamf Protect

Source configuration for Jamf Protect

Integrating with Jamf Protect

Jamf Protect integration uses Amazon S3 and Amazon SQS to ingest log data into CloudWatch pipelines. Jamf Protect supports native Amazon S3 delivery through Action Configurations (for macOS Security data) and Data Streams (for Jamf Security Cloud data), eliminating the need for an intermediate log forwarder such as Fluent Bit. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles
- A Jamf Protect tenant with administrative access to configure Action Configurations or Data Streams
- IAM credentials for Jamf Protect to write to Amazon S3

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for Jamf Protect log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store Jamf Protect logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:us-east-1:111122223333:queue-name",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        "StringEquals": {
          "aws:SourceAccount": "111122223333"
        }
      }
    }
  ]
}
```

Step 5: Configure Jamf Protect to export logs to Amazon S3

Configure Jamf Protect to deliver log data directly to your Amazon S3 bucket.

macOS Security (Action Configuration)

1. In the Jamf Protect console, navigate to Action Configurations.
2. Create or edit an Action Configuration.
3. Configure the Amazon S3 destination with your bucket name, region, and IAM credentials.

Jamf Security Cloud (Data Streams)

1. In the Jamf Protect console, navigate to Integrations, then choose Data Streams.
2. Create a new Data Stream with Amazon S3 as the destination.
3. Provide the bucket name, region, and IAM credentials.

Step 6: Attach bucket policy

Apply the following bucket policy to your Amazon S3 bucket to allow the Jamf IAM user to write objects:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3Access",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:user/JAMF-IAM-USER"
      },
      "Action": [
        "s3:PutObject",
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/jamf-protect-logs/*"
    },
    {
      "Sid": "S3ListBucket",
      "Effect": "Allow",
      "Principal": {
```

```
        "AWS": "arn:aws:iam::111122223333:user/JAMF-IAM-USER"
      },
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
      "Condition": {
        "StringLike": {
          "s3:prefix": "jamf-protect-logs/*"
        }
      }
    }
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose Jamf Protect as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between Jamf Protect data types and OCSF event classes.

Event name	OCSF event class
Alerts	Detection Finding [2004]
Telemetry	Pass-through
Unified Logs	Pass-through
Threat Events	Detection Finding [2004]

Event name	OCSF event class
Network Traffic	Network Activity [4001] / DNS Activity [4003]
Access Events (ZTNA)	Pass-through
Device Data	Device Inventory Info [5001]
App Insights	Software Inventory Info [5020]
Vulnerability Data	Vulnerability Finding [2002]

CloudWatch pipelines configuration for Jamf Protect

The Jamf Protect setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::111122223333:role/role-name"
    compression: "automatic"
    codec:
      ndjson:
    data_source_name: "jamf_protect"
    default_bucket_owner: "111122223333"
    bucket_owners:
      amzn-s3-demo-bucket: "111122223333"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.us-east-1.amazonaws.com/111122223333/queue-name"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Must be "jamf_protect".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

JumpCloud integration configuration

JumpCloud is a cloud-based open directory platform that unifies identity, access, and device management across IT resources. It provides centralized directory services, Single Sign-On (SSO), Multi-Factor Authentication (MFA), RADIUS, LDAP, and device management for organizations managing hybrid environments. CloudWatch pipelines use version 1 of the JumpCloud Directory Insights API to retrieve security and audit events from your JumpCloud tenant. The pipeline requests events from every Directory Insights service, so all of the events that your organization records are delivered to the sink. Events from the directory, SSO, RADIUS, systems, LDAP, and alerts services are transformed into Open Cybersecurity Schema Framework (OCSF) format. Events from any other Directory Insights service are forwarded to the sink without transformation. The API provides a single POST endpoint with cursor-based pagination and API key authentication for comprehensive identity and access event data.

Topics

- Source configuration for JumpCloud
- CloudWatch pipelines configuration for JumpCloud

Source configuration for JumpCloud

Supported API and platform versions

Component	Version	Notes
Directory Insights API	v1	Security and audit event retrieval across all services
Open Cybersecurity Schema Framework (OCSF) schema	v1.5.0	Open Cybersecurity Schema Framework mapping
API key authentication	v1	API key sent in the `x-api-key` header

Prerequisites

Before you begin, make sure you have the following:

- An active JumpCloud organization with Directory Insights enabled. Directory Insights is included in some JumpCloud package plans. JumpCloud stores 90 days of event logs and removes logs that are older than 90 days.
- A JumpCloud administrator account with permissions to generate API keys.
- The JumpCloud API hostname for your organization's data residency region.
- An AWS account with permissions to create and manage CloudWatch pipelines. For more information, see the section called “API caller permissions”.
- An AWS account with permissions to create and update secrets in AWS Secrets Manager, and a source role that can retrieve the stored credentials. For more information, see the section called “Third-party sources (API Pull)”.
- An AWS account with permissions to create and manage CloudWatch Logs log groups. For more information, see the section called “CloudWatch Logs API operations and required permissions for actions”.

Integrating with JumpCloud

To integrate CloudWatch pipelines with JumpCloud, complete the following high-level steps:

- Generate an API key in the JumpCloud Admin Console.

- Identify the API hostname for your organization's data residency region.
- Store the API key in AWS Secrets Manager.
- Create a destination CloudWatch Logs log group and the required source IAM role.
- Create a CloudWatch pipeline with JumpCloud as the data source.
- Verify that data is flowing into the configured CloudWatch Logs log group.

Authenticating with JumpCloud

JumpCloud uses API key authentication. The pipeline sends the API key as an `x-api-key` header with every request to the JumpCloud Directory Insights API. API keys are prefixed with `jca_` and are tied to an individual administrator account.

Configure authentication for JumpCloud

To configure authentication credentials for the pipeline:

1. Log in to the JumpCloud Admin Console with your administrator credentials.
2. Navigate to your administrator profile settings and select **My API Key**.
3. Generate a new API key. The key is prefixed with `jca_`.
4. Copy and securely store the API key immediately. You cannot view it again.
5. Identify the API hostname for your organization's data residency region:
   - US (default): `api.jumpcloud.com`
   - EU (European Union): `api.eu.jumpcloud.com`
   - IN (India): `api.in.jumpcloud.com`

   > **Note**
   >
   > The hostname must not include `https://`. Provide only the domain, such as `api.jumpcloud.com`.

6. In AWS Secrets Manager, choose **Store a new secret**, and then choose **Other type of secret**. Add the key-value pair `api_key` with the JumpCloud API key as the value. For example, name the secret `jumpcloud/pipeline-credentials`.

Configuring the CloudWatch pipeline

1. Create the destination CloudWatch Logs log group. For example, use `/aws/cloudwatch/pipelines/jumpcloud`.
2. Create a source IAM role with the required permissions. For information about the required policies and permissions, see the section called “CloudWatch pipelines IAM policies and permissions”.
3. Open the CloudWatch console, navigate to **Pipelines**, and choose JumpCloud as the data source.
4. Provide the API `hostname` for your organization's data residency region and the `api_key` stored in AWS Secrets Manager.
5. Select the destination log group.
6. Verify the destination log group resource policy. For a new log group, the console creates the resource policy automatically. If the log group already has a resource policy, the console warns you, and you must update that policy within five minutes of pipeline creation to include the required pipeline write permissions. For more information, see the section called “Resource policies”.
7. Wait a few minutes for the initial data pull, check the destination log group for incoming events, and monitor pipeline metrics for successful ingestion.

After you create and activate the pipeline, security and audit events from JumpCloud begin flowing into the selected CloudWatch Logs log group.

> **Note**
>
> When you create the pipeline using the AWS CLI or API, a resource policy is never created automatically, regardless of whether the log group is new or existing. You must create the CloudWatch Logs resource policy manually before the pipeline becomes active.

Supported Open Cybersecurity Schema Framework event classes

This integration supports OCSF schema version v1.5.0. Each JumpCloud service maps to one or more of the following OCSF event classes.

> **Note**
>
> Events that do not match an OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

Authentication (3002)

- **Directory authentication events** (`directory`) – Admin portal login attempts, admin API key authentication, and user portal login attempts.
- **SSO authentication events** (`sso`) – User authentications to SSO applications. The authentication protocol of the target application is reported as SAML or OpenID.
- **Systems authentication events** (`systems`) – Device-level login attempts, including SSH and console login attempts, on JumpCloud-managed systems, and remote session start, join, and end events.
- **RADIUS authentication events** (`radius`) – RADIUS-based network authentication attempts with PAP, CHAP, and EAP support.
- **LDAP Bind authentication events** (`ldap`) – LDAP Bind operations representing directory authentication attempts.

Account Change (3001)

Directory account lifecycle events (`directory`) – User and administrator account lifecycle operations including creation, modification, deletion, activation, suspension, lockout, unlock, password change or reset, and MFA factor enable or disable operations.

Entity Management (3004)

- **Directory entity management events** (`directory`) – Create, read, update, and delete operations on directory objects including groups, policies, applications, SSO integrations, resource associations, SCIM provisioning, and platform configurations.
- **Systems entity management events** (`systems`) – System and device lifecycle management including creation, update, deletion, operating system upgrades, rollbacks, and Google EMM operations.
- **Alerts rule configuration events** (`alerts`) – Alert rule lifecycle management including rule creation, modification, and deletion.

Detection Finding (2004)

Alert detection finding events (`alerts`) – Alert creation, update, and status change events generated by JumpCloud security rules for device compliance and policy violations.

Datastore Activity (6005)

LDAP Search events (`ldap`) – LDAP directory query operations including search filter, base DN, and result tracking.

Known platform limitations

Limitation	Details	Impact
Directory Insights entitlement	Directory Insights is included in only some JumpCloud package plans. JumpCloud stores 90 days of event logs and removes logs that are older than 90 days.	If your plan does not include Directory Insights, no events are available until your JumpCloud account manager enables it. You cannot backfill events that are older than 90 days.
API key scope	API keys are tied to an individual administrator account.	If that administrator account is deactivated, the API key becomes invalid.
Data residency	The API hostname must match the data residency region that is configured for your organization.	If you use a hostname for another region, authentication fails.
Event delivery delay	Events can take a few minutes to appear in the Directory Insights API.	Near-real-time monitoring might not capture the most recent events.
API rate limits	JumpCloud does not publish explicit rate limit numbers for the Directory Insights API.	The connector handles HTTP 429 responses automatically by backing off and retrying.

Troubleshooting

Error	Likely cause	Resolution or connector behavior
`401 Unauthorized`	The API key is invalid or expired.	Verify that the `api_key` stored in AWS Secrets Manager is correct and that the associated administrator account is active. Regenerate the key if necessary.
`403 Forbidden`	Insufficient permissions, or the hostname does not match your region.	Make sure that the API key belongs to an administrator who has Directory Insights access. Verify that `hostname` matches your organization's data residency region.
`429 Too Many Requests`	The API rate limit was exceeded.	The connector automatically backs off and retries.
No data appears in the log group.	The pipeline resource policy was not added within five minutes of pipeline creation, before the pipeline became active.	Delete and recreate the pipeline, and then immediately add the CloudWatch Logs resource policy.
Empty responses	Directory Insights is not enabled for your organization, or no events exist in the requested time range.	Verify that Directory Insights is enabled for your JumpCloud plan, and check that events exist within the configured `range` period.

No events from a specific service

- Verify that the service, such as SSO, RADIUS, or LDAP, is actively used in your JumpCloud organization. Services without activity do not generate events.
- Check that the service is enabled and configured in the JumpCloud Admin Console.

The API key becomes invalid unexpectedly

- API keys are tied to an individual administrator account. If that account is deactivated or deleted, or if its permissions change, the key becomes invalid.
- Regenerate the API key from an active administrator account, and then update the secret in AWS Secrets Manager.

Events are missing after a data residency change

- If your organization changed data residency regions, update the `hostname` parameter to the API hostname for the new region.

CloudWatch pipelines configuration for JumpCloud

The following pipeline configuration collects security and audit events from JumpCloud using API key authentication, and transforms the events from the directory, Single Sign-On (SSO), RADIUS, systems, LDAP, and alerts services into Open Cybersecurity Schema Framework (OCSF) format. Replace the placeholder values shown between << and >> with values for your environment.

```
extension:
  aws:
    secrets:
      jumpcloud_credentials:
        secret_id: <<arn:aws:secretsmanager:<region>:<account-id>:secret:<secret-
name>>>
        region: <<region>>
        sts_role_arn: <<arn:aws:iam::<account-id>:role/<role-name>>>
pipeline:
  source:
    jumpcloud:
      hostname: "api.jumpcloud.com"
      authentication:
        api_key: "${{aws_secrets:jumpcloud_credentials:api_key}}"
      range: "P90D"
  sink:
    - cloudwatch_logs:
        log_group: <<jumpcloud-log-group>>
  processor:
    - ocsf:
        schema:
```

```
          jumpcloud: null
        version: "1.5"
        mapping_version: 1.5.0
```

The AWS extension configures AWS Secrets Manager access for securely retrieving credentials at runtime. Define a named secret block, such as `jumpcloud_credentials`, with `secret_id` set to the ARN of your AWS Secrets Manager secret, `region` set to the AWS Region where the secret is stored, and `sts_role_arn` set to the IAM role ARN to assume when accessing the secret. Reference credentials in the pipeline using `${{aws_secrets:<name>:<key>}}`. The name in the `aws_secrets` reference must match the secret block name under `extension.aws.secrets`. For the complete configuration reference, see the AWS Secrets Manager extension.

Source parameters

`hostname` (required)

The JumpCloud API hostname for your organization's data residency region. Use `api.jumpcloud.com` for the US, `api.eu.jumpcloud.com` for the European Union, or `api.in.jumpcloud.com` for India. Do not include `https://`.

`authentication.api_key` (required)

The JumpCloud API key, prefixed with `jca_`, for authenticating API requests. Store the key in AWS Secrets Manager and reference it using `${{aws_secrets:jumpcloud_credentials:api_key}}`.

`range` (optional)

The lookback duration for events on the first run, in ISO 8601 duration format. The minimum value is `PT1H`, the maximum value is `P90D`, and the default is `P90D`. JumpCloud retains 90 days of events, so you cannot backfill events that are older than 90 days.

Note

The `api_key` value is retrieved from AWS Secrets Manager. Generate the API key in the JumpCloud Admin Console under your administrator profile settings by choosing **My API Key**.

Sink parameters

`log_group` (required)

The name of the destination CloudWatch Logs log group, such as `jumpcloud-log-group`. For complete configuration options, see the CloudWatch Logs sink.

Processor parameters

`schema.jumpcloud` (required)

Set this parameter to `null`. The presence of the key activates the JumpCloud schema mapping and transforms ingested events into OCSF format.

`version` (required)

The OCSF schema version. Set this parameter to `"1.5"`.

`mapping_version` (required)

The mapping version. Set this parameter to `1.5.0`. For the full parameter reference, see the OCSF processor.

Microsoft 365 integration configuration

This section describes how to configure Microsoft 365 as a data source for CloudWatch Pipeline.

Topics

- Source configuration for Microsoft 365
- CloudWatch pipelines configuration for Microsoft 365

Source configuration for Microsoft 365

Integrating with Microsoft 365

Microsoft 365 is a product family of productivity software, collaboration, and cloud-based services owned by Microsoft. CloudWatch Pipeline uses the Office 365 Management Activity API to retrieve information about user, admin, system, and policy actions and events from Office 365 and Microsoft Entra activity logs. Office 365 Management Activity API (also known as the Unified Auditing API) is a part of Office 365 security and compliance offerings. Customers and partners

can use this information to create new or enhance existing operations, security, and compliance-monitoring solutions for the enterprise.

Authenticating with Office 365 Management Activity API

To retrieve the activities Office 365, pipelines needs to authenticate with your account. Follow the instructions in Office 365 Management APIs:

- Register an application in Azure with Supported account types, Accounts in this organizational directory only (Single tenant). After registration is complete, note down the Application (client) ID and Directory (tenant) ID.
- Generate a new key for your application. Key is also known as client secret, which are used when exchanging an authorization code for an access token.
- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`
- Specify the permissions your application requires to access the Office 365 Management APIs. The permissions you need are:
  - ActivityFeed.Read: Required for all the audit content types you listed, including Audit.AzureActiveDirectory, Audit.Exchange, Audit.SharePoint, and Audit.General.
  - ActivityFeed.ReadDlp: Required specifically for the DLP.All content type
- Before you can access data through the Office 365 Management Activity API, you must enable unified audit logging for your Office 365 organization. You do this by turning on the Office 365 audit log. For instructions, see Turn Office 365 audit log search on or off.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read activities from Office 365, choose Microsoft 365 as the data source. Fill in the required information like Tenant Id using Directory (tenant) ID and the secret where `client_id` and `client_secret` are stored. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. Actions from various workloads like Exchange, SharePoint, Teams, and Azure Active Directory are mapped to Account Change (3001), Authentication (3002), User Access Management (3005), Group Management (3006), Email Activity (4009), Web Resources Activity (6001), File Hosting Activity (6006), Application Lifecycle

(6002), (2003), Detection Finding (2004), Incident Finding (2005), Vulnerability Finding (2002) and Unknown (0).

Compliance Finding

Compliance Finding contains the following actions:

- ApplyRecordLabel
- ComplianceSettingChanged
- ExclusionConfigurationDeleted
- NewComplianceTag
- NewRetentionCompliancePolicy
- NewRetentionComplianceRule
- CreateRulePackage
- CreateSuppressionRule
- ApproveDisposal
- RemoveComplianceTag
- SetComplianceTag
- SetRestrictiveRetentionUI
- SupervisionPolicyCreated
- SupervisionPolicyUpdated
- SupervisionPolicyDeleted
- HoldUpdated
- HoldCreated
- HoldRemoved
- DlpInfo

Detection Finding

Detection Finding contains the following actions:

- FileMalwareDetected
- DocumentSensitivityMismatchDetected

- TIMailData
- DeviceOffBoarding
- AddIndicator
- ChangeCustomDetectionRuleStatus
- CreateCustomDetection
- DeleteIndicator
- EditIndicator
- MonitoringAlertUpdated
- RunCustomDetection
- Trigger CMD Agent Canary check.
- DlpRuleMatch
- AlertEntityGenerated
- AlertTriggered

Incident Finding

Incident Finding contains the following actions:

- AddCommentToIncident
- AddTagsToIncident
- AssignUserToIncident
- CollectInvestigationPackage
- EditIncidentClassification
- RemediationActionAdded
- RemediationActionUpdated
- RemoveTagsFromIncident
- UnAssignUserFromIncident
- UpdateIncidentStatus
- CaseUpdated
- CaseAdded
- CaseRemoved

Account Change

Account Change contains the following actions:

- Add member to role
- Add service principal
- Add user
- Added role
- Change user license
- Change user password
- Delete user
- Deleted app permission
- Deleted role
- Edited global role assignment
- Edited role
- NetworkUserSuspended
- Remove member from role
- Remove delegation entry
- Reset user password
- Set force change user password
- AdministratorAddedToTermStore
- AdministratorDeletedFromTermStore
- AlertNotificationsRecipientDeleted
- CaseAdminUpdated
- CaseAdminAdded
- CaseAdminRemoved
- User added

Authentication

Authentication contains the following actions:

- MailboxLogin

- ClockedIn
- ClockedOut
- TeamsSessionStarted
- Logon
- SignInEvent
- SSOUserCredentialsSet
- User logged in
- UserLoggedIn
- UserLoggedOff
- UserLoginFailed

User Access Management

User Access Management contains the following actions:

- Add-MailboxPermission
- ModifyFolderPermissions
- Remove-MailboxPermission
- ApplicableAdaptiveScopeChange
- CaseMemberAdded

Group Management

Group Management contains the following actions:

- RemovedFromSecureLink
- BotAddedToTeam
- BotRemovedFromTeam
- MemberAdded
- MemberRemoved
- MemberRoleChanged
- ScheduleGroupAdded
- ScheduleGroupEdited

- ScheduleGroupDeleted
- TeamCreated
- TeamDeleted
- Add group
- Add member to group
- Created group
- Delete group
- Deleted group
- Edited group memberships
- Edited group
- GroupCreation
- GroupDeletion
- GroupRemoved
- GroupAdded
- GroupUpdated
- RemovedFromGroup
- AddedToGroup
- Remove member from group
- RemoveSpecificResponder
- RosterMemberAdded
- RosterMemberDeleted
- CaseMemberUpdated
- CaseMemberRemoved
- Team added
- Team deleted
- UserAddedToGroup
- UserRemovedFromGroup

Email Activity

Email Activity contains the following actions:

- Send
- SendAs
- SendOnBehalf
- MessageDeletedNotification
- QuarantineDelete
- QuarantineExport
- QuarantinePreview
- QuarantineRelease
- QuarantineReleaseRequest
- QuarantineReleaseRequestDeny
- QuarantineViewHeader
- SupervisionRuleMatch
- SupervisoryReviewTag
- SupervisoryReviewOLAudit

Web Resources Activity

Web Resources Activity contains the following actions:

- UpdateCalendarDelegation
- AddFolderPermissions
- Copy
- Create
- New-InboxRule
- SoftDelete
- Move
- MailItemsAccessed
- MoveToDeletedItems
- Set-InboxRule
- HardDelete
- UpdateInboxRules

- Update
- LockRecord
- UnlockRecord
- SearchQueryPerformed
- PageViewed
- PageViewedExtended
- FolderCreated
- ClientViewSignaled
- PagePrefetched
- FolderModified
- ListColumnCreated
- ListContentTypeCreated
- ListItemCreated
- Site ContentType Created
- List Column Deleted
- ListCreated
- List Item Deleted
- SiteColumnDeleted
- ListDeleted

CloudWatch pipelines configuration for Microsoft 365

Collects log data from Microsoft Office 365 Management API using OAuth2 authentication.

Configure the Microsoft Office 365 source with the following parameters:

```
source:
  microsoft_office365:
    tenant_id: "<example-tenant-ID>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`tenant_id` (required)

The Microsoft Entra ID tenant ID for your Office 365 organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Microsoft Office 365 Management API authentication. Can reference AWS Secrets Manager using `${{aws_secrets:secret-name:key}}` syntax.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Microsoft Office 365 Management API authentication. Can reference AWS Secrets Manager using `${{aws_secrets:secret-name:key}}` syntax.

> **Note**
>
> Store sensitive credentials like client IDs and secrets in AWS Secrets Manager and reference them using the `${{aws_secrets:secret-name:key}}` syntax in your configuration.

Netskope integration configuration

Netskope is a cloud-native Security Service Edge (SSE) and SASE platform that provides real-time data and threat protection for cloud services, websites, and private applications. CloudWatch pipelines use the Netskope REST API v2 endpoints to retrieve security events and alerts from your Netskope tenant, including application activity, network traffic, audit events, infrastructure logs, and threat detections across DLP, malware, and policy violations.

Topics

- Source configuration for Netskope
- CloudWatch pipelines configuration for Netskope

Source configuration for Netskope

Integrating with Netskope

Netskope is a cloud-native Security Service Edge (SSE) and SASE platform that provides real-time data and threat protection for cloud services, websites, and private applications. CloudWatch Pipeline uses the Netskope REST API v2 endpoints to retrieve security events and alerts from your Netskope tenant. The REST API v2 provides access to security event and alert logs through dedicated endpoints for each log type: application, page, network, infrastructure, audit, incident, endpoint, and alert. Alert logs cover threat detections and policy violations across alert types such as DLP, malware, malsite, policy, compromised credential, and UBA.

Authenticating with Netskope

To read Netskope event and alert logs, the pipeline needs to authenticate with your tenant using a REST API v2 token issued through a Service Account under the RBACv3 framework. Follow these steps to create a Service Account and generate an API token:

1. Log in to your Netskope Admin Console at https://<your-tenant>.goskope.com.
2. Navigate to **Settings** > **Administration** > **Administrators & Roles**.
3. Choose the **Roles** tab, then choose **Create Role**.
4. Enter a Role Name (for example, "CloudWatch-API-Role") and configure the following functional area permissions:
   - **Steering**: Application Events, Page Events, Network Events, Infrastructure Events, Incident Events, Endpoint Events, Alerts — all set to View.

- **Administration**: Audit Log — set to View.
- **Access Control**: Infrastructure — set to View.
- **DLP**: DLP Incident — set to View.

5. Choose **Save** to create the role.
6. Choose the **Administrators** tab, then choose the **Service Accounts** button.
7. Choose **New Service Account** and configure:
   - **Service Account Name**: Enter a descriptive name (for example, "CloudWatch-Collector").
   - **Role**: Select the role created in step 5 (for example, "CloudWatch-API-Role").
   - **Expire In**: Set an appropriate expiration period (for example, 365 days).
8. Choose **Create**. A dialog displays the generated REST API token. Copy this token immediately — it will not be shown again.
9. In AWS Secrets Manager, create a secret and store the API token.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read event and alert logs from Netskope, choose Netskope as the data source. Fill in the required information such as your tenant hostname and the AWS Secrets Manager secret ARN for your credentials where api_token is stored. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms the following events that map to Authentication (3002), Entity Management (3004), Account Change (3001), Network Activity (4001), Detection Finding (2004), Data Security Finding (2006), File Hosting Activity (6006), and Device Inventory Info (5001). Events that are not listed but pulled are not mapped to OCSF and will be forwarded to the sink as raw logs.

Authentication (3002) contains the following events from two event types:

Application Events, using the "activity" field. The supported activity values are:

- Login Attempt
- Login Failed
- Login Successful
- Logout

- Other Events which contain the keyword "login"

Audit Events, using the "audit_log_event" field. The supported audit_log_event values are:

- Login Failed
- Login Successful
- Logout Successful
- SSO Login Failed
- SSO Login Successful
- SSO Login Successful by Netskope Support
- SSO Login Failed by Netskope Support
- Admin logged out because of successive login failures

Entity Management (3004) contains the following events from Audit Events:

- Created new inline policy
- Set dedicated egress ip policy
- Created new rbi template
- Created new tunnel group
- Created new introspection policy
- Next Gen CASB API instance created
- Created a new Next Gen CASB API policy
- Next Gen CASB API retroscan created
- Edited inline policy
- Update default actions for inline policies
- Edited rbi template
- Edited tunnel group
- Edit introspection policy record
- Next Gen CASB API instance updated
- Edited Next Gen CASB API policy
- Next Gen CASB API retroscan edited

- Deleted inline policy
- Deleted rbi template
- Deleted tunnel group
- Deleted introspection policy
- Next Gen CASB API instance deleted
- Deleted Next Gen CASB API policy
- Next Gen CASB API retroscan deleted
- Pushed inline policy
- Pushed rbi template
- Pushed tunnel groups
- Applied Phoenix policy record(s)
- Pushed Introspection policies
- Pushed Next Gen CASB API policies
- Next Gen CASB API retroscan stopped
- Next Gen CASB API retroscan paused

Account Change (3001) contains the following events from Audit Events:

- Created new admin
- Added SSO Admin
- Created new support admin
- Enabled admin
- Password Change Failed Attempt
- Password Change Successful
- Reset password
- Disabled admin
- Deleted admin
- Deleted Netskope SSO admin
- Enabled Netskope Support SSO
- Disabled Netskope Support SSO

- Unlocked admin
- Edited SSO Admin Record
- Edit admin record
- Updated admin settings

Network Activity (4001) contains the following events:

Network Events are categorized using the record_type="network" and "action" fields. The supported "action" values are:

- Allow
- Block
- Bypass
- Closed
- Idle Timeout
- Proceed

All events with the value of /record_type = "connection" are also included.

Detection Finding (2004) contains the following events:

Alerts are categorized using the "alert_type" and "alert" fields, where the "alert" field value is set to "yes". The supported "alert_type" values are:

- Compromised Credential
- Malsite
- Malware
- Policy
- UBA
- C2

Data Security Finding (2006) contains the following events:

- /record_type = "alert" and /alert_type = "DLP"
- /record_type = "incident"

- /record_type = "epdlp" and /type = "endpoint"

File Hosting Activity (6006) contains the following events:

Application Events are categorized using the "activity" field, with the "alert" field value set to "no". The supported activity values are:

- Browser File Upload
- Attach
- Create
- Download
- Download All
- Download Installer
- Edit
- Quick Edit
- Insert
- Delete
- Delete All
- Copy
- Move
- Preview
- Formshare
- File Share Access
- Upload
- Share
- Post
- View
- Archive
- Bluetooth File Transfer
- Detach
- Print

- Publish

Device Inventory Info (5001) contains the following events:

All infrastructure logs with record_type="infrastructure".

CloudWatch pipelines configuration for Netskope

Collects security events and alerts from Netskope using REST API v2 token-based authentication.

Configure the Netskope source with the following parameters:

```
source:
  netskope_cloudexchange:
    tenant_url: "<<your-tenant-url>>"
    range: "P7D"
    authentication:
      api_token: "${{aws_secrets:netskope-account-credentials:apiToken}}"
```

Parameters

`tenant_url` (required)

Netskope tenant URL (for example, mycompany.goskope.com).

`authentication.api_token` (required)

REST API v2 token generated from the Netskope Service Account under RBACv3.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

Microsoft Entra ID integration configuration

Microsoft Entra ID (formerly Azure Active Directory) is Microsoft's cloud-based identity and access management service that helps organizations manage user identities and secure access to resources.

Topics

- Source configuration for Microsoft Entra ID

- CloudWatch pipelines configuration for Microsoft Entra ID

Source configuration for Microsoft Entra ID

Integrating with Microsoft Entra ID

Microsoft Entra ID (formerly Azure Active Directory) is Microsoft's cloud-based identity and access management service that helps organizations manage user identities and secure access to resources. CloudWatch Pipeline uses the Microsoft Graph API to retrieve comprehensive identity and security information from Microsoft Entra ID audit logs. The Microsoft Graph API provides access to three primary log types: Directory Audit Logs (tracking directory-level changes and administrative actions), Sign-In Logs (capturing user authentication events and activities), and Provisioning Logs (monitoring user and group provisioning operations).

Authenticating with Microsoft Entra ID

To retrieve the Audit Logs EntraID, pipelines needs to authenticate with your account. The plugin supports OAuth2 Authentication. Follow the instructions in Microsoft Graph APIs and should have the Microsoft Entra ID P1 or P2 license.

- Register an application in Azure with Supported account types, Accounts in this organizational directory only (Single tenant). After registration is complete, note down the Application (client) ID and Directory (tenant) ID.
- Generate a new key for your application. Key is also known as client secret, which are used when exchanging an authorization code for an access token.
- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`
- Specify the permissions your application requires to access the Microsoft Graph APIs. The permissions you need are:
  - AuditLog.Read.All: Required to read audit logs, sign-in logs, and provisioning logs
  - Directory.Read.All: Required to read directory data

Configuring the CloudWatch Pipeline

When configuring the pipeline to read Audit Logs from Microsoft EntraID, choose Microsoft EntraID as the data source. Fill in the required information like Tenant Id using Directory (tenant) ID. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Entra ID events that map to Authentication (3002), Account Change (3001), User Access Management (3005), and Entity Management (3004).

Authentication contains the following events with type in brackets:

- Invalid Username or Password (Sign-in)
- User Strong Auth ClientAuthN Required Interrupt (Sign-in)
- Pass Through User Mfa Error (Sign-in)
- Authentication Failed During Strong Auth (Sign-in)

Account Change contains the following events with type in brackets:

- Add user (Audit)
- Update user (Audit)
- Delete user (Audit)
- Hard delete user (Audit)
- Reset password (Audit)
- User changed default security info (Audit)
- Enable Strong Authentication (Audit)
- Disable Strong Authentication (Audit)

User Access Management contains the following events with type in brackets:

- Add eligible member to role (Audit)
- Remove eligible member from role (Audit)
- Add eligible member to role in PIM completed (Audit)
- Remove eligible member from role in PIM completed (Audit)
- Add member to role (Audit)
- Remove member from role (Audit)
- Remove permanent direct role assignment (Audit)
- Add permanent direct role assignment (Audit)

- Triggered PIM alert (Audit)
- Add delegated permission grant (Audit)
- Remove delegated permission grant (Audit)

Entity Management contains the following events with type in brackets:

- Create (Provisioning)
- Update (Provisioning)
- Add app role assignment to service principal (Audit)
- Remove app role assignment to service principal (Audit)
- Add service principal credentials (Audit)
- Remove service principal credentials (Audit)
- Update service principal (Audit)
- Add service principal (Audit)
- Hard delete service principal (Audit)
- Remove service principal (Audit)
- Consent to application (Audit)
- Add application (Audit)
- Add owner to application (Audit)
- Hard Delete application (Audit)
- Delete application (Audit)
- Update application (Audit)
- Update application – Certificates and secrets management (Audit)
- Add device (Audit)
- Update device (Audit)
- Delete device (Audit)
- Hard delete device (Audit)

CloudWatch pipelines configuration for Microsoft Entra ID

Collects log data from Microsoft Entra ID (formerly Azure Active Directory) using OAuth2 authentication.

Configure the Microsoft Entra ID source with the following parameters:

```
source:
  microsoft_entraid:
    tenant_id: "<example-tenant-ID>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`tenant_id` (required)

The Microsoft Entra ID tenant ID for your organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Microsoft Graph API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Microsoft Graph API authentication.

Microsoft Windows Events integration configuration

Microsoft Windows Event Logs provide a comprehensive logging system that records system, security, and application events on Windows operating systems.

Topics

- Source configuration for Microsoft Windows Events
- CloudWatch pipelines configuration for Microsoft Windows Events

Source configuration for Microsoft Windows Events

Integrating with Windows Event

Microsoft Windows Event Logs provide a comprehensive logging system that records system, security, and application events on Windows operating systems. CloudWatch Pipeline uses the Log Analytics API to retrieve information about system operations, security events, user activities,

and application behaviors from Windows servers and workstations. The Log Analytics API enables access to event data through KQL (Kusto Query Language) queries, allowing retrieval of Windows Event logs from Log Analytics workspaces.

Authenticating with Windows Event

To read Windows Event audit Logs, the pipeline needs to authenticate with your account. The plugin supports OAuth2 Authentication. Follow these instructions to get started with Microsoft Windows Event: Log Analytics APIs.

- Register an application in Azure with Supported account types, Accounts in this organizational directory only (Single tenant). After registration is complete, note down the Application (client) ID and Directory (tenant) ID.
- Generate a new client secret for your application. The client secret is used when exchanging an authorization code for an access token. Copy the secret value immediately as it won't be shown again.
- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`.
- Specify the API permissions your application requires to access the Log Analytics API. The permission you need is: Data.Read: Required to execute KQL queries and read log data from Log Analytics workspaces, including Windows Event logs.
- Create and configure a Log Analytics Workspace: Create a workspace in Azure portal (Monitor → Log Analytics workspaces). Create a Data Collection Rule (DCR) to specify which Windows Event Logs to collect (System, Application, Security). Connect your Windows servers/VMs to the workspace through the DCR. Note down your Workspace ID from the workspace Overview page (required for API queries)
- Grant workspace access to your application: Navigate to your Log Analytics workspace → Access control (IAM). Assign the Log Analytics Reader role to your registered application. This RBAC role works together with the API permission to provide secure access: OAuth confirms API usage rights, while IAM confirms workspace data access rights.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read logs, choose Microsoft Windows Events as the data source. Fill in the required information like Tenant Id using Directory (tenant) ID and Workspace Id (workspace_id). After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Windows audit events that map to Account Change (3001), Authentication (3002), Entity Management (3004), Event Log Activity (1008), File System Activity (1001), Group Management (3006), and Kernel Activity (1003).

Account Change contains the following events:

- 4740

Authentication contains the following events:

- 4624
- 4625
- 4634
- 4647
- 4648
- 4649
- 4672

Entity Management contains the following events:

- 4616
- 4907
- 4719
- 4902

Event Log Activity contains the following events:

- 1100
- 1102
- 1104
- 1105

File System Activity contains the following events:

- 4608
- 4660
- 4688
- 4696
- 4826
- 5024
- 5033
- 5058
- 5059
- 5061
- 5382
- 5379

Group Management contains the following events:

- 4732
- 4798
- 4799
- 4733
- 4731
- 4734
- 4735

Kernel Activity contains the following events:

- 4674

CloudWatch pipelines configuration for Microsoft Windows Events

Collects log data from Microsoft Windows Event logs using OAuth2 authentication.

Configure the Microsoft Windows Event source with the following parameters:

```
source:
```

```
  microsoft_windows:
    tenant_id: "<example-tenant-ID>"
    workspace_id: "<example-workspace-ID>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`tenant_id` (required)

The Microsoft tenant ID for your organization.

`workspace_id` (required)

The Microsoft Log Analytics workspace ID.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Log Analytics workspace API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Log Analytics workspace API authentication.

Okta Auth0

CloudWatch pipelines enables you to collect logs from Okta Auth0. Okta Auth0 is a flexible identity platform designed for modern application authentication and authorization.

Topics

- Source configuration for Okta Auth0
- Pipeline configuration for Okta Auth0

Source configuration for Okta Auth0

Integrating with Okta Auth0

Okta Auth0 is a flexible identity platform designed for modern application authentication and authorization. Auth0 provides developers with powerful tools to integrate secure login, user management, and access control into applications while maintaining scalability and customization.

CloudWatch Pipeline uses the Auth0 Management API to retrieve Authentication (successful and failed logins), and API Activity logs from Auth0 log events.

Authenticating with Okta Auth0

To read logs, the pipeline needs to authenticate with your Okta Auth0 tenant. Auth0 Management API access requires a Client ID and Client Secret belonging to a Machine-to-Machine (M2M) application.

Generate Client Credentials see API Settings for more details.

- Sign in to the Auth0 Dashboard using an admin account.
- Navigate to Applications → Applications.
- Select an existing Machine-to-Machine Application or create a new one.
- Make sure the application has the required scope permissions for the Management API, specifically: `read:logs`
- In the AWS Secrets Manager, create a secret and store the Client ID under the key `client_id` and the Client Secret under the key `client_secret`
- Identify your Auth0 Tenant Domain (for example: `yourtenant.us.auth0.com`) and give it in pipeline.

Once configured, the pipeline can authenticate using the Client Credentials flow and retrieve log events from Auth0.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose Okta Auth0 as the data source. Select the Source Type as Tenant and provide the required details such as your Auth0 Tenant Domain and Client Credentials. After you create the pipeline, log data from Okta Auth0 will be collected and made available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the Auth0 events that maps to Authentication (3002) and API Activity (6003)

Authentication contains the following events:

- f

- fu
- fp
- feccft
- fepft
- feacft
- fc
- fco
- fcoa
- fd
- ferrt
- fertft
- fsa
- limit_wc
- limit_sul
- limit_mu
- pwd_leak
- reset_pwd_leak
- signup_pwd_leak
- gd_auth_fail_email_verification
- gd_auth_failed
- gd_auth_rejected
- gd_otp_rate_limit_exceed
- gd_recovery_failed
- gd_recovery_rate_limit_exceed
- gd_webauthn_challenge_failed
- passkey_challenge_failed
- scp
- sv
- ss
- s

- fi
- fv
- feoobft
- feotpft
- fercft
- ss_sso_failure
- fepotpft
- fvr
- flo

API Activity contains the following events:

- api_limit
- limit_delegation
- mgmt_api_read
- sapi
- api_limit_warning

Pipeline configuration for Okta Auth0

Collects log data from Okta Auth0 using OAuth2 authentication.

Configure the Okta Auth0 source with the following parameters:

```
source:
  okta_auth0:
    domain: "<example-domain-name>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`domain` (required)

The Okta Auth0 domain name for your organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Okta Auth0 API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Okta Auth0 API authentication.

Okta SSO integration configuration

CloudWatch pipelines enables you to collect logs from Okta SSO. Okta SSO is a leading cloud-based identity and access management solution that provides secure, centralized authentication for users and applications.

Topics

- Source configuration for Okta SSO
- CloudWatch pipelines configuration for Okta SSO

Source configuration for Okta SSO

Integrating with Okta SSO

CloudWatch Pipeline uses the Okta System Log API to retrieve Authentication, API Activity, Detection Finding and Entity Management events from your Okta SSO tenant.

Authenticating with Okta SSO

To read the logs, the pipeline needs to authenticate with your Okta SSO tenant. For Okta SSO, authentication is performed using the OAuth 2.0 Client Credentials (JWT Assertion) flow through an Okta API Services application.

Generate the private/public key pair for authentication

- Sign in to the Okta Admin Console using an administrator account.
- Navigate to Applications → Applications.
- Select an existing API Services Application or create a new one.
- Under General → Client Credentials, upload a public key or generate a new key. This key pair will be used to authenticate using a signed JWT assertion.

- Make sure the application has the required OAuth scopes assigned, specifically: `okta.logs.read`
- Admin Roles → Edit assignments → Role(Select Read-only Administrator)
- Copy the Client ID of the application.
- Store the client_id and client_secret(private key) in AWS Secrets Manager: `client_id` and `client_secret(private_key)` (the RSA private key used to sign the JWT assertion)
- Identify your Okta Organization URL and configure in the pipeline (for example: `https://yourdomain.okta.com`).

Once configured, the pipeline can authenticate using Okta's OAuth 2.0 Client Credentials (JWT Assertion) flow and begin retrieving audit log events from the Okta System Log API.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose Okta SSO as the data source. Fill in the required information like Okta Domain name. After you create and activate the pipeline, audit log data from Okta SSO will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Okta events that map to Authentication (3002), API Activity (6003), Detection Finding (2004), and Entity Management (3004).

Authentication contains the following events:

- user.authentication.auth
- user.authentication.auth_via_AD_agent
- user.authentication.auth_via_IDP
- user.authentication.auth_via_LDAP_agent
- user.authentication.auth_via_inbound_SAML
- user.authentication.auth_via_inbound_delauth
- user.authentication.auth_via_iwa
- user.authentication.auth_via_mfa
- user.authentication.auth_via_radius
- user.authentication.auth_via_richclient

- user.authentication.auth_via_social
- user.authentication.authenticate
- user.authentication.sso
- user.session.start
- user.session.impersonation.grant
- app.oauth2.signon
- user.session.impersonation.initiate
- user.authentication.universal_logout
- user.session.clear
- user.session.end
- user.authentication.slo
- user.authentication.universal_logout.scheduled
- user.session.expire
- user.session.impersonation.end
- user.authentication.verify
- policy.evaluate_sign_on
- user.mfa.attempt_bypass
- user.mfa.okta_verify
- user.mfa.okta_verify.deny_push
- user.mfa.okta_verify.deny_push_upgrade_needed
- user.mfa.factor.activate
- user.mfa.factor.deactivate
- user.mfa.factor.reset_all
- user.mfa.factor.suspend
- user.mfa.factor.unsuspend
- user.mfa.factor.update
- user.session.impersonation.extend
- user.session.impersonation.revoke
- user.session.access_admin_app

- user.session.context.change
- application.policy.sign_on.deny_access
- user.authentication.auth_unconfigured_identifier
- user.authentication.dsso_via_non_priority_source
- app.oauth2.invalid_client_credentials
- policy.auth_reevaluate.fail

API Activity contains the following events:

- oauth2.claim.created
- oauth2.scope.created
- security.trusted_origin.create
- system.api_token.create
- workflows.user.table.view
- app.oauth2.as.key.rollover
- app.saml.sensitive.attribute.update
- system.api_token.update
- oauth2.claim.updated
- oauth2.scope.updated
- security.events.provider.deactivate
- system.api_token.revoke
- oauth2.claim.deleted
- oauth2.scope.deleted

Detection Finding contains the following events:

- security.attack.start
- security.breached_credential.detected
- security.request.blocked
- security.threat.detected
- security.zone.make_blacklist

- system.rate_limit.violation
- user.account.report_suspicious_activity_by_enduser
- user.risk.change
- user.risk.detect
- zone.make_blacklist
- security.attack.end

Entity Management contains the following events:

- iam.role.create
- system.idp.lifecycle.create
- application.lifecycle.create
- group.lifecycle.create
- user.lifecycle.create
- policy.lifecycle.create
- zone.create
- oauth2.as.created
- event_hook.created
- inline_hook.created
- pam.security_policy.create
- iam.resourceset.create
- pam.secret.create
- analytics.reports.export.download

CloudWatch pipelines configuration for Okta SSO

Collects log data from Okta SSO using OAuth2 authentication.

Configure the Okta SSO source with the following parameters:

```
source:
  okta_sso:
    domain: "<example-domain-name>"
    range: "P7D"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`domain` (required)

The Okta domain name for your organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Okta SSO API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Okta SSO API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

OneLogin Identity integration configuration

OneLogin is a cloud-based identity and access management (IAM) platform that provides single sign-on (SSO), multi-factor authentication (MFA), and user provisioning capabilities.

Topics

- Source configuration for OneLogin Identity
- CloudWatch pipelines configuration for OneLogin Identity

Source configuration for OneLogin Identity

Integrating with OneLogin Identity

OneLogin is a cloud-based identity and access management (IAM) platform that provides single sign-on (SSO), multi-factor authentication (MFA), and user provisioning capabilities. CloudWatch pipelines uses the OneLogin Events API to retrieve information about authentication events, user activities, policy decisions, and administrative changes across your OneLogin environment. The Events API enables access to event data through REST endpoints, allowing retrieval of security and access logs from your OneLogin account.

Authenticating with OneLogin Identity

To read the logs, the pipeline needs to authenticate with your OneLogin account. For OneLogin, authentication is performed using OAuth2.

Configure OAuth2 authentication for OneLogin

- Log in to the OneLogin Admin Portal and navigate to Developers → API Credentials. Create a new API credential pair. Note the Client ID and Client Secret immediately.
- Assign the appropriate permissions. Select Read All or Manage All scope to make sure the credentials can access event log data.
- In AWS Secrets Manager, create a secret and store the Client ID under key `client_id` and the client secret under key `client_secret`.
- Note your Account ID (subdomain) from the OneLogin Admin Portal under Settings → Account Settings.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose OneLogin as the data source. Fill in the required information like subdomain and authentication credentials. Optionally, specify the Range duration format (for example, PT21H for the last 21 hours). After you create and activate the pipeline, event log data from OneLogin will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and OneLogin events that map to Account Change (3001), Authentication (3002), and Entity Management (3004).

Account Change contains the following events:

- User requested new password
- Changed password for user
- User deactivated
- Password request approved from user
- User locked
- User suspended
- User locked out of app
- OTP device unlocked for user
- User suspended in app
- User suspended in directory
- Unlocked user in directory
- User granted permission to manage role
- User permission to manage role revoked
- User enabled desktop SSO
- User disabled desktop SSO
- Admin changed password for user
- Redirected to an external site for password reset
- API - password updated for user
- API - user locked
- User suspended through API
- User locked through API
- User enabled adaptive login for account
- User disabled adaptive login for account
- Profile change password
- Manually added user to app

- Manually removed user from app
- Failed to change password for user
- User granted permission to manage role failed
- User permission to manage role revoked failed
- Smart password updated for user
- Smart password could not be updated for user
- API - password not updated for user

Authentication contains the following events:

- User logged into OneLogin
- User logged out of OneLogin
- User logged into app
- User logged out of app
- User authenticated by RADIUS configuration
- User authenticated through API
- User successfully authenticated with VLDAP
- User signed in into OneLogin through social network
- User successfully authenticated with VLDAP (OneLogin Desktop Mac)
- API - user logged out
- API - verify factor called
- API - confirm OTP for user succeeded
- User was force logged out
- User successfully logged in on a trusted device
- User successfully logged in through OneLogin Desktop
- User denied auth through OTP push request
- User challenged for OTP
- User reauthenticated into app
- User verified OTP device
- OIDC password for app success

- API - trigger factor for user succeeded
- OIDC implicit flow for app success
- OIDC authorization code for app success
- OIDC get code for app success
- OIDC validate token for app success
- User failed authentication
- User failed to log into app
- User rejected by RADIUS configuration
- Failed to login to app through IDP
- Could not authenticate to app
- User failed authentication through API
- User failed authentication with VLDAP
- User authentication policy does not allow sign-in through social network
- User failed authentication with VLDAP (OneLogin Desktop Mac)
- API - user failed to log out
- API - verify factor failed
- API - confirm OTP for user failed
- User failed to log in on a trusted device
- User failed to login through OneLogin Desktop
- User failed to authenticate through OneLogin Desktop
- User failed OTP challenge
- OIDC implicit flow for app failed
- OIDC authorization code for app failed
- OIDC password for app failed
- OIDC validate token for app failed
- OIDC general fail
- OIDC get code for app failed

Entity Management contains the following events:

- Assigned role to user

- User was created
- User updated
- User deactivated
- User was activated
- User was deleted
- OTP device registered for user
- OTP device deregistered for user
- Updated credit card
- User provisioned in app
- User updated in app
- User suspended in app
- User reactivated in app
- User deleted in app
- Account granted permission to privilege
- Account revoked permission to privilege
- User granted permission to privilege
- User permission to privilege revoked
- Added trusted IDP
- Removed trusted IDP
- Modified trusted IDP
- User provisioned in directory
- User updated by directory
- User suspended in directory
- User reactivated in directory
- User deleted in directory
- Deleted secure note
- Updated user login information
- Attempted to update login information
- Changed the default trusted IDP

- User added to role
- User removed from role
- Created policy
- Updated policy
- Deleted policy
- Created proxy agent
- Deleted proxy agent

CloudWatch pipelines configuration for OneLogin Identity

Collects event logs from OneLogin using OAuth2 authentication.

Configure the OneLogin Identity source with the following parameters:

```
source:
  onelogin_identity:
    range: "P7D"
    subdomain: "<your-subdomain>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`range` (optional)

For pulling historical logs. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for the last 21 hours). The default is 0 hours, and the maximum is 90 days.

`subdomain` (required)

Your OneLogin account subdomain. Must be alphanumeric with hyphens only, between 1–35 characters.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for OneLogin Events API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for OneLogin Events API authentication.

> **Note**
>
> The `client_id` and `client_secret` values are retrieved from AWS Secrets Manager. The above parameter information can be obtained from the API credentials generated while setting up your OneLogin application.

Palo Alto Networks Next-Generation Firewalls integration configuration

CloudWatch pipelines enables you to collect network security logs from Palo Alto Networks Next-Generation Firewalls. Palo Alto Networks provides network security solutions, including firewall, VPN, and threat detection services.

Topics

- Source configuration for Palo Alto Networks Next-Generation Firewalls
- CloudWatch pipelines configuration for Palo Alto Networks Next-Generation Firewalls

Source configuration for Palo Alto Networks Next-Generation Firewalls

Integrating with Palo Alto Networks Next-Generation Firewalls

CloudWatch Pipeline integrates with Palo Alto Networks NGFW using the PAN-OS XML API to retrieve security, authentication, network activity, process activity, detection finding and threat activity. The PAN-OS XML API enables structured access, allowing the retrieval of System Logs, GlobalProtect, Traffic Logs, Threat Logs and URL Filtering Log.

Authenticating with Palo Alto NGFW

To read network security logs, the pipeline needs to authenticate with your Palo Alto Networks NGFW login device interface. The plugin supports Basic Authentication.

- Create and Manage Users on a Palo Alto Networks NGFW Firewall by using the CLI
- Login firewall using with hostname using user admin and your password
- Store this username and password in a secret in AWS Secrets Manager under the keys `username` and `password`.
- Identify and note down your PAN-OS hostname.

Once configured, the pipeline can authenticate using the username and password and retrieve log activity from PAN-OS.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read logs from Palo Alto Networks NGFW, choose Palo Alto Networks Next-Generation Firewalls as the data source. Fill in the required information like

`hostname`. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Authentication (3002), Network Activity (4001), Process Activity (1007), and Detection Finding (2004).

Authentication contains the following type and subtypes:

- GlobalProtect
  - data
  - file
  - flood
  - packet
  - scan
  - spyware
  - url
  - virus
  - vulnerability
  - wildfire
  - wildfire-virus
- System Logs
  - auth

Network Activity contains the following types and subtypes:

- Traffic Logs
  - start
  - end
  - drop
  - deny
- System Logs
  - vpn

- url-filtering
- app-cloud-engine
- dhcp
- ssh
- dnsproxy
- dns-security
- wildfire
- wildfire-appliance
- ntpd
- userid

Process Activity contains the following type and subtypes:

- System Logs
  - general
  - satd
  - ras
  - sslmgr
  - hw
  - iot
  - ctd-agent
  - routing
  - port
  - device-telemetry

Detection Finding contains the following type and subtypes:

- Threat Logs
  - data
  - file
  - flood
  - packet

- scan
- spyware
- url
- ml-virus
- virus
- vulnerability
- wildfire
- wildfire-virus

- URL Filtering Log

CloudWatch pipelines configuration for Palo Alto Networks Next-Generation Firewalls

Collects log data from Palo Alto Next-Generation Firewall using basic authentication.

Configure the Palo Alto NGFW source with the following parameters:

```
source:
  paloaltonetworks_nextgenerationfirewall:
    hostname: "<example-host-name>"
    authentication:
      basic:
        username: "${{aws_secrets:<secret-name>:username}}"
        password: "${{aws_secrets:<secret-name>:password}}"
```

Parameters

`hostname` (required)

The Palo Alto NGFW hostname for your firewall.

`authentication.basic.username` (required)

Basic authentication username for Palo Alto NGFW API authentication.

`authentication.basic.password` (required)

Basic authentication password for Palo Alto NGFW API authentication.

Palo Alto Prisma Cloud integration configuration

Palo Alto Prisma Cloud is a cloud-native application protection platform (CNAPP) that secures cloud infrastructure, workloads, and applications across multi-cloud environments. CloudWatch pipelines use the Prisma Cloud CSPM and Compute (CWPP) APIs to retrieve security alerts, vulnerability findings, asset inventories, compliance posture, audit logs, and workload data from your Prisma Cloud tenant.

Topics

- Source configuration for Palo Alto Prisma Cloud
- CloudWatch pipelines configuration for Palo Alto Prisma Cloud

Source configuration for Palo Alto Prisma Cloud

Integrating with Palo Alto Prisma Cloud

CloudWatch pipelines use the Prisma Cloud CSPM and Compute (CWPP) APIs to retrieve security alerts, vulnerability findings, asset inventories, compliance posture, audit logs, and workload data from your Prisma Cloud tenant. The APIs expose REST endpoints that allow fetching security data for monitoring and analysis.

To integrate CloudWatch Pipelines with Palo Alto Prisma Cloud, complete the following high-level steps:

- Generate an Access Key and Secret Key in the Prisma Cloud Console.
- Identify the CSPM API URL, Compute Console URL, and Compute API version.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Palo Alto Prisma Cloud as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, make sure you have the following:

- An active Palo Alto Prisma Cloud Enterprise tenant with API access
- A Prisma Cloud user with System Admin or Account Group Read Only role

- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager
- An AWS account with permissions to create and manage CloudWatch Logs log groups

Authenticating with Palo Alto Prisma Cloud

Palo Alto Prisma Cloud uses an Access Key and Secret Key for authentication. The pipeline sends these credentials to the CSPM login endpoint, which returns a JWT token for subsequent API access.

Configure Authentication for Palo Alto Prisma Cloud

To configure authentication credentials for the pipeline:

1. Log in to the Prisma Cloud Console and navigate to Settings > Access Control > Access Keys.
2. Choose **Add** > **Access Key**.
3. Note the Access Key ID and Secret Key.
4. Identify the CSPM API URL based on your tenant region (for example, `https://api.prismacloud.io`).
5. Identify the Compute Console URL by navigating to Compute > Manage > System > Utilities > Path to Console.
6. Identify the Compute API version (available from the bell icon in the Console).
7. Store the Access Key ID as `username` and Secret Key as `password` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Palo Alto Prisma Cloud as the data source. Provide the `cspm_base_url`, `compute_console_url`, `compute_api_version`, `access_key`, and `secret_key`. After you create and activate the pipeline, security data from Prisma Cloud will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Page sizes** – Configure the number of records retrieved per API request page.
- **Polling intervals** – Valid range is 10 minutes to 7 days. Uses ISO 8601 duration format.

- **Backfill durations** – Valid range is 1 hour to 90 days. Uses ISO 8601 duration format.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Base Event [0]** – Applications
- **Detection Finding [2004]** – Alerts
- **Vulnerability Finding [2002]** – Vulnerabilities
- **Cloud Resources Inventory Info [5023]** – Assets
- **Entity Management [3004]** – Audit Logs
- **Compliance Finding [2003]** – Compliances, Alerts
- **Device Inventory Info [5001]** – Hosts
- **Scan Activity [6007]** – Images, Containers

CloudWatch pipelines configuration for Palo Alto Prisma Cloud

Collects security data from Palo Alto Prisma Cloud using Access Key and Secret Key authentication through the CSPM and Compute APIs.

Configure the Palo Alto Prisma Cloud source with the following parameters:

```
source:
  paloaltonetworks_prismacloud:
    cspm_base_url: "https://api.prismacloud.io"
    compute_console_url: "https://us-east1.cloud.twistlock.com/us-1-123456789"
    compute_api_version: "33.01"
    authentication:
      oauth2:
        access_key: "${{aws_secrets:my-prismacloud-secret:username}}"
        secret_key: "${{aws_secrets:my-prismacloud-secret:password}}"
    range: "P30D"
```

Parameters

`cspm_base_url` (required)

The base URL for the Prisma Cloud CSPM API, determined by your tenant region (for example, `https://api.prismacloud.io`).

`compute_console_url` (required)

The URL of the Prisma Cloud Compute Console (for example, `https://us-east1.cloud.twistlock.com/us-1-123456789`).

`compute_api_version` (required)

The Compute API version for your Prisma Cloud tenant (for example, `33.01`).

`authentication.oauth2.access_key` (required)

The Prisma Cloud Access Key ID, stored in AWS Secrets Manager.

`authentication.oauth2.secret_key` (required)

The Prisma Cloud Secret Key, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `PT1H`, maximum is `P90D`. Default is `P30D`.

Ping Identity PingAccess integration configuration

Ping Identity PingAccess is an enterprise-grade access management solution that serves as a centralized policy enforcement point for web applications and APIs. It provides fine-grained authorization, URL-level access control, and web session management across enterprise resources. CloudWatch pipelines allow ingestion of Ping Identity PingAccess audit log data into CloudWatch Logs.

Topics

- Source configuration for Ping Identity PingAccess
- CloudWatch pipelines configuration for Ping Identity PingAccess

Source configuration for Ping Identity PingAccess

Integrating with Ping Identity PingAccess

Ping Identity PingAccess integration uses Amazon S3 and Amazon SQS to ingest audit log data into CloudWatch pipelines. PingAccess is deployed on-premises and does not expose a REST API for audit log retrieval. Fluent Bit tails the JSON-formatted audit log files on the PingAccess host and delivers them to an Amazon S3 bucket. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles
- A Ping Identity PingAccess server with administrative access
- A Linux host with Fluent Bit installed (can be the same host as PingAccess)
- Network connectivity between the PingAccess host and AWS

Log forwarding setup

PingAccess writes audit logs to local files using Log4j2. You configure JSON-formatted output by adding JsonTemplateLayout appenders to the `log4j2.xml` configuration file. Fluent Bit tails these JSON log files and delivers them to Amazon S3. For detailed configuration instructions, see Step 5 in the following section.

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for Ping Identity PingAccess log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store PingAccess audit logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
```

```
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        "StringEquals": {
          "aws:SourceAccount": "<account-id>"
        }
      }
    }
  ]
}
```

Step 5: Configure Ping Identity PingAccess log export and Fluent Bit

Enable JSON logging on PingAccess by editing <PA_HOME>/conf/log4j2.xml. Add the following RollingFile appenders:

```
<RollingFile name="AdminAudit-JsonTemplateLayout"
             fileName="${sys:pa.log.dir}/admin_audit_json.log"
             filePattern="${sys:pa.log.dir}/admin_audit_json.%d{yyyy-MM-dd}.log"
             ignoreExceptions="false">
    <JsonTemplateLayout eventTemplateUri="${sys:pa.log4j.json.templates.uri}/admin-
audit-log.json"/>
    <Policies>
        <TimeBasedTriggeringPolicy maxRandomDelay="45"/>
    </Policies>
</RollingFile>

<RollingFile name="AccessAudit-JsonTemplateLayout"
             fileName="${sys:pa.log.dir}/audit_json.log"
             filePattern="${sys:pa.log.dir}/audit_json.%d{yyyy-MM-dd}.log"
             ignoreExceptions="false">
```

```
    <JsonTemplateLayout eventTemplateUri="${sys:pa.log4j.json.templates.uri}/access-
audit-log.json"/>
    <Policies>
        <TimeBasedTriggeringPolicy maxRandomDelay="45"/>
    </Policies>
</RollingFile>
```

Update the Loggers section to reference the new appenders:

```
<Logger name="com.pingidentity.pa.admin.audit" level="INFO" additivity="false">
    <AppenderRef ref="AdminAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="com.pingidentity.pa.audit.AccessAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="AccessAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="com.pingidentity.pa.audit.PolicyAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="AccessAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="com.pingidentity.pa.audit.SessionAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="AccessAudit-JsonTemplateLayout"/>
</Logger>
```

Configure Fluent Bit to collect both audit log files and deliver them to Amazon S3:

```
########################################
# SERVICE SECTION
########################################
[SERVICE]
    Flush        5
    Daemon       Off
    Log_Level    info
    storage.path /etc/fluent-bit/db/storage
    storage.sync normal
    storage.checksum off
    storage.backlog.mem_limit 10M

########################################
# INPUT SECTION - Access Audit Log
########################################
[INPUT]
```

```
    Name              tail
    Path              /opt/pingaccess/log/audit_json.log
    Tag               pingaccess.audit
    Read_from_Head    True
    DB                /etc/fluent-bit/db/audit_checkpoint.db
    DB.Sync           Normal
    storage.type      filesystem
    Rotate_Wait       30
    Refresh_Interval 60

########################################
# INPUT SECTION - Admin Audit Log
########################################
[INPUT]
    Name              tail
    Path              /opt/pingaccess/log/admin_audit_json.log
    Tag               pingaccess.admin
    Read_from_Head    True
    DB                /etc/fluent-bit/db/admin_checkpoint.db
    DB.Sync           Normal
    storage.type      filesystem
    Rotate_Wait       30
    Refresh_Interval 60

########################################
# OUTPUT SECTION
########################################
[OUTPUT]
    Name               s3
    Match              pingaccess.*
    Bucket             amzn-s3-demo-bucket
    Region             <region>
    S3_Key_Format      /pingaccess/%Y/%m/%d/%H/%M/%S.log.gz
    compression        gzip
    use_put_object     On
    store_dir          /etc/fluent-bit/db/s3
    total_file_size    1M
    log_key            log
    upload_timeout     60
```

> **Note**
>
> PingAccess writes independent log files per cluster node. Fluent Bit must be installed on each node.

The `audit_json.log` captures runtime access control events (request URL, client IP, policy decision, response code, latency). The `admin_audit_json.log` captures administrative console activity (configuration changes, admin logins, rule and application modifications).

Fluent Bit delivers gzip-compressed NDJSON files to Amazon S3. The `storage.type filesystem` setting ensures buffering to disk for reliability.

> **Important**
>
> Use only the default PingAccess-provided JSON templates.

Step 6: IAM permissions

Create an IAM policy with the following permissions for the Fluent Bit host to write objects to the Amazon S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FluentBitS3Write",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetBucketLocation",
        "s3:ListBucket",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/pingaccess/*"
      ]
    }
```

```
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose Ping Identity PingAccess as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between PingAccess audit log types and OCSF event classes.

Event name	OCSF event class
Access Audit (runtime HTTP activity)	HTTP Activity [4002]
API Audit (admin API operations)	API Activity [6003]

CloudWatch pipelines configuration for Ping Identity PingAccess

The Ping Identity PingAccess setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
```

```
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "pingidentity_pingaccess"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Use "pingidentity_pingaccess" for Ping Identity PingAccess.

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Use `ndjson` for PingAccess JSON audit logs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

Ping Identity PingFederate integration configuration

Ping Identity PingFederate is an enterprise-grade identity federation server that serves as a central broker for Single Sign-On (SSO), token issuance, and protocol translation across SAML 2.0, OAuth 2.0, OpenID Connect, WS-Federation, and WS-Trust. CloudWatch pipelines allow ingestion of Ping Identity PingFederate audit log data into CloudWatch Logs.

Topics

- Source configuration for Ping Identity PingFederate
- CloudWatch pipelines configuration for Ping Identity PingFederate

Source configuration for Ping Identity PingFederate

Integrating with Ping Identity PingFederate

Ping Identity PingFederate integration uses Amazon S3 and Amazon SQS to ingest audit log data into CloudWatch pipelines. PingFederate is deployed on-premises and does not expose a REST API for audit log retrieval. Fluent Bit tails the JSON-formatted audit log files on the PingFederate host and delivers them to an Amazon S3 bucket. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles
- A Ping Identity PingFederate server with administrative access
- A Linux host with Fluent Bit installed (can be the same host as PingFederate)
- Network connectivity between the PingFederate host and AWS

Log forwarding setup

PingFederate writes audit logs to local files using Log4j2. You configure JSON-formatted output by adding JsonTemplateLayout appenders to the `log4j2.xml` configuration file. Fluent Bit tails these JSON log files and delivers them to Amazon S3. For detailed configuration instructions, see Step 5 in the following section.

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for Ping Identity PingFederate log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store PingFederate audit logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        "StringEquals": {
          "aws:SourceAccount": "<account-id>"
```

```
        }
      }
    }
  ]
}
```

Step 5: Configure Ping Identity PingFederate log export and Fluent Bit

Enable JSON logging on PingFederate by editing <PF_HOME>/server/default/conf/log4j2.xml. Add the following RollingFile appenders:

```
<RollingFile name="AdminAudit-JsonTemplateLayout"
             fileName="${sys:pf.log.dir}/admin_json.log"
             filePattern="${sys:pf.log.dir}/admin_json.%d{yyyy-MM-dd}.log"
             ignoreExceptions="false">
    <JsonTemplateLayout eventTemplateUri="${sys:pf.log4j.json.templates.uri}/admin-
audit-log.json"/>
    <Policies>
        <TimeBasedTriggeringPolicy maxRandomDelay="45"/>
    </Policies>
</RollingFile>

<RollingFile name="SecurityAudit-JsonTemplateLayout"
             fileName="${sys:pf.log.dir}/audit_json.log"
             filePattern="${sys:pf.log.dir}/audit_json.%d{yyyy-MM-dd}.log"
             ignoreExceptions="false">
    <JsonTemplateLayout eventTemplateUri="${sys:pf.log4j.json.templates.uri}/runtime-
audit-log.json"/>
    <Policies>
        <TimeBasedTriggeringPolicy maxRandomDelay="45"/>
    </Policies>
</RollingFile>
```

Update the Loggers section to reference the new appenders for the multiple audit loggers:

```
<Logger name="org.sourceid.websso.profiles.sp.SpAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="org.sourceid.websso.profiles.idp.IdpAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
```

```
<Logger name="org.sourceid.websso.profiles.idp.AsAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="org.sourceid.websso.profiles.idp.ClientRegistrationAuditLogger"
 level="INFO" additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="org.sourceid.wstrust.log.STSAuditLogger" level="INFO" additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="com.pingidentity.sdk.logging.LoggingUtil" level="INFO"
 additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="AuditLogger" level="INFO" additivity="false">
    <AppenderRef ref="AdminAudit-JsonTemplateLayout"/>
</Logger>
```

Configure Fluent Bit to collect both audit log files and deliver them to Amazon S3:

```
########################################
# SERVICE SECTION
########################################
[SERVICE]
    Flush        5
    Daemon       Off
    Log_Level    info
    storage.path /etc/fluent-bit/db/storage
    storage.sync normal
    storage.checksum off
    storage.backlog.mem_limit 10M

########################################
# INPUT SECTION - Audit Log
########################################
[INPUT]
    Name             tail
    Path             /opt/pingfederate/log/audit_json.log
    Tag              pingfederate.audit
    Read_from_Head   True
    DB               /etc/fluent-bit/db/audit_checkpoint.db
    DB.Sync          Normal
```

```
    storage.type     filesystem
    Rotate_Wait      30
    Refresh_Interval 60

########################################
# INPUT SECTION - Admin Log
########################################
[INPUT]
    Name             tail
    Path             /opt/pingfederate/log/admin_json.log
    Tag              pingfederate.admin
    Read_from_Head   True
    DB               /etc/fluent-bit/db/admin_checkpoint.db
    DB.Sync          Normal
    storage.type     filesystem
    Rotate_Wait      30
    Refresh_Interval 60

########################################
# OUTPUT SECTION
########################################
[OUTPUT]
    Name              s3
    Match             pingfederate.*
    Bucket            amzn-s3-demo-bucket
    Region            <region>
    S3_Key_Format     /pingfederate/%Y/%m/%d/%H/%M/%S.log.gz
    compression       gzip
    use_put_object    On
    store_dir         /etc/fluent-bit/db/s3
    total_file_size   1M
    log_key           log
    upload_timeout    60
```

Note

PingFederate writes independent log files per cluster node. You must install Fluent Bit on each node.

- The `audit_json.log` file captures runtime authentication events (SSO, credential validation, assertion issuance).

- The `admin_json.log` file captures administrative console activity (configuration changes, admin logins).
- Fluent Bit delivers gzip-compressed NDJSON files to Amazon S3.
- The `storage.type filesystem` setting ensures buffering to disk for reliability.

> **Important**
>
> Use only the default PingFederate-provided JSON templates. Modifying the `.json` template files changes the output schema and might break downstream processing.

Step 6: IAM permissions

Create an IAM policy with the following permissions for the Fluent Bit host to write objects to the Amazon S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FluentBitS3Write",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetBucketLocation",
        "s3:ListBucket",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/pingfederate/*"
      ]
    }
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose Ping Identity PingFederate as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between PingFederate audit log types and OCSF event classes.

Event name	OCSF event class
Security Audit (runtime authentication lifecycle)	Authentication [3002]
Administrator Audit (admin login/logout)	Authentication [3002]
Administrator Audit (CRUD on configuration objects)	Entity Management [3004]

CloudWatch pipelines configuration for Ping Identity PingFederate

The Ping Identity PingFederate setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
```

```
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "pingidentity_pingfederate"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Use "pingidentity_pingfederate" for Ping Identity PingFederate.

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Use `ndjson` for PingFederate JSON audit logs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

PingIdentity PingOne integration configuration

PingOne is a cloud-based identity and access management (IAM) platform offered by Ping Identity, designed to provide secure access to applications and services across various platforms.

Topics

- Source configuration for PingIdentity PingOne
- CloudWatch pipelines configuration for PingIdentity PingOne

Source configuration for PingIdentity PingOne

Integrating with PingIdentity PingOne

PingOne is Ping Identity's cloud-based identity-as-a-service (IDaaS) platform that provides identity and access management capabilities. CloudWatch Pipeline uses the PingOne Audit Logs API to retrieve information about authentication events, user activities, policy decisions, and administrative changes across your PingOne environment. The Audit Logs API enables access to event data through REST endpoints, allowing retrieval of security and access logs from your PingOne organization.

Authenticating with PingIdentity PingOne

To read the logs, the pipeline needs to authenticate with your PingOne environment. For PingOne, authentication is performed using OAuth2.

Configure OAuth2 authentication for PingOne

- Log in to the PingOne Console and navigate to Applications → Applications. Create a new application of type Worker. Note the Client ID and Environment ID.
- Generate a new Client Secret from the Configuration tab. Copy the secret immediately.
- In AWS Secrets Manager, create a secret and store the Client ID under key `client_id` and the client secret under key `client_secret`.
- Assign Environment Admin and Application Owner roles to the application.
- Identify your PingOne Region (NA, EU, AP, AU, CA, SG).
- Note the Environment ID from Settings → Environment → Properties.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose PingOne as the data source. Fill in the required information like Environment ID. Optionally, specify the Region (defaults to NA) and the Range duration format (for example, PT21H for the last 21 hours). The default range is 0 hours, and the maximum is 90 days. After you create and activate the pipeline, audit log data from PingOne will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and PingOne events that map to Account Change (3001), Authentication (3002), and Entity Management (3004).

Account Change contains the following events:

- USER.CREATED
- USER.INVITED
- USER.REINVITED
- USER.INVITE_ACCEPTED
- PASSWORD.FORCE_CHANGE
- PASSWORD.RECOVERY
- PASSWORD.RESET
- USER.INVITE_REVOKED
- USER.DELETED
- USER.LOCKED
- MFA_SETTINGS.UPDATED
- PASSWORD.UNLOCKED
- USER.UNLOCKED

Authentication contains the following events:

- AUTHENTICATION.CREATED
- RADIUS_SESSION.CREATED
- SESSION.CREATED
- SESSION.UPDATED

- SESSION.DELETED
- USER.SLO_FAILURE
- USER.SLO_PARTIAL_LOGOUT
- USER.SLO_REQUESTED
- USER.SLO_SUCCESS
- USER.KERBEROS_FAILED
- USER.KERBEROS_SUCCEEDED
- DEVICE.ACTIVATION_OTP_FAILED
- DEVICE.ACTIVATION_OTP_INVALID
- DEVICE_PAYLOAD.CHECK_INVALID
- DEVICE_PAYLOAD.CHECK_SUCCESS
- OTP.CHECK_FAILED
- OTP.CHECK_INVALID
- OTP.CHECK_SUCCESS
- PASSWORD.CHECK_FAILED
- PASSWORD.CHECK_SUCCEEDED

Entity Management contains the following events:

- ACTION.CREATED
- AGREEMENT.CREATED
- AGREEMENT_LANGUAGE.CREATED
- AGREEMENT_LANGUAGE_REVISION.CREATED
- APPLICATION.CREATED
- AUTHORIZE_POLICY.CREATED
- CERTIFICATE.CREATED
- DEVICE.CREATED
- DEVICE_AUTHENTICATION_POLICY.CREATED
- FIDO_POLICY.CREATED
- FLOW.CREATED
- FLOW_DEFINITION.CREATED

- FLOW_EXECUTION.CREATED
- GROUP.CREATED
- IDENTITY_PROVIDER.CREATED
- IDP_ATTRIBUTE.CREATED
- INSTANT_MESSAGING_DELIVERY_SETTINGS.CREATED
- KEY.CREATED
- LICENSE.CREATED
- NOTIFICATION.CREATED
- NOTIFICATION_POLICY.CREATED
- ORGANIZATION.CREATED

- ROLE.DELETED

CloudWatch pipelines configuration for PingIdentity PingOne

Collects audit logs from PingIdentity PingOne using OAuth2 authentication.

Configure the PingIdentity PingOne source with the following parameters:

```
source:
  pingidentity_pingone:
    range: "P7D"
    region: "NA"
    environment_id: "<your-environment-id>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`range` (optional)

For pulling historical logs. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for the last 21 hours). The default is 0 hours, and the maximum is 90 days.

`region` (optional)

PingOne region code (NA, EU, AP, AU, CA, SG). The default is "NA".

`environment_id` (required)

The PingOne environment ID.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for PingIdentity PingOne API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for PingIdentity PingOne API authentication.

Proofpoint TAP integration configuration

Proofpoint TAP is an advanced email security solution that detects, analyzes, and blocks advanced threats before they reach users' inboxes. CloudWatch pipelines use the Proofpoint TAP SIEM API, Campaign API, and Forensics API to retrieve security event data including message and click events, threat campaign information, and sandbox analysis results.

Topics

- Source configuration for Proofpoint TAP
- CloudWatch pipelines configuration for Proofpoint TAP

Source configuration for Proofpoint TAP

Integrating with Proofpoint TAP

CloudWatch Pipelines use the Proofpoint TAP SIEM API, Campaign API, and Forensics API to retrieve security event data. The SIEM API returns message and click events within configurable time windows, while the Campaign and Forensics APIs provide detailed threat campaign information and sandbox analysis results. All API endpoints are available at `https://tap-api-v2.proofpoint.com`.

To integrate CloudWatch Pipelines with Proofpoint TAP, complete the following steps:

1. Configure Proofpoint TAP authentication credentials:
   - Log in to the Proofpoint TAP Threat Insight Dashboard.
   - Navigate to Settings > Connected Applications > Service Credentials.
   - Generate a new service credential.
   - Note the Service Principal and Secret values.
2. Store the `servicePrincipal` and `secret` in AWS Secrets Manager.
3. Create a CloudWatch Logs log group for the pipeline output.
4. Create an IAM role with AWS Secrets Manager access and a trust relationship for the pipeline.
5. Configure and create the CloudWatch pipeline.

Prerequisites

Before you begin, make sure you have the following:

- An active Proofpoint TAP account with Threat Insight Dashboard access
- A TAP service credential with SIEM, Campaign, and Forensics API access
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with Proofpoint TAP

Proofpoint TAP uses HTTP Basic authentication with a service principal and secret. The pipeline sends these credentials with each API request to authenticate access to the SIEM, Campaign, and Forensics endpoints.

Configure Authentication for Proofpoint TAP

To configure authentication credentials for the pipeline:

1. Log in to the Proofpoint TAP Threat Insight Dashboard.
2. Navigate to Settings > Connected Applications > Service Credentials.
3. Generate a new service credential.
4. Note the Service Principal and Secret values.
5. Store the `servicePrincipal` and `secret` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Proofpoint TAP as the data source. Provide the required `service_principal` and `secret` credentials. After you create and activate the pipeline, security event data from Proofpoint TAP will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Polling intervals** – `siem_polling_interval` (default `PT10M`), `clicks_permitted_polling_interval` (default `PT5M`), `campaign_polling_interval` (default `P1D`)
- **Backfill durations** – `siem_backfill` (default `P1D`), `campaign_backfill` (default `P1D`). Valid range: `PT30S` to `P1D`.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Email Activity [4009]** – Message Delivered, Click Permitted
- **Detection Finding [2004]** – Message Blocked, Click Blocked
- **OSINT Inventory Info [5021]** – Campaign, Forensic Evidence

CloudWatch pipelines configuration for Proofpoint TAP

Collects email security event data from Proofpoint TAP using HTTP Basic authentication.

Configure the Proofpoint TAP source with the following parameters:

```
source:
  proofpoint_tap:
    authentication:
      basic:
        service_principal: "${{aws_secrets:proofpoint-tap-account-
credentials:servicePrincipal}}"
        secret: "${{aws_secrets:proofpoint-tap-account-credentials:secret}}"
    range: "P1D"
```

Parameters

`authentication.basic.service_principal` (required)

The Proofpoint TAP service principal for HTTP Basic authentication, stored in AWS Secrets Manager.

`authentication.basic.secret` (required)

The Proofpoint TAP secret for HTTP Basic authentication, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `PT30S`, maximum is `P1D`. Default is `P1D`.

Qualys CSAM integration configuration

Qualys CyberSecurity Asset Management (CSAM) provides visibility into your IT asset inventory, software components, and domain intelligence. It discovers and catalogs assets across on-premises, cloud, and container environments, and it tracks the software installed on them, including lifecycle and authorization status. It also identifies vulnerabilities in your internet-facing assets through External Attack Surface Management (EASM), and it detects unresolved and typosquatted domains.

CloudWatch pipelines use the Qualys CSAM REST API to retrieve asset inventory, software components, vulnerability findings, and domain intelligence data from your Qualys tenant. The API provides paginated REST endpoints with JSON Web Token (JWT) bearer token authentication for retrieving security asset data for monitoring and analysis.

Topics

- Source configuration for Qualys CSAM
- CloudWatch pipelines configuration for Qualys CSAM
- Known Qualys CSAM platform limitations
- Troubleshooting the Qualys CSAM integration

Source configuration for Qualys CSAM

Supported API and platform versions

The following table lists the supported API and platform versions.

Component	Version	Notes
Qualys CSAM API	v2.0	CSAM and Global AssetView (GAV) APIs
OCSF schema	v1.5.0	Open Cybersecurity Schema Framework mapping
OAuth 2.0 token exchange	Not applicable	Form-urlencoded username and password exchange for a JWT bearer token

Qualys Cloud Platform prerequisites

Before you begin, make sure you have the following:

- An active Qualys subscription with the Qualys CSAM module enabled
- A Qualys user account with API access permissions to CSAM endpoints
- Your platform-specific Qualys API Gateway hostname, such as `gateway.qg3.apps.qualys.com`

Configure Qualys CSAM

Use the following procedure to create a Qualys Reader user for the integration.

1. Log in to the Qualys Cloud Platform and identify your Qualys API Gateway hostname.
2. From the module picker, choose **Administration** under **Platform And Sensor Management**.

3. On the Administration page, choose the **Users** tab. From the **Create User** menu, choose **Create Reader User**.
4. On the **General Information** tab, complete all required fields: first name, last name, address, country, state, ZIP code, and email address.
5. Choose **User Role** in the left navigation pane, and then configure the following settings:
   - For **User Role**, choose **Reader**.
   - Under **Allow access to**, select **API**. API access is required for the account to authenticate to the Qualys API.
   - Leave **Business Unit** set to **Unassigned** unless your organization uses business units to segment access.
6. Choose **Asset Groups** in the left navigation pane. Use **Add asset groups** to select the asset groups that the user, and therefore the connector, can access. Select all asset groups to retrieve every asset in the subscription, or select specific groups to limit the scope.
7. Choose **Permissions** in the left navigation pane. The extended permissions to manage the VM module, purge host information or history, and manage the PC module are not required for API read access. Leave them cleared unless your process requires this account to manage those modules.
8. Complete the remaining **Options** and **Security** tabs. Configure options such as IP-based login restrictions only if your organization requires them.
9. Choose **Save** or **Create User**. Qualys sends the new user a temporary password.
10. Log in to the Qualys user interface with the temporary password and complete the required password reset. The credentials do not work with the connector until this first-time password reset is complete.
11. Save the final `username` and `password` for use in the AWS connector configuration.

Qualys API Gateway hostnames

The following list shows the Qualys API Gateway hostname for each platform.

US Platform 1

```
gateway.qg1.apps.qualys.com
```

US Platform 2

```
gateway.qg2.apps.qualys.com
```

US Platform 3

```
gateway.qg3.apps.qualys.com
```

US Platform 4

```
gateway.qg4.apps.qualys.com
```

EU Platform 1

```
gateway.qg1.apps.qualys.eu
```

EU Platform 2

```
gateway.qg2.apps.qualys.eu
```

India Platform

```
gateway.qg1.apps.qualys.in
```

Canada Platform

```
gateway.qg1.apps.qualys.ca
```

UAE Platform

```
gateway.qg1.apps.qualys.ae
```

Australia Platform

```
gateway.qg1.apps.qualys.com.au
```

AWS prerequisites

Before you configure the data source, make sure you have the following:

- An AWS account with permissions to create and manage CloudWatch pipelines. For more information, see the section called “API caller permissions”.
- An AWS account with permissions to create and update secrets in AWS Secrets Manager, and a source role that can retrieve the stored credentials. For more information, see the section called “Third-party sources (API Pull)”.
- An AWS account with permissions to create and manage CloudWatch Logs log groups. For more information, see the section called “CloudWatch Logs API operations and required permissions for actions”.
- The Qualys username and password from the product configuration procedure

Configure the CloudWatch pipeline resources

1. Store the Qualys credentials in AWS Secrets Manager.
   - Open the AWS Secrets Manager console and choose **Store a new secret**.
   - For the secret type, choose **Other type of secret**.
   - Add a `username` key with your Qualys platform username.
   - Add a `password` key with your Qualys platform password.
   - Name the secret, for example, `qualys-csam-credentials`.
2. Create the destination CloudWatch Logs log group. Use a descriptive name, such as `/aws/cloudwatch/pipelines/qualys-csam`.
3. Create the source IAM role with the required permissions. For information about the required trust and permissions policies, see the section called “CloudWatch pipelines IAM policies and permissions”.
4. Open the CloudWatch console and navigate to **Pipelines**. Choose **Qualys CSAM** as the data source, configure authentication with the Qualys API Gateway hostname, username, and password, and then select the destination log group. For the complete pipeline configuration and parameter reference, see the section called “Pipeline configuration”.
5. Configure the CloudWatch Logs resource policy. The required action depends on how you create the pipeline and whether the log group already exists.
   - When you use the console with a new log group, the resource policy is created automatically.
   - When you use the console with an existing log group that already has a resource policy, the console displays the message *Resource Policy Detected: The log group you selected already has a resource policy. Please verify that this policy includes permissions for pipelines to write to the destination log group. You may need to modify the existing resource policy to add the necessary permissions.* Review and update the existing policy to include the required pipeline write permissions. Add the permissions within five minutes of pipeline creation.
   - When you use the AWS CLI or API, a resource policy is never created automatically. Create the CloudWatch Logs resource policy manually before the pipeline becomes active.
6. Wait a few minutes for the initial data retrieval. Check the destination log group for incoming events and monitor pipeline metrics for successful ingestion.

Authentication mechanism

Qualys CSAM uses OAuth 2.0 token exchange for authentication.

The pipeline sends a form-urlencoded POST request containing the username, password, and `token=true` to the Qualys `/auth` endpoint. The endpoint returns a JSON Web Token (JWT) that the connector sends as a bearer token with subsequent API calls.

The token remains valid for four hours, and the connector automatically renews it before expiration. The connector retrieves credentials securely from AWS Secrets Manager at runtime.

Supported Open Cybersecurity Schema Framework event classes

This integration supports OCSF schema version v1.5.0 and maps Qualys CSAM events to the following OCSF classes.

Event type	Application or endpoint ID	OCSF class	Description
Assets	`POST /rest/2.0/search/am/asset`	Device Inventory Info (5001)	Discovered hosts and devices with operating system, hardware, network interface, agent, and risk score information
Software Components	`POST /rest/2.0/am/asset/component`	Software Inventory Info (5020)	Software packages discovered on assets, including name, version, and installation metadata
Vulnerabilities	`POST /rest/2.0/search/am/easm/vulns`	Vulnerability Finding (2002)	Vulnerabilities detected on external-facing assets, including CVE, CVSS, and Qualys Vulnerability Score (QVS) information
Unresolved Domains	`POST /rest/2.0/am/domain/list`	OSINT Inventory Info (5021)	Unresolved subdomains under monitored domains
Typosquatted Domains	`POST /rest/2.0/am/domain/list?do`	OSINT Inventory Info (5021)	Typosquatted domains discovered through permutation analysis that impersonate legitimate domains

Event type	Application or endpoint ID	OCSF class	Description
	`mainType=TYPOSQUATTED_DOMAINS`		

Events that do not match an OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

CloudWatch pipelines configuration for Qualys CSAM

With this pipeline, you can collect asset inventory, software component, External Attack Surface Management (EASM) vulnerability finding, and domain intelligence data from Qualys CSAM. The pipeline uses the Global AssetView (GAV) and CSAM REST APIs with OAuth 2.0 authentication and a JWT exchange.

The following example shows the complete pipeline configuration:

```
extension:
  aws:
    secrets:
      qualys_csam:
        secret_id: "arn:aws:secretsmanager:<region>:<account-id>:secret:<secret-name>"
        region: "<region>"
        sts_role_arn: "arn:aws:iam::<account-id>:role/<role-name>"
pipeline:
  source:
    qualys_csam:
      hostname: "gateway.qg3.apps.qualys.com"
      range: "P1D"
      authentication:
        oauth2:
          username: "${{aws_secrets:qualys_csam:username}}"
          password: "${{aws_secrets:qualys_csam:password}}"
  sink:
    - cloudwatch_logs:
        log_group: "<qualys-csam-log-group>"
  processor:
    - ocsf:
```

```
        schema:
          qualys_csam: null
        version: "1.5"
        mapping_version: 1.5.0
```

AWS extension parameters

The AWS extension configures AWS Secrets Manager access for securely retrieving credentials at runtime. Define a named secret block, such as `qualys_csam`. Set `secret_id` to the ARN of your secret, `region` to the AWS Region where the secret is stored, and `sts_role_arn` to the IAM role ARN to assume when accessing the secret. Reference credentials in the pipeline with `${{aws_secrets:<name>:<key>}}`. For more information, see the AWS Secrets Manager extension.

Source parameters

Parameters

`hostname` (string, required)

The customer-specific Qualys API Gateway hostname for your platform subscription, such as `gateway.qg3.apps.qualys.com`. Do not include `https://`.

`authentication.oauth2.username` (string, required)

The Qualys platform username for JWT token exchange. Store the value in AWS Secrets Manager and reference it by using `${{aws_secrets:qualys_csam:username}}`.

`authentication.oauth2.password` (string, required)

The Qualys platform password for JWT token exchange. Store the value in AWS Secrets Manager and reference it by using `${{aws_secrets:qualys_csam:password}}`.

`range` (string, optional)

The lookback duration for the initial data backfill, in ISO 8601 duration format. The minimum is one hour (`PT1H`), the maximum is one day (`P1D`), and the default is `P1D`.

> **Note**
>
> The connector retrieves credential values from AWS Secrets Manager. You can find the Qualys user name in the Qualys Cloud Platform on the **Administration** page, on the **Users**

tab. You can use the same credentials as Qualys VMDR or Policy Compliance (PC) if the account has access to the CSAM module.

Sink parameters

The sink delivers processed events to a CloudWatch Logs log group. Set `log_group` to the name of your destination log group, such as `qualys-csam-log-group`. For complete configuration options, see the CloudWatch Logs sink.

Processor parameters

The processor transforms ingested events into OCSF format using the `qualys_csam` schema key. Set `schema.qualys_csam` to `null`; the presence of the key activates the Qualys CSAM schema mapping. Set `version` to `"1.5"` and `mapping_version` to `1.5.0`. For the full parameter reference, see the OCSF processor.

Known Qualys CSAM platform limitations

The following table describes known Qualys CSAM platform limitations.

Limitation	Details	Impact
Customer-specific API Gateway hostname	The API Gateway URL varies by Qualys platform region. There is no universal endpoint.	You must identify your platform and configure the correct gateway hostname.
API rate limits	With the default Standard API Service, Qualys permits 300 API calls per subscription for each API in a rolling 3,600-second window. When the limit is exceeded, Qualys returns HTTP 409 Conflict with error code 1965 and an `X-RateLimit-ToWait-Sec` header.	The connector waits for the interval in the `X-RateLimit-ToWait-Sec` header and then retries. Large environments might experience a slower initial backfill.
Pagination on list endpoints	CSAM uses cursor-based pagination for assets, software, vulnerabilities,	Large inventories have higher retrieval latency. The connector handles pagination internally.

Limitation	Details	Impact
	and domains. Each page requires a separate API call.	
JWT token expiration	The bearer token expires after approximately four hours.	The connector automatically renews the token before expiration. No action is required.
No sort-order support	The CSAM API does not document an ascending or descending sort parameter.	Records are not guaranteed to arrive in a specific order within a window.
Shared credentials with VMDR	Qualys CSAM and VMDR share platform credentials but use different API endpoints and hostnames.	If you use both connectors, you can store credentials separately for each connector or use a shared secret.
CSAM module licensing	Qualys CSAM is separately licensed. Individual EASM vulnerability and domain APIs require their corresponding submodules.	API calls fail if your subscription does not include the corresponding module.

Troubleshooting the Qualys CSAM integration

Common errors

The following table lists common errors and their resolutions.

Error	Likely cause	Resolution or connector behavior
401 Unauthorized	Invalid or expired credentials	The connector automatically renews credentials and retries up to six times. Verify the username and password in AWS Secrets Manager.
403 Forbidden	Insufficient permissions or the CSAM module is not licensed	Make sure that API access is enabled for the Qualys account and that the subscription

Error	Likely cause	Resolution or connector behavior
		includes the CSAM module. This error is not retryable and stops processing immediately.
409 Conflict (CODE 1965)	API rate limit exceeded	The connector reads the `X-RateLimit-ToWait-Sec` header and retries after the specified wait time.
409 Conflict (CODE 1960)	Concurrent call limit exceeded	The connector retries with progressive backoff of 5, 10, 30, 60, 120, and 300 seconds.
5xx Server Error	Qualys platform server-side issue	The connector automatically retries with backoff intervals of 1, 2, 5, 10, 20, and 40 seconds.
No data appears in the log group	The pipeline resource policy was not added within five minutes	Delete and recreate the pipeline, and then immediately add the CloudWatch Logs resource policy.
Empty results	No scans or discovery ran on the hosts in the configured time range	Verify that scans are active and that hosts were evaluated within the range window.

Identify your Qualys API Gateway hostname

- The CSAM connector uses the Qualys API Gateway hostname, such as `gateway.qg3.apps.qualys.com`. This differs from the VMDR API hostname, such as `qualysapi.qg3.apps.qualys.com`.
- Log in to the Qualys Cloud Platform and navigate to **Help** > **About** to identify your platform assignment.
- If you are not sure which platform you use, see Qualys Platform Identification.
- Enter only the domain. Don't include `https://` in the hostname.

Difference between CSAM and VMDR hostnames

- Qualys VMDR uses `qualysapi.<platform>.apps.qualys.com`, such as `qualysapi.qg3.apps.qualys.com`.
- Qualys CSAM uses `gateway.<platform>.apps.qualys.com`, such as `gateway.qg3.apps.qualys.com`.
- Both hostnames correspond to the same Qualys platform but use different API surfaces. Use the `gateway` hostname for the Qualys CSAM connector.

Qualys Policy Audit integration configuration

Qualys Policy Audit (PA) is a cloud-native configuration assessment and compliance monitoring solution. It evaluates IT assets against security benchmarks, such as CIS, DISA STIG, and vendor hardening guides, and regulatory frameworks, such as PCI-DSS, HIPAA, SOX, and NIST.

As part of the Qualys Cloud Platform, it uses lightweight Cloud Agents and Scanner Appliances to assess on-premises, cloud, and hybrid environments. It includes out-of-the-box compliance policies, continuous assessment scheduling, and evidence-based reporting.

Compliance posture findings report whether each host passed or failed a policy control. CloudWatch pipelines use the Policy Compliance Reporting Service (PCRS) streaming API to ingest these findings. The connector uses the following retrieval flow:

1. Authenticate through OAuth 2.0 by exchanging credentials for a JSON Web Token (JWT).
2. Resolve all host IDs with their `policyId` and `subscriptionId`.
3. Retrieve per-host compliance posture findings within time-partitioned windows.

The following table lists the supported API and platform versions.

Component	Version	Notes
Qualys PCRS API	v5.0	Policy Compliance Reporting Service posture endpoints under `/pcrs/5.0/posture/*`
Qualys Cloud Platform	Platform-specific	Regional gateways such as qg1, qg2, and qg3. See Qualys Platform Identification.

Component	Version	Notes
OCSF schema	v1.5.0	Open Cybersecurity Schema Framework mapping
OAuth 2.0	2	Form-urlencoded username and password JWT token exchange

Topics

- Source configuration for Qualys Policy Audit
- CloudWatch pipelines configuration for Qualys Policy Audit

Source configuration for Qualys Policy Audit

Prerequisites

Before you begin, make sure you have the following:

- An active Qualys subscription with the Policy Compliance (Policy Audit) module enabled
- A Qualys user account with API access permissions to PCRS endpoints
- A Qualys API user account that is not SSO-only. API authentication uses a username and password, so the account must be able to authenticate directly.
- Your platform-specific Qualys API Gateway hostname, such as `gateway.qg3.apps.qualys.com`
- The final Qualys username and password from the Qualys console procedure, after the first-time password reset is complete
- An AWS account with permissions to create and manage CloudWatch pipelines. For more information, see the section called “API caller permissions”.
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager, and a source role that can retrieve the stored credentials. For more information, see the section called “Third-party sources (API Pull)”.
- An AWS account with permissions to create and manage CloudWatch Logs log groups. For more information, see the section called “CloudWatch Logs API operations and required permissions for actions”.

Integrating with Qualys Policy Audit

To integrate Qualys Policy Audit with CloudWatch pipelines, complete the following high-level steps:

- Identify your platform-specific Qualys API Gateway hostname.
- Create a Qualys Reader user with API access and the required asset groups.
- Store the Qualys username and password in AWS Secrets Manager.
- Create a destination CloudWatch Logs log group and the source IAM role.
- Create a CloudWatch pipeline with Qualys Policy Audit as the data source.
- Verify that compliance posture findings are flowing into the configured log group.

Configure Qualys Policy Audit

1. **Identify your Qualys API Gateway hostname**

   Log in to the Qualys Cloud Platform. Use the Qualys Platform Identification page to determine your platform-specific API Gateway hostname, such as `gateway.qg3.apps.qualys.com`.

2. **Open the Administration module**

   From the module picker, select **Administration** under Platform And Sensor Management.

3. **Start the New User wizard**

   On the Administration page, choose the **Users** tab. Choose **Create User**, and then choose **Create Reader User**.

4. **Enter General Information**

   On the General Information tab, complete the required fields marked with an asterisk: First Name, Last Name, Address 1, Country, State, ZIP Code, and E-mail Address.

5. **Set the User Role and enable API access**

   Choose **User Role** in the left navigation. Set **User Role** to **Reader**. Under **Allow access to**, select **API**. You must select **API**, because this setting is what allows the account to authenticate to the Qualys API for the connector. Leave **Business Unit** set to **Unassigned** unless your organization uses Business Units to segment access.

6. **Assign Asset Groups**

Choose **Asset Groups** in the left navigation. Use **Add asset groups** to select the asset groups that should be visible to this user and to the connector. Select **All** to retrieve data for every asset in the subscription, or select specific groups to limit the scope.

7. **Review Permissions**

   Choose **Permissions** in the left navigation. The Extended Permissions options for Manage VM module, Purge host information/history, and Manage PC module grant administrative rights and are not required for API read access. Leave them unselected unless your process requires the account to manage those modules.

8. **Complete the remaining tabs and create the user**

   Continue through the remaining Options and Security tabs, changing settings only if your organization has specific requirements such as IP-based login restrictions. Create the user. Qualys emails the new user a temporary password.

   Log in once through the Qualys user interface with the temporary password and complete the required password reset. The API user credentials do not work for the connector until this first-time password reset is complete. Save the final username and password for the pipeline configuration.

Authenticating with Qualys Policy Audit

Qualys Policy Audit uses OAuth 2.0 with a username and password exchange for a JWT. The connector performs the following authentication flow:

1. Retrieves the credentials securely from AWS Secrets Manager at runtime.
2. Sends a form-urlencoded `POST` request to the Qualys `/auth` endpoint with `username`, `password`, and `token=true`.
3. Receives the JWT as a raw plain-text string. The token remains valid for approximately four hours.
4. Uses `Authorization: Bearer <token>` for all subsequent API requests and automatically renews the token before it expires.

Configure the CloudWatch pipeline resources

1. **Store credentials in AWS Secrets Manager**

In AWS Secrets Manager, choose **Store a new secret**, and then choose **Other type of secret**. Add the following key-value pairs:

- `username` – Your Qualys platform username
- `password` – Your Qualys platform password

Name the secret, for example `qualys-policyaudit/pipeline-credentials`.

2. **Create the destination CloudWatch Logs log group**

   In the CloudWatch console, choose **Logs**, **Log groups**, and **Create log group**. Choose a descriptive name, such as `/aws/cloudwatch/pipelines/qualys-policyaudit`.

3. **Create the source IAM role**

   Create an IAM role with the required permissions. For information about the required policies and permissions, see the section called “CloudWatch pipelines IAM policies and permissions”.

4. **Create the CloudWatch pipeline**

   In the CloudWatch console, navigate to Pipelines and choose **Qualys Policy Audit** as the data source. Configure authentication with the Qualys API Gateway hostname, username, and password. Select the destination log group. For the complete pipeline YAML configuration and parameter reference, see the section called “Pipeline configuration”.

5. **Configure the CloudWatch Logs resource policy**

   The behavior depends on whether the destination log group is new or already exists. For a new log group created through the console, the resource policy is created automatically and no action is required. If the selected log group already has a resource policy, the console displays a Resource Policy Detected warning. In that case, verify that the existing policy includes permissions for pipelines to write to the destination log group, and add or update the CloudWatch Logs resource policy within five minutes of pipeline creation.

   > **Note**
   >
   > When you create the pipeline by using the AWS CLI or API, a resource policy is never created automatically, regardless of whether the log group is new or existing. You must create the resource policy manually before the pipeline becomes active.

6. **Verify data flow**

Allow time for the initial data retrieval to complete. Check the destination log group for incoming events, and monitor pipeline metrics for successful ingestion.

Supported Open Cybersecurity Schema Framework event classes

This integration supports OCSF schema version v1.5.0. Qualys Policy Audit compliance posture findings are mapped to the Compliance Finding OCSF class, capturing per-host, per-control evaluation results including pass, fail, and error status; control statements; rationale; remediation guidance; severity; and scan timestamps.

Compliance Finding (2003)

The Compliance Posture event from the `/pcrs/5.0/posture/postureInfo` endpoint maps to Compliance Finding (2003). Each event contains a per-host, per-control compliance evaluation including pass, fail, or error status; control statements; rationale; remediation; severity or criticality; and scan timestamps.

> **Note**
>
> Events that do not match an OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

Known platform limitations

The following table describes known Qualys Policy Audit platform limitations.

Limitation	Details	Impact
Backfill window	The first-run backfill is bounded by `range`, with a minimum of `P1D`, maximum of `P5D`, and default of `P5D`.	Historical posture data older than the backfill window is not retrieved on the first run.
Posture availability delay	Posture data becomes available only after a compliance scan completes and is evaluated by the Qualys	Findings are delivered only after the Qualys platform finishes evaluating a scan, so delivery lags scan completion.

Limitation	Details	Impact
	platform. Qualys does not document an exact delay.	
No sort-order support	The PCRS API does not document an ascending or descending sort parameter.	Records are not guaranteed to arrive in a specific order within a window.
Shared API rate limit	With the default Standard API Service, Qualys permits 300 API calls per subscription for each API in a rolling 3,600-second window. When the limit is exceeded, Qualys returns HTTP 409 Conflict with error code 1965 and an `X-RateLimit-ToWait-Sec` header. Qualys Support can customize the limit for your subscription.	The pipeline shares one quota with every other user and integration in the subscription, so heavy API use elsewhere slows pipeline ingestion, especially during the initial backfill. The connector waits for the interval in the header and retries, so throughput is reduced but data is not lost.
Concurrent call limit	With the default Standard API Service, Qualys permits two concurrent API calls for each API. Qualys checks the concurrency limit before the rate limit and returns HTTP 409 Conflict with error code 1960 when the limit is exceeded. Concurrency errors take precedence over rate-limit errors and don't include rate-limit headers.	High-volume environments might experience throttling during the initial backfill. The connector retries with backoff, so throughput is reduced but data is not lost.
Customer-specific hostname	There is no universal endpoint. The API Gateway hostname is assigned per Qualys subscription and region.	You must supply the exact gateway fully qualified domain name for your platform.
Token time to live	JWT tokens expire approximately four hours after issue.	The connector automatically renews the token before it expires.

Troubleshooting

The following table lists common errors and their resolutions.

Error	Likely cause	Resolution or connector behavior
401 Unauthorized	Invalid or expired credentials, or credentials rotated in AWS Secrets Manager	The connector renews the token and retries up to six times. Verify that the username and password in AWS Secrets Manager are current, API access is enabled, and the account is not SSO-only.
403 Forbidden	Insufficient permissions for the API user	This error is not retryable, and the connector stops immediately. Verify that the Reader user has API access and the required asset groups assigned.
5xx Server Error	Transient Qualys platform error	The connector retries with exponential backoff at 1, 2, 5, 10, 20, and 40 seconds.
No data in the log group	The pipeline resource policy was not added within five minutes of creation.	Delete and recreate the pipeline, and then immediately add the CloudWatch Logs resource policy.
Wrong hostname or connection failure	A VMDR hostname was used instead of the PCRS gateway hostname, or the hostname includes a scheme.	Use the `gateway.<platform>.apps.qualys.com` form without `https://`.

Identify the Qualys API Gateway hostname

- The Policy Audit connector uses the Qualys API Gateway hostname, such as `gateway.qg3.apps.qualys.com`. This differs from the VMDR API hostname, such as `qualysapi.qg3.apps.qualys.com`.

- Identify your platform from the platform identifier embedded in your Qualys username. For example, the character 3 indicates US Platform 3, a hyphen indicates EU Platform 1, and the character C indicates the US federal platform.
- Use the Qualys Platform Identification page to map your platform identifier to the gateway hostname.
- Provide only the domain. Do not include `https://`.

Policy Audit and VMDR use different hostnames

- Qualys VMDR uses `qualysapi.<platform>.apps.qualys.com` on most platforms, such as `qualysapi.qg3.apps.qualys.com`. US Platform 1 and EU Platform 1 are exceptions and use the shorter legacy forms `qualysapi.qualys.com` and `qualysapi.qualys.eu`, with no platform segment and no `apps` segment.
- Qualys Policy Audit uses `gateway.<platform>.apps.qualys.com`, such as `gateway.qg3.apps.qualys.com`.
- Both hostnames are on the same Qualys platform but use different API surfaces. Use the gateway hostname for this connector.

No compliance findings are returned

- Confirm that the Policy Compliance module is active in your Qualys subscription.
- Verify that compliance policies are assigned to hosts or asset groups and that scans have completed.
- Check the `range` parameter. The default is `P5D`. If no scans occurred in that window, no data is returned.

CloudWatch pipelines configuration for Qualys Policy Audit

Collects compliance posture findings from Qualys Policy Audit by using the PCRS streaming API with OAuth 2.0 authentication and a JWT exchange.

Configure the Qualys Policy Audit pipeline with the following YAML:

```
extension:
  aws:
    secrets:
      qualys-policyaudit-credentials:
        secret_id: "<<secret-arn>>"
        region: "<<secret-region>>"
        sts_role_arn: "<<secret-access-role-arn>>"

pipeline:
  source:
    qualys_policyaudit:
      hostname: "gateway.qg3.apps.qualys.com"
      authentication:
        oauth2:
          username: "${{aws_secrets:qualys-policyaudit-credentials:username}}"
          password: "${{aws_secrets:qualys-policyaudit-credentials:password}}"
      range: "P5D"               # optional (default); from P1D to P5D

  processor:
    - ocsf:
        schema:
          qualys_policyaudit: null
        version: "1.5"
        mapping_version: 1.5.0

  sink:
    - cloudwatch_logs:
        log_group: "/aws/cloudwatch/pipelines/qualys-policyaudit"
```

Source parameters

`hostname` (required)

The Qualys API Gateway hostname, such as `gateway.qg3.apps.qualys.com`. Do not include a scheme. The connector adds `https://` automatically. The hostname varies by platform, such as qg1, qg2, or qg3.

`authentication.oauth2.username` (required)

The Qualys platform username for the JWT token exchange. Store it in AWS Secrets Manager and reference it with `${{aws_secrets:qualys-policyaudit-credentials:username}}`.

`authentication.oauth2.password` (required)

The Qualys platform password for the JWT token exchange. Store it in AWS Secrets Manager and reference it with `${{aws_secrets:qualys-policyaudit-credentials:password}}`.

`range` (optional)

How far back to retrieve posture data on the first run. Use an ISO 8601 duration from `P1D` through `P5D`. Default: `P5D`.

AWS Secrets Manager extension parameters

Define a named secret block, such as `qualys-policyaudit-credentials`, under `extension.aws.secrets`. Set `secret_id` to the ARN of the AWS Secrets Manager secret, `region` to the AWS Region where the secret is stored, and `sts_role_arn` to the role that accesses the secret. Reference credentials with `${{aws_secrets:<name>:<key>}}`.

Processor parameters

The `ocsf` processor transforms ingested events into OCSF format. Under `schema`, specify the single source key `qualys_policyaudit` with a null value. Set `version` to `1.5` and `mapping_version` to `1.5.0`.

Sink parameters

The `cloudwatch_logs` sink delivers processed events to a CloudWatch Logs log group. Set `log_group` to the name of your destination log group, such as `/aws/cloudwatch/pipelines/qualys-policyaudit`. The sink writes to the AWS Region in which you create the pipeline, and you do not specify an AWS Region in the sink configuration.

> **Note**
>
> The credential values are retrieved from AWS Secrets Manager. You can find your Qualys credentials in the Qualys Cloud Platform under Administration > User Management. The same credentials used for Qualys VMDR can be used for this connector if the account has access to the Policy Compliance module and can authenticate with a username and password.

Qualys VMDR integration configuration

Qualys Vulnerability Management, Detection and Response (VMDR) is a cloud-native vulnerability management platform. It provides continuous discovery, assessment, prioritization, and remediation of vulnerabilities across on-premises, cloud, container, and hybrid environments. It combines asset discovery and vulnerability scanning with prioritization based on TruRisk, the proprietary Qualys risk-scoring model, and integrated patch management.

CloudWatch pipelines poll the Qualys REST APIs to ingest vulnerability knowledge base data, asset inventory, host detection findings, and platform activity logs.

Topics

- Source configuration for Qualys VMDR
- CloudWatch pipelines configuration for Qualys VMDR

Source configuration for Qualys VMDR

Integrating with Qualys VMDR

CloudWatch pipelines use versions 2.0, 4.0, and 5.0 of the Qualys Vulnerability Management (VM) and Policy Compliance (PC) APIs across the supported endpoints. The APIs use HTTP Basic authentication and return XML for Knowledge Base, Assets, and Host Detection data, and CSV for Activity Log data. The connector handles the response parsing internally.

To integrate CloudWatch pipelines with Qualys VMDR, complete the following high-level steps:

- Identify the API hostname for your Qualys platform.
- Create a Qualys user with the Manager role, enable API access, and assign the asset groups that the connector can access.

- Store the Qualys username and password in AWS Secrets Manager.
- Create a CloudWatch pipeline with Qualys VMDR as the data source.
- Verify that data is flowing into the destination CloudWatch Logs log group.

Supported API and platform versions

The following table lists the supported API and platform versions.

Component	Version	Notes
Qualys Vulnerability Management and Policy Compliance (VMPC) API	v2.0, v4.0, v5.0	Multiple API versions are used across the supported endpoints
Open Cybersecurity Schema Framework (OCSF) schema	v1.5.0	Event mapping to the OCSF schema
HTTP Basic authentication	Not applicable	Base64-encoded `username:password` credentials with each request

Prerequisites

Before you begin, make sure you have the following:

- An active Qualys VMDR subscription with API access enabled
- A Qualys user account with the Manager role, or a role with equivalent permissions, and with API access enabled
- The hostname for your Qualys platform, such as `qualysapi.qg3.apps.qualys.com`
- A Qualys subscription that includes the VMDR module
- An AWS account with permissions to create and manage CloudWatch pipelines. For more information, see the section called “API caller permissions”.
- An AWS account with permissions to create and update secrets in AWS Secrets Manager, and a source role that can retrieve the stored credentials. For more information, see the section called “Third-party sources (API Pull)”.

- An AWS account with permissions to create and manage CloudWatch Logs log groups. For more information, see the section called “CloudWatch Logs API operations and required permissions for actions”.

Configure Qualys VMDR

To configure a Qualys user for the integration:

1. Log in to the Qualys Cloud Platform and identify your Qualys API hostname. You can find your platform assignment under **Help > About** or use the Qualys Platform Identification page.
2. From the module picker, choose **Administration** under Platform and Sensor Management.
3. On the Administration page, choose the **Users** tab, and then choose **Create User**.
4. On the **General Information** tab, complete the required fields: First Name, Last Name, Address 1, Country, State, ZIP Code, and E-mail Address.
5. Choose **User Role** in the left navigation pane. Set the role to **Manager**, and under **Allow access to**, select **API**. Leave Business Unit set to Unassigned unless your organization uses business units to segment access.
6. Choose **Asset Groups**. Add the asset groups that should be visible to this user, and therefore to the connector. Select all asset groups if the connector should retrieve data for every asset in the subscription, or select specific groups to limit the scope.
7. Choose **Permissions**. The extended permissions to manage the VM module, purge host information or history, and manage the PC module are not required for API read access. Leave them cleared unless your process requires this account to manage those modules.
8. Complete the remaining Options and Security tabs. Configure settings such as IP-based login restrictions only if required by your organization, and then create the user. Qualys emails the new user a temporary password.
9. Log in to the Qualys user interface with the temporary password and complete the required password reset. The API credentials do not work with the connector until this first-time password reset is complete.
10. Save the final `username` and `password` for the pipeline configuration.

Qualys platform hostnames

Use the hostname that corresponds to your Qualys platform. Do not include `https://`.

US Platform 1

```
qualysapi.qualys.com
```

US Platform 2

```
qualysapi.qg2.apps.qualys.com
```

US Platform 3

```
qualysapi.qg3.apps.qualys.com
```

US Platform 4

```
qualysapi.qg4.apps.qualys.com
```

EU Platform 1

```
qualysapi.qualys.eu
```

EU Platform 2

```
qualysapi.qg2.apps.qualys.eu
```

India Platform

```
qualysapi.qg1.apps.qualys.in
```

Canada Platform

```
qualysapi.qg1.apps.qualys.ca
```

UAE Platform

```
qualysapi.qg1.apps.qualys.ae
```

Australia Platform

```
qualysapi.qg1.apps.qualys.com.au
```

Authenticating with Qualys VMDR

Qualys VMDR uses HTTP Basic authentication. The pipeline sends Base64-encoded `username:password` credentials in an Authorization header with each API request. The credentials are retrieved securely from AWS Secrets Manager at runtime and are not stored in the pipeline configuration.

Configure the CloudWatch pipeline resources

1. In AWS Secrets Manager, choose **Store a new secret**, and then choose **Other type of secret**. Add a `username` key with your Qualys API username and a `password` key with your Qualys API password. Name the secret, for example, `qualys-vmdr/pipeline-credentials`.
2. Create the destination CloudWatch Logs log group, for example, `/aws/cloudwatch/pipelines/qualys-vmdr`.
3. Create the source IAM role with the required permissions. For information about the required policies, see the section called "CloudWatch pipelines IAM policies and permissions".
4. In the CloudWatch console, navigate to Pipelines and choose **Qualys VMDR** as the data source. Configure the Qualys hostname and authentication credentials, and select the destination log group.
5. Configure the CloudWatch Logs resource policy:
   - For a new log group created in the console, the resource policy is created automatically.
   - If the selected log group already has a resource policy, review and update it within 5 minutes of pipeline creation to include the required pipeline write permissions.
   - When you create the pipeline with the AWS CLI or API, a resource policy is not created automatically. Create the policy manually before the pipeline becomes active.
6. Wait a few minutes for the initial data retrieval. Check the destination log group for incoming events and monitor pipeline metrics for successful ingestion.

Supported Open Cybersecurity Schema Framework event classes

This integration supports OCSF schema version v1.5.0. Qualys VMDR events are mapped to OCSF classes based on the data type. Vulnerability definitions map to Vulnerability Finding, asset inventory maps to Device Inventory Info, and activity log events map to Authentication, API Activity, Account Change, or Entity Management based on the action type.

Event type	Application or endpoint ID	OCSF event class	Description
Vulnerability (Knowledge Base)	`/api/4.0/fo/knowledge_base/vuln/?action=list`	Vulnerability Finding (2002)	QID, CVE IDs, severity level 1 through 5, solution text, vendor references, exploitability,

Event type	Application or endpoint ID	OCSF event class	Description
			patchable flag, and published dates
Assets	`/api/5.0/fo/asset/host/?action=list`	Device Inventory Info (5001)	Host asset inventory including IP, operating system, DNS, NetBIOS, agent status, and scan timestamps
Activity Log – login and logout	`/api/2.0/fo/activity_log/?action=list`	Authentication (3002)	User login and logout events with source IP and user role
Activity Log – all non-authentication actions	`/api/2.0/fo/activity_log/?action=list`	API Activity (6003)	API requests, appliance downloads, and vulnerability edits, plus operational actions such as scan launch, scan completion, and report generation. Actions that do not match a more specific class map to API Activity with an activity of Other.
Activity Log – activate, set password, and set authentication	`/api/2.0/fo/activity_log/?action=list`	Account Change (3001)	Account activation, password changes, and credential setup events
Activity Log – administrative configuration, appliance, and asset group	`/api/2.0/fo/activity_log/?action=list`	Entity Management (3004)	Administrative configuration changes, scanner appliance create, update, and delete operations, and asset group and domain management

Ingestion-only event types

The following event type is ingested but is not currently mapped to an OCSF class:

Event type	Application or endpoint ID	Description
Asset Host Detection	`/api/5.0/fo/asset/host/vm/detection/?action=list`	Per-host vulnerability detection records. The records contain nested detection arrays that require sub-array record extraction, which is not currently supported for OCSF mapping.

Activity log actions that do not match a more specific class, such as scan launch, scan completion, and report generation, are mapped to API Activity (6003) with an activity of Other. They are not ingestion-only.

Events that do not match an OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

Known platform limitations

The following table describes known Qualys VMDR platform limitations.

Limitation	Details	Impact
Customer-specific API hostname	The API base URL varies by Qualys platform. There is no universal endpoint.	You must identify your platform and configure the correct hostname.
XML and CSV response formats	The APIs return XML for Knowledge Base, Assets, and Host Detection data, and CSV for Activity Log data. There is no JSON response option.	The connector handles the parsing internally.
API rate limits	With the default Standard API Service, Qualys permits 300 API calls per subscription for each API in a rolling 3,600-second window.	The connector backs off and retries based on the rate-limit headers.

Limitation	Details	Impact
	When the limit is exceeded, Qualys returns HTTP 409 Conflict with error code 1965 and an `X-RateLimit-ToWait-Sec` header.	
Concurrent call limit	With the default Standard API Service, Qualys permits two concurrent API calls per subscription for each API.	High-volume environments might experience throttling during the initial backfill.
No OAuth 2.0 support	The version 2, 4, and 5 API endpoints support only HTTP Basic authentication.	Credentials must be rotated manually. There is no token refresh mechanism.
Asset Host Detection nested arrays	Each host record contains multiple detection entries in a nested array.	These events are ingested without Open Cybersecurity Schema Framework (OCSF) mapping because sub-array extraction is not supported.
Server-driven pagination	Qualys caps the page size at 1,000 records for Assets, 100 records for Host Detection, and 1,000 records for Activity Log.	Large datasets require multiple paginated requests in each polling cycle.
Activity Log shared across modules	The Activity Log captures events from all Qualys modules, not only VMDR.	Some ingested events can relate to Policy Compliance (PC), Web Application Scanning (WAS), or CyberSecurity Asset Management (CSAM).

Troubleshooting

Error	Likely cause	Resolution or connector behavior
401 Unauthorized	Invalid or expired credentials	Verify the username and password stored in AWS Secrets Manager, and make sure that the Qualys account has API access enabled.
403 Forbidden	Insufficient permissions or API access is not enabled	Make sure that the Qualys user has the Manager role, or a role with equivalent permissions, and that the API access option is enabled.
409 Conflict (CODE 1965)	API rate limit exceeded	The connector reads the `X-RateLimit-ToWait-Sec` header and retries after the specified wait time.
409 Conflict (CODE 1960)	Concurrent call limit exceeded	The connector retries with progressive backoff of 5, 10, 30, 60, 120, and 300 seconds.
No data appears in the log group	The pipeline resource policy was not added within 5 minutes	Delete and recreate the pipeline, and then immediately add the CloudWatch Logs resource policy.
XML parse errors	Unexpected response format or API version change	Verify that the hostname is correct and that the Qualys subscription includes access to the VMDR module.

During initial backfill, the connector retrieves data for the configured `range` across all four streams. If rate limiting occurs, the connector handles it automatically and no action is required. Enterprise Qualys subscriptions can have higher rate limits; contact Qualys Support to verify your API tier.

The Qualys Activity Log is shared across VMDR, Policy Compliance, Web Application Scanning, and CyberSecurity Asset Management. Events from other modules are ingested and available for search, but might not include VMDR-specific context. This is expected behavior.

CloudWatch pipelines configuration for Qualys VMDR

Collects vulnerability management data, asset inventory, host detection findings, and platform activity logs from Qualys VMDR using HTTP Basic authentication.

The following example shows the complete pipeline configuration:

```
extension:
  aws:
    secrets:
      qualys-vmdr-credentials:
        secret_id: "<secret-arn>"
        region: "<secret-region>"
        sts_role_arn: "<secret-access-role-arn>"
pipeline:
  source:
    qualys_vmdr:
      hostname: "qualysapi.qg3.apps.qualys.com"
      range: "P1D"
      authentication:
        basic:
          username: "${{aws_secrets:qualys-vmdr-credentials:username}}"
          password: "${{aws_secrets:qualys-vmdr-credentials:password}}"
  sink:
    - cloudwatch_logs:
        log_group: "<qualys-vmdr-log-group>"
  processor:
    - ocsf:
        schema:
          qualys_vmdr: null
        version: "1.5"
        mapping_version: 1.5.0
```

The name in each `aws_secrets` reference must match the secret block name under `extension.aws.secrets`.

The following four fields are the only source fields that you configure for `qualys_vmdr`. A configuration that sets any other source field fails validation.

Source parameters

`hostname` (required)

The customer-specific Qualys API hostname for your platform subscription, for example, `qualysapi.qg3.apps.qualys.com`. Do not include `https://`.

`authentication.basic.username` (required)

The Qualys API username. Store the value in AWS Secrets Manager and reference it using `${{aws_secrets:qualys-vmdr-credentials:username}}`.

`authentication.basic.password` (required)

The Qualys API password. Store the value in AWS Secrets Manager and reference it using `${{aws_secrets:qualys-vmdr-credentials:password}}`.

`range` (optional)

The lookback duration for initial data collection, in ISO 8601 duration format. The minimum is one hour (`PT1H`) and the maximum is one day (`P1D`). The value applies to all four streams. If you omit it, each stream backfills `P1D`.

> **Note**
>
> The credential values are retrieved from AWS Secrets Manager. You can manage the Qualys API user in the Qualys Cloud Platform under Administration > User Management.

AWS extension parameters

The AWS extension configures AWS Secrets Manager access so that the pipeline can retrieve credentials at runtime. Define a named secret block, such as `qualys-vmdr-credentials`. Set `secret_id` to the ARN of your secret, `region` to the AWS Region where the secret is stored, and `sts_role_arn` to the IAM role ARN to assume when accessing the secret. Reference the credentials in the pipeline with `${{aws_secrets:<name>:<key>}}`. For more information, see the AWS Secrets Manager extension.

Sink parameters

The sink delivers processed events to a CloudWatch Logs log group. Set `log_group` to the name of your destination log group, such as `/aws/cloudwatch/pipelines/qualys-vmdr`. For complete configuration options, see the CloudWatch Logs sink.

Processor parameters

The processor transforms ingested events into Open Cybersecurity Schema Framework (OCSF) format by using the `qualys_vmdr` schema key. Set `schema.qualys_vmdr` to `null`; the presence of the key activates the Qualys VMDR schema mapping. Set `version` to `"1.5"` and `mapping_version` to `1.5.0`. Events that do not match an OCSF mapping pass through to the sink unchanged. For the full parameter reference, see the OCSF processor.

SailPoint ISC integration configuration

SailPoint Identity Security Cloud (ISC) is a cloud-based identity governance and administration platform. It provides identity security capabilities such as access certifications (periodic reviews of who has access to what), provisioning (granting and removing access), password management, and single sign-on. The platform generates audit events covering authentication, user management, provisioning, access requests, certifications, and system configuration changes. CloudWatch pipelines integrate with SailPoint ISC through its Search API to continuously collect identity governance audit events for centralized security monitoring and analysis.

Topics

- Source configuration for SailPoint ISC
- CloudWatch pipelines configuration for SailPoint ISC

Source configuration for SailPoint ISC

Supported API and schema versions

- **SailPoint ISC Search API v2026** – Primary endpoint for retrieving audit events.
- **OCSF schema v1.5.0** – Open Cybersecurity Schema Framework mapping.
- **OAuth 2.0 Client Credentials** – Token-based authentication using Personal Access Token (PAT) credentials.

Prerequisites

Before you begin, make sure you have the following:

- An active SailPoint Identity Security Cloud tenant with API access enabled.
- A user account with the `ORG_ADMIN` user level, which is required to access all audit events.
- Your SailPoint tenant name and API domain.
- An AWS account with permissions to create and manage CloudWatch pipelines. For more information, see the section called "API caller permissions".
- An AWS account with permissions to create and update secrets in AWS Secrets Manager, and a source role that can retrieve the stored credentials. For more information, see the section called "Third-party sources (API Pull)".
- An AWS account with permissions to create and manage CloudWatch Logs log groups. For more information, see the section called "CloudWatch Logs API operations and required permissions for actions".

Configuring SailPoint ISC

To configure SailPoint ISC for the integration:

1. Sign in to SailPoint Identity Security Cloud as an `ORG_ADMIN` user.
2. In the SailPoint Admin UI, find **Org Details**. Note your tenant name and the API base URL, which uses the format `https://{tenant}.api.identitynow.com`. Do not derive the base URL from the address that you use to open the user interface, because that address might be a vanity URL.
3. Choose your user name, and then choose **Preferences**.
4. Choose **Personal Access Tokens**, and then choose **New Token**.
5. Enter a description for the token.
6. Turn on the `sp:scopes:all` scope, and then choose **Create Token**.
7. Copy the Client ID and Client Secret for API authentication.

Authenticating with SailPoint ISC

The connector uses the OAuth 2.0 Client Credentials Grant flow. The pipeline exchanges the stored `client_id` and `client_secret` at the SailPoint token endpoint for a short-lived bearer access

token in JSON Web Token (JWT) format. SailPoint reports the remaining lifetime of each token in the `expires_in` field of the token response, and the connector refreshes the token before it expires. No user interaction is required after initial setup.

Open the AWS Secrets Manager console, choose **Store a new secret**, choose **Other type of secret**, and then add the following key-value pairs:

- `client_id` – Your SailPoint PAT Client ID.
- `client_secret` – Your SailPoint PAT Client Secret.

For example, name the secret `sailpoint-isc/pipeline-credentials`.

Configuring the CloudWatch pipeline

1. Create the destination CloudWatch Logs log group. In the CloudWatch console, choose **Logs**, **Log groups**, **Create log group**, and then enter a descriptive name. For example, use `/aws/cloudwatch/pipelines/sailpoint-isc`.
2. Create a source IAM role with the required permissions. For information about the required policies and permissions, see the section called “CloudWatch pipelines IAM policies and permissions”.
3. Open the CloudWatch console, navigate to **Pipelines**, and choose SailPoint ISC as the data source.
4. Configure OAuth 2.0 client credentials using the `client_id` and `client_secret` stored in AWS Secrets Manager.
5. Provide the SailPoint ISC API base URL and select the destination log group.
6. Verify the destination log group resource policy. For a new log group, the console creates the resource policy automatically. If the log group that you select already has a resource policy, the console warns you that the log group already has a resource policy and that you might need to modify the existing policy to add the permissions that pipelines need to write to the destination log group. In that case, update the existing resource policy within five minutes of pipeline creation to include the required pipeline write permissions. For more information, see the section called “Resource policies”.
7. Wait a few minutes for the initial data pull, check the destination log group for incoming events, and monitor pipeline metrics for successful ingestion.

> **Note**
>
> When you create the pipeline using the AWS CLI or API, a resource policy is never created automatically, regardless of whether the log group is new or existing. You must create the CloudWatch Logs resource policy manually before the pipeline becomes active.

Supported Open Cybersecurity Schema Framework event classes

This integration supports OCSF schema version v1.5.0. All SailPoint ISC audit events are retrieved from a single SailPoint ISC Search API endpoint and mapped to OCSF classes based on their event type category.

> **Note**
>
> Events that do not match an OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

Authentication (3002)

`AUTH` – Authentication events for Personal Access Token lifecycle operations, including token usage.

Account Change (3001)

- `PASSWORD_ACTIVITY` – Password change, reset, and policy enforcement events.
- `PROVISIONING` – Account provisioning and deprovisioning actions across connected sources.

Entity Management (3004)

- `USER_MANAGEMENT` – User lifecycle events including creation, modification, and deletion.
- `ACCESS_ITEM` – Access item creation, modification, and removal events.
- `CERTIFICATION` – Access certification campaign events including decisions and sign-offs.
- `SOURCE_MANAGEMENT` – Source connector configuration and management events.
- `SYSTEM_CONFIG` – System configuration and platform settings change events.
- `NON_EMPLOYEE` – Non-employee lifecycle management events.

- `IDENTITY_MANAGEMENT` – Identity profile and attribute management events.

User Access Management (3005)

`ACCESS_REQUEST` – Access request submission, approval, and denial events.

Ingestion-only event types

The following event types do not have an OCSF mapping and are forwarded to the sink without additional processing:

- `SSO` – Single sign-on events.
- `IAI_ADMIN_AUDIT` – AI-based identity analytics administrator audit events.

Known platform limitations

- **Search result paging limit** – The SailPoint Search API returns a maximum of 10,000 records for each page and limits offset-based paging to a total of 10,000 records for a single query. The connector uses one-hour time partitions so that each query window stays within the 10,000-record paging ceiling. High-volume tenants that generate more than 10,000 events in one hour might exceed the paging ceiling for that window.
- **API rate limits** – The limit is 100 requests per `client_id`, per API version, per 10 seconds, which is effectively 10 requests per second. When SailPoint returns an HTTP 429 response, the connector retries with progressively increasing delays. The limit applies per `client_id`, not per access token.
- **Token expiration** – SailPoint issues short-lived access tokens and reports the remaining lifetime of each token in the `expires_in` field of the token response. The connector refreshes the token before it expires, so no manual intervention is required.
- **Maximum PATs per user** – SailPoint supports a maximum of 10 Personal Access Tokens per user. Plan your token allocation if the same administrator user needs Personal Access Tokens for multiple integrations.
- **Event time-based filtering** – The connector collects events by the time in the `created` field, not by the time that SailPoint indexed the event. Because the connector queries a closed time window, an event that becomes searchable after the window that contains its `created` time was queried is not collected.

Troubleshooting

`401 Unauthorized`

The client credentials are invalid or expired. Verify the `client_id` and `client_secret` stored in AWS Secrets Manager, and generate a new PAT in SailPoint if necessary.

`403 Forbidden`

The PAT might have insufficient permissions. Make sure that the `sp:scopes:all` scope is turned on for the token, and that the token was generated by a user with the `ORG_ADMIN` user level. Create a new PAT with the correct user and scope if necessary.

`429 Too Many Requests`

The API rate limit of 10 requests per second for each `client_id` was exceeded. The connector automatically retries with progressively increasing delays. If the error persists, verify that other integrations are not sharing the same `client_id`.

No data appears in the log group

The pipeline resource policy might not have been added within five minutes. Delete and recreate the pipeline, and then immediately add the CloudWatch Logs resource policy.

`400 Bad Request`

The API base URL might be malformed or contain an incorrect tenant or domain. Verify that `base_url` uses the format `https://{tenant}.api.{domain}.com`. Check the tenant name in the SailPoint Admin UI under **Org Details**.

No events are returned despite valid credentials

- Verify that the PAT user has `ORG_ADMIN` privileges. Users with lower privilege levels might not have access to all audit event types.
- Check whether the tenant has events within the configured `range`. A newly provisioned tenant might not have historical data.

Some event types are missing

- Confirm that the `sp:scopes:all` scope is turned on for the PAT. Restricted scopes might limit which event types are accessible.

- Check whether the event type has an OCSF mapping. Event types that have no mapping, such as SS0, are still delivered to the sink, but they are delivered in their original form instead of as OCSF events.

Vanity URL confusion

Some SailPoint deployments use vanity URLs, such as `iga.acme.com`, for the user interface. The `base_url` must use the API endpoint format `https://{tenant}.api.{domain}.com`. Find your tenant name in the SailPoint Admin UI under **Org Details**. After you know your API host, you can call the OAuth information endpoint at `https://{tenant}.api.identitynow.com/oauth/info` to confirm the tenant ID and the OAuth endpoints for the tenant.

CloudWatch pipelines configuration for SailPoint ISC

The following pipeline configuration collects identity governance audit events from SailPoint ISC using OAuth 2.0 client credentials authentication. Replace the placeholder values shown between << and >> with values for your environment.

```
extension:
  aws:
    secrets:
      sailpoint_isc:
        secret_id: <<arn:aws:secretsmanager:<region>:<account-id>:secret:<secret-
name>>>
        region: <<region>>
        sts_role_arn: <<arn:aws:iam::<account-id>:role/<role-name>>>
pipeline:
  source:
    sailpoint_isc:
      base_url: "https://your-tenant.api.identitynow.com"
      authentication:
        oauth2:
          client_id: "${{aws_secrets:sailpoint_isc:client_id}}"
          client_secret: "${{aws_secrets:sailpoint_isc:client_secret}}"
      range: P90D
  sink:
    - cloudwatch_logs:
        log_group: <<sailpoint-isc-log-group>>
  processor:
    - ocsf:
        schema:
```

```
          sailpoint_isc: null
        version: "1.5"
        mapping_version: 1.5.0
```

Configure AWS Secrets Manager access for securely retrieving credentials at runtime. Define a named secret block, such as `sailpoint_isc`, with `secret_id` set to the ARN of your AWS Secrets Manager secret, `region` set to the AWS Region where the secret is stored, and `sts_role_arn` set to the IAM role ARN to assume when accessing the secret. Reference credentials in the pipeline using `${{aws_secrets:<name>:<key>}}`. For more information, see the AWS Secrets Manager extension.

Source parameters

`base_url` (required)

The SailPoint ISC API base URL. Use the format `https://{tenant}.api.{domain}.com`. The tenant name and domain are specific to your SailPoint deployment. Find the base URL in the SailPoint Admin UI under **Org Details**.

`range` (optional)

The lookback duration for audit events in ISO 8601 format. Minimum: `PT1H`. Maximum: `P90D`. Default: `P90D`.

`authentication.oauth2.client_id` (required)

The OAuth 2.0 Client ID from the SailPoint PAT. Store it in AWS Secrets Manager and reference it using `${{aws_secrets:sailpoint_isc:client_id}}`.

`authentication.oauth2.client_secret` (required)

The OAuth 2.0 Client Secret from the SailPoint PAT. Store it in AWS Secrets Manager and reference it using `${{aws_secrets:sailpoint_isc:client_secret}}`.

Note

Both `client_id` and `client_secret` must be stored in AWS Secrets Manager. Generate the credentials by creating a Personal Access Token in SailPoint ISC under **Preferences**, **Personal Access Tokens**. The PAT must be created by a user with `ORG_ADMIN` privileges, and the `sp:scopes:all` scope must be turned on, to provide access to all audit event types.

Sink parameters

`log_group` (required)

The name of the destination CloudWatch Logs log group, such as `sailpoint-isc-log-group`. For complete configuration options, see the CloudWatch Logs sink.

Processor parameters

`schema.sailpoint_isc` (required)

Set this parameter to `null`. The presence of the key activates the SailPoint ISC schema mapping and transforms ingested events into OCSF format.

`version` (required)

The OCSF schema version. Set this parameter to `"1.5"`.

`mapping_version` (required)

The mapping version. Set this parameter to `1.5.0`. For the full parameter reference, see the OCSF processor.

Salesforce ELF integration configuration

Salesforce is a cloud-based Customer Relationship Management (CRM) platform that provides business applications for sales, service, marketing, and IT operations. It generates detailed operational logs through Event Log Files (ELF) including login activity, API usage, report execution, and administrative changes, with hourly or daily granularity, along with audit trail events. CloudWatch pipelines use the Salesforce REST API to poll these logs for ingestion into CloudWatch Logs.

Topics

- Source configuration for Salesforce ELF
- CloudWatch pipelines configuration for Salesforce ELF

Source configuration for Salesforce ELF

Prerequisites

Before you begin, make sure you have the following:

- A Salesforce account with the EventLogFile feature enabled
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create and manage Amazon S3 buckets, AWS Secrets Manager secrets, and IAM roles

Integrating with Salesforce ELF

To integrate Salesforce ELF with CloudWatch Logs, you must configure a pipeline. First, set up a Salesforce account and an AWS Secrets Manager secret with required authentication credentials to receive data from Salesforce. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Salesforce ELF exports 50+ event types through EventLogFile (CSV) and SetupAuditTrail (JSON) using the Salesforce REST API, which delivers logs directly to the configured sink (CloudWatch Logs).

Instructions to set up Salesforce account

1. **Create Salesforce Account**
   - Go to the Salesforce developer sign-up page.
   - Register with your name, email, and a unique username (email format).
   - Verify your email and set your password.
   - Note your instance URL (for example, `https://yourorg-dev-ed.my.salesforce.com`) – this is the `instance_url` for pipeline configuration.
2. **Create an External Client App**
   - In **Setup**, search **External Client App Manager** in Quick Find.
   - Choose **New External Client App**.
   - Fill in **App Name** (for example, "CloudWatch-Collector") and **Contact Email**.
   - Under **API (Enable OAuth Settings)**, check **Enable OAuth**.
   - Set **Callback URL**: `https://login.salesforce.com/services/oauth2/callback`
   - Move these OAuth Scopes from Available to Selected: `Full access (full)`, `Manage user data through APIs (api)`, `Perform requests at any time (refresh_token, offline_access)`
   - Choose **Create**.
3. **Configure Policies**

- Open your app in **External Client App Manager**.
- **Policies** tab > **Edit**.
- **Permitted Users**: Select "Admin approved users are pre-authorized" > **OK**.
- **Select Profiles**: Add **System Administrator**.
- Under **OAuth Flows and External Client App Enhancements**: Check **Enable Client Credentials Flow**.
- **Run As (Username)**: Enter the System Administrator's username (find it under **Setup > Users**).
- Choose **Save**.

4. **Get Consumer Key and Secret**
   - Open your app > **Settings** tab > **OAuth Settings**.
   - Choose **Consumer Key and Secret** button (verify identity by email code if prompted).
   - Copy **Consumer Key** (`client_id`) and **Consumer Secret** (`client_secret`).
5. **Create and Assign Permission Set**
   - **Setup > Permission Sets** > **New** (for example, "CloudWatch-Collector-Permissions").
   - **System Permissions > Edit** – enable: **API Enabled**, **View Event Log Files**, **View Setup and Configuration**.
   - **Save**, then **Manage Assignments > Add Assignment** > select the Run-As user > **Assign**.
6. **Enable Event Log File**
   - **Setup > Event Monitoring**.
   - Enable the **Generate event log files** toggle.
7. **Store Credentials in AWS Secrets Manager**
   - In AWS Secrets Manager, choose **Store a new secret** > **Other type of secret**.
   - Add key/value pairs: `client_id` = Consumer Key, `client_secret` = Consumer Secret.
   - Name the secret (for example, `salesforce-credentials`) and copy the ARN.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Salesforce, choose `salesforce_elf` as the data source. Provide the `instance_url`, `client_id`, and `client_secret`. After creating the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms the following events. Events that are not listed but pulled are not mapped to OCSF and will be forwarded to the sink as raw logs.

Account Change (3001)

Contains the following events:

createduser, createdcustomersuccessuser, createdpartneruser, activateduser, unfrozeuser, changedpassword, resetpassword, deactivateduser, frozeuser, CSPUserDisabled, PRMUserDisabled, PermSetAssign, PermSetAssign_HasExpiration, PermSetGroupAssign, PermSetLicenseAssign, addeduserpackagelicense, granteduserpackagelicense, enabledForIntegrations, loginasgrantedtopartnerbt, loginasgrantedtosfdc, PermSetUnassign, PermSetUnassign_HasExpiration, PermSetGroupUnassign, PermSetLicenseUnassign, removeduserpackagelicense, revokeduserpackagelicense, disabledForIntegrations, loginasrevokedtopartnerbt, loginasrevokedtosfdc, insertTwoFactorInfo2, insertTwoFactorWebAuthN, insertAuthenticatorPairing, lightningloginenroll, insertTwoFactorTempCode, deleteTwoFactorInfo2, deleteTwoFactorWebAuthN, deleteAuthenticatorPairing, lightninglogincancel, unlockeduser

Authentication (3002)

Contains the following events:

- Login
- LoginAs
- Logout

API Activity (6003)

Contains the following events:

- ApiTotalUsage
- BulkApi
- BulkApi2
- CompositeApi

- CompositeApiSubrequest
- RestApi
- API
- ContinuationCalloutSummary
- ExternalCrossOrgCallout
- ExternalCustomApexCallout
- ExternalDataSourceCallout
- ExternalODataCallout
- NamedCredential
- MetadataApiOperation

Datastore Activity (6005)

Contains the following events:

- AsynchronousReportRun
- Dashboard
- DatabaseSave
- MultiblockReport
- Report
- ReportExport
- Search
- UniqueQuery

Detection Finding (2004)

Contains the following events:

- BlockedRedirect
- CorsViolation
- CspViolation
- HostnameRedirects

- InsecureExternalAssets
- InsufficientAccess
- TransactionSecurity

Entity Management (3004)

Contains SetupAuditTrail events for entity creation, modification, deletion, and configuration changes. This includes a large number of Salesforce administrative actions such as creating/deleting Apex classes, custom fields, permission sets, profiles, workflows, and system configuration toggles.

File Hosting Activity (6006)

Contains the following events:

- ContentDistribution
- ContentDocumentLink
- ContentTransfer
- DocumentAttachmentDownloads

HTTP Activity (4002)

Contains the following event:

- URI – user interaction with the web browser UI

CloudWatch pipelines configuration for Salesforce ELF

Collects EventLogFile and Setup AuditTrail events from Salesforce using OAuth2 authentication.

Configure the Salesforce ELF source with the following parameters:

```
source:
  salesforce_elf:
    instance_url: "<<your-instance-url>>"
    authentication:
      client_id: "${{aws_secrets:salesforce-credentials:client_id}}"
```

```
      client_secret: "${{aws_secrets:salesforce-credentials:client_secret}}"
```

Parameters

`instance_url` (required)

Salesforce instance URL. Must use HTTPS.

`authentication.client_id` (required)

OAuth2 Consumer Key. Supports `${{aws_secrets:...}}`.

`authentication.client_secret` (required)

OAuth2 Consumer Secret. Supports `${{aws_secrets:...}}`.

`range` (optional)

Set backfill duration in ISO 8601 format (for example, `PT24H`, `P7D`, `P30D`). When set, overwrites both `elf_backfill` and `setup_audit_trail_backfill` with the same duration. When omitted, `elf_backfill` defaults to `P30D` (30 days) and `setup_audit_trail_backfill` defaults to `P180D` (180 days).

Salesforce RTEM integration configuration

Salesforce is a cloud-based Customer Relationship Management (CRM) platform that provides business applications for sales, service, marketing, and IT operations. It generates real-time security events through the Pub/Sub API (gRPC) covering login activity, API usage, file events, and data access across 19+ event channels with sub-second delivery. CloudWatch pipelines use the Salesforce Pub/Sub API to stream these events into CloudWatch Logs.

Topics

- Source configuration for Salesforce RTEM
- CloudWatch pipelines configuration for Salesforce RTEM

Source configuration for Salesforce RTEM

Prerequisites

Before you begin, make sure you have the following:

- A Salesforce account with the Event Monitoring feature enabled
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create and manage Amazon S3 buckets, AWS Secrets Manager secrets, and IAM roles

Integrating with Salesforce RTEM

To integrate Salesforce RTEM with CloudWatch Logs, you must configure a pipeline. First, set up a Salesforce account and an AWS Secrets Manager secret with required authentication credentials to receive data from Salesforce. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Salesforce RTEM streams 19 default RTEM channels plus optional CDC and custom Platform Events through the Pub/Sub API, which delivers logs directly to the configured sink (CloudWatch Logs).

Instructions to set up Salesforce account

1. **Create Salesforce Account**
   - Go to the Salesforce developer sign-up page.
   - Register with your name, email, and a unique username (email format).
   - Verify your email and set your password.
   - Note your instance URL (for example, `https://yourorg-dev-ed.my.salesforce.com`) – this is the `instance_url` for pipeline configuration.
2. **Create an External Client App**
   - In **Setup**, search **External Client App Manager** in Quick Find.
   - Choose **New External Client App**.
   - Fill in **App Name** (for example, "CloudWatch-Collector") and **Contact Email**.
   - Under **API (Enable OAuth Settings)**, check **Enable OAuth**.
   - Set **Callback URL**: `https://login.salesforce.com/services/oauth2/callback`
   - Move these OAuth Scopes from Available to Selected: `Full access (full)`, `Perform requests at any time (refresh_token, offline_access)`, `Access Pub/Sub API (pubsub_api)`
   - Choose **Create**.
3. **Configure Policies**

- Open your app in **External Client App Manager**.
- **Policies** tab > **Edit**.
- **Permitted Users**: Select "Admin approved users are pre-authorized" > **OK**.
- **Select Profiles**: Add **System Administrator**.
- Under **OAuth Flows and External Client App Enhancements**: Check **Enable Client Credentials Flow**.
- **Run As (Username)**: Enter the System Administrator's username (find it under **Setup > Users**).
- Choose **Save**.

4. **Get Consumer Key and Secret**
   - Open your app > **Settings** tab > **OAuth Settings**.
   - Choose **Consumer Key and Secret** button (verify identity by email code if prompted).
   - Copy **Consumer Key** (`client_id`) and **Consumer Secret** (`client_secret`).
5. **Create and Assign Permission Set**
   - **Setup > Permission Sets** > **New** (for example, "CloudWatch-Collector-Permissions").
   - **System Permissions > Edit** – enable: **API Enabled**, **View Real-Time Event Monitoring Data**.
   - **Save**, then **Manage Assignments > Add Assignment** > select the Run-As user > **Assign**.
6. **Enable Event Storage and Streaming**

   If storage is not enabled for an event type, the Pub/Sub API subscription connects but receives zero events silently.
   - **Setup > Event Manager**.
   - For each event type, choose the dropdown > **Enable Storage and Streaming**.
7. **Find Your Organization ID**
   - **Setup > Company Information**.
   - Copy the **Salesforce.com Organization ID** (15 or 18 character alphanumeric, for example, `00D5e000003TIrB`).
8. **Store Credentials in AWS Secrets Manager**
   - In AWS Secrets Manager, choose **Store a new secret** > **Other type of secret**.
   - Add key/value pairs: `client_id` = Consumer Key, `client_secret` = Consumer Secret.
   - Name the secret (for example, `salesforce-credentials`) and copy the ARN.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Salesforce, choose `salesforce_rtem` as the data source. Provide the `instance_url`, `org_id`, and use the `client_id` and `client_secret`. After creating the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms the following events. Events not listed are not mapped to OCSF and are forwarded to the sink as raw logs.

Authentication (3002)

Covers the following events:

- LoginEventStream
- LoginAsEventStream
- LogoutEventStream

File Hosting Activity (6006)

Covers the following event:

- FileEvent

API Activity (6003)

Covers the following events:

- BulkApiEventStream
- ApiEventStream

Datastore Activity (6005)

Covers the following events:

- ReportEvent
- ListViewEventStream

CloudWatch pipelines configuration for Salesforce RTEM

Collects real-time events from Salesforce using OAuth2 authentication.

Configure the Salesforce RTEM source with the following parameters:

```
source:
  salesforce_rtem:
    instance_url: "<<your-instance-url>>"
    org_id: "<<your-org-id>>"
    authentication:
      client_id: "${{aws_secrets:salesforce-credentials:client_id}}"
      client_secret: "${{aws_secrets:salesforce-credentials:client_secret}}"
```

Parameters

`instance_url` (required)

Salesforce instance URL (for example, `https://myorg.my.salesforce.com`). Must use HTTPS.

`org_id` (required)

Salesforce organization ID (15 or 18 character alphanumeric).

`authentication.client_id` (required)

OAuth2 Consumer Key. Supports `${{aws_secrets:...}}`.

`authentication.client_secret` (required)

OAuth2 Consumer Secret. Supports `${{aws_secrets:...}}`.

`additional_topics` (optional)

Extra topics beyond the 19 defaults (CDC, custom Platform Events).

`replay_preset` (optional)

Controls where to start consuming events. Valid values: `LATEST`, `EARLIEST`. Default: `EARLIEST`.

SentinelOne Singularity Endpoint integration configuration

To integrate SentinelOne Singularity Endpoint with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your SentinelOne source by configuring Amazon S3 and

Amazon SQS to receive endpoint logs. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Topics

- Source configuration for SentinelOne
- CloudWatch pipelines configuration for SentinelOne

Source configuration for SentinelOne

Integrating with SentinelOne Singularity Endpoint

SentinelOne Singularity Endpoint is an AI-powered endpoint security platform that provides real-time protection against malware, ransomware, and zero-day attacks. It uses behavioral analysis and machine learning to detect and stop threats autonomously. The platform supports automated response, rollback, and threat remediation. It gives centralized visibility and control across all endpoints. CloudWatch pipelines enables you to collect this data in CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring SentinelOne Singularity Endpoint to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, IAM roles, and then configuring the Amazon Telemetry Pipeline.

- Create Amazon S3 bucket that stores SentinelOne Singularity Endpoint logs.
- Configure Singularity Cloud Funnel or intermediate Syslog server with Amazon S3 bucket details to push logs.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose SentinelOne Singularity Endpoint as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the SentinelOne Singularity Endpoint events that maps to File System Activity (1001), Process Activity (1007), HTTP Activity (4002) and DNS Activity (4003).

File System Activity contains the following events:

- MALICIOUSFILE
- FILECREATION
- FILEDELETION
- FILEMODIFICATION
- FILERENAME
- FILESCAN

Process Activity contains the following events:

- PROCESSCREATION
- PROCESSTERMINATION
- DUPLICATETHREAD
- REMOTETHREAD
- PROCESSMODIFICATION
- DUPLICATEPROCESS
- OPENPROCESS
- PROCESSINJECTION
- PROCESSMODIFIER
- PROCESSEXIT
- OPENPRIVILEGEDPROCESSFROMKERNEL

HTTP Activity contains the following events:

- HTTP

DNS Activity contains the following events:

- DNS

CloudWatch pipelines configuration for SentinelOne

The SentinelOne setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the SentinelOne source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "sentinelone_endpointsecurity"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "sentinelone_endpointsecurity".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

ServiceNow CMDB Audit Log

ServiceNow is an enterprise platform that provides IT service management (ITSM) and configuration management database (CMDB) capabilities for tracking and managing IT assets, configurations, and changes across organizations.

Topics

- Source configuration for ServiceNow CMDB Audit Log
- CloudWatch pipelines configuration for ServiceNow CMDB Audit Log

Source configuration for ServiceNow CMDB Audit Log

Integrating with ServiceNow CMDB

ServiceNow is an enterprise platform that provides IT service management (ITSM) and configuration management database (CMDB) capabilities for tracking and managing IT assets, configurations, and changes across organizations. CloudWatch Pipeline uses the ServiceNow Table API to retrieve information about sys_audit, syslog, sysevent, and syslog_transactions from your ServiceNow instance.

Authenticating with ServiceNow CMDB

To read the logs, the pipeline needs to authenticate with your ServiceNow instance. The ServiceNow Table API supports OAuth 2.0.

- Make sure the REST API is enabled on your ServiceNow instance.
- Enable OAuth 2.0 Client Credentials grant type in your ServiceNow instance
- Create an OAuth Application Registry for external client authentication
- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`.
- Configure OAuth Application User and assign required roles

Configuring the CloudWatch Pipeline

When configuring the pipeline to read audit logs from ServiceNow choose ServiceNow CMDB as the data source. Fill in the required information like `instance_url` and the secret where `client_id` and `client_secret` are stored. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Entity Management (3004), API Activity (6003), and Datastore Activity (6005). These events are from specific tables and filtered for CMDB reference.

Entity Management contains events from following tables:

- sys_audit

API Activity contains events from following tables:

- sysevent
- syslog

Datastore Activity contains events from following tables:

- syslog_transactions

CloudWatch pipelines configuration for ServiceNow CMDB Audit Log

Collects configuration management database (CMDB) data from ServiceNow using OAuth2 authentication.

Configure the ServiceNow CMDB source with the following parameters:

```
source:
  servicenow_cmdb:
    instance_url: "<example-instance-url>"
    range: "P7D"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`instance_url` (required)

ServiceNow instance URL.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for ServiceNow API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for ServiceNow API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

Slack Audit Log integration configuration

Slack is a cloud-based collaboration and messaging platform that enables team communication through channels, direct messages, file sharing, and integrations with external applications. CloudWatch pipelines use the Slack APIs (such as Events API and Audit Logs API) to retrieve information about user activities, messages, channel events, app interactions, and administrative actions across your Slack workspace.

Topics

- Source configuration for Slack Audit Log
- CloudWatch pipelines configuration for Slack Audit Log

Source configuration for Slack Audit Log

Integrating with Slack Audit Log

Slack is a cloud-based collaboration and messaging platform that enables team communication through channels, direct messages, file sharing, and integrations with external applications. CloudWatch pipelines use the Slack APIs (such as Events API and Audit Logs API) to retrieve information about user activities, messages, channel events, app interactions, and administrative actions across your Slack workspace. These APIs provide REST endpoints that allow access to event data, enabling the collection of communication and audit logs from your Slack environment for monitoring and analysis.

Authenticating with Slack

To read Slack audit logs, the pipeline needs to authenticate with your Slack workspace. The plugin supports OAuth API token authentication. Follow these instructions to get started with Slack APIs:

1. Before creating an app, register for the Slack Developer Program by visiting: `https://api.slack.com/developer-program`.
2. Log in to the Slack API portal and navigate to "Your Apps" then "Create New App." Choose "From scratch" and provide an app name and workspace. After creation, note down the Client ID and Client Secret from the "Basic Information" section.
3. Configure OAuth scopes under "OAuth & Permissions." Add required scopes such as `auditlogs:read`, `channels:read`, `groups:read`, `users:read`, and `channels:history` depending on your use case. Install the app to your workspace by choosing the install button in the Slack API portal. After installation, copy the User OAuth Token (starts with `xoxp-`). The `auditlogs:read` scope requires a user OAuth token.
4. In AWS Secrets Manager, create a secret that will hold the Slack token obtained in step 3. The secret's value must be a JSON object with a key that stores the token. Pick any secret name and any key name you prefer, but remember both — the pipeline configuration references them together using the syntax `${{aws_secrets:<secret-name>:<key-name>}}`.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read logs, choose Slack as the data source. Specify the range duration format (for example, PT21H for the last 21 hours) to control the time window of logs retrieved. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Web Resources Activity (6001), Authentication (3002), Entity Management (3004), Account Change (3001), User Access Management (3005), File Hosting Activity (6006), and Detection Finding (2004). These events are sourced from the Slack AuditLogs API. Events that are not listed are not mapped to OCSF and will be forwarded to the sink as raw logs.

Web Resources Activity (6001) contains the following event types:

- private_channel_created
- private_channel_archive
- private_channel_converted_to_public
- private_channel_deleted
- private_channel_unarchive
- public_channel_archive
- public_channel_converted_to_private
- public_channel_created
- public_channel_deleted
- public_channel_preview
- public_channel_unarchive
- file_public_link_created
- file_public_link_revoked
- huddle_screenshare_on
- huddle_ended
- huddle_knock_accepted
- huddle_participant_dropped

- huddle_participant_joined
- huddle_participant_left
- huddle_started
- huddle_screenshare_off
- huddle_transcription_cancelled
- huddle_transcription_paused
- huddle_transcription_resumed
- huddle_transcription_started
- huddle_transcription_start_notification
- slack_ai_huddle_notes_generated
- list_linksharing_enabled
- canvas_linksharing_enabled
- list_linksharing_disabled
- canvas_linksharing_disabled

Entity Management (3004) contains the following event types:

- external_shared_channel_invite_accepted
- external_shared_channel_invite_approved
- external_shared_channel_invite_auto_revoked
- external_shared_channel_invite_created
- external_shared_channel_access_upgraded
- external_shared_channel_disconnect_and_archived
- external_shared_channel_disconnected
- external_shared_channel_invite_declined
- external_shared_channel_invite_expired
- external_shared_channel_invite_revoked
- channels_export_completed
- channels_export_deleted
- channels_export_downloaded

- channels_export_started
- scheduled_export_completed
- scheduled_export_deleted
- scheduled_export_downloaded
- scheduled_export_started
- manual_export_completed
- manual_export_deleted
- manual_export_downloaded
- manual_export_started
- manual_user_export_downloaded
- manual_user_export_completed
- manual_user_export_deleted
- manual_user_export_started
- external_shared_channel_connected

Account Change (3001) contains the following event types:

- role_change_to_owner
- role_change_to_admin
- role_change_to_guest
- role_change_to_user
- role_removed
- role_assigned
- guest_created
- guest_deactivated
- guest_reactivated
- user_created
- user_deactivated
- user_reactivated
- user_email_updated

- user_profile_updated
- user_profile_deleted
- guest_expiration_cleared
- guest_expiration_set
- guest_expired
- user_force_upgrade_non_compliant_mobile_app_version
- owner_transferred
- service_owner_transferred
- user_password_reset_requested
- user_password_reset_slack_security
- custom_tos_accepted
- user_session_settings_changed
- role_added_to_usergroup
- role_removed_from_usergroup

Authentication (3002) contains the following event types:

- bulk_session_reset_by_admin
- user_session_reset_by_admin
- user_logout_non_compliant_mobile_app_version
- user_logout
- user_logout_compromised
- user_login
- user_login_failed
- cli_login
- user_sessions_reset_by_anomaly_event_response
- user_session_invalidated

User Access Management (3005) contains the following event types:

- permissions_assigned

- user_channel_join
- guest_channel_join
- user_added_to_usergroup
- workflow_trigger_permission_added
- workflow_trigger_permission_set
- app_resources_granted
- app_resources_added
- app_scopes_expanded
- permissions_removed
- user_channel_leave
- guest_channel_leave
- user_removed_from_usergroup
- workflow_trigger_permission_removed
- role_modified_on_usergroup

File Hosting Activity (6006) contains the following event types:

- file_deleted
- file_download_blocked
- file_downloaded
- file_shared
- file_uploaded

Detection Finding (2004) contains the following event types:

- file_malicious_content_detected
- Anomaly

CloudWatch pipelines configuration for Slack Audit Log

Collects event logs from Slack using API token authentication.

Configure the Slack source with the following parameters:

```
source:
  slack_auditlogs:
    authentication:
        api_token: "${{aws_secrets:slack-account-credentials:apiToken}}"
    # Provide the time range (e.g., P7D for the last 7 days)
    range: "P7D"
```

Parameters

`authentication` (required)

Block containing Slack authentication settings. Contains the nested parameters listed in the following entry.

`api_token` (required)

Slack API token (`xoxp-...`) with the `auditlogs:read` scope. Typically sourced from AWS Secrets Manager using the `${{aws_secrets:<secret-name>:<key>}}` reference syntax.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

> **Note**
>
> The `api_token` value is retrieved from AWS Secrets Manager. The preceding parameter information can be obtained from the API credentials generated while setting up your Slack application.

Tanium integration configuration

Tanium is an endpoint management and security platform that provides real-time visibility and control across enterprise endpoints. CloudWatch pipelines collect detailed telemetry from Tanium including endpoint inventory, compliance posture, vulnerability findings, threat response alerts, and audit logs covering authentication, account changes, and group management activities.

Topics

- Source configuration for Tanium
- CloudWatch pipelines configuration for Tanium

Source configuration for Tanium

Integrating with Tanium

Tanium is an endpoint management and security platform that provides real-time visibility and control across enterprise endpoints. It collects detailed telemetry such as endpoint activity, security events, authentication events, and network activity. This data can be exported and integrated with AWS services for centralized monitoring and analytics. CloudWatch pipelines enable the ingestion of this data into CloudWatch Logs for further analysis and alerting.

Instructions to setup Tanium Connect, Amazon S3 and Amazon SQS

Prerequisites

- Access to the AWS Management Console with IAM administrative privileges.
- Access to the Tanium Console with permissions to configure Tanium Connect.

To set up Tanium Connect, Amazon S3, and Amazon SQS

1. In the AWS Console, create an Amazon S3 bucket in your desired region. Create separate prefixes (sub-folders) within the bucket for each log type to make sure clear log segregation and easier downstream processing.
2. Create an Amazon SQS Queue for Event Notifications. Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. Configure Amazon S3 Event Notifications on the bucket to send `s3:ObjectCreated:*` events to the Amazon SQS queue. This enables downstream consumers to be notified when new log files are delivered.
3. Create an IAM User with Programmatic Access. In IAM, create a new user with programmatic (CLI) access only. Attach a policy granting the minimum required permissions like `s3:PutObject`. Scope the policy to the target Amazon S3 bucket and prefixes. Generate an Access Key ID and Secret Access Key for the user. Store these credentials securely (for example, in a secrets manager). These will be needed in the following step.
4. Configure the Tanium Connect Destination. Log in to the Tanium Console. Navigate to Tanium Connect and create a new connection, select the type of log data and other general information. Select Amazon S3 as the destination. Enter the following details:

a. AWS Access Key ID

b. AWS Secret Access Key

c. S3 Bucket Name

d. AWS Region

e. Object key prefix (matching the sub-folder for the relevant log type)

5. Validate the Configuration. Save the connection and execute a test run. Verify that log data is successfully delivered to the expected Amazon S3 bucket and prefix. Confirm that the Amazon SQS queue is receiving event notifications for newly created objects.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Tanium, choose Tanium as the data source. Using Tanium Connect, data from Tanium custom and default reports is exported to Amazon S3, with event notifications delivered through Amazon SQS. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms the following report data and maps them to one of the 8 OCSF Classes: Device Inventory Info (5001), Vulnerability Finding (2002), Compliance Finding (2003), Detection Finding (2004), Authentication (3002), Account Change (3001), Entity Management (3004), and Group Management (3006). Out of all the custom reports pushed to S3 by the end user, the reports from the following listed datasources are transformed to the respective OCSF Classes. The rest of the data is ingested in raw format.

There is no specific event type in Tanium (except for audit logs). The following custom reports are generated by choosing the relevant modules in Tanium Connect:

- Tanium Platform
- Compliance Data – Comply Module
- Vulnerability Data – Comply Module
- Discovery Data – Discover Module
- Threat Response Alerts – Threat Response Module

The following sections describe the audit log mappings to OCSF event classes.

Authentication (3002)

From audit logs where `object_type_name` = "authentication":

- New Session Created
- New System User Session Created
- Authentication Failed
- User Logged Out
- User Failed to Log Out

Account Change (3001)

From audit logs where `object_type_name` = "api_token" or "user":

- `type_name` = CreateObject and `object_type_name` = api_token
- `type_name` = DeleteObject and `object_type_name` = api_token
- `type_name` = CreateObject and `object_type_name` = user
- `type_name` = DeleteObject and `object_type_name` = user
- `type_name` = UpdateObject and `object_type_name` = user

Entity Management (3004)

From audit logs where `reportName` = "TaniumThreatAuditLog":

- action = create
- action = update
- action = deleteBulk

Group Management (3006)

From audit logs where `object_type_name` = "user_group":

- action = UpdateObject and details containing "Assigned role" / "updated with role ids"
- action = UpdateObject and details containing "removed role"
- action = UpdateObject and details containing "user ids added"
- action = UpdateObject and details containing "user ids removed"

- action = UpdateObject and details containing "persona updated with user groups"
- action = DeleteObject
- action = CreateObject

CloudWatch pipelines configuration for Tanium

The Tanium setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    acknowledgments: true
    sqs:
      queue_url: "https://sqs.us-east-1.amazonaws.com/1234567890/tanium-sqs"
      maximum_messages: '10'
      visibility_duplication_protection: true
      visibility_timeout: 180s
    aws:
      region: "us-east-1"
    notification_type: sqs
    notification_source: s3
    bucket_owners:
      tanium-test-logs-test: '1234567890'
    default_bucket_owner: '1234567890'
    codec:
      ndjson: {}
    compression: none
```

Parameters

`acknowledgments` (required)

Prevents data loss by only considering logs successfully processed after they are received by the sink. Set to `true` to enable.

`sqs.queue_url` (required)

The Amazon SQS queue URL that receives Amazon S3 event notifications when new objects land.

`sqs.maximum_messages` (optional)

Max number of Amazon SQS messages to pull per poll (batch size, up to Amazon SQS max of 10).

`sqs.visibility_duplication_protection` (optional)

Uses Amazon SQS visibility timeout to prevent duplicate processing of the same message by multiple workers.

`sqs.visibility_timeout` (optional)

How long (in seconds) a message stays invisible to other consumers after being picked up, giving the worker time to process it.

`aws.region` (required)

AWS region where the Amazon SQS queue and Amazon S3 bucket live.

`notification_type` (required)

`sqs` – Tells the plugin to expect notifications through Amazon SQS.

`notification_source` (optional)

`s3` – Indicates the Amazon SQS notifications originate from Amazon S3 event notifications.

`bucket_owners` (required)

Maps specific bucket names to their owning AWS account IDs, needed for cross-account access.

`default_bucket_owner` (required)

Fallback AWS account ID used for any bucket not explicitly listed in `bucket_owners`.

`codec` (required)

`ndjson` – Parses each Amazon S3 object as newline-delimited JSON (one JSON record per line).

`compression` (required)

none – Indicates the Amazon S3 objects are not compressed, so no decompression is applied before parsing.

Tenable Vulnerability Management integration configuration

Tenable Vulnerability Management is a cloud-based vulnerability management platform that provides continuous visibility into assets, vulnerabilities, compliance posture, and security findings.

CloudWatch pipelines use the Tenable REST API to retrieve asset inventories, vulnerability findings, compliance data, scan results, audit logs, and plugin metadata from your Tenable environment.

Topics

- Source configuration for Tenable Vulnerability Management
- CloudWatch pipelines configuration for Tenable Vulnerability Management

Source configuration for Tenable Vulnerability Management

Integrating with Tenable Vulnerability Management

CloudWatch pipelines use the Tenable REST API to retrieve asset inventories, vulnerability findings, compliance data, scan results, audit logs, and plugin metadata from your Tenable environment. The API exposes REST and bulk export endpoints that allow fetching security data for monitoring and analysis.

To integrate CloudWatch Pipelines with Tenable Vulnerability Management, complete the following high-level steps:

- Generate an Access Key and Secret Key from the Tenable UI.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Tenable as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, make sure you have the following:

- An active Tenable account with the Administrator role
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager
- An AWS account with permissions to create and manage CloudWatch Logs log groups

Authenticating with Tenable Vulnerability Management

Tenable uses API key authentication with an access key and secret key. The pipeline passes these credentials through the `X-ApiKeys` header to authenticate each API request.

Configure Authentication for Tenable Vulnerability Management

To configure authentication credentials for the pipeline:

1. Log in to the Tenable Vulnerability Management UI.
2. Navigate to Settings > My Account > API Keys.
3. Generate a new API key pair. Note the Access Key and Secret Key values.
4. Make sure your account has the Administrator role.
5. Store the `access_key` and `secret_key` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Tenable as the data source. Provide the `access_key` and `secret_key`. After you create and activate the pipeline, vulnerability management data from Tenable will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Export settings** – chunk`_size` (default 1000, range 100–10,000), `export_backfill` (default `P30D`, range 30 minutes–90 days), `export_polling_interval` (default `P1D`, range 30 minutes–7 days)
- **Backfill durations** – Configure historical backfill for audit logs, plugins, and scans independently.
- **Polling intervals** – Configure independent polling intervals for audit, scan, and plugin streams.
- **Page sizes** – Configure the number of records retrieved per API request page.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Device Inventory Info [5001]** – Assets
- **Compliance Finding [2003]** – Compliance
- **Vulnerability Finding [2002]** – Vulnerability
- **Scan Activity [6007]** – Scans
- **Authentication [3002]** – Audit Logs (authentication-related actions)
- **API Activity [6003]** – Audit Logs (API-related actions)

- **Account Change [3001]** – Audit Logs (account modification actions)

Plugins are passed as raw data and are not mapped to OCSF event classes.

CloudWatch pipelines configuration for Tenable Vulnerability Management

Collects vulnerability management data from Tenable using API key authentication.

Configure the Tenable Vulnerability Management source with the following parameters:

```
source:
  tenable_vulnerabilitymanagement:
    authentication:
      access_key: "${{aws_secrets:<secret-name>:access_key}}"
      secret_key: "${{aws_secrets:<secret-name>:secret_key}}"
    range: "P30D"
```

Parameters

`authentication.access_key` (required)

The Tenable API access key, stored in AWS Secrets Manager.

`authentication.secret_key` (required)

The Tenable API secret key, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `P1D`, maximum is `P90D`. Default is `P30D`.

Wazuh Platform integration configuration

Wazuh is an open-source security platform that provides unified XDR and SIEM capabilities including threat detection, integrity monitoring, incident response, and compliance across on-premises, cloud, and hybrid environments. The Wazuh Platform is the central component built on OpenSearch that stores and indexes security alerts, providing near real-time search and analytics through a RESTful API. Use CloudWatch pipelines with the Wazuh Platform API to retrieve security alerts, vulnerability findings, system inventory, and agent monitoring data.

Topics

- Source configuration for Wazuh Platform
- CloudWatch pipelines configuration for Wazuh Platform

Source configuration for Wazuh Platform

Integrating with Wazuh Platform

Wazuh Platform is an open-source security monitoring platform that delivers threat detection, file integrity monitoring, vulnerability assessment, and compliance across endpoints and cloud workloads. Use CloudWatch pipelines with the Wazuh Platform API (an Elasticsearch-compatible REST API) to retrieve security alerts, vulnerability findings, system inventory, and agent monitoring data from your self-hosted Wazuh Platform instance. The Indexer API provides search endpoints that you can use to access event data stored in daily-rotated indices, so you can collect security logs from your Wazuh Platform environment for centralized monitoring and analysis.

To integrate CloudWatch Pipelines with Wazuh Platform, complete the following high-level steps:

- Obtain the Wazuh Indexer host URL and credentials.
- Store the username and password in AWS Secrets Manager.
- Create a CloudWatch pipeline with Wazuh Platform as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, make sure you have the following:

- The Wazuh Indexer installed and running. Follow the official quickstart guide to install: Quickstart - Wazuh documentation
- Wazuh Indexer accessible over HTTPS (port 9200 or 443 with reverse proxy)
- Network connectivity from the pipeline to the Wazuh Indexer host (if behind a firewall, allow the pipeline's egress IPs)
- Valid credentials with Basic Auth (username/password) that have read permissions on the target indices
- User role permissions with at minimum `indices:data/read/search` on the target index patterns (for example, `wazuh-alerts-*`, `wazuh-states-*`)

- A sortable `timestamp` field present in the documents for incremental ingestion and `search_after` pagination (for inventory indices this may need to be added manually)
- If using self-signed TLS certificates, the pipeline must trust the CA
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with Wazuh Platform

To read Wazuh Platform data, the pipeline needs to authenticate with your Wazuh Indexer instance. The plugin supports HTTP Basic Authentication (username/password).

Follow these steps to configure authentication:

1. Ensure your Wazuh Indexer is installed and running. The Indexer runs on port 9200 over HTTPS. Verify access by running: `curl -k -u <username>:<password> https://<wazuh-host>:9200/`
2. Identify or create a user with read access to the required indices (`wazuh-alerts-*`, `wazuh-monitoring-*`, `wazuh-states-inventory-*`). The default `admin` user has full access. For production, create a dedicated read-only user through the Security plugin API.
3. In AWS Secrets Manager, create a secret that will hold the Wazuh Indexer credentials. The secret's value must be a JSON object with keys for `username` and `password`. For example, create a secret named `wazuh-credentials` with the following JSON value:

   ```
   {"username": "admin", "password": "your-wazuh-indexer-password"}
   ```

   The corresponding pipeline references are `${{aws_secrets:wazuh-credentials:username}}` and `${{aws_secrets:wazuh-credentials:password}}`.
4. Ensure network connectivity from the pipeline to the Wazuh Indexer host on port 9200/443.
5. If using self-signed TLS certificates (default for Wazuh), configure the pipeline to trust the Wazuh CA certificate, or disable certificate verification in the pipeline configuration.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read logs, choose Wazuh Platform as the data source. Provide the Host URL (your Wazuh Indexer endpoint including port 9200/443) and Authentication credentials.

The pipeline will poll for new data at the configured interval. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms the following events. Events that are not listed but pulled are not mapped to OCSF and will be forwarded to the sink as raw logs.

Authentication (3002)

Contains authentication success and failure events including SSH, PAM, and Windows logon events.

Vulnerability Finding (2002)

Contains Vulnerability Detection findings including CVE findings from vulnerability scanning.

File System Activity (1001)

Contains File Integrity Monitoring events including file addition, modification, and deletion.

Device Inventory Info (5001)

Contains System Inventory and Agent monitoring events.

Detection Finding (2004)

Contains Rootcheck events generated for malware detection.

Application Lifecycle (6002)

Contains Container Security events.

Compliance Finding (2003)

Contains SCA compliance events.

Remediation Activity (7001)

Contains Active Response events.

API Activity (6003)

Contains Cloud Security events from Amazon, Azure, GCP, GitHub, and Office365.

CloudWatch pipelines configuration for Wazuh Platform

Collects audit logs from Wazuh Platform using Basic authentication.

Configure the Wazuh Platform source with the following parameters:

```
source:
  wazuh_platform:
    host: "https://<wazuh-indexer-host>:9200"
    authentication:
      username: "${{aws_secrets:wazuh-credentials:username}}"
      password: "${{aws_secrets:wazuh-credentials:password}}"
    acknowledgments: true
```

Parameters

`host` (required)

Wazuh Indexer base URL including scheme and port (for example, `https://<wazuh-indexer-host>:9200`). This is a customer-configured domain – each customer hosts their own Wazuh Indexer instance.

`authentication` (required)

Block containing Wazuh Indexer authentication settings. Contains the nested parameters listed below.

`authentication.username` (required)

Wazuh Indexer username for HTTP Basic Authentication. Typically sourced from AWS Secrets Manager using the `${{aws_secrets:<secret-name>:<key>}}` reference syntax.

`authentication.password` (required)

Wazuh Indexer password for HTTP Basic Authentication. Typically sourced from AWS Secrets Manager using the `${{aws_secrets:<secret-name>:<key>}}` reference syntax.

`acknowledgments` (optional)

Prevents data loss by only considering logs successfully processed after they are received by the sink. Accepts `true` or `false`. Default: `true`.

> **Note**
>
> The `username` and `password` values are retrieved from AWS Secrets Manager. The above parameter information can be obtained from the Wazuh Indexer installation or user management configuration.

WIZ CNAPP integration configuration

To integrate WIZ CNAPP with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your WIZ source by authenticating with OAuth2 and configuring API access. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Topics

- Source configuration for WIZ CNAPP
- CloudWatch pipelines configuration for WIZ

Source configuration for WIZ CNAPP

Integrating with Wiz CNAPP

Wiz is a cloud-native application protection platform (CNAPP) that provides comprehensive visibility and security across multi-cloud environments. CloudWatch Pipeline uses the Wiz GraphQL API to retrieve information about security posture, vulnerabilities, misconfigurations, threats, and audit activities from your cloud infrastructure. The Wiz GraphQL API enables access to security data through flexible GraphQL queries, allowing retrieval of audit logs, issues, vulnerability findings, configuration findings, and detections from the Wiz platform.

Authenticating with Wiz CNAPP

To read Wiz Cnapp audit Logs, the pipeline needs to authenticate with your account. The plugin supports OAuth2 Authentication. Follow these instructions to get started.

- Create a Service Account in Wiz with appropriate permissions. You must be logged in as a Wiz user with Write (W) permission on service accounts.
- Configure the Service Account and get newly created Client ID and Client Secret.

- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`.
- Configure API permissions (scopes) for your Service Account.

  Required scope: `read:issues`, `read:detections`, `read:cloud_events_cloud`, `read:cloud_events_sensor`, `read:security_scans`, `read:vulnerabilities`, `read:cloud_configuration`, `admin:audit`
- Identify your GraphQL API endpoint: To find your specific endpoint check Tenant Info in the Wiz portal. The Wiz GraphQL API endpoint is `https://api.<region>.app.wiz.io/graphql`, where `<region>` corresponds to your Wiz tenant's datacenter (for example, us1, us2, eu1, eu2).

Configuring the CloudWatch Pipeline

When configuring the pipeline to read audit logs from Wiz, choose Wiz CNAPP as the data source. Fill in the required information like Region. After you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Detection Finding (2004), Vulnerability Finding (2002), Compliance Finding (2003), Authentication (3002), and API Activity (6003).

Detection Finding contains all events from following sources:

- Issues
- Detections

Vulnerability Finding contains all events from following sources:

- Vulnerability Findings

Compliance Finding contains all events from following sources:

- Cloud Configuration Findings

Authentication contains events from following sources and given actions:

- Audit logs
- DeviceLogin
- Login

API Activity contains events from following sources and given actions:

- Audit logs

CloudWatch pipelines configuration for WIZ

Collects cloud-native application protection platform (CNAPP) data from Wiz using OAuth2 authentication.

Configure the Wiz CNAPP source with the following parameters:

```
source:
  wiz_cnapp:
    region: "<example-region>"
    range: "P7D"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`region` (required)

Wiz region for your organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Wiz API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Wiz API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

Zscaler Internet Access

CloudWatch pipelines enables you to collect logs from Zscaler Internet Access (ZIA). ZIA is a cloud-based secure web gateway that protects users connecting to the internet.

Topics

- Source configuration for Zscaler Internet Access

- Pipeline configuration for Zscaler Internet Access

Source configuration for Zscaler Internet Access

Integrating with Zscaler Internet Access

Zscaler Internet Access (ZIA) is a cloud-based secure web gateway that protects users connecting to the internet. It inspects all internet traffic to block malware, phishing, and data leaks using advanced threat detection and SSL inspection. ZIA enforces security policies in real time without requiring on-premises hardware. It ensures safe and compliant internet access for users anywhere. CloudWatch pipelines enables you to collect this data in CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring ZIA to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, IAM roles, and then configuring the Amazon Telemetry Pipeline.

- Create Amazon S3 bucket that stores ZIA logs and create separate folders for each log type. Create IAM user and grant s3 write permission, console access not needed only CLI and create Access key and Secret key for this account.
- Configure NSS feeds with Amazon S3 bucket details to push logs.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Zscaler Internet Access, choose Zscaler Internet Access (ZIA) as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to DNS Activity (4003), HTTP Activity (4002), Network Activity (4001), and Authentication (3002). Each event comes from a source as mentioned below.

DNS Activity covers all events from source:

- DNS Logs

HTTP Activity covers all events from source:

- Web Logs

Network Activity covers all events from source:

- Firewall Logs

Authentication covers events from source:

- Admin Audit Logs - Event actions: SIGN_IN, SIGN_OUT

Pipeline configuration for Zscaler Internet Access

The Zscaler setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Zscalar source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "zscaler_internetaccess"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "zscaler_internetaccess".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

Zeek integration configuration

Zeek is an open-source network security monitoring platform widely used for analyzing network traffic and generating detailed logs about network activities across an organization's infrastructure. It passively monitors network traffic and provides deep visibility into communications by producing structured logs for multiple network protocols and security-relevant events. CloudWatch pipelines allow ingestion of Zeek log data into CloudWatch Logs, providing scalable collection, processing, normalization, and integration with downstream AWS security and monitoring services.

Topics

- Source configuration for Zeek
- CloudWatch pipelines configuration for Zeek

Source configuration for Zeek

Integrating with Zeek

To integrate Zeek with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your Zeek source by configuring Amazon S3 and Amazon SQS to receive data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring Zeek with Fluent Bit to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, IAM roles, and then configuring the CloudWatch Pipeline.

Configuring Zeek logs using Fluent Bit

- Install Fluent Bit (a lightweight log collector that reads log files and forwards them to destinations such as Amazon S3) on the Zeek host and configure it to tail Zeek log files (for example, `/opt/zeek/logs/current/*.log`).
- Configure AWS credentials (IAM role or `aws configure`) so Fluent Bit has permission to upload objects to the Amazon S3 bucket.
- Update the Fluent Bit configuration to use the S3 output plugin, specifying the bucket name, Region, and S3 key path for Zeek logs.
- Start and enable the Fluent Bit service to continuously collect Zeek logs and upload them to Amazon S3 for downstream ingestion.

Amazon S3 and Amazon SQS configuration

- Amazon S3 bucket that stores the Zeek logs should reside in the same AWS Region.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Zeek, choose Zeek as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to multiple OCSF classes. The following table lists the supported event mappings.

Event name	OCSF class
conn	Network Activity (4001)
dns	DNS Activity (4003)
http	HTTP Activity (4002)
ssl	Network Activity (4001)
ssh	SSH Activity (4007)
kerberos	Authentication (3002)
rdp	RDP Activity (4005)
files	Network Activity (4001)
notice	Detection Finding (2004)
known_hosts	Base Event (0)
x509	Network Activity (4001)
ftp	FTP Activity (4008)
smtp	Email Activity (4009)
dhcp	DHCP Activity (4004)
ntlm	Authentication (3002)

Event name	OCSF class
smb_files	SMB Activity (4006)
smb	SMB Activity (4006)
dce_rpc	SMB Activity (4006)
ldap	Authentication (3002)
ldap_search	Network Activity (4001)
quic	Network Activity (4001)
tunnel	Tunnel Activity (4014)
pe	Base Event (0)
weird	Base Event (0)
known_services	Base Event (0)
software	Software Inventory Info (5020)
reporter	Base Event (0)

Events that do not match any OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

CloudWatch pipelines configuration for Zeek

The Zeek setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Zeek source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
```

```
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "zeek"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "zeek".

`aws.region` (required)

The AWS Region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

on_error (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

Custom log data from CloudWatch Logs or an Amazon S3 bucket

You can create pipelines for custom data sources using the following approaches:

1. **CloudWatch Custom Logs** – Define pipelines on your existing CloudWatch custom log groups by providing:
   - A data source name
   - A data source type

   For more information on data source name and type, see the CloudWatch Logs User Guide.
2. **CloudWatch Logs Syslog service** – Process Syslog messages delivered to a CloudWatch Logs log group. Before creating the pipeline, complete Setting up syslog ingestion and verify that messages are arriving in the destination log group.

   In the console, choose **CloudWatch Logs syslog service** and select RFC 5424, RFC 3164, Cisco, or F5. For API or AWS CLI configuration, use the cloudwatch_logs source with syslog as the data source name and the corresponding data source type: rfc5424, rfc3164, cisco, or f5_bigip.

   ```
   source:
     cloudwatch_logs:
       aws:
         sts_role_arn: "arn:aws:iam::123456789012:role/MyCloudWatchLogsRole"
       log_event_metadata:
         data_source_name: "syslog"
         data_source_type: "rfc5424"
   ```

   A pipeline matches one data source name and type. Create a separate pipeline for each Syslog format that you want to process. Syslog messages are parsed during ingestion, so pipeline processors are optional.

   For the shared source parameter reference and restrictions, see the section called “AWS service logs from CloudWatch Logs”. For pipeline IAM requirements, see the section called “Custom and Syslog data from CloudWatch Logs”.

3. **S3 Custom Sources** – Process arbitrary logs stored in S3 buckets by configuring source for the pipeline:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "my_custom_logs"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

> **Note**
>
> The CSV processor can't be used with S3 custom sources. Instead, use the CSV codec in the S3 source.

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name`

Identifies the data source. This can be any string value that represents your data source. Example: "my_custom_logs".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports `csv`, `json`, `ndjson` codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either `retain_messages` or `delete_messages`. Default is `retain_messages`.

Custom source configuration

When creating a pipeline for custom sources:

- A parser must be the first processor in the pipeline if the data source is CloudWatch Logs
- You can specify any supported processor for custom log pipelines

Topics

- Configuring Custom S3 Bucket Sources

Configuring Custom S3 Bucket Sources

With CloudWatch pipelines, you can process arbitrary logs stored in S3 buckets.

Prerequisites

To use Amazon S3 as the source for a pipeline, first create an S3 bucket. For instructions, see Creating a general purpose bucketin the *Amazon S3 User Guide*.

> **Note**
>
> If the S3 bucket used as a source in the pipeline is in a different AWS account, you also need to enable cross-account read permissions on the bucket. This allows the pipeline to read and process the data. To enable cross-account permissions, see Bucket owner granting cross-account bucket permissions in the *Amazon S3 User Guide*.
> If your S3 buckets are in multiple accounts, use a `bucket_owners` map. For an example, see Cross-account S3 access in the *OpenSearch* documentation.

To set up S3-SQS processing, you also need to perform the following steps:

- Create an Amazon SQS queue.
- Enable event notifications on the S3 bucket with the SQS queue as a destination.

Configure the pipeline role

Unlike other source plugins that push data to a pipeline, the S3 source plugin has a read-based architecture in which the pipeline pulls data from the source. Therefore, in order for a pipeline to read from S3, you must specify a role within the pipeline's S3 source configuration that has access to both the S3 bucket and the Amazon SQS queue. The pipeline will assume this role in order to read data from the queue.

You can find example role permissions in Source-specific IAM policies. Note that this role must have a trust relationship with the CloudWatch pipelines service principle. You can find an example trust policy configuration for your pipeline role in Trust relationships.

Create the pipeline

After you've set up your permissions, you can configure a pipeline depending on your Amazon S3 use case.

Select **Create pipeline** in the **Pipelines** tab under **Ingestion** in the CloudWatch Console. Follow the pipeline wizard steps and provide the SQS queue ARN and required pipeline IAM role when prompted. Optionally provide a data source name and type to attach to the log group destination in CloudWatch Logs.

Be sure to configure a CloudWatch Logs resource policy if one isn't already configured to the destination log group and then select **Create pipeline** in the **Review and create** step. The pipeline will be created and data will begin to flow within 5 minutes if successful.

Amazon S3 cross account as a source

You can grant access across accounts with Amazon S3 so that CloudWatch pipelines can access S3 buckets in another account as a source. To enable cross-account access, see Bucket owner granting cross-account bucket permissions in the *Amazon S3 User Guide*. After you have granted access, make sure that your pipeline role has the required permissions.

Then, you can create a pipeline using `bucket_owners` to enable cross-account access to an Amazon S3 bucket as a source.

Custom source configuration

When creating a pipeline for custom sources:

- A parser must be the first processor in the pipeline
- You can specify any supported processor for custom log pipelines

AWS service logs from CloudWatch Logs

Intercepts log events from CloudWatch Logs that match the log event metadata configuration.

> **Important**
>
> Pipelines with processors mutate the log events in the original CloudWatch log group they are intercepted from for logs from AWS services. To preserve unmodified copies of your log data, enable the `include_original` option in the `cloudwatch_logs` sink configuration, or use the **Keep original log** toggle in the console. For more information, see the section called “Sinks”.

Configuration

Configure the CloudWatch Logs source with the following parameters:

```
source:
```

```
  cloudwatch_logs:
    aws:
      sts_role_arn: "arn:aws:iam::123456789012:role/MyCloudWatchLogsRole"
    log_event_metadata:
      data_source_name: "<data_source_name>"
      data_source_type: "<data_source_type>"
```

Parameters

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for CloudWatch Logs interception.

`log_event_metadata.data_source_name` (required)

Identifies the specific AWS service that generated the log events or a custom log source name. For custom logs, this can be any string up to 15 characters when `data_source_type` is "default".

`log_event_metadata.data_source_type` (required)

Specifies the category or type of logs within the AWS service, or "default" for custom logs. Set to "default" to enable custom log source names.

For more information on data source name and type, see the CloudWatch Logs User Guide.

Restrictions

The following restrictions apply to CloudWatch Logs sources:

- No two pipelines can use the `cloudwatch_logs` source with identical `data_source_name` and `data_source_type` metadata criteria.
- When `data_source_name` is `aws_cloudtrail`, only empty processors (`[]`) or the `ocsf` processor are allowed.

CloudWatch pipelines processors

CloudWatch pipelines processors transform, parse, and enrich log data as it flows through the pipeline. Log pipelines support up to 20 processors that are applied sequentially in the order they are defined. Metrics pipelines support up to 20 processors, applied sequentially in the order you define them. For metrics pipeline processors, see the section called “Metrics processors”.

Transformation metadata

When a pipeline processes log events, CloudWatch pipelines automatically adds transformation metadata to each processed log entry. This metadata indicates that the log has been transformed, making it easy to distinguish between original and processed data. If you enable the **Keep original log** option during pipeline creation, you can compare the original log with the transformed version at any time.

The following table describes the processor categories.

Category	Description
Parsers	Convert raw log data into structured formats, such as Open Cybersecurity Schema Framework (OCSF), CSV, JSON, and so on
Transformers	Modify log data structure; add, copy, move, or delete fields
String Processors	Manipulate string values; case conversion, trimming, substitution
Metrics processors	Add, delete, rename attributes and metrics on OTel metric datapoints

Topics

- Parser processors
- Transformation processors
- String manipulation processors
- Filter processors
- Common processor use cases
- Processor compatibility and restrictions
- Metrics pipeline processors

Parser processors

Parser processors convert raw or semi-structured log data into structured formats. Each pipeline can have at most one primary parser processor, which must be the first processor in the pipeline.

The XML parser is an exception: it operates on fields produced by a primary parser and you can add at most 5 instances to a single pipeline.

Conditional processing not supported

Parser processors (except Grok and XML) do not support conditional processing with the `when` parameter. This includes OCSF, CSV, JSON, KeyValue, VPC, Route53, RDS, WAF, Postgres, and Amazon CloudFront parsers. For more information, see the section called "Expression syntax for conditional processing".

OCSF processor

Parses and transforms log data according to Open Cybersecurity Schema Framework (OCSF) standards.

Configuration

Configure the OCSF processor with the following parameters:

```
processor:
  - ocsf:
      version: "1.5"
      mapping_version: 1.5.0
      schema:
          microsoft_office365_management_activity:
```

Parameters

`version` (required)

The OCSF schema version to use for transformation. Must be 1.5

`mapping_version` (required)

The OCSF mapping version for transformation. Must be 1.5.0.

`schema` (required)

Schema object specifying the data source type. The supported schemas depend on the pipeline source type - each source type has its own set of compatible OCSF schemas. You must use a schema that matches your pipeline's source type.

This table lists the supported schema combinations.

Pipeline source type	Supported Schemas	Version	Mapping Version
cloudwatch_logs	cloud_trail:	1.5	Not required
cloudwatch_logs	route53_resolver:	1.5	Not required
cloudwatch_logs	vpc_flow:	1.5	Not required
cloudwatch_logs	eks_audit:	1.5	Not required
cloudwatch_logs	aws_waf:	1.5	Not required
cloudwatch_logs	aws_nlb:	1.5	Not required
s3	Any OCSF schema	Any	Any
microsoft_office365	microsoft_office365:	1.5	1.5.0
microsoft_entraid	microsoft_entraid:	1.5	1.5.0
microsoft_windows_event	microsoft_windows_event:	1.5	1.5.0
paloaltonetworks_nextgenerationfirewall	paloaltonetworks_nextgenerationfirewall:	1.5	1.5.0
okta_auth0	okta_auth0:	1.5	1.5.0
okta_sso	okta_sso:	1.5	1.5.0
crowdstrike_falcon	crowdstrike_falcon:	1.5	1.5.0

Pipeline source type	Supported Schemas	Version	Mapping Version
github_auditlogs	github_auditlogs:	1.5	1.5.0
sentinelone_endpointsecurity	sentinelone_endpointsecurity:	1.5	1.5.0
servicenow_cmdb	servicenow_cmdb:	1.5	1.5.0
wiz_cnapp	wiz_cnapp:	1.5	1.5.0
zscaler_internetaccess	zscaler_internetaccess:	1.5	1.5.0

CSV processor

Parses CSV formatted data into structured fields.

Configuration

Configure the CSV processor with the following parameters:

```
processor:
  - csv:
      column_names: ["col1", "col2", "col3"]
      delimiter: ","
      quote_character: '"'
```

Parameters

`column_names` (optional)

Array of column names for parsed fields. Maximum 100 columns, each name up to 128 characters. If not provided, defaults to column_1, column_2, and so on.

`delimiter` (optional)

Character used to separate CSV fields. Must be a single character. Defaults to comma (,).

`quote_character` (optional)

Character used to quote CSV fields containing delimiters. Must be a single character. Defaults to double quote (").

To use the processor without specifying additional parameters, use the following command:

```
processor:
  - csv: {}
```

Grok processor

Parses unstructured data using Grok patterns. At most 1 Grok is supported per pipeline. For details on the Grok transformer in CloudWatch Logs see Processors that you can use in the *CloudWatch Logs User Guide*.

Configuration

Configure the Grok processor with the following parameters:

When the data source is a dictionary, you can use this configuration:

```
processor:
  - grok:
      match:
       source_key: ["%{WORD:level} %{GREEDYDATA:msg}"]
```

When the data source is CloudWatch Logs, you can use this configuration:

```
processor:
  - grok:
      match:
       source_key: ["%{WORD:level} %{GREEDYDATA:msg}"]
```

Parameters

`match` (required)

Field mapping with Grok patterns. Only one field mapping allowed.

`match.<field>` (required)

Array with single Grok pattern. Maximum 512 characters per pattern.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

> **Important**
>
> If the Grok processor is used as the parser (first processor) in a pipeline and its `when` condition evaluates to false, the entire pipeline does not execute for that log event. Parsers must run for downstream processors to receive structured data.

VPC processor

Parses VPC Flow Log data into structured fields.

Configuration

Configure the VPC processor with the following parameters:

```
processor:
  - parse_vpc: {}
```

JSON processor

Parses JSON data into structured fields.

Configuration

Configure the JSON processor with the following parameters:

```
processor:
  - parse_json:
      source: "message"
      destination: "parsed_json"
```

Parameters

`source` (optional)

The field containing the JSON data to parse. If omitted, the entire log message is processed

`destination` (optional)

The field where the parsed JSON will be stored. If omitted, parsed fields are added to the root level

Route 53 processor

Parses Route 53 resolver log data into structured fields.

Configuration

Configure the Route 53 processor with the following parameters:

```
processor:
  - parse_route53: {}
```

Amazon RDS processor

Parses Amazon RDS Aurora log data into structured fields. The `parse_rds` processor is supported only when the pipeline's `data_source_name` is `amazon_rds`. It applies the parsing logic that matches the pipeline's `data_source_type`.

Configuration

Configure the Amazon RDS processor with the following parameters:

```
processor:
  - parse_rds: {}
```

Key-value processor

Parses key-value pair formatted data into structured fields.

Configuration

Configure the key-value processor with the following parameters:

```
processor:
  - key_value:
      source: "message"
      destination: "parsed_kv"
      field_delimiter: "&"
      key_value_delimiter: "="
```

Parameters

`source` (optional)

Field containing key-value data. Maximum 128 characters.

`destination` (optional)

Target field for parsed key-value pairs. Maximum 128 characters.

`field_delimiter` (optional)

Pattern to split key-value pairs. Maximum 10 characters.

`key_value_delimiter` (optional)

Pattern to split keys from values. Maximum 10 characters.

`overwrite_if_destination_exists` (optional)

Whether to overwrite existing destination field.

`prefix` (optional)

Prefix to add to extracted keys. Maximum 128 characters.

non_match_value (optional)

Value for keys without matches. Maximum 128 characters.

To use the processor without specifying additional parameters, use the following command:

```
processor:
  - key_value: {}
```

XML parser

Use the XML parser to convert a specified field that contains an XML string to JSON format. Use the XML parser when your log events contain embedded XML fields that you want to query as

structured data. The XML parser operates on a named field that already contains an XML string. Place this parser after a primary parser in the pipeline. You can add at most 5 `parse_xml` parsers to a single pipeline.

Configuration

Configure the XML parser with the following parameters:

```
processor:
  - parse_json:
      source: "@message"
  - parse_xml:
      source: "body"
      destination: "parsed_xml"
```

Parameters

`source` (Required)

Specifies the field that contains the XML string to parse. Use dot notation to access nested fields. For example, `event.body`. Maximum 128 characters.

`destination` (Optional)

Specifies the field where the parsed XML structure is stored. If you omit this parameter, the parsed fields are added to the root level. Maximum 128 characters.

`when` (Optional)

A conditional expression that determines whether this parser runs. Maximum length is 256 characters. For more information, see the section called “Expression syntax for conditional processing”.

Example – XML parser output

Given the following JSON log event with an embedded XML field:

```
{
  "body": "<Person id=\"123\" active=\"true\"><name>John</name><age>30</age></Person>"
}
```

With the following configuration:

```
processor:
  - parse_json:
      source: "@message"
  - parse_xml:
      source: "body"
      destination: "parsed_xml"
```

The XML parser produces the following output:

```
{
  "body": "<Person id=\"123\" active=\"true\"><name>John</name><age>30</age></Person>",
  "parsed_xml": {
    "id": "123",
    "active": "true",
    "name": "John",
    "age": "30"
  }
}
```

Behavior notes

Nesting depth

The XML parser supports a maximum nesting depth of 25 levels. Elements nested beyond this limit produce an error.

Error handling

Malformed XML does not fail the pipeline. The parser preserves the original `@message` and sets `@pipeline.processing.status = "error"` on the event.

Transformation processors

Transformation processors modify the structure of log events by adding, copying, moving, or removing fields.

add_entries processor

Adds static key-value pairs to log events. At most 1 `add_entries` processor can be added to a pipeline.

Configuration

Configure the add_entries processor with the following parameters:

```
processor:
  - add_entries:
      entries:
        - key: "environment"
          value: "production"
          overwrite_if_key_exists: false
```

Parameters

`entries` (required)

Array of key-value pairs to add to each log event.

`entries[].key` (required)

The field name to add to the log event. Supports nested fields using dot notation.

`entries[].value` (required)

The static value to assign to the key.

`entries[].overwrite_if_key_exists` (optional)

Boolean flag that determines behavior when the key already exists. Defaults to false.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider.

Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

copy_values processor

Copies values from one field to another. At most 1 `copy_values` processor can be added to a pipeline.

Configuration

Configure the copy_values processor with the following parameters:

```
processor:
  - copy_values:
      entries:
        - from_key: "user_id"
          to_key: "backup_user"
          overwrite_if_to_key_exists: false
```

Parameters

`entries` (required)

Array of copy operations to perform on each log event.

`entries[].from_key` (required)

The field name to copy the value from. Uses dot notation for nested fields.

`entries[].to_key` (required)

The field name to copy the value to. Will create nested structures if using dot notation.

`entries[].overwrite_if_to_key_exists` (optional)

Boolean flag controlling behavior when target field already exists. Defaults to false.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

delete_entries processor

Removes specified fields from log events.

Configuration

Configure the delete_entries processor with the following parameters:

```
processor:
  - delete_entries:
      with_keys: ["temp_field", "debug_info"]
```

Parameters

`with_keys` (required)

Array of field names to remove from each log event. Supports nested field deletion using dot notation.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

move_keys processor

Moves fields from one location to another.

Configuration

Configure the move_keys processor with the following parameters:

```
processor:
  - move_keys:
      entries:
        - from_key: "old_field"
          to_key: "new_field"
          overwrite_if_to_key_exists: true
```

Parameters

`entries` (required)

Array of move operations. Maximum 5 entries.

`entries[].from_key` (required)

Source field name. Maximum 128 characters.

`entries[].to_key` (required)

Target field name. Maximum 128 characters.

`entries[].overwrite_if_to_key_exists` (optional)

Whether to overwrite existing target field.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

flatten processor

Flattens nested object structures.

Configuration

Configure the flatten processor with the following parameters:

```
processor:
  - flatten:
      source: "metadata"
      target: "flattened"
      remove_processed_fields: true
      exclude_keys: ["sensitive_data"]
```

Parameters

`source` (required)

Field containing nested object to flatten.

`target` (required)

Target field prefix for flattened keys.

`remove_processed_fields` (optional)

Whether to remove the original nested field after flattening.

`exclude_keys` (optional)

Array of keys to exclude from flattening. Maximum 20 keys, each up to 128 characters.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

lookup processor

Enriches log events with data from a CloudWatch Logs lookup table. The processor matches fields in your log events against fields in the lookup table and appends specified fields to your log events. Use this processor for data enrichment scenarios such as mapping user IDs to user details, product codes to product information, or error codes to error descriptions. At most 1 `lookup` processor can be added to a pipeline.

> **Note**
>
> If a lookup table is used in a pipeline, you must provide an execution role with `logs:GetLookupTable` permissions on the table. For more information, see the section called “CloudWatch pipelines IAM policies and permissions”.

Configuration

Configure the lookup processor with the following parameters:

```
processor:
  - lookup:
      lookup_table: "arn:aws:logs:us-east-1:123456789012:lookup-table:my_lookup_table"
      match_keys:
        - log_key: "src_ip"
          lookup_key: "ip_address"
      entries:
        - source: "hostname"
          target: "src_hostname"
          overwrite_if_exists: true
          default_value: "UNKNOWN"
```

Parameters

`lookup_table` (required)

The ARN of the CloudWatch Logs lookup table to use for enrichment. Maximum length is 2048 characters.

`match_keys` (required)

Array of key pairs that define how to match log event fields to lookup table fields. Minimum 1, maximum 5 match keys. When multiple match keys are specified, a lookup table row must match all keys to produce a result (AND logic).

`match_keys[].log_key` (required)

The field name in the log event to match against. Maximum 128 characters.

`match_keys[].lookup_key` (required)

The column name in the lookup table to match against. Maximum 128 characters.

`entries` (required)

Array of fields to add to the log event from the matching lookup table row. Minimum 1, maximum 10 entries.

`entries[].source` (required)

The column name in the lookup table to retrieve the value from. Maximum 128 characters.

`entries[].target` (optional)

The field name to add to the log event. If not specified, the `source` column name is used as the field name. Maximum 128 characters.

`entries[].overwrite_if_exists` (optional)

Boolean flag that determines behavior when the target field already exists in the log event. Defaults to false.

`entries[].default_value` (optional)

The value to use when the lookup table has no matching row. If not specified, no field is added to the log event on a miss. Minimum length is 1, maximum length is 512 characters.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

Example

Consider a lookup table named `network_assets` with the following rows:

ip_address	hostname	owner	location
10.0.1.12	web-server-01	team-alpha	us-east-1
10.0.2.45	db-server-03	team-beta	us-west-2
10.0.3.78	cache-node-07	team-alpha	eu-west-1

Given the following log event:

```
{
  "timestamp": "2026-05-04T12:00:00Z",
  "src_ip": "10.0.2.45",
  "action": "connection_opened",
  "bytes": 2048
}
```

And the following processor configuration:

```
processor:
  - lookup:
      lookup_table: "arn:aws:logs:us-east-1:123456789012:lookup-table:network_assets"
      match_keys:
        - log_key: "src_ip"
          lookup_key: "ip_address"
      entries:
        - source: "hostname"
          target: "src_hostname"
        - source: "owner"
          default_value: "unassigned"
        - source: "location"
          target: "src_region"
          overwrite_if_exists: false
```

The processor produces the following enriched log event:

```
{
  "timestamp": "2026-05-04T12:00:00Z",
  "src_ip": "10.0.2.45",
  "action": "connection_opened",
  "bytes": 2048,
  "src_hostname": "db-server-03",
  "owner": "team-beta",
  "src_region": "us-west-2"
}
```

IAM permissions

When a pipeline uses the lookup processor, the pipeline's execution role must include `logs:GetLookupTable` permission for the referenced table. The following example policy statement grants this permission:

```
{
  "Effect": "Allow",
  "Action": "logs:GetLookupTable",
  "Resource": "arn:aws:logs:<region>:<account-id>:lookup-table:<table-name>"
}
```

geoip processor

The geoip processor enriches log events with geographic location data based on IP addresses. The processor uses MaxMind databases to resolve IP addresses to geographic information such as city, country, continent, coordinates, and autonomous system number (ASN) details. Use this processor for network traffic analysis, user location enrichment, and security investigation scenarios.

Configuration

Configure the geoip processor with the following parameters:

```
processor:
  - geoip:
      entries:
        - source: "client_ip"
          target: "client_geo"
          include_fields:
            - "city_name"
            - "country_name"
            - "country_iso_code"
            - "continent_name"
            - "latitude"
            - "longitude"
          when: '.client_ip != "127.0.0.1"'
```

Parameters

`entries` (required)

Array of entry objects that define which IP fields to enrich with geographic data. Minimum 1, maximum 10 entries.

`entries[].source` (required)

The field name in the log event that contains the IP address to look up. Must reference a valid IPv4 or IPv6 address. Maximum 128 characters.

`entries[].target` (required)

The field name where the processor writes geographic enrichment data in the log event. Maximum 128 characters.

`entries[].include_fields` (required)

Array of geographic fields to include in the enrichment result. Minimum 1, maximum 12 fields. The following fields are available:

- `continent_code` – Two-letter continent code (for example, "NA").
- `continent_name` – Name of the continent (for example, "North America").
- `country_name` – Name of the country (for example, "United States").
- `country_iso_code` – ISO 3166-1 alpha-2 country code (for example, "US").
- `city_name` – Name of the city (for example, "Seattle").
- `postal_code` – Postal code associated with the IP address location.
- `time_zone` – IANA time zone name (for example, "America/Los_Angeles").
- `latitude` – Latitude coordinate of the IP address location.
- `longitude` – Longitude coordinate of the IP address location.
- `network` – CIDR notation of the network associated with the IP address.
- `asn` – Autonomous system number associated with the IP address.
- `asn_organization` – Organization name associated with the autonomous system number.

`entries[].when` (optional)

Conditional expression that determines whether this entry executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

`when` (optional)

Top-level conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

Example

The following example shows a sample log event with IP address fields:

```
{
  "timestamp": "2026-05-04T12:00:00Z",
```

```
  "src_ip": "203.0.113.50",
  "dst_ip": "198.51.100.25",
  "action": "ALLOW",
  "bytes": 4096
}
```

The following processor configuration maps both source and destination IP fields to geographic enrichment targets:

```
processor:
  - geoip:
      entries:
        - source: "src_ip"
          target: "src_geo"
          include_fields:
            - "city_name"
            - "country_name"
            - "country_iso_code"
            - "latitude"
            - "longitude"
            - "asn"
            - "asn_organization"
        - source: "dst_ip"
          target: "dst_geo"
          include_fields:
            - "country_name"
            - "country_iso_code"
```

The processor produces the following enriched log event:

```
{
  "timestamp": "2026-05-04T12:00:00Z",
  "src_ip": "203.0.113.50",
  "dst_ip": "198.51.100.25",
  "action": "ALLOW",
  "bytes": 4096,
  "src_geo": {
    "city_name": "Seattle",
    "country_name": "United States",
    "country_iso_code": "US",
    "latitude": 47.6062,
    "longitude": -122.3321,
    "asn": 16509,
```

```
    "asn_organization": "Amazon.com, Inc."
  },
  "dst_geo": {
    "country_name": "Germany",
    "country_iso_code": "DE"
  }
}
```

String manipulation processors

String processors modify text values within log events through operations like case conversion, trimming, and pattern matching.

lowercase_string processor

Converts specified fields to lowercase.

Configuration

Configure the lowercase_string processor with the following parameters:

```
processor:
  - lowercase_string:
      with_keys: ["status", "method"]
```

Parameters

`with_keys` (required)

Array of field names to convert to lowercase. Only processes string values.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

uppercase_string processor

Converts specified fields to uppercase.

Configuration

Configure the uppercase_string processor with the following parameters:

```
processor:
  - uppercase_string:
      with_keys: ["status_code", "method"]
```

Parameters

`with_keys` (required)

Array of field names to convert to uppercase. Only processes string values.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

trim_string processor

Removes leading and trailing whitespace from specified fields.

Configuration

Configure the trim_string processor with the following parameters:

```
processor:
  - trim_string:
      with_keys: ["message", "user_input"]
```

Parameters

`with_keys` (required)

Array of field names to trim whitespace from. Only processes string values.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

substitute_string processor

Performs string substitution using regular expressions.

Configuration

Configure the substitute_string processor with the following parameters:

```
processor:
  - substitute_string:
      entries:
        - source: "message"
          from: "ERROR"
          to: "WARN"
```

Parameters

`entries` (required)

Array of substitution operations to perform on each log event.

`entries[].source` (required)

The field to perform string substitution on.

`entries[].from` (required)

The regular expression pattern to match and replace.

`entries[].to` (required)

The replacement string for matched patterns.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

truncate processor

Truncates field values to specified length.

Configuration

Configure the truncate processor with the following parameters:

```
processor:
  - truncate:
      source_keys: ["message", "description"]
      length: 100
      start_at: 0
```

Parameters

`source_keys` (required)

Array of field names to truncate. Each field name maximum 128 characters.

`length` (optional)

Maximum length after truncation. Range: 1-8192.

`start_at` (optional)

Starting position for truncation. Range: 0-8192. Defaults to 0.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

extract_value processor

Extracts values using regular expressions.

Configuration

Configure the extract_value processor with the following parameters:

```
processor:
  - extract_value:
      entries:
```

```
        - source: "message"
          target: "extracted_data"
          from: "user=(?<user>\\w+)"
          to: "${user}"
          target_type: "string"
```

Parameters

`entries` (required)

Array of extraction operations. Maximum 20 entries.

`entries[].source` (required)

Field to extract from. Maximum 128 characters.

`entries[].target` (required)

Target field for extracted value. Maximum 128 characters.

`entries[].from` (required)

Regular expression pattern. Maximum 128 characters.

`entries[].to` (required)

Replacement pattern with capture groups. Maximum 128 characters.

`entries[].target_type` (optional)

Target data type ("integer", "double", "string", "boolean").

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider.

Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

convert_entry_type processor

Converts field values between different data types.

Configuration

Configure the convert_entry_type processor with the following parameters:

```
processor:
  - convert_entry_type:
      key: "count"
      type: "integer"
```

Parameters

`key` (required)

Single field name to convert.

`type` (required)

Target data type. Options: "integer", "double", "string", "boolean".

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

date processor

Parses and formats date/time fields.

Configuration

Configure the date processor with the following parameters:

```
processor:
  - date:
      match:
        - key: "timestamp"
```

```
          patterns: ["yyyy-MM-dd'T'HH:mm:ss.SSSSSS'Z'"]
      destination: "@timestamp"
      source_timezone: "UTC"
      destination_timezone: "America/New_York"
```

Parameters

`match` (required)

Array of date matching configurations. Maximum 10 entries.

`match[].key` (required)

Field containing the date string. Maximum 128 characters.

`match[].patterns` (required)

Array of date format patterns to try. Maximum 5 patterns, each up to 256 characters.

`destination` (optional)

Single target field for all parsed dates. Maximum 128 characters.

`source_timezone` (optional)

Source timezone for parsing.

`destination_timezone` (optional)

Target timezone for output.

`output_format` (optional)

Output date format. Maximum 64 characters.

`destination_type` (optional)

Output type - "timestampz", "long", or "string".

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

dissect processor

Extracts structured data using pattern matching.

Configuration

Configure the dissect processor with the following parameters:

```
processor:
  - dissect:
      map:
        message: "%{timestamp} %{level}"
```

Parameters

`map` (required)

Field mapping with dissect patterns.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

list_to_map processor

Converts array fields to map structures.

Configuration

Configure the list_to_map processor with the following parameters:

```
processor:
  - list_to_map:
      source: "tags"
      key: "name"
      value_key: "value"
      target: "tag_map"
```

Parameters

`source` (required)

Field containing array data. Maximum 128 characters.

`key` (required)

Field name to use as map key. Maximum 128 characters.

`value_key` (optional)

Field name to use as map value. Maximum 128 characters.

`target` (optional)

Target field for map structure. Maximum 128 characters.

`flatten` (optional)

Whether to flatten the resulting map.

`flattened_element` (optional)

Which element to use when flattening ("first" or "last").

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

rename_keys processor

Renames fields in log events.

Configuration

Configure the rename_keys processor with the following parameters:

```
processor:
  - rename_keys:
      entries:
        - from_key: "old_name"
          to_key: "new_name"
          overwrite_if_to_key_exists: true
```

Parameters

`entries` (required)

Array of rename operations. Maximum 5 entries.

`entries[].from_key` (required)

Current field name. Maximum 128 characters.

`entries[].to_key` (required)

New field name. Maximum 128 characters.

`entries[].overwrite_if_to_key_exists` (optional)

Whether to overwrite existing target field.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

select_entries processor

Selects only specified fields from events.

Configuration

Configure the select_entries processor with the following parameters:

```
processor:
  - select_entries:
      include_keys: ["timestamp", "level", "message"]
```

Parameters

`include_keys` (required)

Array of field names to keep. Maximum 50 keys, each up to 128 characters.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

translate processor

Translates field values using lookup tables.

Configuration

Configure the translate processor with the following parameters:

```
processor:
  - translate:
      mappings:
        - source: "status_code"
          targets:
            - target: "status_text"
              map:
                "200": "OK"
                "404": "Not Found"
```

Parameters

`mappings` (required)

Array of translation configurations. Maximum 10 mappings.

`mappings[].source` (required)

Field to translate. Maximum 128 characters.

`mappings[].targets` (required)

Array of target configurations. Maximum 10 targets.

`mappings[].targets[].target` (required)

Target field name. Maximum 128 characters.

`mappings[].targets[].map` (required)

Translation mapping. Maximum 100 entries, each value up to 512 characters.

when (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

Filter processors

Filter processors let you selectively remove log entries from the pipeline based on conditions you define.

drop_events processor

Filters out unwanted log entries based on conditional expressions. Use this processor to reduce noise from third-party pipeline connectors and lower storage costs by removing log events that match specified conditions.

Configuration

Configure the drop_events processor with the following parameters:

```
processor:
  - drop_events:
      when: "log.level == 'DEBUG' or log.level == 'TRACE'"
```

Parameters

when (required)

Conditional expression that determines which log entries to drop. Log entries matching this expression are removed from the pipeline. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing” for expression syntax.

handle_expression_failure (optional)

Behavior when the when expression evaluation fails. Allowed values: "skip" (default) keeps the event, or "apply" drops the event regardless of the failure.

Example Drop low-severity log entries

The following configuration drops all DEBUG and TRACE log entries, keeping only higher-severity events:

```
processor:
  - drop_events:
      when: "log.level in {'DEBUG', 'TRACE'}"
      handle_expression_failure: "skip"
```

Common processor use cases

Here are common scenarios and example configurations for combining processors.

Logs pipeline examples

Example Standardize log formats and add metadata

Parse JSON logs, standardize field names, and add environment information:

```
processor:
  - parse_json: {}
  - rename_keys:
      entries:
        - from_key: "timestamp"
          to_key: "@timestamp"
        - from_key: "log_level"
          to_key: "level"
  - add_entries:
      entries:
        - key: "environment"
          value: "production"
        - key: "application"
          value: "payment-service"
```

Example Clean and normalize field values

Standardize status codes and remove sensitive data:

```
processor:
  - uppercase_string:
      with_keys: ["status", "method"]
  - delete_entries:
      with_keys: ["credit_card", "password"]
  - substitute_string:
      entries:
        - source: "status"
```

```
          from: "SUCCESS"
          to: "OK"
```

Example Extract and transform specific fields

Extract user information and format for analysis:

```
processor:
  - extract_value:
      entries:
        - source: "user_agent"
          target: "browser"
          from: "(?<browser>Chrome|Firefox|Safari)"
          to: "${browser}"
  - lowercase_string:
      with_keys: ["browser"]
  - move_keys:
      entries:
        - from_key: "browser"
          to_key: "user_data.browser"
```

Example Conditional processing with entry-level conditions

Add different metadata based on log severity using entry-level when conditions:

```
processor:
  - add_entries:
      entries:
        - key: "alert_level"
          value: "critical"
          when: "log.level == 'ERROR'"
        - key: "alert_level"
          value: "info"
          when_else: "log.level == 'ERROR'"
```

Example Drop unwanted log entries

Filter out debug and trace log entries from a third-party source to reduce noise and storage costs:

```
processor:
  - drop_events:
      when: "log.level in {'DEBUG', 'TRACE'}"
```

```
      handle_expression_failure: "skip"
```

Example Processor-level conditional with delete_entries

Remove sensitive fields only when the environment is production:

```
processor:
  - delete_entries:
      with_keys: ["password", "api_key", "ssn"]
      when: "environment in {'prod', 'staging'}"
```

Metrics pipeline examples

The following examples show processor configurations for metrics pipelines. Metrics processors use OTTL path expressions to target attributes at different scopes.

Example Add business context to metrics

Add team ownership and environment tags to metric datapoints:

```
processor:
  - add_attributes:
      attributes:
        - key: resource.attributes["team"]
          value: "platform-engineering"
        - key: resource.attributes["cost_center"]
          value: "CC-1234"
```

Example Remove high-cardinality attributes

Strip attributes that drive up storage costs. Does not apply to cumulative metrics or vended metrics — if any metrics in the selection criteria have unsupported temporality, the pipeline emits an `UnsupportedTemporality` warning metric that you can monitor in the `AWS/Observability Admin` namespace:

```
processor:
  - delete_attributes:
      with_keys:
        - resource.attributes["host.id"]
        - datapoint.attributes["http.request.id"]
```

Example Standardize naming conventions

Rename metrics and attributes to align with OpenTelemetry semantic conventions. Does not apply to cumulative metrics or vended metrics:

```
processor:
  - rename_metrics:
      metrics:
        - from: "cpu_usage_percent"
          to: "system.cpu.utilization"
  - rename_attributes:
      attributes:
        - from_key: resource.attributes["hostname"]
          to_key: resource.attributes["host.name"]
```

Processor compatibility and restrictions

General processor rules

Maximum count

A pipeline can have at most 20 processors.

Parser placement

Parser processors (OCSF, CSV, Grok, and so on), if used, must be the first processor in a pipeline.

Unique processors

The following processors can appear only once per pipeline:

- `add_entries`
- `copy_values`

Processor Type	CloudWatch Logs Source	S3 Source	API-based Sources
OCSF	Must be first processor	Must be first processor	Must be first processor
parse_vpc	Must be first processor	Not applicable	Not applicable

Processor Type	CloudWatch Logs Source	S3 Source	API-based Sources
parse_route53	Must be first processor	Not applicable	Not applicable
parse_rds	Must be first processor	Not applicable	Not applicable
parse_json	Must be first processor	Must be first processor	Must be first processor
grok	Must be first processor	Must be first processor	Must be first processor
csv	Must be first processor	Not compatible	Not compatible
key_value	Must be first processor	Must be first processor	Must be first processor
add_entries	Must be first processor	Must be first processor	Must be first processor
copy_values	Must be first processor	Must be first processor	Must be first processor
String processors (lowercase, uppercase, trim)	Must be first processor	Must be first processor	Must be first processor
Field processors (move_keys, rename_keys)	Must be first processor	Must be first processor	Must be first processor
Data transformation (date, flatten)	Must be first processor	Must be first processor	Must be first processor

Compatibility definitions

Must be first processor

When used, must be the first processor in the pipeline configuration

Not compatible

Cannot be used with this source type

Not applicable

Processor is not relevant for this source type

Processor-specific restrictions

The following table describes processor restrictions by source type.

Processor	Source Type	Restrictions
OCSF	CloudWatch Logs with CloudTrail	• Only allowed when `data_source_name` is `aws_cloudtrail` • Must use CloudTrail-specific schema version • Cannot be combined with other processors
OCSF	API-based Sources	• Must use source-specific schema (for example, microsoft_office365_management_activity for Office 365) • Requires specific mapping version for each source type • Must be first processor in pipeline
parse_vpc	CloudWatch Logs	• Only valid for VPC Flow Logs • Must be first processor • Input must contain raw VPC Flow Log format
parse_route53	CloudWatch Logs	• Only valid for Route 53 Resolver Query Logs

Processor	Source Type	Restrictions
		• Must be first processor • Input must contain Route 53 Resolver query log format
parse_rds	CloudWatch Logs	• Only valid when `data_source_name` is `amazon_rds` • Must be first processor • Takes no parameters; the log type is inferred from the pipeline's `data_source_type`
add_entries	All Sources	• Maximum one instance per pipeline • Key names must be valid according to field naming rules
copy_values	All Sources	• Maximum one instance per pipeline • Source fields must exist in the event

Important

When using processors with restrictions:

- Always validate your pipeline configuration using the `ValidateTelemetryPipelineConfiguration` API before deployment
- Test the pipeline with sample data using the `TestTelemetryPipeline` API to make sure proper processing
- Monitor pipeline metrics after deployment to make sure events are being processed as expected

Metrics pipeline processors

Metrics pipeline processors transform OTel metric datapoints during ingestion. A metrics pipeline can have up to 20 processors, applied sequentially in the order they are defined.

Processors use OTTL path expressions to target attributes at different scopes:

Path	Scope	Example
`resource.attributes["key"]`	Resource-level	`resource.attributes["service.name"]`
`instrumentation_scope.attributes["key"]`	Scope attribute	`instrumentation_scope.attributes["library"]`
`datapoint.attributes["key"]`	Datapoint-level	`datapoint.attributes["status_code"]`
`attributes["key"]`	Short form for datapoint	`attributes["environment"]`

add_attributes processor

Adds or overwrites attributes on metric datapoints. Works with all temporality types.

OTTL equivalent: `set(attributes["key"], "value")`

Configuration

Configure the add_attributes processor with the following parameters:

```
processor:
  - add_attributes:
      attributes:
        - key: resource.attributes["team"]
          value: "payments"
        - key: attributes["environment"]
          value: "production"
        - key: instrumentation_scope.attributes["version"]
          value: "1.0"
          overwrite_if_key_exists: true
```

Parameters

`attributes` (required)

Array of attribute objects to add.

`attributes[].key` (required)

OTTL attribute path specifying where to add the attribute.

`attributes[].value` (required)

String value to assign.

`attributes[].overwrite_if_key_exists` (optional)

Boolean. When `true`, overwrites existing values. Defaults to `false`. When set to `true`, this operation is considered destructive and does not apply to cumulative metrics or vended metrics.

delete_attributes processor

Removes specific attributes from metric datapoints. **Does not apply to cumulative metrics or vended metrics.**

OTTL equivalent: `delete_key(attributes, "key")`

Configuration

Configure the delete_attributes processor with the following parameters:

```
processor:
  - delete_attributes:
      with_keys:
        - resource.attributes["obsolete"]
        - attributes["temp"]
        - datapoint.attributes["debug"]
```

Parameters

`with_keys` (required)

Array of OTTL attribute paths to remove.

rename_attributes processor

Renames attribute keys on metric datapoints. **Does not apply to cumulative metrics or vended metrics.**

OTTL equivalent: `set() + delete_key()`

Configuration

Configure the rename_attributes processor with the following parameters:

```
processor:
  - rename_attributes:
      attributes:
        - from_key: resource.attributes["old_key"]
          to_key: resource.attributes["new_key"]
          overwrite_if_to_key_exists: true
```

Parameters

`attributes` (required)

Array of rename operations.

`attributes[].from_key` (required)

Source OTTL attribute path.

`attributes[].to_key` (required)

Target OTTL attribute path.

`attributes[].overwrite_if_to_key_exists` (optional)

Boolean. When `true`, overwrites if target key exists. Defaults to `false`.

rename_metrics processor

Renames metric names. **Does not apply to cumulative metrics or vended metrics.**

OTTL equivalent: `set(name, "new.metric.name") where name == "old.metric.name"`

Configuration

Configure the rename_metrics processor with the following parameters:

```
processor:
  - rename_metrics:
      metrics:
        - from: "old.metric.name"
```

```
          to: "new.metric.name"
```

Parameters

`metrics` (required)

Array of rename operations.

`metrics[].from` (required)

Current metric name.

`metrics[].to` (required)

New metric name.

substitute_attribute_values processor

Maps attribute values by using a lookup table. **Does not apply to cumulative metrics or vended metrics.**

OTTL equivalent: `replace_match()`

Configuration

Configure the substitute_attribute_values processor with the following parameters:

```
processor:
  - substitute_attribute_values:
      attributes:
        - key: resource.attributes["region"]
          from: "us-east-1a"
          to: "us-east-1"
```

Parameters

`attributes` (required)

Array of substitution operations.

`attributes[].key` (required)

OTTL attribute path to match against.

`attributes[].from` (required)

Value to match.

`attributes[].to` (required)

Replacement value.

Full example

The following example uses all five processors in a single pipeline:

```
pipeline:
  source:
    cloudwatch_metrics:
      format: otlp
      selection_criteria:
        - match_all:
            - 'resource.attributes["service.name"] == "my-service"'
            - 'metric.name == "CPUUtilization"'
  processor:
    - add_attributes:
        attributes:
          - key: resource.attributes["env"]
            value: "prod"
            overwrite_if_key_exists: true
    - delete_attributes:
        with_keys:
          - resource.attributes["internal.trace"]
    - rename_attributes:
        attributes:
          - from_key: resource.attributes["old_key"]
            to_key: resource.attributes["new_key"]
    - rename_metrics:
        metrics:
          - from: "CPUUtilization"
            to: "system.cpu.utilization"
    - substitute_attribute_values:
        attributes:
          - key: resource.attributes["environment"]
            from: "dev"
            to: "development"
  sink:
```

```
    - cloudwatch_metrics: {}
```

Processor compatibility and restrictions

Maximum processors

A metrics pipeline can have at most 20 processors.

Destructive processors and temporality

Destructive processors (`delete_attributes`, `rename_attributes`, `rename_metrics`, `substitute_attribute_values`, and `add_attributes` with `overwrite_if_key_exists: true`) do not apply to cumulative metrics or vended metrics. These metrics are passed through unchanged.

Vended metrics protection

Destructive processors cannot modify metrics where `instrumentation_scope.name` starts with `cloudwatch.aws/`. These metrics are passed through unchanged.

Expression syntax for conditional processing

CloudWatch pipelines processors and CloudWatch Logs sink routes that support conditional processing accept a `when` parameter containing an expression. When the expression evaluates to true, the processor or entry executes, or the event is sent to that sink route. Expressions use dot notation (`.`) for nested field access. For example, `user.role` accesses the `role` field inside the `user` object. For details about conditional sink routes, see the section called "Route logs to multiple log groups". For details about processors that support conditional processing, see the section called "Processors". For processor configuration examples, see the section called "Common processor use cases".

> **Note**
>
> Conditional processing applies to log pipelines only. Metrics pipelines do not support the `when` parameter.

Processor-level and entry-level conditions

There are two levels at which you can apply a `when` condition, depending on the processor.

Processor-level `when` (outer level)

A `when` placed at the top level of the processor configuration. If the expression evaluates to false, the entire processor is skipped and no operations within it execute. All processors that support conditional processing support this level.

Example Processor-level condition — skip entire processor

The following `delete_entries` processor only runs when the environment is production or staging. If the condition is false, none of the keys are deleted.

```
processor:
  - delete_entries:
      with_keys: ["password", "api_key", "ssn"]
      when: "environment in {'prod', 'staging'}"
```

Entry-level `when` (within each entry)

A `when` placed inside an individual entry in the `entries` array. Each entry is evaluated independently — if the expression is false, only that specific entry is skipped while other entries in the same processor still execute. Only processors with an `entries` array support this level (such as `add_entries`, `copy_values`, `rename_keys`, `move_keys`, `extract_value`, and `substitute_string`).

Example Entry-level condition — skip individual entries

The following `add_entries` processor adds different keys depending on each entry's condition. The first entry only adds `severity` when the log level is ERROR. The second entry always adds `processed` because it has no condition.

```
processor:
  - add_entries:
      entries:
        - key: "severity"
          value: "high"
          when: "log.level == 'ERROR'"
        - key: "processed"
          value: "true"
```

Processors that support both levels can use them together. When both are specified, the processor-level condition is evaluated first. If it is false, the entire processor is skipped and no entry-level conditions are evaluated.

Example Both levels combined

The processor-level `when` ensures the entire processor only runs for production traffic. Within that, each entry has its own condition to control which key is added.

```
processor:
  - add_entries:
      when: "environment == 'prod'"
      entries:
        - key: "alert_level"
          value: "critical"
          when: "log.level == 'ERROR'"
        - key: "alert_level"
          value: "warning"
          when: "log.level == 'WARN'"
```

For a table showing which processors support which level, see the the section called “Conditional processing support” section below.

Fallback with `when_else`

Processors that support entry-level conditions also support `when_else`. An entry with `when_else` acts as a fallback — it executes only when none of the other `when` conditions in the same processor matched. The expression value provided to `when_else` identifies which set of `when` conditions to consider, but the entry itself runs based solely on whether those conditions all evaluated to false. There is no explicit negation check — the entry simply runs when no other `when` matched.

Example Fallback entry with when_else

The first entry runs when the log level is ERROR. The second entry uses `when_else` and runs only when the first entry's `when` condition did not match (that is, the log level is anything other than ERROR).

```
processor:
  - add_entries:
      entries:
        - key: "alert_level"
          value: "critical"
```

```
          when: "log.level == 'ERROR'"
        - key: "alert_level"
          value: "info"
          when_else: "log.level == 'ERROR'"
```

Conditional processing support

The following table shows which processors support conditional processing and at what level.

Processor	Conditional support	Level
add_entries	Yes	Processor and entry
copy_values	Yes	Processor and entry
delete_entries	Yes	Processor
move_keys	Yes	Processor and entry
flatten	Yes	Processor
lowercase_string	Yes	Processor
uppercase_string	Yes	Processor
trim_string	Yes	Processor
substitute_string	Yes	Processor and entry
truncate	Yes	Processor
extract_value	Yes	Processor and entry
convert_entry_type	Yes	Processor
date	Yes	Processor
dissect	Yes	Processor
list_to_map	Yes	Processor

Processor	Conditional support	Level
rename_keys	Yes	Processor and entry
select_entries	Yes	Processor
translate	Yes	Processor
grok	Yes	Processor
drop_events	Yes	Processor (required)
OCSF, CSV, JSON, KeyValue, WAF, Postgres, CloudFront, VPC, Route53	No	—

Operators

The following table lists the supported operators.

Category	Operators	Example
Relational	<, <=, >, >=	`status_code >= 200 and status_code < 300`
Equality	==, !=	`log.level == "ERROR"`
Conditional	and, or, not	`log.level == "ERROR" or log.level == "FATAL"`
Arithmetic	+, -, *, /	`response_time * 1000 > 5000`
Set membership	in, not in	`environment in {"prod", "staging", "preprod"}`
Regex matching	=~, !~	`message =~ "^ERROR.*timeout"`

Functions

`length(value)`

Returns the length of a string or array. Example: `length(message) > 100`

`contains(value, search)`

Checks whether a string contains a substring or an array contains an element. Example: `contains(message, "error")`

`startsWith(field, prefix)`

Checks whether a string starts with a specified prefix. Example: `startsWith(message, "ERROR")`

Expression examples

```
log.level == "ERROR"
status_code >= 200 and status_code < 300
environment in {"prod", "staging", "preprod"}
message =~ "^ERROR.*timeout"
user.role == "admin" and user.permissions.write == true
length(message) > 100 and contains(message, "error")
(log.level == "ERROR" or log.level == "FATAL") and environment == "prod"
```

Limitations

- Expression maximum length is 256 characters.
- Parser processors (except Grok) do not support conditional processing. This includes JSON, CSV, KeyValue, WAF, Postgres, CloudFront, VPC, Route53, and OCSF parsers.
- If the Grok processor is used as the parser (first processor) in a pipeline and its `when` condition evaluates to false, the entire pipeline does not execute for that log event.

Sinks

Sinks define the destination where processed data is sent. Logs pipelines use the `cloudwatch_logs` sink and can route events among multiple log groups. Metrics pipelines use exactly one `cloudwatch_metrics` sink.

CloudWatch Logs sink (`cloudwatch_logs`)

For logs pipelines, the `cloudwatch_logs` sink sends processed log events to a CloudWatch Logs log group.

Source Type	Log group configuration	Behavior
CloudWatch Logs	Use `@original` for a pipeline with one sink, or configure conditional sinks for routing	Events are returned to their original log group or routed to the selected destination log group
S3	Custom log group path	Events are sent to the specified log group
Third-party APIs	Custom log group path	Events are sent to the specified log group

Configuration

Configure the sink with the following parameters:

Example Non-CloudWatch Logs source configuration

```
sink:
  cloudwatch_logs:
    log_group: "/aws/my-application/logs"
```

Example CloudWatch Logs source configuration

```
sink:
  cloudwatch_logs:
    log_group: "@original"
```

Parameters

`log_group` (required)

The name of the CloudWatch Logs log group where processed events will be sent. For pipelines with non-`cloudwatch_logs` sources, this must be an existing log group name. For a pipeline

that has one `cloudwatch_logs` sink and uses a `cloudwatch_logs` source, the value must be `@original`. A pipeline that uses conditional routing can use `@original` or another destination log group in any route.

`when` (optional)

An expression that selects events for this route. Conditions are evaluated in sink order, and the first matching route is used. The expression can contain up to 4,096 characters. For syntax, see Expression syntax for conditional processing.

`is_default` (optional)

Set to `true` on exactly one sink when the pipeline has multiple sinks. This route receives events that don't match an earlier `when` expression. Place the default route last.

`include_original` (optional)

When present, stores a copy of each raw log event before any transformation takes place in the `@original_message` system field of the event. This preserves the original data for audit or compliance purposes. Specify as an empty object (`{}`). Available only for pipelines with `cloudwatch_logs` sources. At least one processor must be configured when this option is enabled.

Example CloudWatch Logs sink with original log preservation

```
sink:
  - cloudwatch_logs:
      log_group: "@original"
      include_original: {}
```

Route logs to multiple log groups

A logs pipeline can contain up to 10 `cloudwatch_logs` sinks, including the default route. Define a `when` expression on each conditional route and set `is_default: true` on exactly one fallback route. Each event is delivered to one destination only.

Example Route by log level and return unmatched events to the source log group

```
sink:
  - cloudwatch_logs:
      log_group: "/app/errors"
      when: 'level == "ERROR"'
```

```
- cloudwatch_logs:
    log_group: "/app/warnings"
    when: 'level == "WARN"'
- cloudwatch_logs:
    log_group: "@original"
    is_default: true
```

For an S3 source, a destination log group can contain one template variable. Use `{s3.path.N}` to select the Nth segment of the S3 object key, starting at 1, or use a field beneath `{@pipeline_metadata.source.s3}`, such as `{@pipeline_metadata.source.s3.bucket}`. For example, `/customers/{s3.path.1}` routes an object with the key `customer-a/audit.json` to `/customers/customer-a`.

A resolved template value must contain 1–64 letters, numbers, periods, underscores, or hyphens. Each template route can resolve to at most five distinct destination log groups for one input batch. Events that exceed this limit, or whose template can't be resolved, use the configured default route. Static routes don't count toward this template limit.

Requirements and limitations

Log group existence

If created using the AWS Management Console, CloudWatch will attempt to create the specified log group and appropriate resource policy if it does not exist when using a non-CloudWatch logs source. Otherwise, the specified log group must exist before creating the pipeline. For conditional routing, a physical default-route log group must exist before you create the pipeline. Conditional destination log groups are created when first used. The `@original` alias resolves to the source log group and is not created.

Event size

Each log event cannot exceed 256 KB in size after processing.

Log group retention

The pipeline uses the retention settings configured on the destination log group.

Log group resource policy

CloudWatch Logs resource policies are required for the direct destination of S3-based and third-party API pipelines. For a `cloudwatch_logs` source, the `@original` destination does not require a resource policy. Additional named conditional and templatized destinations

use the pipeline source role. When you use the AWS Management Console to configure the pipeline, CloudWatch will attempt to add the direct-destination resource policy if needed. If you create the pipeline using the AWS CLI or an API, you must create the policy manually. For more information, see Resource policies and Permissions for routed destinations.

Cross-Region support

The destination log group must be in the same Region as the pipeline.

Important

For pipelines using the `cloudwatch_logs` source type:

- A pipeline with one sink must use `@original` as the log group value. Conditional routing can use other destination log groups.
- Use `@original` in any route that should return matching events to their source log group.
- The original log group must exist throughout the pipeline's lifecycle.
- Pipelines with processors mutate the log events in the original CloudWatch log group they are intercepted from for logs from AWS services. To preserve the original data, enable `include_original` in the sink configuration. The original log copy is stored in the `@original_message` system field of the event.

Note

Log events are subject to CloudWatch Logs quotas and limitations.

CloudWatch Metrics sink (`cloudwatch_metrics`)

For metrics pipelines, the `cloudwatch_metrics` sink stores processed metrics in CloudWatch. Processed metrics are queryable through PromQL in Query Studio and fully compatible with CloudWatch Alarms, Anomaly Detection, and Dashboards.

Configuration

The `cloudwatch_metrics` sink has no parameters:

```
sink:
  - cloudwatch_metrics: {}
```

CloudWatch pipelines IAM policies and permissions

This section provides IAM requirements for CloudWatch pipelines. Permissions vary based on your data source and integration method.

The following table helps you identify which IAM sections apply to your use case.

Use case	Integration method	Source type in pipeline configuration	IAM sections you need
Third-party integrations (API Pull)	Pipeline pulls from vendor API using stored credentials	`microsoft_office365` , `okta_sso`, `palo_alto_ngfw` , and so on.	the section called “API caller permissions” + the section called “Third-party sources (API Pull)” + the section called “Resource policies”
Third-party integrations (S3 delivery)	Vendor delivers files to your S3 bucket	`s3`	the section called “API caller permissions” + the section called “Third-party sources (S3 delivery)” + the section called “Resource policies”
Custom data from S3	Your applications write to S3, pipeline reads from bucket	`s3`	the section called “API caller permissions” + the section called “Custom data from S3” + the section called “Resource policies”
Custom and Syslog data from CloudWatch Logs	Your applications or the CloudWatch Logs Syslog service deliver logs to a log group	`cloudwatch_logs`	the section called “API caller permissions” + the section called “Custom and Syslog data from CloudWatch Logs”

Use case	Integration method	Source type in pipeline configuration	IAM sections you need
Vended AWS service logs	AWS services deliver logs to CloudWatch Logs (VPC Flow Logs, Route 53)	`cloudwatch_logs`	the section called "API caller permissions" + the section called "Vended AWS service logs"
CloudWatch Metrics (OTel)	AWS services emit metrics through OTLP	`cloudwatch_metrics`	the section called "Pipeline rule permissions for CloudWatch Metrics sources"

> **Note**
>
> S3-based and third-party API sources require a resource policy for their direct CloudWatch Logs destination. For CloudWatch Logs sources, the `@original` destination does not require a resource policy. Named conditional and templatized destinations use the pipeline source role. For more information, see the section called "Permissions for routed destinations".

API caller permissions

The IAM principal that calls `CreateTelemetryPipeline` needs `iam:PassRole` permission for any roles referenced in the pipeline configuration.

Example PassRole policy template

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PassRoleForPipelineSource",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::111122223333:role/your-source-role",
```

```
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "service-principal"
                    ],
                    "iam:AssociatedResourceARN": [
                        "arn:aws:observabilityadmin:us-east-1:111122223333:telemetry-
pipeline/*"
                    ]
                }
            }
        }
    ]
}
```

Replace *service-principal* with the value from the following table based on your use case.

Use case	Service principal value
Third-party (API Pull)	telemetry-pipelines.observabilityadmin.amazonaws.com
Third-party (S3 delivery)	telemetry-pipelines.observabilityadmin.amazonaws.com
Custom data from S3	telemetry-pipelines.observabilityadmin.amazonaws.com
Custom data from CloudWatch Logs	logs.amazonaws.com
Vended AWS service logs	logs.amazonaws.com

Note

The Condition block is recommended but optional. Without it, the role can be passed to any service.
For third-party pipelines that use a lookup processor or conditional routing, also allow logs.amazonaws.com in iam:PassedToService.

Pipeline rule permissions (CloudWatch Logs sources only)

When using `cloudwatch_logs` as a source, the API caller also needs permissions for pipeline rule operations. The `logs:PutPipelineRule` permission is required for `CreateTelemetryPipeline` and `UpdateTelemetryPipeline` operations. The `logs:DeletePipelineRule` permission is required for `DeleteTelemetryPipeline` operations.

Example IAM policy for CloudWatch Logs pipeline rules

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PipelineRuleForCloudWatchLogs",
            "Effect": "Allow",
            "Action": [
                "logs:PutPipelineRule",
                "logs:DeletePipelineRule"
            ],
            "Resource": "*"
        }
    ]
}
```

Pipeline rule permissions for CloudWatch Metrics sources

When you use `cloudwatch_metrics` as a source, you need permissions for pipeline rule operations. To create or update a pipeline, grant the `cloudwatch:PutPipelineRule` permission. To delete a pipeline, grant the `cloudwatch:DeletePipelineRule` permission. Metrics pipelines do not require `iam:PassRole` or CloudWatch Logs resource policies. You can scope these actions down to the `dataset/default` resource.

Example IAM policy for CloudWatch metrics pipeline rules

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PipelineRuleForCloudWatchMetrics",
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutPipelineRule",
```

```
                "cloudwatch:DeletePipelineRule"
            ],
            "Resource": "arn:aws:cloudwatch:us-east-1:111122223333:dataset/default"
        }
    ]
}
```

Reducing scope with condition keys

Source role policies

Each pipeline requires a dedicated IAM role that the service assumes to read your data. The following subsections provide the complete policies (permission and trust) for each use case.

Third-party sources (API Pull)

This section applies to Microsoft Office 365, Microsoft Entra ID, Okta SSO, Palo Alto NGFW, and other vendor API integrations that store credentials in AWS Secrets Manager.

Permission policy

The following policy allows the role to retrieve your stored API credentials.

Example IAM policy for Secrets Manager sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "secretsmanageraccess",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws:secretsmanager:us-east-1:111122223333:secret:your-
secret-name*"
        },
        {
            "Sid": "kmsaccess",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/your-key-id"
        }
```

```
    ]
}
```

> **Note**
>
> The `kms:Decrypt` statement is only required if your secret in Secrets Manager is encrypted with a customer-managed KMS key.

Trust policy

Example Trust policy for API Pull sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Complete IAM setup for API Pull pipelines

The following example shows all the IAM policies needed to create a third-party API Pull pipeline end to end.

Caller identity policy — attach to the principal calling `CreateTelemetryPipeline`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateApiPullPipeline",
            "Effect": "Allow",
            "Action": "observabilityadmin:CreateTelemetryPipeline",
            "Resource": "*"
```

```
        },
        {
            "Sid": "PassRoleForApiPullPipeline",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::111122223333:role/your-source-role",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "telemetry-pipelines.observabilityadmin.amazonaws.com"
                    ],
                    "iam:AssociatedResourceARN": [
                        "arn:aws:observabilityadmin:us-east-1:111122223333:telemetry-
pipeline/*"
                    ]
                }
            }
        }
    ]
}
```

Source role permission policy — attach to the role the pipeline assumes:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SecretsManagerAccess",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws:secretsmanager:us-east-1:111122223333:secret:your-
secret-name*"
        }
    ]
}
```

Source role trust policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Note

After creating the pipeline, you must also create a resource policy within 5 minutes. See the section called “Resource policies”.

Note

For production use, scope down `iam:PassRole` by using the condition keys shown in the section called “API caller permissions”. If your secret uses a customer-managed KMS key, add `kms:Decrypt` to the source role permission policy.

Third-party sources (S3 delivery)

This section applies to any third-party vendor that delivers log files to your S3 bucket (for example, CrowdStrike Falcon, Wiz, or Cisco Umbrella).

Permission policy

The following policy allows the role to read objects from S3 and consume SQS notifications.

Example IAM policy for S3 sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "s3access",
            "Effect": "Allow",
            "Action": [
```

```
                "s3:GetObject"
            ],
            "Resource": "arn:aws:s3:::your-bucket-name/*"
        },
        {
            "Sid": "sqsaccess",
            "Effect": "Allow",
            "Action": [
                "sqs:ReceiveMessage",
                "sqs:DeleteMessage",
                "sqs:ChangeMessageVisibility"
            ],
            "Resource": "arn:aws:sqs:us-east-1:111122223333:your-queue-name"
        },
        {
            "Sid": "kmsaccess",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/your-key-id"
        }
    ]
}
```

> **Note**
>
> The `kms:Decrypt` statement is only required if your S3 bucket or SQS queue uses a customer-managed KMS key for encryption.

Trust policy

Example Trust policy for S3 delivery sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
```

```
        }
    ]
}
```

Complete IAM setup for S3 delivery pipelines

The following example shows all the IAM policies needed to create an S3 delivery pipeline end to end.

Caller identity policy — attach to the principal calling `CreateTelemetryPipeline`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateS3Pipeline",
            "Effect": "Allow",
            "Action": "observabilityadmin:CreateTelemetryPipeline",
            "Resource": "*"
        },
        {
            "Sid": "PassRoleForS3Pipeline",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::111122223333:role/your-source-role",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "telemetry-pipelines.observabilityadmin.amazonaws.com"
                    ],
                    "iam:AssociatedResourceARN": [
                        "arn:aws:observabilityadmin:us-east-1:111122223333:telemetry-
pipeline/*"
                    ]
                }
            }
        }
    ]
}
```

Source role permission policy — attach to the role the pipeline assumes:

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3Access",
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": "arn:aws:s3:::your-bucket-name/*"
        },
        {
            "Sid": "SqsAccess",
            "Effect": "Allow",
            "Action": [
                "sqs:ReceiveMessage",
                "sqs:DeleteMessage",
                "sqs:ChangeMessageVisibility"
            ],
            "Resource": "arn:aws:sqs:us-east-1:111122223333:your-queue-name"
        }
    ]
}
```

Source role trust policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

> **Note**
>
> After creating the pipeline, you must also create a resource policy within 5 minutes. See the section called “Resource policies”.

> **Note**
>
> For production use, scope down `iam:PassRole` by using the condition keys shown in the section called "API caller permissions". If your S3 bucket or SQS queue uses a customer-managed KMS key, add `kms:Decrypt` to the source role permission policy.

Custom data from S3

This section applies to your own applications or infrastructure writing log files to an S3 bucket.

The IAM setup is identical to the section called "Third-party sources (S3 delivery)". Use the same permission policy and trust policy. The pipeline reads from your bucket through SQS event notifications regardless of who wrote the data.

Custom and Syslog data from CloudWatch Logs

This section applies to your own applications logging to a CloudWatch Logs log group (for example, Lambda functions, ECS containers, or custom EC2 applications) and to messages delivered through the CloudWatch Logs Syslog service.

Permission policy

The following policy allows the role to process logs from your specified log groups.

Example IAM policy for CloudWatch Logs sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "logsprocessingaccess",
            "Effect": "Allow",
            "Action": [
                "logs:processWithPipeline"
            ],
            "Resource": [
                "arn:aws:logs:us-east-1:111122223333:log-group:your-log-group-01",
                "arn:aws:logs:us-east-1:111122223333:log-group:your-log-group-02"
            ]
        }
```

```
    ]
}
```

You can scope down this permission by using the `logs:data_source_name` and `logs:data_source_type` condition keys to restrict which pipeline sources can invoke transformations. The `logs:data_source_name` value corresponds to the `data_source_name` in your pipeline configuration, and `logs:data_source_type` corresponds to the `data_source_type` in your pipeline configuration.

Example Permission policy for CloudWatch Logs sources (scoped down with condition keys)

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowProcessWithPipelineScopedDown",
            "Effect": "Allow",
            "Action": "logs:ProcessWithPipeline",
            "Resource": "arn:aws:logs:us-east-1:111122223333:log-group:your-log-group-
name",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceAccount": "111122223333",
                    "logs:data_source_name": "your-source-name",
                    "logs:data_source_type": "your-source-type"
                }
            }
        }
    ]
}
```

> **Note**
>
> The IAM role for CloudWatch Logs sources requires both the trust policy (to allow `logs.amazonaws.com` to assume the role) and the permission policy (to grant `logs:ProcessWithPipeline`). Without both policies, CloudWatch pipelines cannot transform log events during ingestion.

Trust policy

Example Trust policy for CloudWatch Logs sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "logs.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

> **Note**
>
> No resource policy is needed for CloudWatch Logs source pipelines.

> **Note**
>
> CloudWatch Logs Syslog ingestion requires a separate resource policy to deliver messages to the source log group. For more information, see Setting up syslog ingestion.

Complete IAM setup for CloudWatch Logs pipelines

The following example shows all the IAM policies needed to create a CloudWatch Logs pipeline end to end.

Caller identity policy — attach to the principal calling `CreateTelemetryPipeline`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateLogsPipeline",
            "Effect": "Allow",
            "Action": [
```

```
                "observabilityadmin:CreateTelemetryPipeline",
                "logs:PutPipelineRule",
                "logs:DeletePipelineRule"
            ],
            "Resource": "*"
        },
        {
            "Sid": "PassRoleForLogsPipeline",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::111122223333:role/your-source-role",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "logs.amazonaws.com"
                    ],
                    "iam:AssociatedResourceARN": [
                        "arn:aws:observabilityadmin:us-east-1:111122223333:telemetry-
pipeline/*"
                    ]
                }
            }
        }
    ]
}
```

Source role permission policy — attach to the role the pipeline assumes:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "LogsProcessing",
            "Effect": "Allow",
            "Action": [
                "logs:processWithPipeline"
            ],
            "Resource": [
                "arn:aws:logs:us-east-1:111122223333:log-group:your-log-group"
            ]
        }
    ]
}
```

Source role trust policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "logs.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

> **Note**
>
> For production use, scope down `iam:PassRole` by using the condition keys shown in the section called "API caller permissions".

Vended AWS service logs

This section applies to AWS service logs delivered to CloudWatch Logs, such as VPC Flow Logs, Route 53 query logs, and other AWS vended log types.

The IAM setup is identical to the section called "Custom and Syslog data from CloudWatch Logs". Use the same permission policy (`logs:processWithPipeline` scoped to the log group) and the same trust policy (`logs.amazonaws.com`).

Because this uses the `cloudwatch_logs` source type, the caller also needs `logs:PutPipelineRule` and `logs:DeletePipelineRule` permissions. See the section called "Pipeline rule permissions (CloudWatch Logs sources only)".

Resource policies

CloudWatch Logs resource policies are required for the direct CloudWatch Logs destination of an S3-based or third-party API pipeline. The direct destination is the single sink, or the named default route when conditional routing is configured.

For a CloudWatch Logs source, the `@original` destination does not require a resource policy. Named conditional and templatized destinations use the pipeline source role instead of the CloudWatch pipelines service principal. For more information, see the section called “Permissions for routed destinations”.

After calling `CreateTelemetryPipeline`, you receive a pipeline ARN. You must then call `logs:PutResourcePolicy` to allow the CloudWatch pipelines service principal to write to the direct destination log group. The principal that creates the policy needs `logs:PutResourcePolicy`. To inspect or update an existing policy, the principal also needs `logs:DescribeResourcePolicies`.

Use a resource-scoped policy for the destination log group. Resource-scoped policies do not count toward the quota of 10 account-level resource policies per account per Region. The destination log group must exist before you create its resource-scoped policy.

> **Timing constraint**
>
> You have less than 5 minutes after receiving the pipeline ARN to create this resource policy. If the pipeline becomes active before the policy is in place, data will be dropped.

Example Resource policy for a direct destination

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": [
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": "arn:aws:logs:us-east-1:111122223333:log-group:your-log-group-name:*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": "arn:aws:observabilityadmin:us-east-1:111122223333:telemetry-pipeline/your-pipeline-id"
```

```
                }
            }
        }
    ]
}
```

Permissions for routed destinations

Additional conditional and templatized destinations are authorized by identity-based permissions on the IAM role in the pipeline source configuration, not by an additional CloudWatch Logs resource policy.

The pipeline source role must allow `logs:CreateLogGroup` for log groups that the pipeline creates automatically. It must also allow `logs:CreateLogStream` and `logs:PutLogEvents` for every named routed destination. A resource policy does not grant `logs:CreateLogGroup`.

Example Permission policy for routed destinations

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateRoutedLogGroups",
            "Effect": "Allow",
            "Action": "logs:CreateLogGroup",
            "Resource": "*"
        },
        {
            "Sid": "WriteRoutedLogEvents",
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": "arn:aws:logs:your-region:your-account-id:log-group:your-routed-log-group-prefix*:*"
        }
    ]
}
```

Scope the write statement to the exact destination log groups or the narrowest prefix that contains them. Include `logs:CreateLogGroup` only when the pipeline must create conditional or templatized destination log groups.

The role trust policy must allow each service that assumes the role:

- For S3 and third-party API sources, allow `telemetry-pipelines.observabilityadmin.amazonaws.com`. When the pipeline uses conditional routing, also allow `logs.amazonaws.com`.
- For CloudWatch Logs sources, use `logs.amazonaws.com`.

Managing resource policies

Use the AWS CLI to create or update CloudWatch Logs resource policies for CloudWatch pipelines.

To check for existing policies

```
aws logs describe-resource-policies \
    --policy-scope RESOURCE \
    --resource-arn arn:aws:logs:us-east-1:111122223333:log-group:your-log-group-name
```

To create a new policy

```
aws logs put-resource-policy \
    --region us-east-1 \
    --resource-arn arn:aws:logs:us-east-1:111122223333:log-group:your-log-group-name \
    --policy-document file://policy.json
```

To merge with an existing policy

Each log group can have one resource-scoped policy. If a policy already exists, add the new statement to the existing `Statement` array, then call `put-resource-policy` with the merged file and the current revision ID.

1. Retrieve the existing policy:

```
aws logs describe-resource-policies \
    --policy-scope RESOURCE \
    --resource-arn arn:aws:logs:us-east-1:111122223333:log-group:your-log-group-name
```

2. Add the new statement to the existing `Statement` array:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "existing-service.amazonaws.com"
            },
            "Action": [
                "logs:PutLogEvents"
            ],
            "Resource": "arn:aws:logs:us-east-1:111122223333:log-group:your-log-
group-name:*"
        },
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": [
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": "arn:aws:logs:us-east-1:111122223333:log-group:your-log-
group-name:*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": "arn:aws:observabilityadmin:us-
east-1:111122223333:telemetry-pipeline/your-pipeline-id"
                }
            }
        }
    ]
}
```

3. Update the policy:

```
aws logs put-resource-policy \
    --region us-east-1 \
    --resource-arn arn:aws:logs:us-east-1:111122223333:log-group:your-log-group-name
 \
```

```
    --expected-revision-id your-revision-id \
    --policy-document file://existing-policy.json
```

Confirm the policy was created or updated successfully:

```
aws logs describe-resource-policies \
    --policy-scope RESOURCE \
    --resource-arn arn:aws:logs:us-east-1:111122223333:log-group:your-log-group-name
```

Replace the following values in the policy:

- The AWS Region (shown as `us-east-1`) – Replace with your own Region
- The 12-digit AWS account ID (shown as 111122223333) – Replace with your own account ID
- *your-log-group-name* – Your CloudWatch Logs log group name
- *your-pipeline-id* – Your telemetry pipeline ID (returned by `CreateTelemetryPipeline`)
- *your-revision-id* – The revision ID returned by `describe-resource-policies` for an existing resource-scoped policy

Pipeline condition keys

CloudWatch pipelines supports IAM condition keys that let you restrict who can create pipelines based on the source name and type. Use these condition keys to enforce governance policies across your organization.

Available condition keys

`observabilityadmin:SourceName`

Restricts pipeline creation to specific source names. Applies to logs pipelines only.

`observabilityadmin:SourceType`

Restricts pipeline creation to specific source types.

Use these condition keys in identity policies to control which pipelines a principal can create.

`observabilityadmin:SourceType`

Restricts pipeline creation to specific source types. Supported values include `cloudwatch_logs`, `s3`, `microsoft_office365`, `okta_sso`, and `palo_alto_ngfw`.

Example Restrict pipeline creation by source type

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowPipelineCreationForSpecificSourceType",
            "Effect": "Allow",
            "Action": "observabilityadmin:CreateTelemetryPipeline",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "observabilityadmin:SourceType": "cloudwatch_logs"
                }
            }
        }
    ]
}
```

Source role trust policy conditions

Use these condition keys in the trust policy of your source role to restrict which account can assume the role. This prevents confused deputy attacks where the service might act on behalf of a different account.

`aws:SourceAccount`

Restricts role assumption to requests originating from a specific AWS account.

`aws:SourceArn`

Restricts role assumption to requests originating from a specific resource ARN (for example, a log group).

Example Trust policy with SourceAccount condition (CloudWatch Logs sources)

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "logs.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:logs:us-east-1:111122223333:log-group:*"
                }
            }
        }
    ]
}
```

AI-assisted processor configuration permissions

To use AI-assisted processor configuration in the CloudWatch pipelines console, the IAM principal must have the `logs:GeneratePipeline` permission. This permission authorizes the generation of processor configurations from natural language descriptions.

Example IAM policy for AI-assisted processor configuration

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowGeneratePipeline",
            "Effect": "Allow",
            "Action": "logs:GeneratePipeline",
            "Resource": "*"
        }
    ]
}
```

Configuring lookup processor permissions

If your pipeline configuration includes a Lookup processor, the source role needs to have the `logs:GetLookupTable` permission on the lookup table ARN. The role must also be assumable by `logs.amazonaws.com`.

Add the following statement to the source role's permissions policy, for all source types.

Example Permissions policy statement for lookup table access

```
{
    "Sid": "LookupTableAccess",
    "Effect": "Allow",
    "Action": "logs:GetLookupTable",
    "Resource": "arn:aws:logs:us-east-1:111122223333:lookup-table:your-lookup-table-
name"
}
```

Replace the following values in the policy:

- The AWS Region (shown as `us-east-1`) – Replace with your own Region
- The 12-digit AWS account ID (shown as 111122223333) – Replace with your own account ID
- *`your-lookup-table-name`* – The name of your lookup table

The source role trust policy requirement differs by source type.

Custom data from CloudWatch Logs and vended AWS service logs

For the section called "Custom and Syslog data from CloudWatch Logs" and the section called "Vended AWS service logs", the role already trusts `logs.amazonaws.com`, so no trust policy change is required. The following trust policy shows the existing configuration.

Example Trust policy for CloudWatch Logs sources (no change required)

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
```

```
            "Principal": {
                "Service": "logs.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Third-party sources

For the section called “Third-party sources (API Pull)” and the section called “Third-party sources (S3 delivery)”, add a second statement to the trust policy so that `logs.amazonaws.com` can assume the role in addition to the existing telemetry service principal. The following trust policy shows both statements.

Example Trust policy for third-party sources (add logs.amazonaws.com)

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        },
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "logs.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                }
            }
        }
    ]
}
```

Note

If your caller identity policy scopes `iam:PassRole` with the `iam:PassedToService` condition, list `logs.amazonaws.com` alongside `telemetry-pipelines.observabilityadmin.amazonaws.com`. An unconditioned `iam:PassRole` grant already covers both. For more information, see the section called “API caller permissions”.

CloudWatch pipelines extensions

CloudWatch pipelines extensions provide additional functionality to the pipeline. You can use the AWS Secrets Manager integration for credential management.

AWS Secrets Manager extension

Configures access to AWS Secrets Manager for retrieving credentials and sensitive configuration values. This extension is only supported for third-party sources that require authentication credentials.

Configuration

Configure the AWS Secrets Manager extension with the following parameters:

```
extension:
  aws:
    secrets:
      <secret-name>:
        secret_id: "<secret arn>"
        region: "<secret region>"
        sts_role_arn: "arn:aws:iam::123456789012:role/Example-Role"
        refresh_interval: PT1H
        disable_refresh: false
```

Parameters

`aws.secrets.<secret-name>.secret_id` (required)

The ARN of the AWS Secrets Manager secret containing the credentials.

`aws.secrets.<secret-name>.region` (required)

The AWS region where the secret is stored.

`aws.secrets.<secret-name>.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing the AWS Secrets Manager secret.

`aws.secrets.<secret-name>.refresh_interval` (optional)

How often to refresh the secret from AWS Secrets Manager. Uses ISO 8601 duration format. Defaults to PT1H (1 hour).

`aws.secrets.<secret-name>.disable_refresh` (optional)

Whether to disable automatic secret refresh. Defaults to false.

Secret reference syntax

Reference secrets in your pipeline configuration using the following syntax:

```
${{aws_secrets:<secret-name>:<key>}}
```

For example, to reference a client ID and secret:

```
source:
  microsoft_office365:
    authentication:
      oauth2:
        client_id: "${{aws_secrets:office365-creds:client_id}}"
        client_secret: "${{aws_secrets:office365-creds:client_secret}}"
```

Requirements and limitations

Secret format

Secrets must be stored as JSON key-value pairs in AWS Secrets Manager.

Cross-Region access

Secrets can be accessed from any Region where AWS Secrets Manager is available.

Refresh interval limits

Minimum refresh interval is 5 minutes (PT5M). Maximum is 24 hours (PT24H).

Maximum secrets

A pipeline can reference up to 10 different secrets.

Important

Consider the following when using secrets:

- Make sure the IAM role has appropriate permissions to access the secrets
- Monitor secret access using AWS CloudTrail
- Use separate secrets for different environments (development, production)

Monitoring pipelines

CloudWatch pipelines publishes metrics to Amazon CloudWatch in the `AWS/Observability Admin` namespace. You can use these metrics to monitor your pipelines' health, performance, and data flow.

Available metrics

The following tables list the available metrics for CloudWatch pipelines.

Note

Pipelines metrics are only emitted when the value is non-zero.

Pipeline health metrics

The following metrics are emitted for all pipeline types (logs and metrics):

Metric	Description	Dimension	Unit
`PipelineErrors`	Aggregate count of errors in pipeline	PipelineName	Count

Metric	Description	Dimension	Unit
PipelineErrorsByErrorType	Detailed error counts by type	PipelineName, ErrorType	Count
PipelineWarnings	Number of warnings encountered	PipelineName	Count
PipelineWarningsByWarningType	Detailed warnings by type	PipelineName, WarningType	Count

> **Note**
>
> For logs pipelines, PipelineErrorsByErrorType includes additional dimensions (ErrorSource, ErrorComponent) and PipelineWarningsByWarningType includes additional dimensions (WarningSource, WarningComponent).

Logs pipeline metrics

The following metrics are emitted for logs pipelines:

Metric	Description	Dimension	Unit
PipelineBytesIn	Volume of log records going into pipeline in uncompressed bytes	PipelineName	Bytes
PipelineBytesInByDataSource	Volume of incoming data with source/type breakdown	PipelineName, DataSource, DataType	Bytes

Metric	Description	Dimension	Unit
PipelineBytesOut	Volume of data routed to destination	PipelineName	Bytes
PipelineBytesOutByDataSource	Volume of outgoing data with source/type breakdown	PipelineName, DataSource, DataType	Bytes
PipelineRecordsIn	Number of records entering the pipeline	PipelineName	Count
PipelineRecordsInByDataSource	Number of incoming records with source/type breakdown	PipelineName, DataSource, DataType	Count
PipelineRecordsOut	Number of records exiting the pipeline	PipelineName	Count
PipelineRecordsOutByDataSource	Number of outgoing records with source/type breakdown	PipelineName, DataSource, DataType	Count
PipelineRecordsUnprocessed	Number of records that couldn't be processed	PipelineName	Count
PipelineRecordsUnprocessedByDataSource	Number of unprocessed records with source/type breakdown	PipelineName, DataSource, DataType	Count

Metrics pipeline metrics

The following metrics are emitted for metrics pipelines:

Metric	Description	Dimension	Unit
`PipelineDataPointsIn`	Number of metric datapoints entering the pipeline (matched selection criteria)	PipelineName, dataset	Count
`PipelineDataPointsOut`	Number of metric datapoints exiting the pipeline after processing	PipelineName, dataset	Count
`PipelineDataPointsUnprocessed`	Number of metric datapoints that matched selection criteria but passed through unchanged because all processors were skipped. For example, this occurs when `UnsupportedTemporality` or `DestructiveOnVended` restrictions apply. You can create an alarm on this metric to detect metrics in your selection criteria that cannot be processed.	PipelineName, dataset	Count

Dimensions

CloudWatch pipelines metrics use the following dimensions:

PipelineName

Name of the pipeline.

ErrorType

Type of error encountered.

WarningType

Type of warning encountered.

DataSource (logs pipelines)

Source of the data (AWS service name or third-party source).

DataType (logs pipelines)

Type of data being processed.

ErrorSource (logs pipelines)

Origin of the error (s3, aws.secrets, cloudwatch_logs).

ErrorComponent (logs pipelines)

Component where error occurred (source, sink, extension).

dataset (metrics pipelines)

The OTel metric dataset identifier. Currently always `default`.

Error types

The following error types are tracked in `PipelineErrorsByErrorType`:

`ALL`

The total count of all errors on the pipeline.

`PARSE_FAILURE`

Data parsing errors.

`PROCESSOR_ERRORS`

Processing operation failures.

`ACCESS_DENIED` (logs pipelines)

Permission-related failures.

`RESOURCE_NOT_FOUND` (logs pipelines)

Specified resource doesn't exist.

`SOURCE_READ_FAILURE` (logs pipelines)

Failures reading from source.

`PAYLOAD_SIZE_EXCEEDED` (logs pipelines)

Data size limit exceeded.

Warning types

The following warning types can occur on a pipeline:

`THROTTLED`

Indicates that the volume of data being sent has exceeded existing rate limits, causing some data points or events to be dropped or delayed to protect the system and make sure stability.

`DestructiveOnVended` (metrics pipelines)

A destructive processor attempted to modify a vended metric (`instrumentation_scope.name` starting with `cloudwatch.aws/`). The pipeline skipped the operation and counted the affected datapoints in `PipelineDataPointsUnprocessed`.

`UnsupportedTemporality` (metrics pipelines)

A destructive processor attempted to modify a metric with cumulative aggregation temporality. The pipeline skipped the operation and passed the metric through unchanged. Cumulative temporality means the metric reports values accumulated since a fixed start time (as defined by the OpenTelemetry metrics data model). The pipeline counts the affected datapoints in `PipelineDataPointsUnprocessed`. Monitor this warning to identify metrics in your selection criteria that cannot be processed by destructive operations.

`UnknownOttlPath` (metrics pipelines)

Processor configuration references an unrecognized OTTL path — attribute operation skipped.

Viewing metrics

You can view CloudWatch pipelines metrics using the following methods:

Using the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/
2. In the navigation pane, choose **Metrics**
3. Choose the **AWS/Observability Admin** namespace
4. Select the metric dimension to view

Using the AWS CLI

```
aws cloudwatch get-metric-statistics \
  --namespace "AWS/Observability Admin" \
  --metric-name "PipelineBytesIn" \
  --dimensions Name=PipelineName,Value=my-pipeline \
  --start-time "2025-10-29T00:00:00" \
  --end-time "2025-10-29T23:59:59" \
  --period 300 \
  --statistics Sum
```

Creating alarms

You can create CloudWatch alarms based on any of these metrics. Here's an example of creating an alarm for pipeline errors:

```
aws cloudwatch put-metric-alarm \
  --alarm-name "HighPipelineErrors" \
  --alarm-description "Alert on high error rate" \
  --metric-name "PipelineErrors" \
  --namespace "AWS/Observability Admin" \
  --dimensions Name=PipelineName,Value=my-pipeline \
  --period 300 \
  --evaluation-periods 2 \
  --threshold 10 \
  --comparison-operator GreaterThanThreshold \
  --statistic Sum \
  --alarm-actions arn:aws:sns:region:account-id:topic-name
```

Best practices for CloudWatch pipelines metrics

Monitor data flow

- Use `PipelineBytesIn` and `PipelineBytesOut` to track data volume
- Monitor `PipelineRecordsIn` and `PipelineRecordsOut` to track record counts
- Watch for unexpected changes in throughput patterns
- To monitor dropped records, compute `PipelineRecordsIn` - `PipelineRecordsOut` over a given period; a sustained positive difference indicates records that did not reach the destination.

Track errors and warnings

- Create alarms for `PipelineErrors` to detect issues quickly
- Use `PipelineErrorsByErrorType` to diagnose specific problems
- Monitor `PipelineWarnings` to identify potential issues early

Configure appropriate thresholds

- Base thresholds on your expected data patterns
- Account for normal variations in data volume
- Consider peak usage periods when setting alarm thresholds

Troubleshooting

This section covers common issues you might encounter when working with CloudWatch pipelines and their solutions.

Pipeline creation failures

- **Issue:** Pipeline creation fails with permission errors

  Solution: Verify that your IAM role has the required PassRole permissions for any roles specified in the pipeline configuration
- **Issue:** Configuration validation errors

  Solution: Use the ValidateTelemetryPipeline API to check your configuration syntax before creating the pipeline

- **Issue:** Log source not available to select

  Possible reason: There is already a log source with the same data source name and type. Duplicate combinations are greyed out since you can only create one of each.

Data processing issues

- **Issue:** No data flowing through pipeline

  Solution: Check that your data source is properly configured and generating data, and verify that CloudWatch Logs resource policies are correctly set
- **Issue:** Processor errors in pipeline

  Solution: Review processor configuration and make sure input data format matches processor expectations

Amazon CloudWatch managed Prometheus collectors

Amazon CloudWatch managed Prometheus collectors provides a fully managed, agentless scraper, or collector, that automatically discovers and pulls Prometheus-compatible metrics. With Amazon CloudWatch managed Prometheus collectors, you eliminate the operational overhead of running and scaling your own metric collection infrastructure. The collectors automatically discover targets in your VPC, scrape Prometheus-compatible metrics, and deliver them to CloudWatch. You don't have to manage, install, patch, or maintain agents, collectors or scrapers for Prometheus metrics. Managed collectors automatically scale to provide highly available, reliable metric collection for your AWS infrastructure.

A managed collector creates an Elastic Network Interface (ENI) for each subnet that you specify when you create the scraper. The collector scrapes metrics through these ENIs using OpenTelemetry Protocol (OTLP). It delivers the metrics to your CloudWatch dataset through a VPC endpoint. The scraped data never travels on the public internet. You can query metrics in CloudWatch with PromQL (Prometheus Query Language) for flexible and scalable analytics.

> **Note**
>
> Scraping metrics might incur VPC data transfer charges between the collector and your targets. To reduce this network transfer cost, configure your Prometheus `/metrics` endpoint to compress responses (for example, with gzip). Compression lowers the volume

of data that the collector transfers across the network. It does not change the number of metrics that CloudWatch ingests.

We charge for Prometheus collectors by the hour, and CloudWatch OpenTelemetry metric ingestion pricing applies. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

Topics

- Integrate Amazon MSK

- VPC-connected managed collector
- Scraper configuration
- Monitor collectors

Integrate Amazon MSK

With an Amazon CloudWatch managed Prometheus collector, you can automatically discover and collect Prometheus metrics from your Amazon MSK clusters. When you enable Open Monitoring on your Amazon MSK cluster, it exposes Prometheus metrics through the Java Management Extensions (JMX) Exporter and Node Exporter. The managed collector connects to your VPC and scrapes these metrics from all brokers using DNS-based service discovery and delivers these metrics directly to CloudWatch. With this integration, you can monitor host-level metrics, JVM-level metrics, and Kafka broker metrics in CloudWatch without deploying any agents.

Note

When a Amazon CloudWatch managed Prometheus collector delivers your Amazon MSK metrics to CloudWatch, it automatically enriches each metric with attributes that identify its origin. Every metric carries the collector's instrumentation scope, cloud attributes that record the AWS account and Region, and a unit that the collector infers from the metric name. You can filter and group on these attributes when you query your metrics with PromQL.

For instructions on collecting consumer-group lag, committed offsets, and membership, see Collect Amazon MSK consumer-group metrics in CloudWatch. That procedure uses a managed Kafka exporter and IAM authentication. The following procedure collects Open Monitoring metrics.

Prerequisites

This procedure assumes familiarity with Amazon MSK cluster administration and Amazon VPC networking concepts.

- Amazon MSK cluster in provisioned mode, with standard or express brokers. Managed collectors do not support Amazon MSK Serverless.
- Open Monitoring enabled on the cluster. For more information, see Open Monitoring with Prometheus in the *Amazon MSK Developer Guide*.
- At least two subnets in different Availability Zones
- Security group allowing the collector to reach broker ports 11001 and 11002

Step 1: Enable Open Monitoring

Enable Open Monitoring on your Amazon MSK cluster to expose Prometheus metrics. For instructions on enabling Open Monitoring, see Open Monitoring with Prometheus in the *Amazon MSK Developer Guide*.

```
aws kafka update-monitoring \
  --cluster-arn "arn:aws:kafka:us-west-2:123456789012:cluster/my-cluster/abc123-def456"
 \
  --current-version "K1A2B3C4D5" \
  --open-monitoring '{
    "Prometheus": {
      "JmxExporter": {"EnabledInBroker": true},
      "NodeExporter": {"EnabledInBroker": true}
    }
  }'
```

Note

The `--open-monitoring` parameter alone exposes the Prometheus endpoints on ports 11001 and 11002. Enhanced monitoring tiers such as `PER_TOPIC_PER_PARTITION` are

separate from Open Monitoring and can incur additional charges, so set them only if you need that level of Amazon MSK metrics.

Step 2: Get your cluster's DNS name

Amazon MSK provides a cluster-level DNS name that resolves to all broker IPs. Using this for service discovery makes your monitoring resilient to broker replacements and cluster scaling.

Get your cluster DNS name (remove the broker-specific prefix like `b-1.` or `b-2.`):

```
aws kafka get-bootstrap-brokers --cluster-arn "arn:aws:kafka:us-
west-2:123456789012:cluster/my-cluster/abc123-def456"
```

For example, if the bootstrap broker returns `b-1.my-cluster.abc123.c4.kafka.us-west-2.amazonaws.com`, use `my-cluster.abc123.c4.kafka.us-west-2.amazonaws.com` as your cluster DNS name.

Step 3: Configure scrape config

The following is an example scrape configuration for Amazon MSK. You reference this configuration when you create the scraper in the next step. For more information about configuration options, see Scraper configuration.

```
global:
  scrape_interval: 60s
  external_labels:
    cluster_name: my-msk-cluster

scrape_configs:
  - job_name: 'msk-jmx'
    dns_sd_configs:
      - names:
          - my-cluster.abc123.c4.kafka.us-west-2.amazonaws.com
        type: A
        port: 11001
    relabel_configs:
      - source_labels: [__meta_dns_name]
        target_label: broker_dns
      - source_labels: [__address__]
        target_label: instance
```

```
      - target_label: compute_platform
        replacement: 'msk'

  - job_name: 'msk-node'
    dns_sd_configs:
      - names:
          - my-cluster.abc123.c4.kafka.us-west-2.amazonaws.com
        type: A
        port: 11002
    relabel_configs:
      - source_labels: [__meta_dns_name]
        target_label: broker_dns
      - source_labels: [__address__]
        target_label: instance
      - target_label: compute_platform
        replacement: 'msk'
```

Step 4: Create the scraper

Create the scraper with a CloudWatch destination, using the scrape configuration for your Amazon MSK brokers from the previous step.

AWS API

Use the `CreateScraper` API operation to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
POST /scrapers HTTP/1.1

{
  "alias": "msk-metrics-scraper",
  "source": {
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  },
  "destination": {
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  },
  "scrapeConfiguration": {
```

```
    "configurationBlob": "base64-encoded-blob"
  }
}
```

AWS CLI

Use the `create-scraper` command to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
aws amp create-scraper \
  --alias "msk-metrics-scraper" \
  --source '{
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  }' \
  --scrape-configuration configurationBlob=$(cat msk-config.yaml | base64 -w 0) \
  --destination '{
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  }'
```

Available metrics

- **JMX Exporter (port 11001)** — Kafka broker internals including topic metrics, partition metrics, request rates, consumer lag, and under-replicated partitions.
- **Node Exporter (port 11002)** — Host-level metrics including CPU, memory, disk I/O, and network throughput.

For a complete list of available metrics, see MSK metrics collected by managed collectors in the *Amazon Managed Service for Prometheus User Guide*.

Validate metrics collection

To confirm that the collector is delivering both JMX and Node Exporter metrics, run the following queries in CloudWatch with Query Studio. If each query returns data points, the collector is scraping the corresponding exporter successfully.

The following query returns a broker-level Kafka metric from the JMX Exporter (port 11001). It reports the mean rate of broker topic activity, such as messages and bytes flowing through the brokers. Data points confirm that the collector is scraping Kafka broker metrics.

```
kafka_server_BrokerTopicMetrics_MeanRate
```

The following query returns host-level CPU utilization from the Node Exporter (port 11002). It subtracts the average idle CPU rate over a five-minute window from 100 to give the percentage of CPU that the brokers are using. Data points confirm that the collector is scraping host-level metrics.

```
100 - (avg by (instance) (rate(node_cpu_seconds_total{mode="idle"}[5m])) * 100)
```

View the automatic dashboard

After the collector begins delivering your Amazon MSK metrics to CloudWatch, the CloudWatch console provides an automatic dashboard named **MSK OTel**. To open it, see MSK OTel, or sign in to the AWS Management Console, open the CloudWatch console, choose **Dashboards** in the navigation pane, choose **Automatic dashboards**, and then choose **MSK OTel**. You can start monitoring your clusters without building any widgets or dashboards yourself.

If the automatic dashboard meets your needs, you can use it as is. To build a tailored monitoring experience, you can add any of its widgets to a custom dashboard. For more information about custom dashboards, see Using CloudWatch dashboards.

Cross-account observability

For cross-account Amazon MSK monitoring, we recommend using Amazon CloudWatch metric centralization. For more information, see CloudWatch metrics centralization.

For alternative cross-account scraper configurations using role chaining, see Cross-account Amazon MSK integration in the *Amazon Managed Service for Prometheus User Guide*.

Current limitations

- Managed collectors do not support Amazon MSK Serverless clusters.
- Managed collectors do not support public access combined with KRaft metadata mode.
- Each Amazon MSK cluster and CloudWatch dataset combination requires one collector.

Collect Amazon MSK consumer-group metrics in CloudWatch

With an Amazon CloudWatch managed Prometheus collector and a managed Kafka exporter, you can collect consumer-group metrics from your Amazon MSK Provisioned clusters, such as consumer lag, committed offsets, and the number of members in each consumer group. The collector runs the exporter for you and delivers the metrics directly to CloudWatch, so you do not deploy or operate an exporter yourself. The collector connects to your cluster with AWS Identity and Access Management (IAM) authentication, and you grant it access with an Amazon MSK cluster policy.

Consumer-group metrics do not require Open Monitoring. If you also collect JMX or Node Exporter metrics, keep the jobs from Integrate Amazon MSK.

Prerequisites

Before you create a scraper, make sure that you have the following:

- An active Amazon MSK Provisioned cluster with Standard brokers and Apache Kafka version 3.6.0 or later. The cluster must have IAM authentication turned on and be in the same account and AWS Region as the scraper.
- At least two subnets in different Availability Zones in the cluster's VPC, with DNS enabled.
- An inbound rule on the cluster's security group that allows TCP traffic on port 9098 from the security group that you provide for the scraper.
- Permission to create a scraper and to read and change the cluster policy (`kafka:GetClusterPolicy` and `kafka:PutClusterPolicy`).

For additional caller-permission and AWS CLI requirements, see Prerequisites in the Amazon Managed Service for Prometheus User Guide.

This exporter does not support Amazon MSK Serverless. Use the metrics that Amazon MSK sends to CloudWatch for Serverless.

Step 1: Create a scraper with a CloudWatch destination

Save the following YAML scrape configuration as `msk-consumer.yaml`. Replace the cluster ARN. For an existing scraper, add this job to its full configuration and keep any existing jobs. Then update the scraper as described in Update or remove the exporter.

```
global:
  scrape_interval: 30s
scrape_configs:
```

```
  - job_name: kafka-exporter
    relabel_configs:
      - target_label: clusterArn
        replacement: 'arn:aws:kafka:us-west-2:111122223333:cluster/my-cluster/cluster-
id'
    metric_relabel_configs:
      - source_labels: [__name__]
        regex: kafka_consumergroup_(current_offset|members|lag)
        action: keep
```

Keep the job name `kafka-exporter`. The collector configures its scrape target automatically. The `clusterArn` label keeps metrics from different clusters apart when you query them. Its value must match the cluster ARN in your request. The `metric_relabel_configs` rule keeps three consumer-group metrics: lag, committed offsets, and members. The exporter can send more metrics, and Amazon MSK already provides some of that information. For details, see Create a scrape configuration.

Run the following AWS CLI command to create the scraper. Replace the Region, account ID, cluster ARN, subnets, security group, and both filters. The example selects topics that start with `orders` and consumer groups that start with `payments`. To select all topics or all consumer groups, omit the filter. Consumer-group metrics can also include other topics that a selected consumer group consumes. To control which metrics reach CloudWatch, use `metric_relabel_configs` in your scrape configuration.

```
aws amp create-scraper \
  --region us-west-2 \
  --alias msk-consumer-metrics \
  --source '{"vpcConfiguration":{"subnetIds":["subnet-subnet-id-1","subnet-subnet-
id-2"],"securityGroupIds":["sg-security-group-id"]}}' \
  --exporters '[{"kafkaConfiguration":{"clusterArn":"arn:aws:kafka:us-
west-2:111122223333:cluster/my-cluster/cluster-id","topicFilter":"^orders.*
$","consumerGroupFilter":"^payments.*$"}}]' \
  --cli-binary-format base64 \
  --scrape-configuration "configurationBlob=$(base64 < msk-consumer.yaml | tr -d '\n')"
 \
  --destination '{"cloudWatchConfiguration":{"datasetArn":"arn:aws:cloudwatch:us-
west-2:111122223333:dataset/default"}}'
```

Record the scraper ID. Check its status with the `aws amp describe-scraper` AWS CLI command, and continue when `scraper.status.statusCode` is `ACTIVE`. The scraper collects no Kafka metrics until you grant it access to the cluster in the next step.

Step 2: Grant the scraper access to the cluster

Add an Amazon MSK cluster policy that allows the scraper's service-linked role to connect to the cluster and to describe its topics and consumer groups. After you add the policy, collection starts on its own, and the first metrics can take a few minutes to appear. You do not need to update the scraper.

Grant the scraper's service-linked role. Do not use an account root principal or a role ARN with a wildcard. Amazon MSK accepts a root principal, but it grants the scraper nothing, and it rejects a wildcard role ARN.

To add the cluster policy

1. Get the scraper's role ARN:

```
aws amp describe-scraper \
  --region us-west-2 \
  --scraper-id scraper-id \
  --query scraper.roleArn --output text
```

2. Save the following policy as `policy.json`. Replace the role ARN, Region, account ID, cluster name, and cluster ID.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": { "AWS": "scraper-role-arn" },
      "Action": "kafka-cluster:Connect",
      "Resource": "arn:aws:kafka:us-west-2:111122223333:cluster/my-cluster/cluster-
id"
    },
    {
      "Effect": "Allow",
      "Principal": { "AWS": "scraper-role-arn" },
      "Action": "kafka-cluster:DescribeTopic",
      "Resource": "arn:aws:kafka:us-west-2:111122223333:topic/my-cluster/cluster-
id/*"
    },
    {
      "Effect": "Allow",
```

```
      "Principal": { "AWS": "scraper-role-arn" },
      "Action": "kafka-cluster:DescribeGroup",
      "Resource": "arn:aws:kafka:us-west-2:111122223333:group/my-cluster/cluster-
id/*"
    }
  ]
}
```

3. Check whether the cluster already has a policy:

```
aws kafka get-cluster-policy \
  --region us-west-2 \
  --cluster-arn arn:aws:kafka:us-west-2:111122223333:cluster/my-cluster/cluster-id
```

   A `NotFoundException` error means that the cluster has no policy.

4. If the cluster has no policy, add yours:

```
aws kafka put-cluster-policy \
  --region us-west-2 \
  --cluster-arn arn:aws:kafka:us-west-2:111122223333:cluster/my-cluster/cluster-id
 \
  --policy file://policy.json
```

   If the cluster already has a policy, `put-cluster-policy` replaces it. The `Policy` value from `get-cluster-policy` is the existing policy as a JSON string. Add its statements to the `Statement` list in `policy.json`. Then run `put-cluster-policy` with `--current-version` and the `CurrentVersion` value from `get-cluster-policy`.

To grant every scraper in the account, to limit the topics and groups, or to see the full merge command, see Grant the scraper access to the cluster in the Amazon Managed Service for Prometheus User Guide.

Step 3: Validate metrics collection

To confirm that the collector is delivering consumer-group metrics, choose the scraper's Region and run each of the following queries separately in CloudWatch with Query Studio. Replace the cluster ARN.

```
kafka_consumergroup_members{"@instrumentation.cloudwatch.managed-collector.scraper-
type"="msk", clusterArn="arn:aws:kafka:us-west-2:111122223333:cluster/my-
cluster/cluster-id"}
```

```
kafka_consumergroup_current_offset{"@instrumentation.cloudwatch.managed-
collector.scraper-type"="msk", clusterArn="arn:aws:kafka:us-
west-2:111122223333:cluster/my-cluster/cluster-id"}
```

```
kafka_consumergroup_lag{"@instrumentation.cloudwatch.managed-collector.scraper-
type"="msk", clusterArn="arn:aws:kafka:us-west-2:111122223333:cluster/my-
cluster/cluster-id"}
```

A matching group must exist for its metrics to appear. The first metrics can take a few minutes to appear after you add the cluster policy.

If the scraper is `ACTIVE` but no `kafka_consumergroup_*` metrics appear under the service name `kafka-exporter`, check the cluster policy. Confirm that it grants the three actions to the scraper's current service-linked role ARN. If you re-created the scraper, its role ARN changed. If you use the account-wide policy, confirm that every statement keeps both `StringEquals` on `aws:PrincipalAccount` and `ArnLike` on `aws:PrincipalArn`. You do not need to update the scraper after you fix the policy.

For other checks, see Validate metrics collection. Those checks cover the cluster policy, caller permissions, IAM broker connectivity, collection filters, and metric labels. The up query on that page applies only to an Amazon Managed Service for Prometheus workspace destination. If the cluster policy is correct and metrics still do not appear on a cluster with many topics and consumer groups, try narrowing `topicFilter` and `consumerGroupFilter`.

For information about these metrics, including the `-1` value when a group has no committed offset for a topic and partition, see Consumer-group metrics.

Update or remove the exporter

Omitting `exporters` in an `update-scraper` request keeps the current exporter. An empty list removes it. Removing the cluster policy does not stop collection right away. First remove the exporter or delete the scraper, and confirm with `aws amp describe-scraper` that the scraper status is `ACTIVE` and the exporter is gone, or that the scraper no longer exists. Then remove the policy statements. For the commands, see Update or remove the exporter.

Integrate Amazon OpenSearch Service

With an Amazon CloudWatch managed Prometheus collector, you can automatically collect Prometheus-compatible metrics from your Amazon OpenSearch Service domains. The managed collector connects to your VPC, collects cluster, node, and index metrics from the domain, and delivers these metrics directly to CloudWatch. With this integration, you can monitor the health and performance of your domains in CloudWatch without deploying any agents or exporters.

> **Note**
>
> When a Amazon CloudWatch managed Prometheus collector delivers your Amazon OpenSearch Service metrics to CloudWatch, it automatically enriches each metric with attributes that identify its origin. Every metric carries the collector's instrumentation scope, cloud attributes that record the AWS account and Region, and a unit that the collector infers from the metric name. You can filter and group on these attributes when you query your metrics with PromQL.

Prerequisites

This procedure assumes that you are familiar with Amazon OpenSearch Service domain administration and Amazon VPC networking concepts.

- An Amazon OpenSearch Service domain with VPC access. Managed collectors support only domains that have VPC access. Domains with public access are not supported.
- At least two subnets in different Availability Zones
- Security group rules that allow the collector to reach your domain endpoint over HTTPS (port 443). Add an inbound rule to the domain's security group that allows HTTPS traffic from the security group that you provide for the collector.

Step 1: Configure scrape configuration

The following is an example scrape configuration for Amazon OpenSearch Service. The managed collector connects to the domain that you specify and collects its metrics automatically, so you do not specify scrape targets in the configuration. The configuration must include a `scrape_configs` section with a job whose `job_name` is exactly `opensearch-exporter`. You

reference this configuration when you create the scraper in the next step. For more information about configuration options, see Scraper configuration.

```
global:
  external_labels:
    domain_name: my-opensearch-domain

scrape_configs:
  - job_name: opensearch-exporter
    scrape_interval: 60s
```

Step 2: Create the scraper

Create the scraper with a CloudWatch destination. You specify the domain to collect from in the `exporters` field, and provide the networking (subnets and security group) in the `source` field.

AWS API

Use the `CreateScraper` API operation to create a scraper with a CloudWatch destination. Replace the subnet, security group, domain, and dataset information with your own values.

```
POST /scrapers HTTP/1.1

{
  "alias": "opensearch-metrics-scraper",
  "source": {
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  },
  "exporters": [
    {
      "openSearchConfiguration": {
        "domainArn": "arn:aws:es:us-west-2:123456789012:domain/my-opensearch-domain"
      }
    }
  ],
  "destination": {
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  },
```

```
  "scrapeConfiguration": {
    "configurationBlob": "base64-encoded-blob"
  }
}
```

AWS CLI

Use the `create-scraper` command to create a scraper with a CloudWatch destination. Replace the subnet, security group, domain, and dataset information with your own values.

```
aws amp create-scraper \
  --alias "opensearch-metrics-scraper" \
  --source '{
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  }' \
  --exporters '[
    {
      "openSearchConfiguration": {
        "domainArn": "arn:aws:es:us-west-2:123456789012:domain/my-opensearch-domain"
      }
    }
  ]' \
  --scrape-configuration configurationBlob=$(base64 -w 0 opensearch-config.yaml) \
  --destination '{
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  }'
```

Available metrics

- **Cluster metrics** — Cluster health and status, number of nodes and data nodes, active and relocating shards, and pending tasks.
- **Node metrics** — CPU usage, JVM heap usage and garbage collection, operating system memory, disk usage, and thread pool activity for each node.
- **Index metrics** — Indexing and search rates and latencies, document counts, merge and refresh activity, and cache usage.

For a complete list of available metrics, see Metrics collected from Amazon OpenSearch Service in the *Amazon Managed Service for Prometheus User Guide*.

Validate metrics collection

To confirm that the collector is delivering metrics from your domain, run the following query in CloudWatch with Query Studio. The query returns the cluster health status for your domain. If it returns data points, the collector is collecting metrics from your domain successfully.

```
opensearch_cluster_health_status
```

Cross-account observability

For cross-account Amazon OpenSearch Service monitoring, we recommend using Amazon CloudWatch metric centralization. For more information, see CloudWatch metrics centralization.

For more information about alternative cross-account scraper configurations using role chaining, see Integrate Amazon OpenSearch Service in the *Amazon Managed Service for Prometheus User Guide*.

Current limitations

- Managed collectors support only domains with VPC access.
- A scraper collects metrics from a single Amazon OpenSearch Service domain. To collect metrics from more than one domain, create a separate scraper for each domain.

Integrate Amazon EKS

An Amazon CloudWatch managed Prometheus collector scrapes metrics that are Prometheus-compatible. For more information about Prometheus-compatible metrics, see What are Prometheus-compatible metrics?. Amazon EKS clusters expose metrics for the API server. Amazon EKS clusters that are Kubernetes version 1.28 or above also expose metrics for the kube-scheduler and kube-controller-manager. For more information, see Fetch control plane raw metrics in Prometheus format in the *Amazon EKS User Guide*.

The *Amazon Managed Service for Prometheus User Guide* provides detailed setup instructions. For instructions on configuring Amazon EKS clusters, access entries, and ConfigMap setup, see Set up managed collectors for Amazon EKS.

Note

The collector enriches each Amazon EKS metric with attributes that identify its origin — the instrumentation scope, the AWS account and Region, an inferred unit, and the cluster name and cluster ARN. You can filter and group on these attributes when you query your metrics with PromQL.

Create a scraper with CloudWatch destination

You can use GetDefaultScraperConfiguration to retrieve a general-purpose scraper configuration, or provide your own.

AWS API

Use the `CreateScraper` API operation to create a scraper with a CloudWatch destination. Replace the AWS account, security group, subnet, Amazon EKS cluster, and dataset information with your own values.

```
POST /scrapers HTTP/1.1

{
  "alias": "eks-metrics-scraper",
  "source": {
    "eksConfiguration": {
      "clusterArn": "arn:aws:eks:us-west-2:123456789012:cluster/my-cluster",
      "securityGroupIds": ["sg-security-group-id"],
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"]
    }
  },
  "destination": {
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  },
  "scrapeConfiguration": {
    "configurationBlob": "base64-encoded-blob"
  }
}
```

AWS CLI

Use the `create-scraper` command to create a scraper with a CloudWatch destination. Replace the AWS account, security group, subnet, Amazon EKS cluster, and dataset information with your own values.

```
aws amp create-scraper \
  --alias "eks-metrics-scraper" \
  --source eksConfiguration="{clusterArn='arn:aws:eks:us-
west-2:123456789012:cluster/my-cluster', \
    securityGroupIds=['sg-security-group-id'], \
    subnetIds=['subnet-subnet-id-1','subnet-subnet-id-2']}" \
  --scrape-configuration configurationBlob=$(cat eks-config.yaml | base64 -w 0) \
  --destination cloudWatchConfiguration="{datasetArn='arn:aws:cloudwatch:us-
west-2:123456789012:dataset/default'}"
```

View the automatic dashboard

After the collector begins delivering your Amazon EKS metrics to CloudWatch, the CloudWatch console provides an automatic dashboard named **EKS OTel**. To open it, see EKS OTel, or sign in to the AWS Management Console, open the CloudWatch console, choose **Dashboards** in the navigation pane, choose **Automatic dashboards**, and then choose **EKS OTel**. You can start monitoring your clusters without building any widgets or dashboards yourself.

If the automatic dashboard meets your needs, you can use it as is. To build a tailored monitoring experience, you can add any of its widgets to a custom dashboard. For more information about custom dashboards, see Using CloudWatch dashboards.

Cross-account observability

For cross-account Amazon EKS monitoring, we recommend using Amazon CloudWatch metric centralization. For more information, see CloudWatch metrics centralization.

For alternative cross-account scraper configurations, see Cross-account scrapers in the *Amazon Managed Service for Prometheus User Guide*.

VPC-connected managed collector

The VPC-connected Amazon CloudWatch managed Prometheus collector scrapes Prometheus-compatible metrics from any resource reachable within your VPC — Amazon EC2 instances and

Amazon ECS tasks. You provide subnets and a security group; the collector creates elastic network interfaces (ENIs) and scrapes Prometheus `/metrics` endpoints according to your configuration.

For detailed, workload-specific walkthroughs, see the CloudWatch observability solutions for Prometheus metric collection: Amazon CloudWatch solution: Prometheus metric collection on Amazon Amazon EC2 and Amazon CloudWatch solution: Prometheus metric collection on Amazon ECS.

Prerequisites

This procedure assumes familiarity with Amazon VPC subnets, security groups, and Prometheus exporter endpoints.

- Amazon VPC with DNS enabled
- At least two subnets in different Availability Zones
- Security group allowing the collector to reach your target exporter ports
- Targets that expose a Prometheus-compatible `/metrics` endpoint

The collector delivers scraped metrics to CloudWatch over the AWS network, without traversing the public internet. The subnets and security groups that you specify provide connectivity to your scrape targets; they do not provide the CloudWatch delivery path. You do not need to configure internet access, a NAT gateway, or a CloudWatch interface VPC endpoint in your VPC for metric delivery.

Create a scraper

You can use GetDefaultScraperConfiguration to retrieve a general-purpose scraper configuration, or provide your own.

AWS API

Use the `CreateScraper` API operation to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
POST /scrapers HTTP/1.1

{
  "alias": "vpc-metrics-scraper",
  "source": {
```

```
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  },
  "destination": {
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  },
  "scrapeConfiguration": {
    "configurationBlob": "base64-encoded-blob"
  }
}
```

AWS CLI

Use the `create-scraper` command to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
aws amp create-scraper \
  --alias "vpc-metrics-scraper" \
  --source '{
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  }' \
  --scrape-configuration configurationBlob=$(cat scrape-config.yaml | base64 -w 0) \
  --destination '{
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  }'
```

Collecting metrics from Amazon EC2

To scrape metrics from Amazon EC2 instances running Prometheus exporters such as DCGM Exporter or Node Exporter, use `static_configs` with the instance private IP addresses:

```
global:
```

```
  scrape_interval: 60s

scrape_configs:
  - job_name: 'ec2-node-exporter'
    static_configs:
      - targets:
          - '10.0.1.10:9100'
          - '10.0.1.11:9100'
    relabel_configs:
      - source_labels: [__address__]
        target_label: instance
      - target_label: compute_platform
        replacement: 'ec2'

  - job_name: 'ec2-dcgm-exporter'
    static_configs:
      - targets:
          - '10.0.1.10:9400'
          - '10.0.1.11:9400'
    relabel_configs:
      - source_labels: [__address__]
        target_label: instance
      - target_label: compute_platform
        replacement: 'ec2'
```

Collecting metrics from Amazon ECS

For Amazon ECS tasks that you register with AWS Cloud Map, use DNS service discovery to automatically find and scrape your containers:

```
global:
  scrape_interval: 60s

scrape_configs:
  - job_name: 'ecs-services'
    dns_sd_configs:
      - names:
          - 'my-service.my-namespace.local'
        type: A
        port: 9090
    relabel_configs:
      - source_labels: [__meta_dns_name]
        target_label: service_name
```

```
      - source_labels: [__address__]
        target_label: instance
      - target_label: compute_platform
        replacement: 'ecs'
```

Cross-account observability

For cross-account VPC monitoring, we recommend using Amazon CloudWatch metric centralization. For more information, see CloudWatch metrics centralization.

For alternative cross-account scraper configurations, see Cross-account scrapers in the *Amazon Managed Service for Prometheus User Guide*.

Security best practices

- Specify private subnets without direct internet access for the collector ENIs.
- Restrict security group ingress to the scraper security group on specific exporter ports only.
- Enable TLS encryption in transit for all exporter endpoints where possible.

Scraper configuration

Amazon CloudWatch managed Prometheus collectors use a Prometheus-compatible YAML configuration to define how the collector scrapes metrics. You provide this configuration as a base64-encoded blob when creating or updating a scraper. The configuration uses standard Prometheus scrape configuration format, with some limitations specific to managed collectors.

You can use GetDefaultScraperConfiguration to retrieve a general-purpose scraper configuration, or provide your own.

Supported configuration sections

The following top-level sections of the Prometheus scrape configuration are supported:

- `global` — Global settings including `scrape_interval`, `scrape_timeout`, and `external_labels`.
- `scrape_configs` — A list of scrape jobs, each defining targets and how to scrape them.

Within each `scrape_configs` entry, the following fields are supported:

- `job_name` — A unique name for the scrape job.
- `metrics_path` — The HTTP path to scrape (defaults to `/metrics`).
- `scheme` — The protocol scheme (`http` or `https`).
- `scrape_interval` — Per-job override of the global scrape interval.
- `scrape_timeout` — Per-job override of the global scrape timeout.
- `static_configs` — Static list of targets.
- `dns_sd_configs` — DNS-based service discovery.
- `relabel_configs` — Relabeling rules applied before scraping.
- `metric_relabel_configs` — Relabeling rules applied after scraping.
- `tls_config` — TLS configuration for HTTPS targets.

Example configuration

The following example demonstrates a basic scrape configuration:

```
global:
  scrape_interval: 60s
  scrape_timeout: 10s
  external_labels:
    environment: production

scrape_configs:
  - job_name: 'my-service'
    metrics_path: /metrics
    scheme: http
    static_configs:
      - targets:
          - '10.0.1.10:9090'
          - '10.0.1.11:9090'
        labels:
          team: platform
    relabel_configs:
      - source_labels: [__address__]
        target_label: instance
    metric_relabel_configs:
      - source_labels: [__name__]
        regex: 'go_.*'
        action: drop
```

Limitations

- The minimum `scrape_interval` is 30 seconds.
- Managed collectors do not support file-based service discovery (`file_sd_configs`).
- Managed collectors do not support Consul, Eureka, or other external service discovery mechanisms.
- Remote write and remote read configurations do not apply, because the collector handles delivery to CloudWatch.
- The maximum configuration size is 256 KB.

Troubleshooting

If your scraper is not collecting metrics as expected, check the following:

- Verify that the security group attached to the scraper allows outbound traffic to your target ports.
- Confirm that your targets are reachable from the subnets that you specified in the scraper configuration.
- Check that DNS names used in `dns_sd_configs` resolve correctly within the VPC.
- Make sure your targets respond on the configured `metrics_path` with valid Prometheus exposition format.

For additional troubleshooting guidance, see Troubleshooting managed collectors in the *Amazon Managed Service for Prometheus User Guide*.

Monitor collectors

Amazon CloudWatch managed Prometheus collectors automatically vend logs to CloudWatch Logs so you can monitor scraper health, diagnose connectivity issues, and track scraping activity. These logs include information about target discovery, scrape successes and failures, and configuration errors. For more information about collector logging, see Logging for managed collectors in the *Amazon Managed Service for Prometheus User Guide*.

List scrapers

Use the following command to list all scrapers in your account and Region:

```
aws amp list-scrapers
```

To filter scrapers by alias:

```
aws amp list-scrapers --filters alias=my-scraper-alias
```

Describe a scraper

To view the details and current status of a specific scraper:

```
aws amp describe-scraper --scraper-id scraper-id
```

Delete a scraper

To delete a scraper that is no longer needed:

```
aws amp delete-scraper --scraper-id scraper-id
```

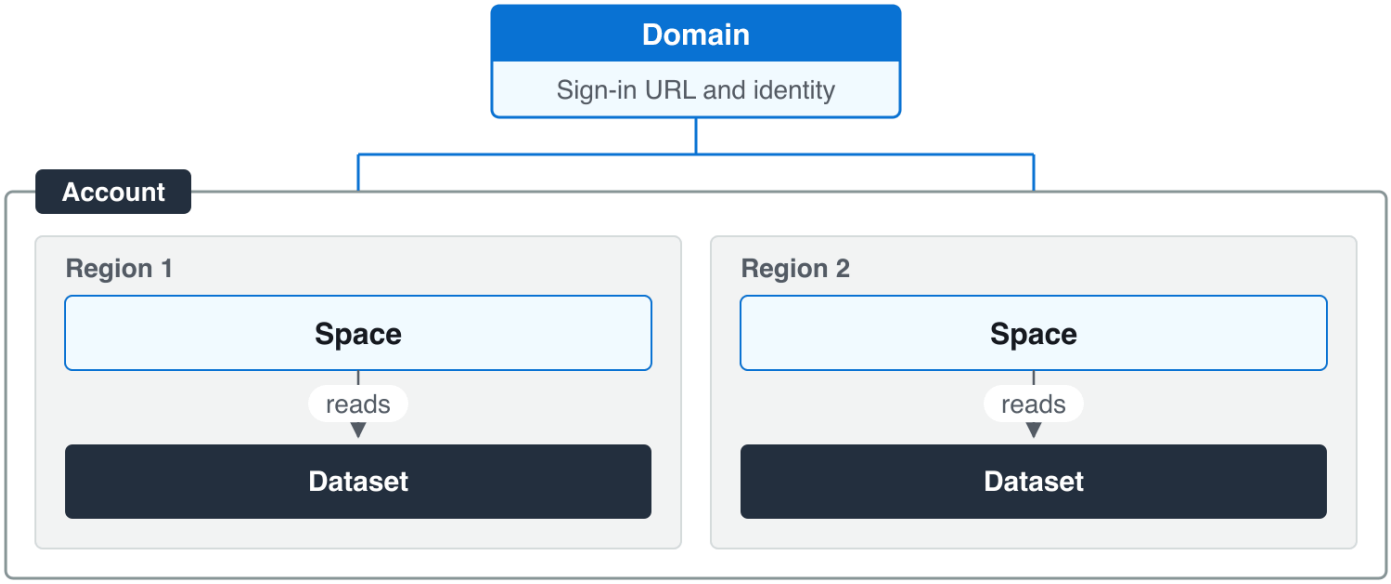
> **Note**
>
> Deleting a scraper removes the ENIs that the collector created in your VPC. Allow a few minutes for the deletion to complete and for CloudWatch to clean up all associated resources.

CloudWatch Omni

CloudWatch Omni is an AI-powered observability experience in Amazon CloudWatch for your applications and AI agents, either alone or together. You reach Omni through a dedicated URL for your organization and sign in with the identities you already manage; Omni is accessible outside the AWS Management Console.

Your applications and your agents, together. Omni is built on OpenTelemetry. Telemetry you already send to CloudWatch appears in Omni with nothing to reconfigure, and any other workload you instrument with OpenTelemetry sends its telemetry to an OpenTelemetry Protocol (OTLP) endpoint. Work in the Omni web UI, or in the IDE extension for VS Code, Kiro, and Cursor while you develop AI agents.

Answers before you build a query. Without manual configuration, Omni discovers your services and their dependencies from your telemetry and reports the RED metrics (the request rate, errors, and duration) of each one. Ask a question in plain language and Omni writes the query for you, in SQL or PromQL (Prometheus Query Language). The Omni agent is Omni's built-in AI assistant, and it answers those questions from your own telemetry. When an alert fires, you can start an investigation with the AWS DevOps Agent to find the root cause. Alerts reach your team in Slack, or any destination of your choice through Amazon Simple Notification Service (Amazon SNS).



Quality signals for agents, alongside the operational ones. Omni scores your agents' responses with evaluators — continuously in production, and on demand against a dataset. This catches failures that error rates do not show: an agent can return a well-formed response that is wrong. The scores appear alongside latency, errors, and token usage on the same trace. You can bring your own evaluators, including custom criteria scored by a judge model.

How CloudWatch Omni is organized

Three concepts determine where your telemetry lives and who can reach it.

- **Domain** — your organization's entry point. You choose a domain name during setup, and that name becomes your team's sign-in URL, in the format `https://<domain-name>.cloudwatch-omni.global.app.aws`. Record your domain name and its URL — the name is what identifies your domain when you sign in. Your identity provider connects at the domain, not per space. See the section called “Set up Omni”.

- **Space** — where you work. A space gives you access to telemetry from the account and Region in which the space is hosted, and controls who can see it. Because a space maps to one account and Region, that boundary is what separates spaces, rather than a filter applied when you query. You create a space inside your domain, and one domain can contain multiple spaces. To observe multiple accounts or Regions, see the section called "Set up Omni for your organization".
- **CloudWatch Dataset** — how Omni brings your telemetry together. A Dataset makes your logs, metrics, and traces queryable and correlated across signals in one place. You continue to manage ingestion and storage through existing CloudWatch endpoints and resources (for example, log groups). Enabling Omni creates one Dataset for your space.

What you can do in CloudWatch Omni

The following sections describe what you can do in CloudWatch Omni:

- Trace, evaluate, and debug AI agents. See the section called "Monitor AI agents".
- View your services, their dependencies, and their health, discovered automatically from your telemetry. See the section called "Monitor applications with the application map".
- Ask questions about your telemetry in plain language. See the section called "Ask the Omni agent".
- Query across logs, metrics, and traces. See the section called "Explore and query your telemetry".
- Build shared views of your systems. See the section called "Dashboards".

- Investigate with your team and keep a record of what you find. See the section called “Threads”.
- Receive a notification when a condition you define is met. See the section called “Alerts”.
- Investigate incidents to find the root cause. See the section called “Investigate with the AWS DevOps Agent”.
- Connect Omni to Slack. See the section called “Connect Slack”.
- Call Omni from code or a coding agent. See the section called “Use Omni skills”.

How Omni relates to CloudWatch

Omni is an interface and set of workflows built on Amazon CloudWatch. It is not a replacement, and enabling it does not change anything you already run.

- **Built on CloudWatch data.** Omni reads from the same CloudWatch data stores you use today. Your existing console pages, metrics, alarms, dashboards, Logs Insights queries, and APIs keep working unchanged.
- **No re-instrumentation.** Instrumentation you already run (the CloudWatch agent, OTLP pipelines, and AWS SDKs) keeps sending telemetry without changes, and that telemetry appears in Omni.
- **Centralization stays with CloudWatch.** Omni does not aggregate telemetry across accounts and Regions on its own. Telemetry you centralize with CloudWatch centralization rules appears in your space like any other telemetry. See the section called “Set up Omni for your organization”.

You continue to configure how telemetry is collected and stored (log groups, retention, and ingestion endpoints) in the CloudWatch console.

Get started

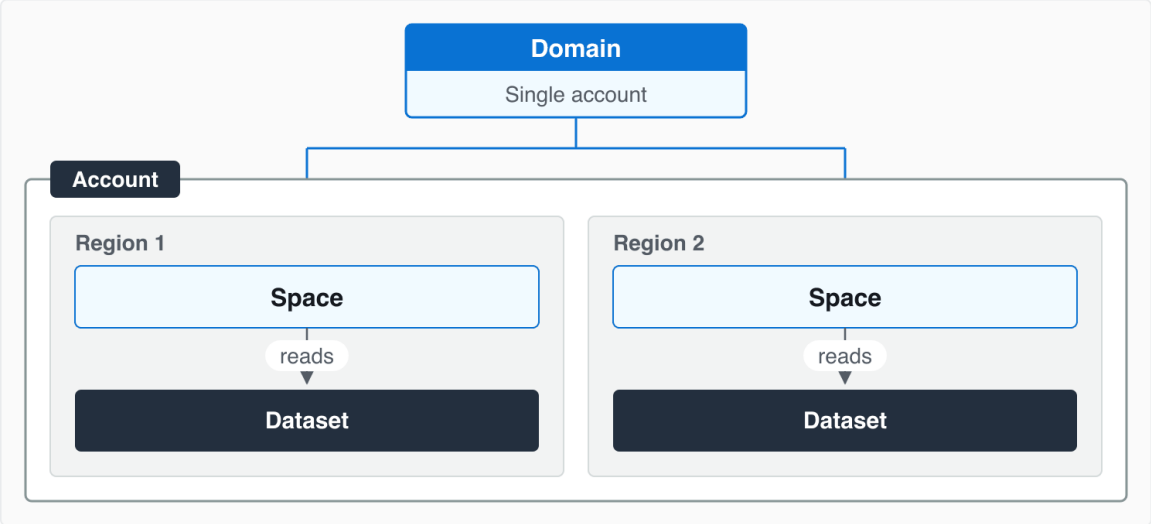
To try Omni before you set anything up, open the playground, a shared environment with sample data that requires no AWS account or setup. Choose **Explore the playground** on the Omni page in the CloudWatch console, or **Try playground** on the sign-in page.

To set up Omni, you need an AWS account and permission to enable Omni and create a domain and space in the CloudWatch console. For the full prerequisites, see the section called “Set up Omni for a single account”.

To set up Omni, complete the following steps:

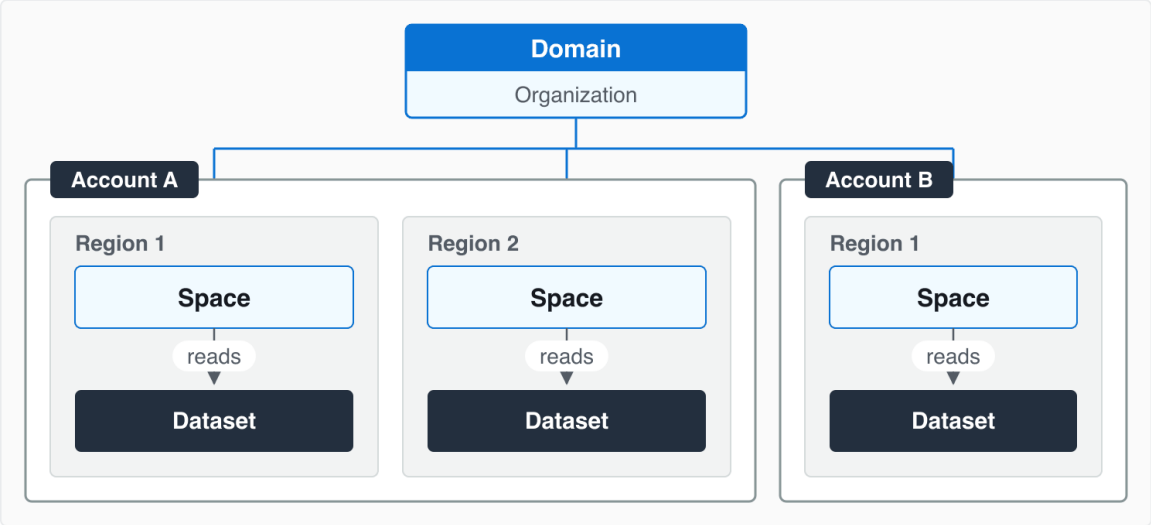
1. Set up your domain and space. See the section called “Set up Omni”.
2. Send telemetry from your applications or agents. See the section called “Send telemetry to CloudWatch Omni”.
3. Follow an end-to-end tutorial. See the section called “Tutorial: Fix a production quality regression” for an AI agent, or the section called “Tutorial: Monitor an application” for an application.

Set up Omni



Setting up CloudWatch Omni involves two steps: creating a **domain** (the identity and access boundary for your organization) and creating a **space** (where you work with your telemetry). Depending on your scenario, these steps might happen together in one session or separately across teams.

> **Note**
>
> Enabling Omni does not change or disable anything in CloudWatch. Your existing metrics, logs, alarms, dashboards, and Logs Insights queries keep working.



Choose your setup path

How you set up Omni depends on whether you work in a single AWS account or across an AWS Organization.

Account-level domain

Organization-level domain

One space per account and Region

Capability	Single account	Multiple accounts (AWS Organizations)
Single sign-in URL for your organization	Per account	Yes
Member accounts create spaces without additional domain setup	No — each account creates its own domain	Yes

Capability	Single account	Multiple accounts (AWS Organizations)
Centralized identity provider configuration (IAM Identity Center)	Yes — configured per domain	Yes — configured once for the organization
Multiple spaces across accounts share one domain	No	Yes
Accounts that can create this domain	Any individual AWS account	AWS Organizations management account

Choose **single account** setup if you operate in one AWS account. Choose **organization** setup if you use multiple AWS accounts and want a single entry point.

Single account

You create an Account domain and a space together in your AWS account.

For instructions, see the section called “Set up Omni for a single account”.

Multiple accounts (AWS Organizations)

An administrator creates the domain once from the management account. Any member account can then create its own space, which is automatically linked to the domain.

This path requires **trusted access** between AWS Organizations and CloudWatch, enabled for your organization.

For prerequisites and instructions, see the section called “Set up Omni for your organization”.

Your organization already has a domain

If an Organization domain already exists for your AWS Organization, you do not need to create a domain. Your account is already linked. Skip to space setup in the section called “Set up Omni for your organization”.

After setup

After you complete either setup path:

- Send telemetry from your applications or agents. See the section called “Send telemetry to CloudWatch Omni”.
- Add your team and choose what each person can do. See the section called “Control access to your space”.
- Bring telemetry from more than one account into your space. See the centralization section of the section called “Set up Omni for your organization”.

Set up Omni for a single account

Use this guide to set up CloudWatch Omni in a single AWS account. You create an Account domain and a space together in one console session. When you finish, you have a working Omni space ready to receive telemetry.

If your organization uses multiple AWS accounts, see the section called “Set up Omni for your organization” instead.

Prerequisites

- An AWS account with permission to access Amazon CloudWatch in the console.
- Permission to enable Omni and create a domain and space. Grant this to administrators only.
- Sign in to the AWS Region in which you want to enable Omni.
- If you plan to use IAM Identity Center for sign-in, its instance must be in the same AWS Region as your domain.

Choose your domain name

Your domain name becomes part of a URL your whole team uses, and it identifies your organization in Omni.

The name must meet these requirements:

- 3–63 characters using lowercase letters, numbers, and hyphens.
- Must start and end with a letter or number.
- Cannot contain consecutive hyphens.
- Certain names are reserved, including AWS service names, Region-like names, and names beginning with `aws-`, `amazon-`, `cloudwatch-`, or `omni-`.

- Must be unique across all CloudWatch domains.

After you create the domain, it is reachable at `https://<domain-name>.cloudwatch-omni.global.app.aws`.

Set up your domain and space

In the Account domain flow, domain creation and space creation happen together in one session.

1. Open the Omni setup page in the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/home#settings:/omni.
2. Choose **Get started**.
3. Select **Account domain**.
4. Enter your domain name.
5. Complete the permissions step. Omni creates the IAM roles it needs on your behalf.
6. When domain creation finishes, space setup continues automatically in the same flow.
7. Enter a space name and confirm the account and Region.
8. Complete the setup. Omni enables the capabilities described later on this page for your account and Region.

Connect your identity provider (optional)

You configure sign-in for your domain through AWS IAM Identity Center, so your team can use the identities you already manage, including an external provider such as Okta or Microsoft Entra ID connected to IAM Identity Center. You configure this at the domain, not per space.

> **Important**
>
> Your IAM Identity Center instance and your domain must be in the **same AWS Region**. If they are not, you cannot configure sign-in for the domain. Enable IAM Identity Center multi-Region replication to include the Region in which your Omni space is hosted.

If you do not connect an identity provider, your team can sign in to Omni using an IAM user or IAM role (for example, through a deep link from the CloudWatch console).

Capabilities enabled when you create a space

Setting up a space enables the following CloudWatch capabilities in your account and Region. You choose the optional capabilities during setup.

Capability	What it does	Learn more
CloudWatch Dataset integration	Enables forwarding of your logs and traces to the CloudWatch Dataset, which makes them queryable and correlated together in Omni. You do not manage a separate store or change how you manage existing CloudWatch resources such as log groups.	*CloudWatch Omni*
OTel metrics enrichment	Enriches AWS metrics with resource attributes in OpenTelemetry format and makes them queryable with PromQL.	CloudWatch OTel metrics enrichment
OTel span ingestion	Enables trace and span ingestion so Omni can receive and correlate distributed traces.	Enable CloudWatch transaction search

These capabilities apply to telemetry received after you complete space setup. Enabling OTel metrics enrichment and Transaction Search follows existing pricing for those capabilities. See Amazon CloudWatch pricing.

On the first enablement, Omni backfills your space with up to 7 days of existing CloudWatch logs and traces. Telemetry older than 7 days, and data encrypted with a customer managed AWS KMS key, are not included in the backfill.

IAM roles created during setup

Space setup creates the following IAM roles in your account. Omni uses these roles to read and correlate your telemetry. Setup adds a numeric suffix to each role name.

IAM role	Purpose
`CloudWatchOmniSpaceAccessRole`	Assumed by Omni to manage your space, query telemetry, and configure integrations.
`CloudWatchOmniDatasetIntegrationExecutionRole`	Assumed by CloudWatch to make your telemetry available in Omni through the Dataset.
`AgentCoreEvaluationRole`	Assumed by Amazon Bedrock AgentCore to run online AI agent evaluations on your telemetry. This role is optional: during setup you keep the default role, choose an existing role, or opt out. See the section called “Online evaluations”.

For the trust policies of these roles, see the section called “Cross-service confused deputy prevention”.

Configure encryption (optional)

By default, Omni manages the encryption of the data it stores for your space. To control encryption with your own key, configure a customer managed AWS KMS key on the space (when you create the space, or later by updating the space's encryption configuration).

The key must meet these requirements:

- A symmetric encryption key (`ENCRYPT_DECRYPT` key usage), and enabled.
- In the same AWS account and Region as the space.
- The identity attaching the key must have `kms:Decrypt` and `kms:GenerateDataKey` permission on it. Both are checked when you attach the key, so a key granting only one is rejected at attach time rather than failing later on reads or writes. The error names the missing permission.

Data Omni stores for your space, such as dashboards, is encrypted under the key.

The key's own key policy must also allow CloudWatch Omni to use the key. For the statements the service needs and a complete sample key policy, see the section called “Data encryption in CloudWatch Omni”.

Next steps

You now have a working Omni space.

- **Send telemetry** from your applications or agents. See the section called “Send telemetry to CloudWatch Omni”.
- **Add your team** and choose what each person can do. See the section called “Control access to your space”.

Set up Omni for your organization

Use this guide to set up CloudWatch Omni across an AWS Organization. An administrator creates an Organization domain once from the management account, and then any member account can create its own space, automatically linked to the domain.

This provides a single sign-in URL for your organization and centralized identity provider configuration, and removes the need for each account to configure its own domain.

If you operate in a single AWS account, see the section called “Set up Omni for a single account” instead.

> **Note**
>
> Enabling Omni does not change or disable anything in CloudWatch. Your existing metrics, logs, alarms, dashboards, and Logs Insights queries keep working.

Who does what

Organization domain setup involves two roles:

- **Organization administrator** — Creates the domain from the AWS Organizations management account. Chooses the domain name and configures the identity provider.

- **Account owner (member account)** — Creates a space in their own account and Region. The space is automatically linked to the Organization domain. Each member account does this independently.

Part 1: Create the domain (Organization administrator)

Prerequisites

- Access to the AWS Organizations **management account** with permission to enable Omni and create a domain.
- **Trusted access** between AWS Organizations and CloudWatch, enabled for your organization. Enabling trusted access requires the `organizations:EnableAWSServiceAccess` and `iam:CreateServiceLinkedRole` permissions. See Amazon CloudWatch and AWS Organizations.
- The AWS Region you want to work in.
- **Note:** If you plan to use IAM Identity Center, the Organization domain must be created in the same Region as the primary Region of IAM Identity Center. If your member accounts need to create spaces in other Regions, enable IAM Identity Center multi-Region replication to include your desired Regions.

Choose your domain name

Your domain name becomes part of a URL your whole team uses, and it identifies your organization in Omni.

The name must meet these requirements:

- 3–63 characters using lowercase letters, numbers, and hyphens.
- Must start and end with a letter or number.
- Cannot contain consecutive hyphens.
- Certain names are reserved, including AWS service names, Region-like names, and names beginning with `aws-`, `amazon-`, `cloudwatch-`, or `omni-`.
- Must be unique across all CloudWatch domains.

After you create the domain, it is reachable at `https://<domain-name>.cloudwatch-omni.global.app.aws`.

Create the domain

1. Sign in to the **AWS Organizations management account**.
2. Open the Omni setup page in the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/home#settings:/omni.
3. Choose **Get started**.
4. Select **Organization domain**.
5. Enter your domain name.
6. Complete the permissions step. Omni creates the IAM roles it needs on your behalf.
7. When domain creation finishes, record your **domain name** and **domain URL**.

Connect your identity provider

You configure sign-in for your domain through AWS IAM Identity Center, so your team uses the identities you already manage, including an external provider such as Okta or Microsoft Entra ID connected to IAM Identity Center. You configure this at the domain, not per space.

> **Important**
>
> Your IAM Identity Center instance and your domain must be in the **same AWS Region**. If they are not, you cannot configure sign-in for the domain. Enable IAM Identity Center multi-Region replication to include the Region in which your Omni space is hosted.

If you do not connect an identity provider, your team can sign in to Omni using an IAM user or IAM role (for example, through a deep link from the CloudWatch console).

Share the domain with your team

Domain setup is complete. Member accounts can now create their own spaces. Each space is automatically linked to this domain. Share the domain URL (`https://<domain-name>.cloudwatch-omni.global.app.aws`) with account owners who need to create spaces.

Part 2: Create a space in a member account

This section is for **account owners** in member accounts. You create a space in your account and Region; the space is automatically linked to the Organization domain.

Only **one space** can exist in a given account and Region combination.

Prerequisites

- An Organization domain must already exist for your AWS Organization. If it does not, ask your Organization administrator to create one (see Part 1).
- Permission to create a space. Grant this to administrators only.
- The AWS Region you want to work in. A space belongs to one Region, and your IAM Identity Center instance must be in that same Region. If your IAM Identity Center instance is in a different Region, enable IAM Identity Center multi-Region replication to include your desired space Region.

Create a space

1. Open the Omni setup page in the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/home#settings:/omni.
2. Choose **Create space**.
3. Enter a space name and confirm the account and Region.
4. Complete the setup. Omni enables the capabilities described in the following section for your account and Region.

Capabilities enabled when you create a space

Setting up a space turns on the following CloudWatch capabilities in your account and Region. These are telemetry features, not permissions. For the IAM roles that space setup creates, see the "IAM roles created during space setup" section of this page.

Capability	What it does	Learn more
CloudWatch Dataset integration	Enables forwarding of your logs and traces to the CloudWatch Dataset, which makes them queryable and correlated together in Omni. You do not manage a separate store or change	*CloudWatch Omni*

Capability	What it does	Learn more
	how you manage existing CloudWatch resources such as log groups.	
OTel metrics enrichment	Enriches AWS metrics with resource attributes in OpenTelemetry format and makes them queryable with PromQL.	CloudWatch OTel metrics enrichment
OTel span ingestion	Enables trace and span ingestion so Omni can receive and correlate distributed traces.	Enable CloudWatch transaction search

These capabilities apply to telemetry received after you complete space setup. Enabling these capabilities does not incur charges on its own. Costs begin when telemetry flows through them. See Amazon CloudWatch pricing.

On the first enablement, Omni backfills your space with up to 7 days of existing CloudWatch logs and traces. Telemetry older than 7 days, and data encrypted with a customer managed AWS KMS key, are not included in the backfill.

IAM roles created during space setup

Space setup creates the following IAM roles in your account. Omni uses these roles to read and correlate your telemetry:

- `CloudWatchOmniOperatorRole` — Omni assumes this role to manage your space, query telemetry, and configure integrations.
- `CloudWatchOmniDatasetIntegrationExecutionRole` — CloudWatch assumes this role to make your telemetry available in Omni through the Dataset.
- `AgentCoreEvaluationRole` — Amazon Bedrock AgentCore assumes this role to run online AI agent evaluations on your telemetry. This role is optional: during setup you keep the default role, choose an existing role, or opt out. See the section called “Online evaluations”.

Centralize telemetry across accounts and Regions

If your workloads span several AWS accounts, you can aggregate telemetry from those accounts into the account and Region that hosts your space. After centralization, you can monitor and investigate your telemetry across all of the source accounts and Regions from the same space.

You aggregate telemetry by creating CloudWatch centralization rules. A centralization rule specifies the **source accounts** and **source Regions** to collect from, and the **destination account** and Region to replicate into. Set the destination to the account and Region that hosts your space. Centralization rules require AWS Organizations and must be created from the management account or by a delegated administrator.

You can create centralization rules before or after you create the space. Centralized telemetry is available in the space after both the space and the rule are active.

For setup instructions, see Cross-account cross-Region log centralization and Cross-account cross-Region metrics centralization.

What centralization adds to your space

- **Logs and metrics from all source accounts and Regions in one place** — Analyze and act on telemetry across all your accounts and Regions from the centralized account. See the section called “Explore and query your telemetry” and the section called “Alerts”.
- **Application map spans accounts** — The application map includes services discovered from all source accounts (when Context Graph is enabled as part of your centralization rules), so you see cross-account dependencies. See the section called “Monitor applications with the application map”.

What to know

- **Centralization does not backfill** — Only telemetry generated after the centralization rule is active is replicated to the destination.
- **Cross-space queries are not supported** — Each space sees the telemetry centralized into its own account and Region. If you need to query across accounts, centralize their telemetry into one account rather than creating separate spaces.
- **Trace centralization requires Transaction Search enablement for each source account** — To centralize traces, enable Transaction Search in all your source accounts. Trace centralization then happens automatically when logs centralization is enabled.

- **Costs** — Centralization replicates telemetry into the destination account. Standard CloudWatch pricing applies to the replicated data. See Amazon CloudWatch pricing.

Configure encryption (optional)

By default, Omni manages the encryption of the data it stores for your space. To control encryption with your own key, configure a customer managed AWS KMS key on the space (when you create the space, or later by updating the space's encryption configuration).

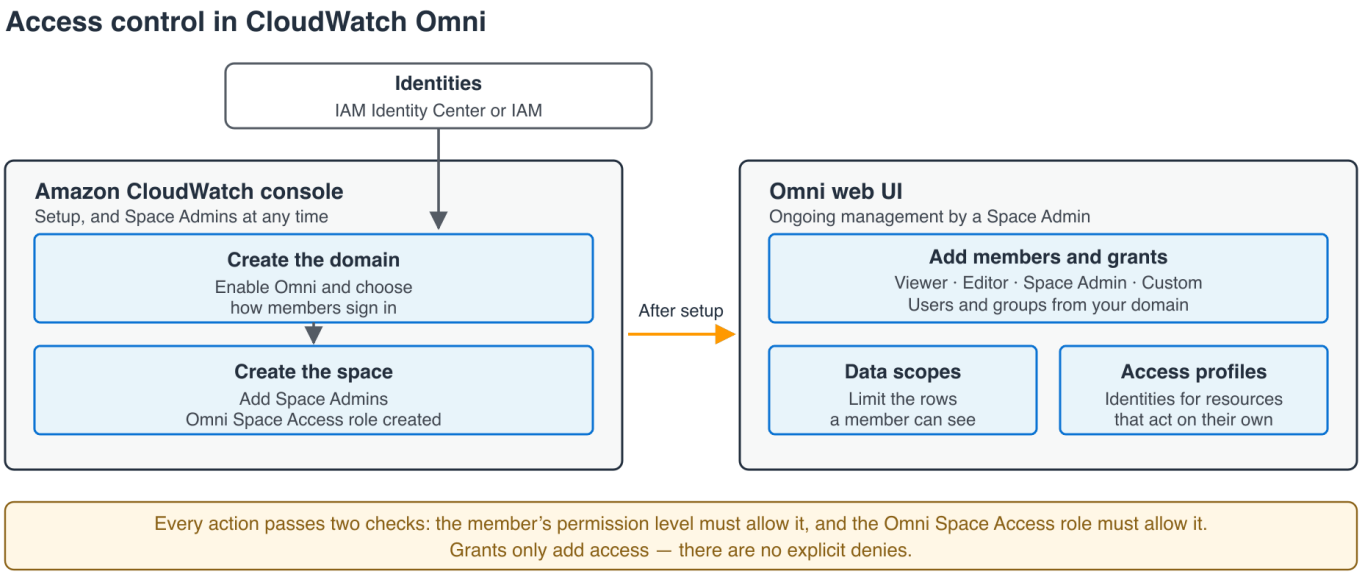
The key must meet these requirements:

- A symmetric encryption key (`ENCRYPT_DECRYPT` key usage), and enabled.
- In the same AWS account and Region as the space.
- The identity attaching the key must have `kms:Decrypt` and `kms:GenerateDataKey` permission on it. Both are checked when you attach the key, so a key granting only one is rejected at attach time rather than failing later on reads or writes. The error names the missing permission.

Data Omni stores for your space, such as dashboards, is encrypted under the key.

The key's own key policy must also allow CloudWatch Omni to use the key. For the statements the service needs and a complete sample key policy, see the section called “Data encryption in CloudWatch Omni”.

Next steps



- **Send telemetry** from your applications or agents. See the section called “Send telemetry to CloudWatch Omni”.
- **Add your team** and choose what each person can do. See the section called “Control access to your space”.

Control access to your space

Omni separates setting up access from managing it. You enable Omni, create your domain and space, and grant the first Space Admins in the Amazon CloudWatch console — the setup that the section called “Set up Omni” covers. The identity that creates the space becomes its first Space Admin automatically: setup adds a system managed Space Admin grant for the IAM role or user

that ran the setup flow. That grant cannot be removed while it is the last Space Admin grant. Space Admins are the one part of access you can keep managing in the CloudWatch console: it has a page for adding and removing them at any time after setup. Everything else is in the Omni web UI (the other permission levels, data scopes, and access profiles), where a Space Admin adds members and each member's grants decide what they can do and see. This page explains the model; the pages under it carry the procedures and the reference.

The following diagram shows where each piece is created. The **Omni Space Access role** in it is the IAM role the space assumes to reach your AWS resources; the next section explains how it works alongside permission levels.

Grants and permission levels

When you add a member to a space or edit their access, you create a **grant** that carries a **permission level**. A grant belongs to a **principal**: a user, a group, an IAM user or role, an access profile, or an alert. This guide calls them all principals, and calls the people among them members.

Each grant carries one permission level:

- **Viewer**: Read-only access to the whole space, including queries and the Omni agent.
- **Editor**: Create, modify, and delete resources other than integrations, run queries, and manage datasets, in addition to everything a Viewer can do.
- **Space Admin**: Full access, including managing members and their permissions, and connecting, changing, or removing integrations.

- **Custom**: Exactly the actions you list, optionally limited to specific resources. See the section called “Custom grant actions”.

A member can hold grants directly and through groups, and the grants combine: their effective access is the union of what all the grants allow. For the tiered levels the highest one wins, and a Custom grant adds exactly the actions it lists. There are no explicit denies; a grant only ever adds access.

A grant applies everywhere the member works (the Omni web UI, the IDE extension, and the API), and one permission level governs every kind of resource: threads, dashboards, alerts, integrations, and agents. You manage grants in the Omni web UI. For the procedure, see the section called “Manage space members and permissions”.

Two layers decide every action

Two conditions must hold for an action to succeed in a space:

- The **member's permission level** decides whether that person is allowed to request the operation.
- The **Omni Space Access role** decides whether the space itself is permitted to carry out the operation against your AWS resources. This is the IAM role you configure for the space when you set it up. The space assumes this role to read your telemetry and, for evaluations, to invoke models on your behalf.

A member can perform an operation only when their permission level allows it and the Space Access role grants the underlying AWS permission it depends on. Raising a member to Space Admin does not add permissions that the Space Access role does not have.

Use permission levels to decide what each person on your team can do, and keep the Space Access role scoped to the AWS permissions the space needs. For how to configure the role during setup, see the section called “Set up Omni”.

Who can sign in and be added

Identities come from your domain, not from the space. Sign-in is configured through AWS IAM Identity Center at the domain, so members use the identities you already manage, including an external provider such as Okta or Microsoft Entra ID connected through IAM Identity Center. A domain without an identity provider uses IAM instead: members sign in with an IAM user or IAM role, for example through a deep link from the CloudWatch console.

Grants attach to those identities. The users and groups you can add as members are the ones your domain's identity provider supplies, and the IAM users and roles of the space's account. To configure the identity provider, see the section called “Set up Omni”.

Limit what members can see

By default, every member can read all of the space's telemetry. A **data scope** on a grant narrows that: it filters log and trace rows at read time, wherever the member reads — queries, dashboards, traces, and the Omni agent's answers.

A data scope is a read-time filter on those rows, not a containment boundary for the space. It does not filter metrics, and it does not extend to dataset creation and export, to AI-assisted summaries, or to prompt playground runs, so a member who is scoped out of a field in queries can still reach that content by building a dataset over the underlying traces. Scope the dataset, export, and AI-feature actions as well. See the section called “Limit what members can see” and the section called “Security best practices for CloudWatch Omni”.

Resources that act on their own

Some resources act when no one is signed in: an alert evaluates its query on a schedule. An **access profile** gives such a resource an identity of its own, with its own grants. See the section called “Access profiles”.

Where to go next

To do this	See
Add members and manage their grants	the section called “Manage space members and permissions”
Narrow which telemetry rows a member sees	the section called “Limit what members can see”
Look up the actions a Custom grant can carry	the section called “Custom grant actions”
Give an alert or other resource its own identity	the section called “Access profiles”
Review the security model end to end	the section called “Security in CloudWatch Omni”

Manage space members and permissions

Add members to your space, give them grants, and remove access when it is no longer needed. Only a Space Admin can add, edit, or delete grants. For what grants and permission levels are and how they combine, see the section called “Control access to your space”.

Available in the Omni web UI only.

Prerequisites

- You are signed in to your space in the Omni web UI.
- You hold a grant with the **Space Admin** permission level.
- The people you want to add can sign in to your domain. The users and groups available depend on how your domain's identity provider is set up; see the section called “Set up Omni”.

Add a member

1. Open **Settings**, and under **Space** choose **Manage permissions**. Choose **Add grants**. To change an existing grant instead, choose the principal's name to open their grants, open the grant, and choose **Edit grant**.
2. Under **Principals**, search for users, groups, access profiles, IAM roles, or alerts, and select one or more. (When editing an existing member, the member is already selected.)
3. Under **Grant name**, enter a name that identifies this grant, such as `dashboard-read`.
4. Under **Permission level**, choose **Viewer**, **Editor**, **Space Admin**, or **Custom**. For what each level allows, see the section called “Control access to your space”. For a custom grant, select the actions to allow and, optionally, the resources they apply to; the actions are listed in the section called “Custom grant actions”.
5. (Optional) To limit the data this grant can see, under **Advanced: limit the data this principal can see**, choose **Add limits to data visibility** and build the data scope. For what a scope can express, see the section called “Limit what members can see”.
6. Choose **Add**, or **Save changes** when editing. The principal appears in the table with the new grant listed beside it.

Remove access

To remove access, choose the principal's name to open their grants, select the grant, and choose **Delete**. Deleting a grant cannot be undone. When you delete a member's last grant, they immediately lose access to every resource in the space.

- A space must always keep at least one Space Admin, so you cannot delete the last grant that provides Space Admin access.
- You cannot edit or delete your own grants. Ask another Space Admin to change your access.
- An IAM Identity Center user also holds every grant given to a group they belong to, and deleting their own grants does not remove that inherited access. To remove all of their access, remove the user from those groups in IAM Identity Center or your identity provider, or delete the group's grants, which affects every member of the group.

System managed grants

Some grants are created by the service. The table marks them as system managed, and they cannot be edited or deleted.

Give a resource its own access

Some resources act when no one is signed in. An alert, for example, evaluates its query on a schedule. An access profile gives such a resource an identity of its own, and you add a profile as a member and give it a permission level as you would a person, with one exception: **Space Admin** is not available to an access profile, because space administration is reserved for people. See the section called “Access profiles”.

Limit what members can see

By default, every member of the space can read all of its telemetry. To give a member a narrower view, add a **data scope** to their grant. A data scope is a set of conditions that a row of telemetry must match for that member to see it. Rows that do not match are filtered out at read time, before results reach the member. The stored data is not changed. To control what telemetry is captured or stored in the first place, see the section called “Protect sensitive data”.

A data scope is enforced on the query path. It applies wherever the member reads telemetry from the CloudWatch Dataset, including query results, dashboards, trace and session views, and the answers the Omni agent gives from its own queries. The same scope applies in the Omni web UI, the IDE extension, and the API.

> **Note**
>
> A data scope applies only to telemetry read from the CloudWatch Dataset. It doesn't filter investigation results from AWS DevOps Agent. It also doesn't filter other data from outside the Dataset, such as CloudWatch Logs log groups or third-party tools.
> If your space is connected to an AWS DevOps Agent space, a member with a data scope can still see investigation content. This content can come from CloudWatch Logs log groups outside their scope. For more information, see the section called "Investigate with the AWS DevOps Agent".

You configure a data scope on the grant, under `Advanced: limit the data this principal can see`, when you add or edit a member (step 5 of the procedure in the section called "Manage space members and permissions").

Fine-grained access control with a data scope

A data scope has two parts: the signal types the conditions apply to, and one or more condition groups.

Signal types. Under `Applies to`, choose `Logs`, `Traces`, or both. The condition groups filter only the signal types you select. A signal type you do not select is not filtered, and the member sees all of its rows.

Condition groups. Each group is a set of conditions on the fields of a row. You can add conditions of four kinds:

- **By agent** matches rows whose resource attribute `service.name` is one of the agents you select and whose `aws.service.type` is `gen_ai_agent`. Use this to give a team access to only the agents it owns.
- **By service** matches rows whose resource attribute `service.name` is one of the services you select. This matches every instrumented service, agents included.
- **By account** matches rows whose resource attribute `cloud.account.id` is one of the AWS accounts you select. Use this when several accounts send telemetry to one space and each team owns an account.
- **By field value** matches rows where a field you choose is any one of the values you enter. You can use any field that appears in your telemetry, such as a deployment environment, a tenant

identifier, or a custom attribute your application sets. The field picker lists fields discovered from your telemetry, and you can also type a field name.

A condition matches when the field is equal to one of the values you list. Within one group, every condition must match (AND). Across groups, a row is visible when it matches any group (OR). A grant with no condition groups applies no data scope, and the member sees everything.

When a member holds more than one grant, their view is the union of what each grant allows. A grant without a data scope gives the member the full view, whatever scopes their other grants carry. To keep a member's view narrow, put a data scope on every grant you give them, including grants they inherit through a group.

You can set a data scope on any permission level, including Space Admin. It limits what the member can read. It does not limit the space-management actions the level allows.

Common patterns

Goal	Data scope
A team sees only the agents it owns	One group. By agent, listing the team's agents.
Each team sees only telemetry from its own AWS account	One grant per team. One group, By account, listing that team's account ID.
An on-call engineer sees production traces for one service	Applies to Traces. One group with By service for the service and By field value for the environment attribute set to the production value.
A reviewer sees two unrelated slices	Two groups, one for each slice. The member sees rows that match either group.

What a data scope does and does not filter

A data scope decides which rows a member can see. It does not hide fields inside a row. A member who can see a span or a log record sees every field on it, including prompt and response content. To keep specific content out of every member's view, redact it before it reaches the space. See the section called “Protect sensitive data”.

Aggregates follow the scope. A count, an error rate, or a latency percentile is computed over the rows the member can see. Two members with different scopes can get different numbers from the same query.

> **Note**
>
> The By agent, By service, and By account pickers suggest values found in your recent telemetry. You can also type a value that has not been seen yet, for example an agent you are about to deploy. A condition on a value that never appears in the data matches no rows.

Data scope in the grant JSON

The `JSON` view of the add-grants form shows the grant definition, and you can edit it directly. You can also reuse it with the API, the AWS CDK, or the AWS CLI. It carries the grant name, permission level, action scopes, and tags. The principal comes from the `Name` picker and is not part of the JSON. A data scope is an action scope on a `DataSet` resource. This example limits a Viewer to traces from two agents, or to any trace whose deployment environment is `prod`. Logs stay unrestricted: the scope names only `TRACES` in `signalTypes`, so the `READ` permission level keeps its default full access to logs.

```
{
  "name": "checkout-team-viewer",
  "permission": "READ",
  "scopedActions": [
    {
      "actions": [
        "cloudwatch:GetRecords",
        "cloudwatch:ListMetrics",
        "cloudwatch:GetMetricData"
      ],
      "resources": [
        {
          "resourceType": "DataSet",
          "signalTypes": ["TRACES"],
          "rowScopeGroups": [
            [
              {
                "operator": "IN",
                "field": "resource['attributes']['service.name']",
                "values": ["checkout-agent", "returns-agent"]
```

```
              },
              {
                "operator": "IN",
                "field": "resource['attributes']['aws.service.type']",
                "values": ["gen_ai_agent"]
              }
            ],
            [
              {
                "operator": "IN",
                "field": "resource['attributes']['deployment.environment']",
                "values": ["prod"]
              }
            ]
          ]
        }
      ]
    }
  ]
}
```

`rowScopeGroups` is a list of groups. Conditions inside a group combine with AND, and groups combine with OR. `IN` is the only operator. A nested attribute is written in bracket notation, so a dotted attribute name such as `service.name` is read as one name.

The example above uses a single group. This one uses two groups, each with two conditions, so it shows both axes at once. It limits a Viewer to traces from the `checkout-agent` **in `prod`**, or to any trace from the `returns-service` **in account 111122223333**. Logs stay unrestricted, since `signalTypes` names only `TRACES`.

```
{
  "name": "returns-reviewer",
  "permission": "READ",
  "scopedActions": [
    {
      "actions": [
        "cloudwatch:GetRecords",
        "cloudwatch:ListMetrics",
        "cloudwatch:GetMetricData"
      ],
      "resources": [
        {
```

```
          "resourceType": "DataSet",
          "signalTypes": ["TRACES"],
          "rowScopeGroups": [
            [
              {
                "operator": "IN",
                "field": "resource['attributes']['service.name']",
                "values": ["checkout-agent"]
              },
              {
                "operator": "IN",
                "field": "resource['attributes']['deployment.environment']",
                "values": ["prod"]
              }
            ],
            [
              {
                "operator": "IN",
                "field": "resource['attributes']['service.name']",
                "values": ["returns-service"]
              },
              {
                "operator": "IN",
                "field": "resource['attributes']['cloud.account.id']",
                "values": ["111122223333"]
              }
            ]
          ]
        }
      ]
    }
  ]
}
```

A trace is visible when it matches group 1 (`service.name` is `checkout-agent` **and** `deployment.environment` is `prod`) or group 2 (`service.name` is `returns-service` **and** `cloud.account.id` is `111122223333`). Every condition inside a group must match (AND); a row that matches any group is visible (OR).

Custom grant actions

A Custom grant allows exactly the actions you list. Nothing is added by default. Each action is named `service:Action`, such as `cloudwatch:GetAlert`. When you choose `Custom` in the add-

grants form, the `Select actions` drawer groups the actions of each service into `Read`, `Write`, and `Permissions management`, the same way the IAM console does. Use this page to decide which actions a member needs for a task, and to see what each action allows. For the add-grants procedure, see the section called “Manage space members and permissions”.

A member who holds a Custom grant and a Viewer, Editor, or Space Admin grant gets the combination of both. To keep a member's access narrow, give them only the Custom grant.

Limits on Custom grants

- **Resource and tag scoping applies only to CloudWatch actions.** You can limit a `cloudwatch:` action to named resources, to resources with a tag, or to a data scope only when the action acts on a resource type: telemetry query actions (a `DataSet` data scope), alerts, dashboards, access profiles, and integrations. Other `cloudwatch:` actions, such as `cloudwatch:GetSpace`, apply to the whole space and accept no scope. Actions from every other service, such as `bedrock-agentcore:` or `logs:`, accept no resource or tag scope. They apply to everything the Omni Space Access role can reach.
- **One service per action group.** An action group in the drawer holds actions from one service. To grant actions from two services, add two groups.
- **Actions from other services also need the Space Access role.** A member can use a `bedrock-agentcore:` or `logs:` action only when the Omni Space Access role for the space also allows it. See the section called “Control access to your space”. Model inference is separate. The base policy lets a space set up and view evaluations, but invoking a model also requires the optional AWS managed policy `CloudWatchOmniModelInferencePolicy` on the role.
- **DevOps Agent actions are not part of the Space Access role.** To use the DevOps Agent from a space, attach the AWS managed policy `AIDevOpsAgentFullAccess` to the role.

Actions by service

Service	Actions	What the actions are used for	Grant it to
CloudWatch	`cloudwatch:StartTelemetryQuerySession` , `cloudwatc`	Run queries in the explorer, in dashboards, and in the alert query preview: open and	Members who read telemetry. Included in Viewer.

Service	Actions	What the actions are used for	Grant it to
	h:ListTelemetryQuerySessions ,cloudwatch:StopTelemetryQuerySession ,cloudwatch:StopTelemetryQuery ,cloudwatch:GetTelemetryQueryResults	close query sessions, cancel a query, and read its results. Each is checked under its own name. The data a query reads is checked separately, as the next two rows describe.	

Service	Actions	What the actions are used for	Grant it to
CloudWatch	`cloudwatch:GetRecords`	Read logs and traces. GetRecords is the permission behind `StartTelemetryQuery` and `ListTelemetryFields` : Omni checks it for every logs or traces dataset a query references, and for the dataset that `ListTelemetryFields` names. A dataset named without a `logs.` or `traces.` prefix, including `default`, counts as both and is checked once.	Members who read logs and traces. Included in Viewer.

Service	Actions	What the actions are used for	Grant it to
CloudWatch	`cloudwatch:GetMetricData`, `cloudwatch:ListMetrics`	Read metrics. When `StartTelemetryQuery` references a `metrics.` dataset, that part is checked as both actions. `ListTelemetryFields` on a metrics dataset is checked as `cloudwatch:ListMetrics` alone. A query that spans logs or traces and metrics needs this row and the `cloudwatch:GetRecords` row.	Members who read metrics. Included in Viewer.
CloudWatch	`cloudwatch:GetContextGraph`	See the application map.	Members who read telemetry. Included in Viewer.

Service	Actions	What the actions are used for	Grant it to
CloudWatch	`cloudwatch:CreateOmniThread ,cloudwatch:GetOmniThread , cloudwatch:UpdateOmniThread ,cloudwatch:ListOmniThreads , cloudwatch:DeleteOmniThread ,cloudwatch:StartOmniThreadSession`	Ask the Omni agent questions and manage conversations. The agent reads with the member's own access, so grant the query actions too.	Members who use the Omni agent. Included in Viewer.
CloudWatch	`cloudwatch:SubmitFeedback`	Rate an answer or send feedback.	Members who use the Omni agent. Included in Editor.

Service	Actions	What the actions are used for	Grant it to
CloudWatch	`cloudwatch:ListAlerts`, `cloudwatch:GetAlert`, `cloudwatch:CreateAlert`, `cloudwatch:UpdateAlert`, `cloudwatch:DeleteAlert`	See alerts and their state, and create, change, or delete them. Creating an alert also needs `cloudwatch:ListAccessProfiles` and `cloudwatch:AssumeAccessProfile` on the profile the alert uses. Can be limited to named alerts or tagged alerts.	Members who work with alerts. Viewer includes the List and Get actions. Editor includes all five.
CloudWatch	`cloudwatch:ListOmniDashboards`, `cloudwatch:GetOmniDashboard`, `cloudwatch:CreateOmniDashboard`, `cloudwatch:UpdateOmniDashboard`, `cloudwatch:DeleteOmniDashboard`	See dashboards, and create, change, or delete them. Viewing a dashboard also needs the query actions. Can be limited to named or tagged dashboards.	Members who work with dashboards. Viewer includes the List and Get actions. Editor includes all five.

Service	Actions	What the actions are used for	Grant it to
CloudWatch	`cloudwatch:ListViews`, `cloudwatch:GetView`, `cloudwatch:CreateView`, `cloudwatch:UpdateView`, `cloudwatch:DeleteView`	See saved views, and create, change, or delete them.	Members who work with saved views. Viewer includes the List and Get actions. Editor includes all five.
CloudWatch	`cloudwatch:GetSpace`, `cloudwatch:ListSpaces`, `cloudwatch:UpdateSpace`	Read the space's details, list the spaces the member can open, and change the space's name and configuration.	Viewer includes `cloudwatch:GetSpace` and `cloudwatch:ListSpaces`. Space Admin includes `cloudwatch:UpdateSpace`.
CloudWatch	`cloudwatch:GetPreferences`, `cloudwatch:UpdatePreferences`	Read and save the member's own preferences.	Any member. Included in Viewer.

Service	Actions	What the actions are used for	Grant it to
CloudWatch	`cloudwatch:ListAccessGrants`, `cloudwatch:GetAccessGrant`, `cloudwatch:CreateAccessGrant`, `cloudwatch:DeleteAccessGrant`	Read the grants in the space, and add or remove them.	Viewer includes the List and Get actions. Space Admin includes `cloudwatch:CreateAccessGrant` and `cloudwatch:DeleteAccessGrant`.
CloudWatch	`cloudwatch:ListAccessProfiles`, `cloudwatch:GetAccessProfile`, `cloudwatch:CreateAccessProfile`, `cloudwatch:UpdateAccessProfile`, `cloudwatch:DeleteAccessProfile`, `cloudwatch:AssumeAccessProfile`	See access profiles, manage them, and act as one. `cloudwatch:AssumeAccessProfile` is what a member needs to set a profile on an alert, and what an alert needs to run. Can be limited to named or tagged profiles.	Viewer includes the List and Get actions. Editor adds `cloudwatch:AssumeAccessProfile`. Space Admin includes all six.

Service	Actions	What the actions are used for	Grant it to
CloudWatch	`cloudwatch:ListIntegrations`, `cloudwatch:GetIntegration`, `cloudwatch:CreateIntegration`, `cloudwatch:UpdateIntegration`, `cloudwatch:DeleteIntegration`	You can see, connect, change, or remove integrations such as Slack and AWS DevOps Agent. You can limit these actions to named or tagged integrations.	Viewer includes the List and Get actions. Space Admin includes all five.
CloudWatch	`cloudwatch:InvokeIntegration`	Send a message through an integration. Can be limited to named integrations and, for Slack, to channels.	Access profiles that alerts use to notify. No permission level includes it.
CloudWatch	`cloudwatch:GetIntelligenceConfiguration`, `cloudwatch:PutIntelligenceConfiguration`	Read the account's intelligence configuration, and turn intelligence features on or off.	Viewer includes `cloudwatch:GetIntelligenceConfiguration`. Editor includes `cloudwatch:PutIntelligenceConfiguration`.

Service	Actions	What the actions are used for	Grant it to
CloudWatch	`cloudwatch:TagResource` , `cloudwatch:UntagResource` , `cloudwatch:ListTagsForResource`	Read, add, and remove tags on Omni resources. Only these resource types accept tags: spaces, domains, organization domains, access grants, organization access grants, access profiles, dashboards, alerts, views, integrations, and datasets. The Space Access role denies tagging of any other CloudWatch resource. These are the tags that a tag-scoped grant matches on.	Members who organize resources by tag, and Space Admins who set up tag-scoped grants.

Service	Actions	What the actions are used for	Grant it to
Bedrock AgentCore	`bedrock-agentcore:ListEvaluators`, `bedrock-agentcore:GetEvaluator`, `bedrock-agentcore:CreateEvaluator`, `bedrock-agentcore:UpdateEvaluator`, `bedrock-agentcore:DeleteEvaluator`, `bedrock-agentcore:Evaluate`	See, author, and run evaluators for agent evaluations.	Members who run or author agent evaluations.

Service	Actions	What the actions are used for	Grant it to
Bedrock AgentCore	bedrock-agentcore:ListDatasets ,bedrock-agentcore:GetDataset ,bedrock-agentcore:ListDatasetVersions ,bedrock-agentcore:ListDatasetExamples ,bedrock-agentcore:CreateDataset ,bedrock-agentcore:UpdateDataset ,bedrock-agentcore:CreateDatasetVersion ,bedrock-agentcore:AddDatasetExamples ,bedrock-agentcore:UpdateDatasetExamples ,bedrock-	See and manage the datasets that evaluations run against. The tag actions also read or change tags on evaluators and online evaluation configs.	Members who author agent evaluations.

Service	Actions	What the actions are used for	Grant it to
	agentcore:DeleteDatasetExamples ,bedrock-agentcore:DeleteDataset ,bedrock-agentcore:TagResource ,bedrock-agentcore:UntagResource ,bedrock-agentcore:ListTagsForResource		

Service	Actions	What the actions are used for	Grant it to
Bedrock AgentCore	`bedrock-agentcore:ListOnlineEvaluationConfigs` ,`bedrock-agentcore:GetOnlineEvaluationConfig` , `bedrock-agentcore:CreateOnlineEvaluationConfig` ,`bedrock-agentcore:UpdateOnlineEvaluationConfig` ,`bedrock-agentcore:DeleteOnlineEvaluationConfig`	Set up online evaluations that run on live traffic without a user.	Members who set up online evaluations.
Bedrock	`bedrock:ListFoundationModels` ,`bedrock:ListInferenceProfiles`	Choose a model when creating an evaluator.	Members who author agent evaluations.

Service	Actions	What the actions are used for	Grant it to
Bedrock	`bedrock:InvokeModel` , `bedrock:InvokeModelWithResponseStream` , `bedrock-mantle:CreateInference` , `bedrock-mantle:CallWithBearerToken`	Invoke the model when an evaluation or the playground runs. The `bedrock-mantle` actions cover models served through the `bedrock-mantle` endpoint in Amazon Bedrock. The Space Access role must also carry the optional `CloudWatchOmniModelInferencePolicy` .	Members who run evaluations or use the playground.
IAM	`iam:PassRole`	Pass a service role in your account to CloudWatch or to Bedrock AgentCore, for example the role that online evaluations run as.	Members who set up the space or online evaluations.

Service	Actions	What the actions are used for	Grant it to
IAM	`iam:ListRoles` ,`iam:GetRole` ,`iam:ListAttachedRolePolicies` ,`iam:ListUsers` ,`iam:ListUserTags` ,`iam:ListServiceSpecificCredentials`	Fill the role picker, inspect an existing role during Azure VM ingestion setup, and list the ingestion users and their OTLP bearer tokens.	Members who set up telemetry sources or choose service roles.
IAM	`iam:CreateServiceLinkedRole`	Create the AWS Config service-linked role that Azure topology needs.	Members who set up Azure topology.
CloudWatch Logs	`logs:CreateLogGroup` ,`logs:CreateLogStream` ,`logs:PutLogEvents`	Write evaluation results to log groups.	Members who run evaluations.
CloudWatch Logs	`logs:DescribeLogGroups`	List log groups for the online evaluation log-group picker.	Members who set up online evaluations.
CloudWatch Logs	`logs:DescribeIndexPolicies` ,`logs:PutIndexPolicy`	Index the service name on the spans log group so online evaluations can sample by service.	Members who set up online evaluations.

Service	Actions	What the actions are used for	Grant it to
KMS	`kms:DescribeKey` , `kms:GenerateDataKey` , `kms:Decrypt`	Validate and use a customer managed key for space encryption and for stored provider keys.	Members who configure encryption or store provider keys.
Lambda	`lambda:InvokeFunction` , `lambda:GetFunction`	Run code-based custom evaluators.	Members who use code evaluators.
Secrets Manager	`secretsmanager:ListSecrets` , `secretsmanager:CreateSecret` , `secretsmanager:TagResource` , `secretsmanager:PutSecretValue` , `secretsmanager:GetSecretValue` , `secretsmanager:DeleteSecret`	Store, read, rotate, and delete model provider API keys used by evaluators.	Members who add provider keys.

Service	Actions	What the actions are used for	Grant it to
Config	`config:PutServiceLinkedConfigurationRecorder`, `config:DeleteServiceLinkedConfigurationRecorder`, `config:DescribeConfigurationRecorder`, `config:DescribeConfigurationRecorderStatus`	Turn the AWS Config recorder on or off, and read its status, to build the Azure topology map.	Members who set up Azure topology.

Access profiles

An access profile is an identity for a resource that acts when no one is signed in. An alert, for example, evaluates its query on a schedule. The profile holds the permissions the resource uses at that time.

A profile is reusable. You create it once, grant it permissions, and choose which resources may assume it, so several alerts can share one profile instead of each carrying a copy of the same permissions.

> **Note**
>
> Access profiles and permission levels solve different problems. A permission level governs a **person** and applies wherever they work. A profile governs a **resource** acting on its own. See the section called “Control access to your space”.

What an access profile contains

Every profile has two halves:

Half	What it answers
Permissions	What this profile is allowed to do: the grants it holds, and the integrations it can invoke.
Who can assume	Which principals are allowed to act as this profile. In the console, you choose alerts: either every alert in the space or specific ones.

Neither half works alone. A profile with permissions that nothing is allowed to assume cannot be used. A profile that resources can assume but that has no permissions authorizes nothing. The console catches this when you create an alert, but a profile that loses its permissions later fails without an error. See the "Alerts and profiles" section of this page.

A profile belongs to one space, and its name must be unique within that space.

System managed access profiles

Creating a space also creates one system managed access profile:

Profile	Purpose
DefaultAccessProfileForAsyncWorkflows	The identity the Omni agent uses when it investigates a Slack mention and no one is signed in. Only the space's Omni agent can assume it. It starts with no permissions, so Slack mention investigations cannot read your data until you grant it Viewer access. See the section called “Connect Slack”.

A system managed profile is created with the space and maintained by the service. You cannot rename, edit, or delete it. You can still grant it permissions, the same way you grant any profile. Profiles that you create are customer managed, and you control them fully.

Create a profile for the resources that need one, scoped to the job it does. For example, an alert that reads one service's telemetry and posts to one Slack channel gets a profile that can do only that.

Create an access profile

1. In the console, open **Settings**, and under **Space** choose **Access Profiles**.
2. Choose **Create profile**.
3. Enter a **Name**. This is what you select from later, so name it for the job it does, such as `Read-only observability`. Add an optional **Description** and **Tags**.
4. Under **Permissions**, leave **Allow alerts that use this profile to read telemetry and send notifications** selected to give the profile the actions that alert evaluation needs. Clear it to start with an empty profile and grant permissions yourself.
5. Under **Who can assume**, choose which alerts may act as this profile. **Allow all alerts** is selected by default. Clear it to pick specific alerts.
6. Choose **Create profile**.

The profile appears in the list with its name and description. To show its ID as well, use the column settings. Open it to see whether *you* can assume it: the detail page reports **You are allowed to assume this access profile** or **You are not allowed to assume this access profile**.

Grant a profile its permissions

The **Permissions** checkbox on the create form gives a new profile the actions that alert evaluation needs. The console creates this grant for you with exactly these actions:

- Query session and results: `cloudwatch:StartTelemetryQuerySession`, `cloudwatch:ListTelemetryQuerySessions`, `cloudwatch:StopTelemetryQuerySession`, `cloudwatch:StopTelemetryQuery`, `cloudwatch:GetTelemetryQueryResults`
- Telemetry reads: `cloudwatch:GetRecords`, `cloudwatch:GetMetricData`, `cloudwatch:ListMetrics`
- Notifications: `cloudwatch:InvokeIntegration`

For what each action allows, see the section called “Custom grant actions”.

To grant anything beyond that, grant it the way you grant a person access: open the profile and choose **Add grant**, or on the **Manage permissions** page add the profile as you would a member. See the section called “Manage space members and permissions”.

A profile's detail page lists every grant it holds in the same grants table as the **Manage permissions** page, and marks the grants the service created as system managed. Those cannot be edited or deleted.

Alerts themselves hold only one kind of grant. When you add a grant for an alert, or for **ALL** alerts, the form locks the grant to the single `cloudwatch:AssumeAccessProfile` action and asks you to pick the access profile it applies to. All of the alert's other permissions come from the profile it assumes.

Two limits apply to whatever you grant:

- **A profile cannot administer the space.** Space administration is reserved for people. A resource acting as a profile can never add members, change permissions, or manage profiles, no matter how it is granted.
- **The Omni Space Access role is the ceiling.** A profile can hold only permissions that the role also holds, and it never adds to them. Both layers apply together, exactly as they do for a member's permission level. The role is created during setup (see the section called “Set up Omni”) and its policies are described in the section called “Identity and access management for CloudWatch Omni”.

A profile can hold **Viewer**, **Editor**, or **Custom** grants. **Space Admin** is not offered for a profile.

Alerts and profiles

Every alert carries a profile. When you create an alert in the console, the **Access profile** field is preselected to the profile in your space with the most grants. Change it if the alert should run with narrower access. The query preview on the create form runs with your own access. When the alert runs, it reads with the profile's access, so results can differ.

An alert evaluates its query *as* its profile. If alerts cannot assume the profile, or the profile cannot read the data the query names, the alert is not created and the console offers a **Manage access profiles** link. This check runs only when you create or update the alert. If the profile later loses read access to the data the query uses, the alert returns no rows and reports **no data** rather than an error.

Two conditions must hold:

- **Both you and the alert must be allowed to assume the profile.** Open the profile to check your own access. Its page reports whether you are allowed to assume it. Leaving **Allow all alerts** selected covers the alert side. If you narrowed a profile to specific alerts, a new alert is not among them until you add it.
- **The profile must be able to read the telemetry.** A profile that can invoke integrations but cannot read your data delivers nothing. Leaving the **Permissions** checkbox selected when you create the profile covers the telemetry reads and the notification call.

If an alert has reported no data since you created it, check the profile before you check the query. See the section called “Alerts”.

Review and manage a profile

Open a profile from the list to see:

- **Whether you can assume it.** You need this to set the profile on an alert.
- **Description** and **Tags**.
- **Its grants.** Every grant the profile holds, in the same table as **Manage permissions**, with its name, ID, permission level, and whether it is system managed. Open a grant to read its JSON, edit it, or delete it. **Add grant** adds one. A system managed grant is read-only.

The profile page does not list who can assume it. To see or change which alerts, users, or groups may act as a profile, open **Manage permissions**, choose the principal (for alerts, the **ALL** row or a specific alert), and review its `cloudwatch:AssumeAccessProfile` grants there.

On the detail page, **Edit access profile** changes the profile's name, description, and tags. From the list, **Actions** offers **Edit** and **Delete**. Deleting a profile does not check whether alerts still use it. An alert whose profile is deleted can no longer evaluate, so move those alerts to another profile or delete them first. A system managed profile cannot be edited or deleted. If you need different permissions for it, add or remove its grants instead.

Next steps

- To understand how access to a space works, see the section called “Control access to your space”.
- To add members and set their permission levels, see the section called “Manage space members and permissions”.

- To create an alert that uses a profile, see the section called “Alerts”.
- To connect the integrations a profile can invoke, see the section called “Connect Slack”.

AWS managed policies for CloudWatch Omni

CloudWatch Omni provides AWS managed policies for the space operator role, for the domain access role of an organization domain, and for the roles that support organization-level Context Graph enablement. Each policy's details — the description, what it attaches to, the version history, and the complete JSON policy document — are published in the AWS Managed Policy Reference, which is generated from the policy itself and updated automatically when a policy changes. The following table links to each policy's page there.

For guidance on which policy you need for which task, which permissions read across your whole account, and the permissions you provide yourself, see the section called “IAM policies to use CloudWatch Omni”.

The policies

Policy	What it grants
CloudWatchOmniSpaceAccessPolicy	The base policy, always attached to the space operator role. The space experience (space and access-grant management, telemetry queries, the context graph, alerts, dashboard s, access profiles, views, threads, and integrati ons), together with the management side of evaluation.
CloudWatchOmniModelInferencePolicy	Model inference only. Attached only to spaces that use the prompt playground or run evaluations that invoke a model.
CloudWatchOmniDomainAccessPolicy	Domain management for an organization domain. Attached to the domain access role, which CloudWatch Omni assumes to operate the domain. The role is created in the management account during organization

Policy	What it grants
	domain setup. Single-account domains do not use it.
CloudWatchOmniAWSIntegrationPolicy	Resource discovery for Context Graph: lets CloudWatch Omni discover resources and their relationships in an account. Optional on the space operator role — you choose it during space setup. In an organization Centralization rule, CloudWatch Omni also attaches it to the integration roles it provisions in each source account.
AWSCloudWatchOmniServiceRolePolicy	Attached to the `AWSServiceRoleForCloudWatch_Omni` service-linked role, which provisions the integration roles and the AWS Config recorder in member accounts. You cannot attach it to your own identities.

CloudWatch Omni updates to AWS managed policies

The following table describes updates to CloudWatch Omni's AWS managed policies.

Change	Description	Date
CloudWatchOmniSpaceAccessPolicy — Updated policy	CloudWatch Omni added the `cloudwatch:GetProfileRecords` permission so you can query continuous profiling data in a space. Like the other space permissions, it requires the `cloudwatch:HasAccessGrant` condition.	November 18, 2026

Change	Description	Date
CloudWatchOmniSpaceAccessPolicy — Updated policy	CloudWatch Omni added IAM Identity Center read permissions, and `kms:Decrypt` for directories encrypted with a customer managed key, so you can look up users and groups when you grant access to a space. It also added `sns:ListTopics` so you can choose an Amazon SNS topic as an alert notification target.	October 14, 2026
AWSCloudWatchOmniServiceRolePolicy — Updated policy	CloudWatch Omni added the `iam:GetRole` permission. This lets the service-linked role read and reuse the integration role it provisions in an account, instead of recreating it.	September 24, 2026
CloudWatchOmniSpaceAccessPolicy — New policy	CloudWatch Omni added a policy that grants the space experience — space and access-grant management, telemetry queries, alerts, dashboards, access profiles, views, threads, and integrations — together with the management side of evaluation.	September 22, 2026

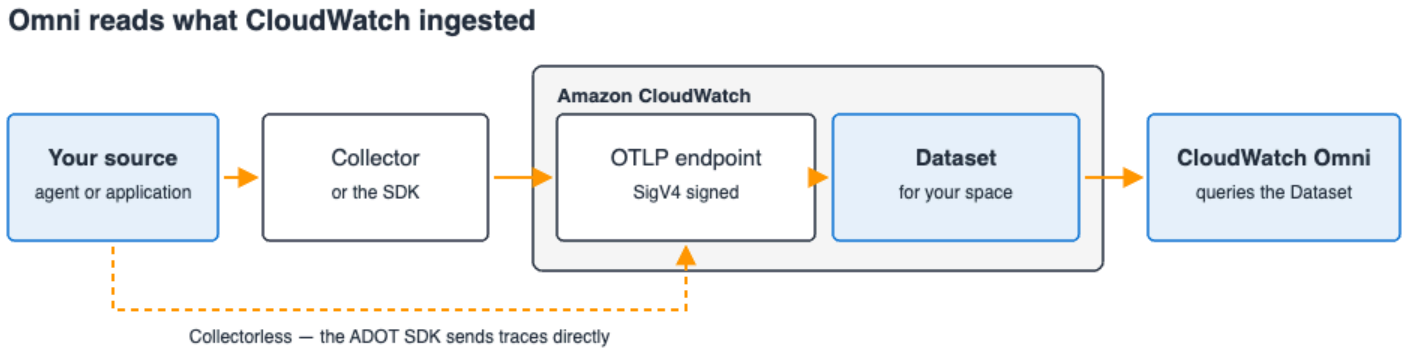
Change	Description	Date
CloudWatchOmniModelInferencePolicy — New policy	CloudWatch Omni added a policy that grants model inference for the prompt playground and for evaluations that invoke a model.	September 22, 2026
CloudWatchOmniDomainAccessPolicy — New policy	CloudWatch Omni added a policy that grants domain management for an organization domain, attached to the domain access role created during organization domain setup.	September 22, 2026
CloudWatchOmniAWSIntegrationPolicy — New policy	CloudWatch Omni added a policy that grants resource discovery for Context Graph. It is optional on the space operator role, and CloudWatch Omni attaches it to the integration roles it provisions in the source accounts of an organization Centralization rule.	September 22, 2026
AWSCloudWatchOmniServiceRolePolicy — New policy	CloudWatch Omni added a policy for the `AWSServiceRoleForCloudWatch_Omni` service-linked role, which provisions the integration roles and the AWS Config recorder in member accounts.	September 22, 2026

Change	Description	Date
CloudWatch Omni started tracking changes	CloudWatch Omni started tracking changes for its AWS managed policies.	September 22, 2026

Send telemetry to CloudWatch Omni

CloudWatch Omni reads what Amazon CloudWatch has ingested. Configure your application, OpenTelemetry exporter, or collector to send telemetry to a CloudWatch OTLP endpoint. After that telemetry is in the CloudWatch Dataset for your space, it is available in CloudWatch Omni.

Where to start



- **Send application telemetry to CloudWatch Omni**
  - **Environment:** Amazon EC2, Amazon ECS, Amazon EKS, Azure VM, Azure AKS, Google Compute Engine, or Google Kubernetes Engine.
  - On AWS Lambda there is no agent to deploy. See Send application telemetry from AWS Lambda.
- **Send AI agent telemetry to CloudWatch Omni**
  - **Environment:** Amazon Bedrock AgentCore, AWS Lambda, Amazon EC2, Amazon ECS, or Amazon EKS. The links open Step 2; Step 1 is the same for every environment.

Your situation	Start here
My application already emits OpenTelemetry and sends it to a collector I run	Nothing to install. Configure your collector to sign requests and send to an endpoint below (see **Bring your own collector** under "Choose how you collect"), then confirm data arrives with the **Your application appears** check in Step 3 of Send application telemetry.
My application already emits OpenTelemetry but has no collector	Step 1 of Send application telemetry, **Deploy the CloudWatch agent**, then Step 2, **Point**

Your situation	Start here
	your application at the agent, and Step 3, **Verify**. Skip Step 4.
My application is not instrumented yet	Send application telemetry to CloudWatch Omni, all four steps.
Telemetry stopped arriving, or never arrived	The troubleshooting table on the page you set up with: applications, Lambda, or AI agents.
My workload runs somewhere not listed	Any OpenTelemetry collector or SDK can send to the endpoints below with SigV4-signed requests. See the collection comparison in Getting started with OTLP in the Amazon CloudWatch User Guide.

> **Note**
>
> **Assisted setup.** The **Add source** wizard in the Omni web UI (**Settings › Ingestion**) walks through the same choices and generates commands for your selections. From your coding agent, the Omni skills in the Agent Toolkit for AWS do the same; see the section called "Use Omni skills". From your editor, see the section called "Develop with the IDE extension".

How telemetry reaches your space

Forwarding to the Dataset

The **CloudWatch Dataset integration** is the step between Amazon CloudWatch and the Dataset in the diagram above: it forwards your CloudWatch logs and traces into the Dataset for your space. Setting up a space in the CloudWatch console also creates the integration and an execution role that the CloudWatch Logs service assumes, so forwarding starts without a separate step. The space and the integration are separate resources — console setup creates them together, and you manage them independently. For the roles setup creates, see the section called “Set up Omni for a single account”. The integration forwards logs and traces together. Metrics are not forwarded; Omni queries them directly from CloudWatch Metrics.

There is one Dataset integration per account in a Region, and forwarding is same-account and same-Region. The execution role's `logs:IntegrateWithDataset` permissions control which log groups forward. Log groups in the Delivery log class do not forward, regardless of the role's permissions.

To manage the integration directly — for example, with the AWS CLI or infrastructure as code — follow these three steps.

Step 1. Create an execution role for the CloudWatch Logs service to assume. This example uses the name `CloudWatchOmniDatasetIntegrationRole`; you can use any name. The role must be in the same account as the Dataset and the integration — IAM does not support passing a role across accounts. Use this trust policy:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": { "Service": "logs.amazonaws.com" },
    "Action": "sts:AssumeRole",
    "Condition": {
      "StringEquals": { "aws:SourceAccount": "<account-id>" },
      "ArnLike": { "aws:SourceArn": "arn:aws:observabilityadmin:<region>:<account-
id>:dataset-integration/default" }
    }
  }]
}
```

In both `Condition` values, `<account-id>` is the account that owns the role, the Dataset, and the integration. With any other account ID the create call still succeeds, but no logs forward.

Step 2. Attach this permissions policy to the role. The `log-group:*` resource forwards all log groups in the account except Delivery-class log groups; to forward only specific log groups, replace * with a log group name. If your space's Dataset is encrypted with a customer managed AWS KMS key, the key's policy must also allow this role `kms:Encrypt`, `kms:Decrypt`, and `kms:GenerateDataKey` on records entering the Dataset — see the `AllowCallerDatasetForwarding` statement in the sample key policy in the section called “Data encryption in CloudWatch Omni”.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "logs:IntegrateWithDataset",
      "Resource": ["arn:aws:logs:<region>:<account-id>:log-group:*"]
    },
    {
      "Effect": "Allow",
      "Action": "cloudwatch:PutRecords",
      "Resource": "*"
    }
  ]
}
```

Step 3. Create the Dataset integration, passing the execution role. Creating or updating the integration requires `iam:PassRole` on the execution role.

```
aws observabilityadmin create-dataset-integration \
    --role-arn arn:aws:iam::<account-id>:role/CloudWatchOmniDatasetIntegrationRole \
    --region <region>
```

Changing what is forwarded. Updates to the execution role's `logs:IntegrateWithDataset` permissions take effect within a few minutes. Changes to what is forwarded apply going forward: removing a log group stops future records from forwarding, and records already in the Dataset remain until they pass their retention period. To change the execution role, use `update-dataset-integration`; to stop all forwarding, use `delete-dataset-integration`.

Choose how you collect

The collection path you choose affects which features you get: entity correlation and Container Insights are not available on every path. For a comparison of the CloudWatch agent, an upstream OpenTelemetry Collector, a custom collector, and collectorless export with the AWS Distro for OpenTelemetry (ADOT) SDK, see Getting started in the Amazon CloudWatch User Guide.

The CloudWatch agent is the recommended path for applications, and it is the path Send application telemetry to CloudWatch Omni uses. AI agents and Lambda functions do not use a collector: an AI agent exports its traces directly from the ADOT SDK, and Lambda delivers segments and logs itself. To configure the CloudWatch agent for OTLP, see Amazon CloudWatch agent in the Amazon CloudWatch User Guide.

Bring your own collector. Point a self-managed OpenTelemetry Collector's exporters at the endpoints below. The collector's role needs the permissions named in the "Authentication" section of this page, and each exporter needs SigV4 signing configured; for the collector configuration, see Getting started with OTLP in the Amazon CloudWatch User Guide.

Choose an endpoint

Endpoint	Use for	Authentication
Traces	Application traces forwarded by the CloudWatch agent, and AgentCore runtime traces. The primary signal for Omni.	SigV4, or a bearer token
Metrics	Custom OpenTelemetry metrics, queryable with PromQL.	SigV4, or a bearer token
Logs	Log records, forwarded to a log group and log stream you name in request headers.	SigV4, or a bearer token

For the hostnames, per-signal request headers, protocol support, and the ingestion limits that apply to each, see OTLP endpoints.

> **Important**
>
> Enable Transaction Search in the Region before you send traces. It is an account-level setting, and until it is enabled spans do not arrive.

Authentication

AWS Signature Version 4 (SigV4) with short-lived credentials is the default for every path. A workload running on AWS compute signs with the role it already has, but that role must carry the permissions for the path you use, and the three paths do not share one permission set. Each procedure page shows the statement to attach.

- Collector path: the CloudWatch agent's managed policy, `CloudWatchAgentServerPolicy`.
- An AgentCore runtime: the trace-delivery actions `xray:GetSamplingRules`, `xray:GetSamplingTargets`, `xray:PutTelemetryRecords`, and `xray:PutTraceSegments` on the runtime's execution role.

Workloads outside AWS can federate for temporary credentials; the Azure and Google Cloud procedures do this. Restrict bearer tokens to scenarios where short-lived credentials are not feasible. The metrics, logs, and traces endpoints accept a long-lived bearer token, with a separate API key for each service. See Setting up bearer token authentication for Metrics, Setting up bearer token authentication for Logs, and Setting up bearer token authentication for traces. Token creation requires IAM mutating actions, so it is an administrator task.

Environment support

For the environments, languages, and frameworks with a documented path, the signals each produces, and the minimum library versions, see Supported environments, languages, and frameworks.

On-premises hosts can obtain temporary AWS credentials with IAM Roles Anywhere, so a collector on your own hosts signs requests with SigV4 instead of storing a long-lived key.

Next steps

When telemetry is arriving, see the section called “Monitor AI agents” and the section called “Monitor applications with the application map”. To control who can access the space, see the

section called “Control access to your space”. To keep sensitive content out of the telemetry you send and store, see the section called “Protect sensitive data”.

Send application telemetry

Deploy the CloudWatch agent where your application runs: Amazon EC2, Amazon ECS, Amazon EKS, an Azure VM, Azure Kubernetes Service, a Google Compute Engine instance, or Google Kubernetes Engine. Then point your application's OpenTelemetry exporter at the agent, and confirm that data arrives in your space. If your application is not instrumented yet, add OpenTelemetry for Python, Node.js, Java, .NET, or Go in the last step. The agent receives OpenTelemetry Protocol (OTLP) data from your application and forwards metrics, traces, and logs to CloudWatch.

If you are monitoring an AI agent, see Send AI agent telemetry. If your application runs on AWS Lambda, see Send application telemetry from AWS Lambda; Lambda has no collector to deploy.

Steps 1 and 2 show one environment at a time: expand the section for where your application runs in each step. Sections are collapsed so you can see the whole page; open only yours.

If your application already uses OpenTelemetry, do Steps 1 to 3 and stop; Step 4 is only for applications that are not instrumented yet. If you already run your own OpenTelemetry collector or the ADOT SDK, you need only an endpoint: see "Choose an endpoint" in Send telemetry to CloudWatch Omni.

> **Note**
>
> **Assisted setup.** The **Add source** wizard in the Omni web UI (**Settings › Ingestion**) generates these commands for your selections. From your coding agent, the Omni skills in the Agent Toolkit for AWS do the same; see the section called “Use Omni skills”. The rest of this page is the manual path.

Prerequisites

- **Transaction Search is enabled** in the account and Region that receive traces. Traces sent before it is enabled are not searchable. See Transaction Search.
- You can attach IAM policies to the role your compute uses: an instance role, a task role, the agent's service account role, or the federated role on Azure or Google Cloud.

- For Step 4, your application's language is one of Python, Node.js, Java, .NET, or Go. For more information about the frameworks with documented notes, see Supported environments, languages, and frameworks. Other frameworks still work with the custom-instrumentation snippets.

Step 1: Deploy the CloudWatch agent (platform team or administrator)

Expand the environment your application runs on. Each section gives the install commands and the same resources as infrastructure as code, as tabs.

Amazon EC2

On Amazon EC2, you attach a managed policy to the instance role, install the agent with the OTLP preset (per instance, or fleet-wide with a State Manager association), then continue to Step 2.

Grant permissions

The instance role needs `CloudWatchAgentServerPolicy`, which covers metrics, logs, and traces, bound to the instance through an instance profile.

Install the agent and enable OTLP

Install the agent

```
# 1. Connect (SSH, or Session Manager — no key or open port needed)
aws ssm start-session --target instance-id

# 2. Install the CloudWatch agent from Amazon S3
curl -fsSL -o /tmp/amazon-cloudwatch-agent.rpm \
  https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/amd64/latest/amazon-
cloudwatch-agent.rpm
sudo rpm -Uvh /tmp/amazon-cloudwatch-agent.rpm

# 3. Enable OTLP
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl \
  -a fetch-config -c default:otel -s
```

Replace *instance-id* with the ID of the Amazon EC2 instance you want to connect to.

- Install version 1.300071.0 or later, the first with OTLP support. The agent is available from Amazon S3, Systems Manager, and Amazon ECR, but not from the Amazon Linux yum repository.

- `default:otel` turns on the OTLP receiver plus host metrics and span metrics.

> **Important**
>
> A manual install does not scale. New or auto-replaced instances launch without a collector. For any Auto Scaling group, keep the agent installed with a State Manager association (in the CDK, Terraform, and CloudFormation tabs), EC2 user data, or a golden AMI.

CDK TypeScript

```
import { Role, ServicePrincipal, ManagedPolicy, InstanceProfile } from 'aws-cdk-lib/
aws-iam';
import { CfnAssociation } from 'aws-cdk-lib/aws-ssm';

const role = new Role(this, 'OmniEC2TelemetryRole', {
  assumedBy: new ServicePrincipal('ec2.amazonaws.com'),
  managedPolicies: [
    ManagedPolicy.fromAwsManagedPolicyName('CloudWatchAgentServerPolicy'),
  ],
});
new InstanceProfile(this, 'OmniEC2TelemetryProfile', { role });
new CfnAssociation(this, 'OmniCollectorAssociation', {
  name: 'AWS-ConfigureAWSPackage',
  associationName: 'omni-cloudwatch-agent',
  targets: [{ key: 'tag:omni:monitor', values: ['true'] }],
  parameters: { action: ['Install'], name: ['AmazonCloudWatchAgent'] },
  scheduleExpression: 'rate(30 days)',
});
```

CDK Python

With the AWS CDK in Python or Java, build the same resources: an IAM role assumable by `ec2.amazonaws.com` with the managed policy `CloudWatchAgentServerPolicy`, an instance profile bound to that role, and a `CfnAssociation` with the same properties as the CloudFormation example.

Terraform

```
resource "aws_ssm_association" "omni_collector" {
```

```
  name             = "AWS-ConfigureAWSPackage"
  association_name = "omni-cloudwatch-agent"
  targets {
    key    = "tag:omni:monitor"
    values = ["true"]
  }
  parameters = { action = "Install", name = "AmazonCloudWatchAgent" }
  schedule_expression = "rate(30 days)"
}

resource "aws_instance" "app" {
  # …
  iam_instance_profile = aws_iam_instance_profile.app.name
  user_data = <<-EOF
    #!/bin/bash
    T=$(curl -sS -X PUT http://169.254.169.254/latest/api/token -H "X-aws-ec2-
metadata-token-ttl-seconds: 600")
    until curl -sf -H "X-aws-ec2-metadata-token: $T" http://169.254.169.254/latest/
meta-data/iam/security-credentials/ | grep -q .; do sleep 5; done
    curl -fsSL -o /tmp/cwa.rpm https://amazoncloudwatch-agent.s3.amazonaws.com/
amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm
    rpm -Uvh /tmp/cwa.rpm
    /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config
 -c default:otel -s
    systemctl enable amazon-cloudwatch-agent
  EOF
}
```

- An instance profile created in the same apply can take a minute to reach the instance metadata service. The user data waits for the role before `fetch-config`, because an agent that starts without credentials never sends telemetry.

CloudFormation

```
Resources:
  OmniEC2TelemetryRole:
    Type: AWS::IAM::Role
    Properties:
      AssumeRolePolicyDocument:
        Statement: [{ Effect: Allow, Action: sts:AssumeRole, Principal: { Service:
 ec2.amazonaws.com } }]
      ManagedPolicyArns:
```

```
        - arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
  OmniEC2TelemetryProfile:
    Type: AWS::IAM::InstanceProfile
    Properties: { Roles: [!Ref OmniEC2TelemetryRole] }
  OmniCollectorAssociation:
    Type: AWS::SSM::Association
    Properties:
      Name: AWS-ConfigureAWSPackage
      AssociationName: omni-cloudwatch-agent
      Targets: [{ Key: tag:omni:monitor, Values: ["true"] }]
      Parameters: { action: [Install], name: [AmazonCloudWatchAgent] }
      ScheduleExpression: rate(30 days)
```

For the full agent configuration reference, see Amazon CloudWatch agent in the Amazon CloudWatch User Guide.

Amazon ECS

On Amazon ECS (Fargate), you attach a managed policy to the task role, add the agent as a second container in the same task with the application depending on it, then continue to Step 2. Your application sends OTLP to `localhost`; the task shares one network namespace.

Grant permissions and egress

The task role needs `CloudWatchAgentServerPolicy`; the execution role needs `AmazonECSTaskExecutionRolePolicy`. The task needs egress to pull the agent image and reach the OTLP endpoints: a public IP in a public subnet, a NAT gateway, or VPC endpoints.

> **Important**
>
> The application container must depend on the agent container with condition `START`. The agent image has no health check, so condition `HEALTHY` hangs startup.

Add the sidecar to the task definition

Setup script

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/
scripts/aws/setup.sh | \
  CWAGENT_PLATFORM=aws_ecs \
```

```
  CWAGENT_AWS_REGION=<region> \
  CWAGENT_AWS_ENABLE_TRANSACTION_SEARCH=true \
  sh
```

- The script creates the task role and prints the agent container definition and the task role ARN. Paste both into your task definition.
- It defaults to the Fargate launch type. For the EC2 launch type, set `CWAGENT_AWS_ECS_LAUNCH_TYPE=ec2`; the printed definition then adds host port mappings and container links.

CDK TypeScript

```
const agent = taskDef.addContainer('cwagent', {
  image: ecs.ContainerImage.fromRegistry('public.ecr.aws/cloudwatch-agent/
cloudwatch-agent:latest'),
  environment: { CW_CONFIG_CONTENT: JSON.stringify({ opentelemetry: { collect:
 { otlp: {} } } }) },
  logging: ecs.LogDrivers.awsLogs({ streamPrefix: 'cwagent' }),
});
app.addContainerDependencies({ container: agent, condition:
 ecs.ContainerDependencyCondition.START });
taskDef.taskRole.addManagedPolicy(ManagedPolicy.fromAwsManagedPolicyName('CloudWatchAgentSer
```

CDK Python

```
agent = task_def.add_container("cwagent",
    image=ecs.ContainerImage.from_registry("public.ecr.aws/cloudwatch-agent/
cloudwatch-agent:latest"),
    environment={"CW_CONFIG_CONTENT": json.dumps({"opentelemetry": {"collect":
 {"otlp": {}}}})},
    logging=ecs.LogDrivers.aws_logs(stream_prefix="cwagent"))
app.add_container_dependencies(
    ecs.ContainerDependency(container=agent,
 condition=ecs.ContainerDependencyCondition.START))
task_def.task_role.add_managed_policy(iam.ManagedPolicy.from_aws_managed_policy_name("CloudW
```

With the AWS CDK (Java), add a second container with image `public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest` and environment variable `CW_CONFIG_CONTENT` set to `{"opentelemetry":{"collect":{"otlp":{}}}}`, make the application container depend on it with condition `START`, and attach `CloudWatchAgentServerPolicy` to the task role.

Terraform

```
container_definitions = jsonencode([
  { name = "cwagent", image = "public.ecr.aws/cloudwatch-agent/cloudwatch-
agent:latest",
    environment = [{ name = "CW_CONFIG_CONTENT", value = "{\"opentelemetry\":
{\"collect\":{\"otlp\":{}}}}" }],
    logConfiguration = { logDriver = "awslogs", options = { "awslogs-group" = "/ecs/
cwagent", "awslogs-region" = "<region>", "awslogs-stream-prefix" = "cwagent" } } },
  { name = "app", image = "<your-image>",
    dependsOn = [{ containerName = "cwagent", condition = "START" }] }
])
```

CloudFormation

```
ContainerDefinitions:
  - Name: cwagent
    Image: public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest
    Environment:
      - { Name: CW_CONFIG_CONTENT, Value: '{"opentelemetry":{"collect":{"otlp":
{}}}}' }
  - Name: app
    Image: <your-image>
    DependsOn: [{ ContainerName: cwagent, Condition: START }]
```

For the agent configuration reference, see Amazon CloudWatch agent.

Amazon EKS

On Amazon EKS, you install the CloudWatch Observability add-on with OTLP enabled and give its agent credentials, then continue to Step 2. The add-on runs the agent as a DaemonSet and exposes a `cloudwatch-agent` Service in the `amazon-cloudwatch` namespace; your pods send OTLP to that Service over cluster DNS, not to `localhost`. The add-on is installed with the AWS CLI regardless of how you deploy your application, so there is one installation path here.

```
curl -fsSL https://raw.githubusercontent.com/aws/amazon-cloudwatch-agent/main/scripts/
aws/setup.sh | \
  CWAGENT_PLATFORM=aws_eks \
  CWAGENT_K8S_CLUSTER_NAME=<my-cluster> \
  CWAGENT_AWS_REGION=<region> \
  CWAGENT_AWS_ENABLE_TRANSACTION_SEARCH=true \
```

```
  sh
```

- The script installs the EKS Pod Identity Agent, creates the agent role with a Pod Identity association, and installs the add-on with OTLP enabled. Pod Identity supplies the agent's credentials, so you do not annotate the service account for IAM roles for service accounts (IRSA).

Three settings must be right or telemetry never arrives, with no error in the agent log:

- The OTLP receiver must be bound to `0.0.0.0`, not the default `localhost`, or it refuses cross-pod traffic. If application OTLP is refused after the script runs, apply the override and restart the DaemonSet:

```
aws eks update-addon --cluster-name <my-cluster> --addon-name amazon-cloudwatch-
observability \
  --configuration-values '{"agent":{"config":{"opentelemetry":{"collect":{"otlp":
{"grpc_endpoint":"0.0.0.0:4317","http_endpoint":"0.0.0.0:4318"}}}}}}'
kubectl -n amazon-cloudwatch rollout restart daemonset/cloudwatch-agent
```

- The agent must have credentials through Pod Identity (the script) or an IRSA-annotated service account. The add-on's `--service-account-role-arn` flag does not annotate the service account; without the annotation the agent falls back to the node role and its exports are rejected.
- Application logs are in the cluster-scoped log group `/aws/cwagent/<my-cluster>/otlp`, not in `/aws/cwagent/otlp`.

For a manual install with IRSA and the add-on configuration reference, see Install the CloudWatch Observability add-on in the Amazon CloudWatch User Guide.

Azure VM

On an Azure VM, you federate the VM's managed identity to an IAM role and install the CloudWatch agent on the VM, then continue to Step 2. The agent sends telemetry with temporary AWS credentials instead of a stored key; your application sends OTLP to `localhost`.

The complete procedure, including the OpenID Connect (OIDC) federation, the IAM role trust policy, and the onboarding script, is in Install the CloudWatch agent on Azure in the Amazon CloudWatch User Guide. Follow the VM section there, then return to Step 2.

Azure AKS

On Azure Kubernetes Service, you federate workload identity for the `cloudwatch-agent` service account to an IAM role and install the CloudWatch Observability Helm chart, then continue to Step 2. Pods send OTLP to the `cloudwatch-agent` Service over cluster DNS.

The complete procedure, including the OIDC federation and the Helm values, is in Install the CloudWatch agent on Azure in the Amazon CloudWatch User Guide. Follow the AKS section there, then return to Step 2.

> **Note**
>
> Unlike the EKS add-on, the AKS Helm chart's OTLP receiver accepts cross-pod traffic by default; no `0.0.0.0` override is needed.

Google Compute Engine

On a Google Compute Engine instance, you federate the instance's service account to an IAM role and install the CloudWatch agent on the instance, then continue to Step 2. The agent sends telemetry with temporary AWS credentials instead of a stored key; your application sends OTLP to `localhost`.

The complete procedure, including the service account federation, the IAM role trust policy, and the onboarding scripts, is in Install the CloudWatch agent on Google Cloud in the Amazon CloudWatch User Guide. Follow the Google Compute Engine (GCE) section there, then return to Step 2.

Google Kubernetes Engine

On Google Kubernetes Engine, you federate the cluster's OIDC issuer for the `cloudwatch-agent` service account to an IAM role and install the CloudWatch Observability Helm chart, then continue to Step 2. Pods send OTLP to the `cloudwatch-agent` Service over cluster DNS.

The complete procedure, including the OIDC federation and the Helm values, is in Install the CloudWatch agent on Google Cloud in the Amazon CloudWatch User Guide. Follow the Google Kubernetes Engine (GKE) section there, then return to Step 2.

Step 2: Point your application at the agent (developer)

Set these environment variables on the application, never on the agent: one agent serves many services and already enriches telemetry with infrastructure attributes. The endpoint and the

place the variables live depend on your environment, and the port and protocol depend on your language; expand the same section you chose in Step 1, then choose your language.

Amazon EC2

On Amazon EC2, set these in the application's service unit or start script, for example `Environment=` lines in a systemd unit:

Python, Java, .NET, Go

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://localhost:4318
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Node.js

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://localhost:4317
OTEL_EXPORTER_OTLP_PROTOCOL=grpc
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Amazon ECS

On Amazon ECS, set these in the application container's `environment` block:

Python, Java, .NET, Go

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://localhost:4318
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Node.js

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://localhost:4317
OTEL_EXPORTER_OTLP_PROTOCOL=grpc
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Amazon EKS

On Amazon EKS, set these in the container's `env` block in the pod spec:

Python, Java, .NET, Go

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://cloudwatch-agent.amazon-
cloudwatch.svc.cluster.local:4318
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Node.js

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://cloudwatch-agent.amazon-
cloudwatch.svc.cluster.local:4317
OTEL_EXPORTER_OTLP_PROTOCOL=grpc
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Azure VM

On an Azure VM, set these in the application's service unit or start script:

Python, Java, .NET, Go

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
```

```
OTEL_EXPORTER_OTLP_ENDPOINT=http://localhost:4318
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Node.js

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://localhost:4317
OTEL_EXPORTER_OTLP_PROTOCOL=grpc
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Azure AKS

On Azure Kubernetes Service, set these in the container's `env` block in the pod spec:

Python, Java, .NET, Go

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://cloudwatch-agent.amazon-
cloudwatch.svc.cluster.local:4318
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Node.js

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://cloudwatch-agent.amazon-
cloudwatch.svc.cluster.local:4317
OTEL_EXPORTER_OTLP_PROTOCOL=grpc
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Google Compute Engine

On a Google Compute Engine instance, set these in the application's service unit or start script:

Python, Java, .NET, Go

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://localhost:4318
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Node.js

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://localhost:4317
OTEL_EXPORTER_OTLP_PROTOCOL=grpc
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Google Kubernetes Engine

On Google Kubernetes Engine, set these in the container's `env` block in the pod spec:

Python, Java, .NET, Go

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://cloudwatch-agent.amazon-
cloudwatch.svc.cluster.local:4318
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Node.js

```
OTEL_SERVICE_NAME=<checkout-api>
OTEL_RESOURCE_ATTRIBUTES=service.namespace=<checkout>
OTEL_EXPORTER_OTLP_ENDPOINT=http://cloudwatch-agent.amazon-
cloudwatch.svc.cluster.local:4317
OTEL_EXPORTER_OTLP_PROTOCOL=grpc
OTEL_METRICS_EXPORTER=otlp
OTEL_LOGS_EXPORTER=otlp
```

Step 3: Verify

Use the automated verification in the Omni web UI. In your space, open **Settings › Ingestion** and choose your source: the **Add source** flow's verification step confirms the agent is reporting and your application's telemetry is arriving, and points at the failing setting when it is not. Run it after every deployment change.

If verification fails, see the "Troubleshoot missing telemetry" section of this page.

Verify manually

The agent is reporting

Amazon EC2

On Amazon EC2, `sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a status` reports `running`. In your space, host metrics for the instance appear within about five minutes.

Amazon ECS

On Amazon ECS, the task shows both containers `RUNNING`. In your space, container metrics for the task appear within about five minutes.

Amazon EKS

On Amazon EKS, `kubectl -n amazon-cloudwatch get daemonset cloudwatch-agent` shows all pods ready. In your space, container metrics for the cluster appear within about five minutes.

Azure VM

On an Azure VM, `amazon-cloudwatch-agent-ctl -a status` reports `running`. In your space, host metrics for the VM appear within about five minutes.

Azure AKS

On Azure Kubernetes Service, `kubectl -n amazon-cloudwatch get daemonset cloudwatch-agent` shows all pods ready. In your space, container metrics for the cluster appear within about five minutes.

Google Compute Engine

On a Google Compute Engine instance, `sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a status` reports `running`. In your space, host metrics for the instance appear within about five minutes.

Google Kubernetes Engine

On Google Kubernetes Engine, `kubectl -n amazon-cloudwatch get daemonset cloudwatch-agent` shows all pods ready. In your space, container metrics for the cluster appear within about five minutes.

Your application appears

If you run your own OpenTelemetry Collector instead of the CloudWatch agent, this is your check. If your application is not instrumented yet, do Step 4 first, then return to this check. Restart the application, then open your space. In **Application map**, the service appears under the `service.name` you set. In **Trace Explorer**, a trace for a recent request shows the entry span for your service with the resource attributes you set. Application logs are in `/aws/cwagent/otlp` on EC2, ECS, Azure VMs, and Compute Engine instances, or `/aws/cwagent/<cluster>/otlp` on EKS, AKS, and GKE. A custom metric is queryable with PromQL by its OpenTelemetry name, for example `sum({__name__="orders.placed"})`.

Step 4 (optional): Instrument your application with OpenTelemetry (developer)

Choose your language. The choice applies to every code sample in this step and is remembered on the other pages in this guide. For Python, Node.js, Java, and .NET, most HTTP frameworks, database clients, and messaging libraries are traced without code changes. Go has no auto-instrumentation agent, so initialize the SDK in code and wrap your handlers with the library instrumentation for your framework. The table in each tab lists the frameworks with documented notes, and the OpenTelemetry registry lists the rest. For a framework not covered, the custom-instrumentation snippet still works.

Install the OpenTelemetry SDK

Python

```
pip install opentelemetry-distro opentelemetry-exporter-otlp
opentelemetry-bootstrap -a install
```

- In a container, both commands belong in the Dockerfile.
- On a host running Amazon Linux 2023, the default `python3` is 3.9 and the CloudWatch plugin requires Python 3.10 or later: install and use `python3.11` (`dnf install -y python3.11 python3.11-pip`).

Node.js

```
npm install @opentelemetry/sdk-node @opentelemetry/auto-instrumentations-node \
  @opentelemetry/exporter-trace-otlp-grpc @opentelemetry/api @opentelemetry/api-logs
```

Java

```
curl -L -o opentelemetry-javaagent.jar \
  https://github.com/open-telemetry/opentelemetry-java-instrumentation/releases/
latest/download/opentelemetry-javaagent.jar
```

- The agent does not put the OpenTelemetry API on your compile classpath. To add custom instrumentation, add `io.opentelemetry:opentelemetry-api` at compile scope, not `provided`, because the agent bridges to the application's own API classes at runtime.

.NET

```
# Console application
dotnet add package OpenTelemetry
dotnet add package OpenTelemetry.Exporter.OpenTelemetryProtocol

# ASP.NET Core or gRPC service
dotnet add package OpenTelemetry.Extensions.Hosting
dotnet add package OpenTelemetry.Exporter.OpenTelemetryProtocol
dotnet add package OpenTelemetry.Instrumentation.AspNetCore
dotnet add package OpenTelemetry.Instrumentation.Http
```

Go

```
go get go.opentelemetry.io/otel \
  go.opentelemetry.io/otel/sdk \
  go.opentelemetry.io/otel/sdk/metric \
  go.opentelemetry.io/otel/sdk/log \
  go.opentelemetry.io/otel/exporters/otlp/otlptrace/otlptracehttp \
```

```

# Library instrumentation for your framework
go get go.opentelemetry.io/contrib/instrumentation/net/http/otelhttp
  # net/http
go get go.opentelemetry.io/contrib/instrumentation/google.golang.org/grpc/otelgrpc
  # gRPC
```

Add the CloudWatch plugin for OpenTelemetry with the SDK. The plugin generates the request, error, and duration span metrics that power the service views (including the **Errors** metric), and it meters every span before sampling, so those metrics reflect all requests rather than the sampled subset. It is available for Python, Node.js, Java, .NET, and Go. The following table lists the package names and links. The plugin needs a metrics pipeline to emit into. If your application exports traces but no metrics, the plugin stays inert and **Errors** remains unpopulated. Configure a metrics exporter alongside your trace exporter.

If you instrument with the ADOT SDK instead and sample, your span metrics are computed from the sampled spans only.

Language	Package	Documentation
Java	`software.amazon.opentelemetry:cloudwatch-plugin-otel`	Java plugin README
Python	`cloudwatch-plugin-otel`	Python plugin README
Node.js	`@aws/cloudwatch-plugin-otel`	Node.js plugin README
.NET	`AWS.OpenTelemetry.CloudWatchPluginOtel`	.NET plugin README

Language	Package	Documentation
Go	`github.com/aws-observability/cloudwatch-plugin-otel-go`	Go plugin README

Enable auto-instrumentation

Run your application under the auto-instrumentation agent for its language. Framework, HTTP, and database calls are traced without code changes. Go has no auto-instrumentation agent. For Go, initialize the SDK once at startup instead.

Python

```
opentelemetry-instrument python <app.py>
# FastAPI
opentelemetry-instrument uvicorn <app:app> --host 0.0.0.0 --port 8000
```

- `opentelemetry-instrument` wraps the process, so it replaces your entry point. For FastAPI under uvicorn, wrap `uvicorn`, not `python app.py`.
- For Django, set `DJANGO_SETTINGS_MODULE` in the environment and run with `--noreload`.
- Python exports logs only when `OTEL_PYTHON_LOGGING_AUTO_INSTRUMENTATION_ENABLED=true` is also set in the environment.

Node.js

```
node --require @opentelemetry/auto-instrumentations-node/register <app.js>
```

Java

```
java -javaagent:./opentelemetry-javaagent.jar -jar <app.jar>
```

.NET

```
# ASP.NET Core or gRPC: install and enable the profiler
curl -sSfL https://github.com/open-telemetry/opentelemetry-dotnet-instrumentation/
releases/latest/download/otel-dotnet-auto-install.sh -o install.sh && sh install.sh
```

```
. $HOME/.otel-dotnet-auto/instrument.sh
dotnet <MyService.dll>
```

```
// Console application: bootstrap once at startup
using var tracerProvider =
 Sdk.CreateTracerProviderBuilder().AddSource("checkout").AddOtlpExporter().Build();
using var meterProvider  =
 Sdk.CreateMeterProviderBuilder().AddMeter("checkout").AddOtlpExporter().Build();
```

Go

The following Go code example initializes the SDK once at startup. Save it in your application as `otel.go`.

```
package main

import (
    "context"
    "log/slog"

    "github.com/aws-observability/cloudwatch-plugin-otel-go/spanmetrics"
    "go.opentelemetry.io/contrib/bridges/otelslog"
    "go.opentelemetry.io/otel"
    "go.opentelemetry.io/otel/exporters/otlp/otlplog/otlploghttp"
    "go.opentelemetry.io/otel/exporters/otlp/otlpmetric/otlpmetrichttp"
    "go.opentelemetry.io/otel/exporters/otlp/otlptrace/otlptracehttp"
    sdklog "go.opentelemetry.io/otel/sdk/log"
    sdkmetric "go.opentelemetry.io/otel/sdk/metric"
    "go.opentelemetry.io/otel/sdk/resource"
    sdktrace "go.opentelemetry.io/otel/sdk/trace"
)

func setupOTel(ctx context.Context) (func(context.Context) error, error) {
    // service.name and service.namespace come from OTEL_SERVICE_NAME and
 OTEL_RESOURCE_ATTRIBUTES.
    res, err := resource.New(ctx, resource.WithFromEnv())
    if err != nil {
        return nil, err
    }

    me, err := otlpmetrichttp.New(ctx)
    if err != nil {
        return nil, err
```

```
    }
    mp := sdkmetric.NewMeterProvider(
        sdkmetric.WithReader(sdkmetric.NewPeriodicReader(me)),
        sdkmetric.WithResource(res),
    )
    otel.SetMeterProvider(mp)

    te, err := otlptracehttp.New(ctx)
    if err != nil {
        return nil, err
    }
    tp := sdktrace.NewTracerProvider(
        sdktrace.WithResource(res),
        // CloudWatch plugin: meter every span before sampling, into mp.

 sdktrace.WithSampler(spanmetrics.NewAlwaysRecordSampler(spanmetrics.SamplerFromEnv())),
        sdktrace.WithSpanProcessor(spanmetrics.NewSpanMetricsProcessor(mp)),
        sdktrace.WithBatcher(te),
    )
    otel.SetTracerProvider(tp)

    le, err := otlploghttp.New(ctx)
    if err != nil {
        return nil, err
    }
    lp := sdklog.NewLoggerProvider(
        sdklog.WithProcessor(sdklog.NewBatchProcessor(le)),
        sdklog.WithResource(res),
    )
    // Send the default slog logger's records through OpenTelemetry.
    slog.SetDefault(slog.New(otelslog.NewHandler("checkout",
 otelslog.WithLoggerProvider(lp))))

    return func(ctx context.Context) error {
        _ = tp.Shutdown(ctx)
        _ = mp.Shutdown(ctx)
        return lp.Shutdown(ctx)
    }, nil
}
```

- Call `setupOTel(ctx)` at the start of `main()`, before you serve requests, and defer the returned function so the final spans, metrics, and logs are exported on shutdown.

- The setup registers the CloudWatch plugin. `NewAlwaysRecordSampler` wraps the sampler that `OTEL_TRACES_SAMPLER` selects, and `NewSpanMetricsProcessor` records the span metrics into the meter provider, so create the meter provider before the tracer provider.
- Log with the default `slog` logger's context methods, such as `slog.InfoContext`, so each record is exported and correlated with the active span. A logger that you create separately with `slog.New` is not connected to OpenTelemetry.

Add custom instrumentation

Set business attributes on the active span, mark your entry span as a server span so it counts in request metrics, and record a custom metric. These snippets assume the SDK is initialized by the step above.

Python

```
from opentelemetry import trace, metrics
from opentelemetry.trace import SpanKind

tracer = trace.get_tracer("checkout")
orders = metrics.get_meter("checkout").create_counter("orders.placed")

def place_order(cart):
    with tracer.start_as_current_span("place_order", kind=SpanKind.SERVER) as span:
        span.set_attribute("cart.items", len(cart))
        orders.add(1)
```

Framework	Notes
FastAPI	Traced automatically under `opentelemetry-instrument uvicorn .`
Flask	Traced automatically under `opentelemetry-instrument python .`
Django	Views are traced automatically when `DJANGO_SETTINGS_MODULE` is set in the environment; run with `--noreload`.

Node.js

```
const { trace, metrics } = require('@opentelemetry/api');
const { logs } = require('@opentelemetry/api-logs');
const orders = metrics.getMeter('checkout').createCounter('orders.placed');
const logger = logs.getLogger('checkout');

function placeOrder(cart) {
  trace.getActiveSpan()?.setAttribute('cart.items', cart.length);
  orders.add(1);
  logger.emit({ body: 'order placed', attributes: { 'cart.items': cart.length } });
}
```

- Logs must go through the OpenTelemetry logs API, as `logger.emit()` does here. Setting `OTEL_LOGS_EXPORTER=otlp` alone produces no records.

Framework	Notes
Express	Traced automatically by the auto-instrumentations package.
gRPC	Server and client calls are traced automatically.

Java

```
static final LongCounter ORDERS =

 GlobalOpenTelemetry.getMeter("checkout").counterBuilder("orders.placed").build();

@WithSpan(kind = SpanKind.SERVER)
public void placeOrder(List<Item> cart) {
  Span.current().setAttribute("cart.items", cart.size());
  ORDERS.add(1);
}
```

- `@WithSpan` needs `io.opentelemetry.instrumentation:opentelemetry-instrumentation-annotations`, whose version tracks the agent release, not the API version.

Framework	Notes
Spring Boot	Controllers are traced by the Java agent; annotate service methods with `@WithSpan` for business spans.
gRPC	Calls are traced by the Java agent.

.NET

```
static readonly Meter Meter = new("checkout");
static readonly Counter<long> Orders = Meter.CreateCounter<long>("orders.placed");

Activity.Current?.SetTag("cart.items", cart.Count);
Orders.Add(1);
```

- Register the `Meter` on the metrics builder with `AddMeter("checkout")`. Without it the counter is dropped.

Framework	Notes
ASP.NET Core	Requests are traced by the profiler or `AddAspNetCoreInstrumentation()`. Add `builder.Logging.AddOpenTelemetry(o => o.AddOtlpExporter())` for logs.
gRPC	Client instrumentation is a separate prerelease package (`OpenTelemetry.Instrumentation.GrpcNetClient`); `.AddHttpClientInstrumentation()` covers the HTTP transport meanwhile.

Go

```
import (
    "context"
    "log/slog"

    "go.opentelemetry.io/otel"
    "go.opentelemetry.io/otel/attribute"
    "go.opentelemetry.io/otel/trace"
)

var (
    tracer    = otel.Tracer("checkout")
    orders, _ = otel.Meter("checkout").Int64Counter("orders.placed")
)

func placeOrder(ctx context.Context, cart []Item) {
    ctx, span := tracer.Start(ctx, "place_order",
 trace.WithSpanKind(trace.SpanKindServer))
    defer span.End()
    span.SetAttributes(attribute.Int("cart.items", len(cart)))
    orders.Add(ctx, 1)
    slog.InfoContext(ctx, "order placed", "cart.items", len(cart))
}
```

- Pass the request's `context.Context` through your calls. Spans, metrics, and logs that use it are linked to the request's trace.

The following table lists notes for the Go frameworks.

Framework	Notes
net/http	Wrap the handler with `otelhttp.NewHandler(mux, "checkout")`. Each request is traced as a server span.
gRPC	Create the server with `grpc.NewServer(grpc.StatsHandler(otelgrpc.NewServerHandler()))`. Each call is traced as a server span.

Query custom metrics with PromQL by their OpenTelemetry name, for example `sum({__name__="orders.placed"})`. Restart the application and repeat Step 3.

Troubleshoot missing telemetry

Symptom	Cause and fix
Logs and spans arrive, metrics do not	A metric attribute value is longer than 1024 characters; the CloudWatch OTLP metrics endpoint rejects the whole batch with HTTP 400. Trim the attribute. For Java, the usual cause is `process.command_args` on a long classpath: set `OTEL_JAVA_DISABLED_RESOURCE_PROVIDERS=io.opentelemetry.instrumentation.resources.ProcessResourceProvider`.
Nothing arrives; the SDK logs connection errors	Port and protocol do not match: `4317` is gRPC and `4318` is HTTP. Set `OTEL_EXPORTER_OTLP_PROTOCOL` to match the port. For Go, the exporter package sets the protocol, so use port `4318` with the OTLP/HTTP exporters.
Nothing arrives on ECS; the task hangs at startup	The application container depends on the agent with condition `HEALTHY`. Use `START`.
Nothing arrives on ECS; the agent logs `AccessDenied` or times out	The task role lacks `CloudWatchAgentServerPolicy`, or the task has no egress to the OTLP endpoints. Attach the policy; add a public IP, NAT gateway, or VPC endpoints.
Nothing arrives on EKS; no agent errors	The receiver is bound to `localhost`, or the agent service account has no credentials. Apply the `0.0.0.0` override; use Pod Identity or annotate the service account for IRSA, then restart the DaemonSet.

Symptom	Cause and fix
Nothing arrives from a new EC2 instance	The agent started before the instance profile reached the instance metadata service. Wait for the role in user data before `fetch-config`, or restart the agent.
Nothing arrives from an Azure VM or AKS	The federation is not complete: the IAM role trust policy does not match the identity, or the service account is not annotated. Recheck the federation steps in Install the CloudWatch agent on Azure.
Nothing arrives from a Compute Engine instance or GKE	The federation is not complete: the IAM role trust policy does not match the instance's service account unique ID or the cluster's OIDC issuer, or the instance has no service account attached. Recheck the federation steps in Install the CloudWatch agent on Google Cloud.
The service appears under the agent's name	`OTEL_SERVICE_NAME` is set on the agent, not the application. Move it to the application.
A Python service shows one process span and no route spans	`opentelemetry-instrument` wrapped `python` instead of the server. Wrap `uvicorn` or `gunicorn`.
Traces exist but are not searchable	Transaction Search was enabled after the traces were sent. Enable it, then send new traces.
Only some requests appear in the trace list	Transaction Search indexes 1 percent of spans by default for the trace list; the spans themselves are all stored. Raise the indexing percentage in Transaction Search settings.

Send application telemetry from AWS Lambda

Lambda functions send traces and logs to CloudWatch without a collector. Turn on active tracing so Lambda records the service segments, add a trace SDK for spans around your handler logic, and emit structured logs that join their traces.

If your application runs on Amazon EC2, ECS, EKS, or Microsoft Azure, see Send application telemetry. If you are monitoring an AI agent, see Send AI agent telemetry.

Prerequisites

- **Transaction Search is enabled** in the account and Region that receive traces. See Transaction Search.
- You can change the function's configuration and attach policies to its execution role.

Step 1: Enable active tracing

```
aws lambda update-function-configuration --function-name <my-function> --tracing-config
 Mode=Active
aws iam attach-role-policy --role-name <my-function-role> --policy-arn
 arn:aws:iam::aws:policy/AWSXRayDaemonWriteAccess
```

- The default `PassThrough` mode records no segments; only `Active` records the `AWS::Lambda` and `AWS::Lambda::Function` service segments, and only for sampled invocations.
- `AWSXRayDaemonWriteAccess` carries the required `xray:PutTraceSegments` and `xray:PutTelemetryRecords`. The Lambda console attaches it when you enable tracing; with infrastructure as code, attach it yourself.

CDK TypeScript

```
import { Function, Runtime, Code, Tracing } from 'aws-cdk-lib/aws-lambda';

new Function(this, 'CheckoutFn', {
  runtime: Runtime.PYTHON_3_12,
  handler: 'app.handler',
  code: Code.fromAsset('lambda'),
  tracing: Tracing.ACTIVE,   // adds AWSXRayDaemonWriteAccess to the role
});
```

Terraform

```
resource "aws_lambda_function" "checkout" {
  function_name = "checkout"
  handler       = "app.handler"
  runtime       = "python3.12"
  role          = aws_iam_role.checkout_exec.arn
  filename      = "lambda.zip"

  tracing_config {
    mode = "Active"
  }
}

resource "aws_iam_role_policy_attachment" "xray" {
  role       = aws_iam_role.checkout_exec.name
  policy_arn = "arn:aws:iam::aws:policy/AWSXRayDaemonWriteAccess"
}
```

CloudFormation

```
Resources:
  CheckoutFn:
    Type: AWS::Lambda::Function
    Properties:
      TracingConfig:
        Mode: Active
      # Handler, Runtime, Role, Code …

  # AWS SAM (AWS::Serverless::Function):
  #   Properties:
  #     Tracing: Active
```

CDK Python

Set the function's tracing mode to `ACTIVE` (`aws_lambda.Tracing.ACTIVE` in Python, `Tracing.ACTIVE` in Java). The CDK `Function` construct adds `AWSXRayDaemonWriteAccess` to the execution role when tracing is active.

Step 2: Add the trace SDK

Attach the AWS Distro for OpenTelemetry (ADOT) Lambda layer for your runtime and set `AWS_LAMBDA_EXEC_WRAPPER` so the layer auto-instruments the handler with no code change, then enrich the active span in your code.

> **Important**
>
> The ADOT layer ARN is Region-, runtime-, and version-specific. Look up the current ARN for your Region and runtime in the ADOT Lambda documentation; do not copy one from another example. Attach it the same way you enabled tracing: `--layers` with the CLI, `layers` in CDK and Terraform, `Layers` in CloudFormation and SAM.

Python

```
# Attach the ADOT Python Lambda layer, then set the exec wrapper:
AWS_LAMBDA_EXEC_WRAPPER=/opt/otel-instrument
```

app.py

```
from opentelemetry import trace

def handler(event, context):
    span = trace.get_current_span()
    span.set_attribute("cart.items", len(event.get("items", [])))
    return {"statusCode": 200, "body": "ok"}
```

Node.js

```
# Attach the ADOT JavaScript Lambda layer, then set the exec wrapper:
AWS_LAMBDA_EXEC_WRAPPER=/opt/otel-handler
```

index.js

```
const { trace } = require('@opentelemetry/api');

exports.handler = async (event) => {
  trace.getActiveSpan()?.setAttribute('cart.items', (event.items ?? []).length);
  return { statusCode: 200, body: 'ok' };
```

```
};
```

Java

```
# Attach the ADOT Java Lambda layer, then set the exec wrapper:
AWS_LAMBDA_EXEC_WRAPPER=/opt/otel-handler   # auto-instrumentation agent
# For the SDK-only wrapper, use /opt/otel-proxy-handler
```

Handler.java

```
import io.opentelemetry.api.trace.Span;

public APIGatewayProxyResponseEvent handleRequest(APIGatewayProxyRequestEvent event,
 Context context) {
  Span.current().setAttribute("cart.items", event.getBody().length());
  return new APIGatewayProxyResponseEvent().withStatusCode(200);
}
```

.NET

There is no auto-instrumentation exec wrapper layer for .NET; configure the OpenTelemetry .NET SDK in code. Build a TracerProvider with the OTLP exporter at process start, and wrap the handler body in a span.

Function.cs

```
using System.Diagnostics;
using OpenTelemetry;
using OpenTelemetry.Trace;

// Build once, outside the handler, so it is reused across invocations:
static readonly TracerProvider Tp = Sdk.CreateTracerProviderBuilder()
    .AddSource("checkout").AddOtlpExporter().Build();
static readonly ActivitySource Source = new("checkout");

public APIGatewayProxyResponse Handler(APIGatewayProxyRequest req, ILambdaContext
 ctx)
{
    using var activity = Source.StartActivity("place_order");
    activity?.SetTag("cart.items", req.Body?.Length ?? 0);
    return new APIGatewayProxyResponse { StatusCode = 200, Body = "ok" };
}
```

Step 3: Emit structured logs

Structured log example (Python shown; the same fields apply in every language)

```
import json, logging
from opentelemetry import trace

log = logging.getLogger()

def handler(event, context):
    ctx = trace.get_current_span().get_span_context()
    log.info(json.dumps({
        "msg": "order placed",
        "requestId": context.aws_request_id,
        "trace_id": format(ctx.trace_id, "032x"),
        "items": len(event.get("items", [])),
    }))
    return {"statusCode": 200, "body": "ok"}
```

- Lambda delivers standard output and error to the log group `/aws/lambda/<my-function>`.
- Set the function's log format to JSON (`LoggingConfig.LogFormat = JSON`, or **Logging configuration** in the console) so records are structured and you can change the application log level without a code change.
- Include `requestId` and `trace_id` in every record so log lines join their spans.
- `AWSLambdaBasicExecutionRole` covers log delivery.

Step 4: Verify

Invoke the function, then open your space and choose **Trace Explorer**. A trace for the invocation shows the `AWS::Lambda` and `AWS::Lambda::Function` segments with your handler span beneath them, within about five minutes. In **Application map**, the function appears as a service, and its request, error, and duration metrics are span metrics generated from every exported span. They reflect all invocations, not only sampled ones. In the log group `/aws/lambda/<my-function>`, the JSON records carry the `trace_id` of the trace you just viewed.

> **Note**
>
> When a traced caller invokes the function, such as an API Gateway stage with tracing enabled, the function's spans join the caller's trace. When the caller is not traced, no tracing

header arrives and Lambda decides not to sample the invocation, but Transaction Search still captures the invocation's spans, because it is unaffected by the sampled flag in the trace context. Enable tracing on whatever invokes the function to get one end-to-end trace.

Troubleshoot missing telemetry

Symptom	Cause and fix
No traces at all	Tracing mode is `PassThrough` . Set it to `Active` and confirm the execution role has `AWSXRayDaemonWriteAccess` .
Service segments appear, but no handler spans	The layer is not attached, is the wrong Region or runtime, or `AWS_LAMBDA_EXEC_WR APPER` is unset or wrong for the runtime.
Traces are intermittent or isolated	The caller is not traced, so no sampling decision propagates inbound and the function's spans are not connected to an upstream trace. Enable tracing on whatever invokes the function, such as the API Gateway stage; Transaction Search captures the spans either way.
Logs do not join traces	The log format is not JSON, or records omit `trace_id`. Set the log format to JSON and include the trace ID as shown in Step 3.
Traces exist but are not searchable	Transaction Search was enabled after the traces were sent. Enable it, then invoke again.
Only some invocations appear in the trace list	Transaction Search indexes only a sampled subset of spans for the trace list; all spans are stored. Raise the indexing percentage in Transaction Search settings.

Send AI agent telemetry

Add OpenTelemetry tracing to an AI agent written in Python or Node.js with LangGraph, LangChain, Strands Agents, CrewAI, OpenAI Agents, or the Vercel AI SDK, then run it on Amazon Bedrock AgentCore, AWS Lambda, or on your own compute (Amazon EC2, Amazon ECS, or Amazon EKS) so that its traces reach CloudWatch. CloudWatch Omni reads the model calls, tool calls, and orchestration steps from those traces to analyze and evaluate the agent. On AgentCore, the runtime exports the traces for you; on other compute, the agent exports them directly, as shown in Step 2.

If you are monitoring an application or service instead, see Send application telemetry. For the endpoints and authentication that every path uses, see "Choose an endpoint" in Send telemetry to CloudWatch Omni.

Step 2 shows one environment at a time: expand the section for where your agent runs (Amazon Bedrock AgentCore, AWS Lambda, Amazon EC2, Amazon ECS, or Amazon EKS).

Choose how to instrument

Three approaches lead to the same instrumented agent. Choose the first that fits how you work; this page is the manual path.

Approach	What happens	Where to go
AI coding assistant (default in the console)	Your coding agent installs the Omni skills from the Agent Toolkit for AWS, reads your repository, makes the changes on this page for you, and runs the verification.	the section called “Use Omni skills”
IDE extension	The CloudWatch Omni extension for Visual Studio Code and Kiro detects your framework, applies the instrumentation, and shows traces in the editor as you develop.	the section called “Develop with the IDE extension”

Approach	What happens	Where to go
Manually	You install a library, set environment variables where your agent runs, and verify in your space. Every command is on this page.	Continue below.

Prerequisites

- **Transaction Search is enabled** in the account and Region that receive traces. Traces sent before it is enabled are not searchable. See Transaction Search. On AgentCore, the administrator part of Step 2 enables it if it is not.
- Your agent is written in **Python** or **Node.js**, and its framework is in Supported environments, languages, and frameworks.
- On **AgentCore**, you can change the runtime's environment variables, and you or an administrator can edit its execution role.
- On **AWS Lambda or your own compute**, you must attach the AWS managed policy AWSXrayWriteOnlyAccess to the role your compute uses. For the endpoints, see "Choose an endpoint" in Send telemetry to CloudWatch Omni.

Step 1: Install an instrumentation library

Choose your agent's language in the tabs. The choice applies to every code sample on this page and is remembered on the other pages in this guide. Then choose one of the two libraries; both export the same OTLP traces to CloudWatch and differ in what the spans contain. Zero-code instrumentation covers the frameworks and languages in Supported environments, languages, and frameworks.

Library	What you get	Choose it when
OpenTelemetry distribution (recommended)	The AWS Distro for OpenTelemetry auto-inst ruments model and tool calls with no code changes	You want the least code and standard semantic conventio ns, or your framework and language pair is listed only

Library	What you get	Choose it when
	and records them as spans with `gen_ai.*` attributes. Frameworks with built-in OpenTelemetry tracing, such as Strands Agents, need no extra wiring.	under the distribution in the section called "Supported environments, languages, and frameworks".
OpenInference	Your framework's OpenInference instrumentor runs on top of the distribution. Spans are framework-native: `AGENT`, `LLM`, and `TOOL` span kinds with structured input and output.	You want framework-native spans and can add a package and, for some frameworks, a few lines of startup code.

Important

On startup, the distribution registers the global tracer provider. OpenTelemetry uses only the first provider registered, so do not create another tracer provider or exporter. Attach instrumentors, processors, and custom spans to the distribution's provider, as shown in every snippet on this page.

OpenTelemetry distribution (recommended)

Python

```
pip install "aws-opentelemetry-distro>=0.20.0"
```

Node.js

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation@">=0.13.0"
```

OpenInference

OpenInference is optional. Choose it if you want its framework spans and accept the additional packages and, for some frameworks, startup code. Otherwise, use the OpenTelemetry distribution setup in the previous section.

Install the packages shown, and add any **startup code** to a module that your entry point imports first, before the agent is created. Every install command includes the distribution, so this path does not also need the previous section.

LangGraph

Python

```
pip install "aws-opentelemetry-distro>=0.20.0" openinference-instrumentation-
langchain
```

- No startup code is needed. Invoke the graph after startup, not at import time.

Node.js

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation@">=0.13.0"
 @opentelemetry/api @arizeai/openinference-instrumentation-langchain @langchain/
core@">=1.0.0" @langchain/openai langchain zod
```

agent.ts

```
import { trace } from "@opentelemetry/api";
import { LangChainInstrumentation } from "@arizeai/openinference-instrumentation-
langchain";
import * as CallbackManager from "@langchain/core/callbacks/manager";
import { ChatOpenAI } from "@langchain/openai";
import { createAgent, tool } from "langchain";
import * as z from "zod";

const instrumentation = new LangChainInstrumentation({
  tracerProvider: trace.getTracerProvider(),
});
instrumentation.manuallyInstrument(CallbackManager);

const getWeather = tool(
```

```
  ({ city }) => `The weather in ${city} is sunny.`,
  {
    name: "get_weather",
    description: "Get the weather for a city",
    schema: z.object({ city: z.string() }),
  },
);

const agent = createAgent({
  model: new ChatOpenAI({ model: "gpt-4o-mini" }),
  tools: [getWeather],
});

const result = await agent.invoke({
  messages: [{ role: "user", content: "What is the weather in Seattle?" }],
});
console.log(result.messages.at(-1)?.content);
```

- Requires `@langchain/core` 1.0.0 or later.
- `manuallyInstrument(CallbackManager)` is required for ESM. It attaches OpenInference to the distribution's global tracer provider; do not create another provider or exporter.
- At startup, the distribution attempts to detect another instrumentation library for the same framework and disables its own. If detection fails, add `aws_langchain` to `OTEL_NODE_DISABLED_INSTRUMENTATIONS` so the distribution's instrumentation does not run alongside OpenInference. If the variable is not already set, use `OTEL_NODE_DISABLED_INSTRUMENTATIONS=fs,dns,aws_langchain`.

Strands Agents

Python

```
pip install "aws-opentelemetry-distro>=0.20.0" openinference-instrumentation-
strands-agents
```

tracing.py

```
from opentelemetry import trace
from strands.telemetry import StrandsTelemetry
from openinference.instrumentation.strands_agents import
 StrandsAgentsToOpenInferenceProcessor
```

```
current = trace.get_tracer_provider()
StrandsTelemetry(tracer_provider=current)
current.add_span_processor(StrandsAgentsToOpenInferenceProcessor())
```

- Pass the distribution's provider into `StrandsTelemetry`. A provider that `StrandsTelemetry` creates itself is orphaned and never exports.
- Use this path or the plain distribution, not both. Strands' native tracer occupies the instrumentation point, so the OpenInference processor is inert when native tracing is already active.

Node.js

Use the OpenTelemetry distribution; Strands' built-in OpenTelemetry tracing needs no extra wiring.

CrewAI

CrewAI is Python only.

```
pip install "aws-opentelemetry-distro>=0.20.0" openinference-instrumentation-crewai
 "crewai[bedrock]>=1.10.1" "setuptools<81"
```

- No startup code is needed.
- Set `CREWAI_DISABLE_TELEMETRY=true` where the agent runs.
- `crewai` earlier than 1.10.1 emits no spans.

OpenAI Agents

Python

```
pip install "aws-opentelemetry-distro>=0.20.0" openinference-instrumentation-openai-
agents
```

- No startup code is needed.
- Remove any `set_tracing_disabled(True)` call from your code. While the built-in tracer is disabled, the instrumentor receives no spans.

Node.js

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation@">=0.13.0"
 @arizeai/openinference-instrumentation-openai-agents
```

agent.ts

```
import * as agents from "@openai/agents";
import { trace } from "@opentelemetry/api";
import { OpenAIAgentsInstrumentation } from "@arizeai/openinference-instrumentation-
openai-agents";

const instrumentation = new OpenAIAgentsInstrumentation({
  tracerProvider: trace.getTracerProvider(),
});
instrumentation.manuallyInstrument(agents);

const agent = new agents.Agent({
  name: "Assistant",
  instructions: "You are a helpful assistant.",
});

const result = await agents.run(agent, "What is the capital of France?");
console.log(result.finalOutput);
```

- At startup, the distribution attempts to detect another instrumentation library for the same framework and disables its own. If detection fails, add `aws_openai_agents` to `OTEL_NODE_DISABLED_INSTRUMENTATIONS` so the distribution's instrumentation does not run alongside OpenInference. If the variable is not already set, use `OTEL_NODE_DISABLED_INSTRUMENTATIONS=fs,dns,aws_openai_agents`.

Vercel AI SDK

The Vercel AI SDK is Node.js only. Use the OpenTelemetry distribution:

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation@">=0.13.0" ai @ai-
sdk/amazon-bedrock
```

Step 2: Run your agent and deliver its traces

Expand the section for where your agent runs. Each one ends at Step 3.

Start the agent with instrumentation

The distribution must load before your application. AgentCore starter toolkit images configure startup automatically. Use these instructions for custom AgentCore images and your own compute.

Python

```
AGENT_OBSERVABILITY_ENABLED=true \
AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true \
OTEL_PYTHON_DISTRO=aws_distro \
OTEL_PYTHON_CONFIGURATOR=aws_configurator \
OTEL_RESOURCE_ATTRIBUTES="service.name=<agent-
name>,deployment.environment.name=<stage>,aws.log.group.names=<your-custom-log-
group>" \
OTEL_EXPORTER_OTLP_TRACES_HEADERS="x-aws-log-group=<your-custom-log-group>,x-aws-
log-stream=<your-custom-log-stream>" \
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
OTEL_TRACES_EXPORTER=otlp \
OTEL_LOGS_EXPORTER=none \
OTEL_METRICS_EXPORTER=none \
opentelemetry-instrument python /path/to/your/agent.py
```

Important

You must set `AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true` to keep GenAI content, including model inputs, outputs, and tool calls, on spans. If it is `false` or unset, this content is removed from spans and emitted as OpenTelemetry log events instead.

Node.js

Determine the module format from the compiled application, not the TypeScript source.

For CommonJS:

```
AGENT_OBSERVABILITY_ENABLED=true \
OTEL_RESOURCE_ATTRIBUTES="service.name=<agent-
name>,deployment.environment.name=<stage>,aws.log.group.names=<your-custom-log-
group>" \
OTEL_EXPORTER_OTLP_TRACES_HEADERS="x-aws-log-group=<your-custom-log-group>,x-aws-
log-stream=<your-custom-log-stream>" \
```

```
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
OTEL_TRACES_EXPORTER=otlp \
OTEL_LOGS_EXPORTER=none \
OTEL_METRICS_EXPORTER=none \
NODE_OPTIONS="--require=@aws/aws-distro-opentelemetry-node-autoinstrumentation/
register" \
node /path/to/your/agent.js
```

For ESM:

```
AGENT_OBSERVABILITY_ENABLED=true \
OTEL_RESOURCE_ATTRIBUTES="service.name=<agent-
name>,deployment.environment.name=<stage>,aws.log.group.names=<your-custom-log-
group>" \
OTEL_EXPORTER_OTLP_TRACES_HEADERS="x-aws-log-group=<your-custom-log-group>,x-aws-
log-stream=<your-custom-log-stream>" \
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
OTEL_TRACES_EXPORTER=otlp \
OTEL_LOGS_EXPORTER=none \
OTEL_METRICS_EXPORTER=none \
NODE_OPTIONS="--experimental-loader=@opentelemetry/instrumentation/hook.mjs --
import=@aws/aws-distro-opentelemetry-node-autoinstrumentation/register" \
node /path/to/your/agent.js
```

Replace `/path/to/your/agent.js` with your compiled entry point. For more ESM startup options, see Using the zero-code option with `@opentelemetry/auto-instrumentations-node`.

Sampling

Sampling determines which traces are recorded and exported.

For the complete list of supported sampler configurations, see https://opentelemetry.io/docs/languages/sdk-configuration/general/#otel_traces_sampler.

We recommend leaving `OTEL_TRACES_SAMPLER` unset. By default, the distribution traces every request that starts at your agent. When a request comes from another traced service, your agent follows that service's decision. Tracing every request keeps metrics that are calculated from spans, such as token usage, accurate.

You can record fewer traces to match your traffic and telemetry requirements, at the cost of incomplete or inaccurate agent metrics. Set the sampler on the service where requests start. For example, if requests start at your hosted agent, you can configure ratio-based sampling:

```
export OTEL_TRACES_SAMPLER=parentbased_traceidratio
export OTEL_TRACES_SAMPLER_ARG=0.9
```

Approximately 90 percent of incoming requests then generate and export traces.

AgentCore

On Amazon Bedrock AgentCore, the runtime exports your agent's spans to CloudWatch; there is no collector to run. Two people are usually involved: the developer sets environment variables on the runtime with every deployment, and an administrator enables trace delivery and grants the runtime role permission once for the account and Region.

Configure the runtime (developer, every deployment)

Set these environment variables on the AgentCore runtime:

```
AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true
```

- `AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true` keeps prompt and response text in the spans, which **Agent traces** and evaluators read. For production redaction and who can read kept content, see the section called “Protect sensitive data”.
- If you build your own container image, its command must start the agent under the OpenTelemetry launcher, as shown in the Amazon EC2, ECS, and EKS sections of Step 2. Images built by the AgentCore starter toolkit do this already.

With the AgentCore starter toolkit:

```
agentcore deploy \
  --env AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true
```

- `--env` is repeatable, and its values are not persisted, so pass them on every deployment.
- The toolkit sets `AGENT_OBSERVABILITY_ENABLED` for you; do not pass it with `--env`.

With infrastructure as code, this is the environment block for the runtime resource. AgentCore Runtime injects `AGENT_OBSERVABILITY_ENABLED=true`. When the AWS Distro for OpenTelemetry starts, that flag configures the trace-export defaults, including `OTEL_TRACES_EXPORTER=otlp`, `OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf`, and the regional X-Ray OTLP endpoint. Do not duplicate those managed defaults in the runtime resource; the only variable to set here is the content-extraction opt-out. The name and value are identical across tooling; only the syntax changes.

CDK TypeScript

```
environmentVariables: {
  AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT: "true",
}
```

CDK Python

```
environment_variables={
    "AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT": "true",
}
```

Terraform

```
environment_variables = {
  AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT = "true"
}
```

CloudFormation

```
EnvironmentVariables:
  AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT: "true"
```

Enable trace delivery and grant permissions (administrator, once per account and Region)

AgentCore delivers spans through the account's trace destination, which is the setting Transaction Search turns on. If Transaction Search is not enabled, set the destination:

```
aws xray update-trace-segment-destination --destination CloudWatchLogs --region
 <region>
```

- The change takes effect after about 10 minutes.

> **Note**
>
> You must configure the AgentCore Runtime execution role with the required telemetry permissions. See Execution role for running an agent in AgentCore Runtime.

- A runtime deployed from a container image also needs permission to pull the image from Amazon ECR.

Continue to Step 3.

AWS Lambda

We recommend the latest OpenTelemetry distribution Lambda layer. For the latest ARN for your language and AWS Region, see Lambda layer ARNs. To use a specific version, select the Lambda layer ARN listed in the Python release notes or JavaScript release notes on the GitHub website. Follow the layer instructions to attach it and configure its execution wrapper. Then set the following environment variables.

Python

```
AGENT_OBSERVABILITY_ENABLED=true
AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true
OTEL_PYTHON_DISTRO=aws_distro
OTEL_PYTHON_CONFIGURATOR=aws_configurator
OTEL_PYTHON_DISABLED_INSTRUMENTATIONS=none
OTEL_AWS_APPLICATION_SIGNALS_ENABLED=false
OTEL_EXPORTER_OTLP_TRACES_HEADERS=x-aws-log-group=<your-custom-log-group>,x-aws-log-
stream=<your-custom-log-stream>
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_TRACES_EXPORTER=otlp
OTEL_LOGS_EXPORTER=none
OTEL_METRICS_EXPORTER=none
```

The Python Lambda layer enables a limited set of instrumentations by default to reduce cold-start duration. `OTEL_PYTHON_DISABLED_INSTRUMENTATIONS=none` enables the agent framework instrumentations, but can increase cold-start duration.

Node.js

```
AGENT_OBSERVABILITY_ENABLED=true
OTEL_AWS_APPLICATION_SIGNALS_ENABLED=false
OTEL_EXPORTER_OTLP_TRACES_HEADERS=x-aws-log-group=<your-custom-log-group>,x-aws-log-
stream=<your-custom-log-stream>
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_TRACES_EXPORTER=otlp
OTEL_LOGS_EXPORTER=none
OTEL_METRICS_EXPORTER=none
```

If you chose the OpenTelemetry distribution, set `OTEL_NODE_ENABLED_INSTRUMENTATIONS` for your framework. The layer enables only `aws-sdk`, `aws-lambda`, and `http` by default, and it appends `aws-lambda` and `http` to any value you set, so do not include them:

Framework	OTEL_NODE_ENABLED_INSTRUMENTATIONS
LangGraph or LangChain	`aws-sdk,undici,aws_langchain`
OpenAI Agents	`aws-sdk,undici,aws_openai_agents`
Vercel AI SDK	`aws-sdk,undici,aws_vercel_ai`
Strands Agents	Leave unset. Strands Agents emits spans through the tracer provider the layer starts.

With OpenInference, leave `OTEL_NODE_ENABLED_INSTRUMENTATIONS` unset. Install and initialize the OpenInference instrumentor before creating your agent, as shown in Step 1.

Note

You must attach the AWS managed policy AWSXrayWriteOnlyAccess to the function's execution role so that the exporter can send traces to X-Ray.

> **Important**
>
> **Custom trace destination requires a resource policy.** If you set `OTEL_EXPORTER_OTLP_TRACES_HEADERS` to deliver spans to your own log group, you must also add an Amazon CloudWatch Logs resource policy. The policy must allow X-Ray (`xray.amazonaws.com`) to call `logs:PutLogEvents` on that log group. Use the same policy shown in Enabling CloudWatch Transaction Search, with your log group's ARN in `Resource`. Without this policy, X-Ray cannot deliver spans to your log group.

Continue to Step 3.

Amazon EC2

On Amazon EC2, the instance role signs the traces.

Start the agent with its environment

Put the variables in the agent's systemd unit (`Environment=` lines) or start script, and make the launcher the unit's command.

Python

```
AGENT_OBSERVABILITY_ENABLED=true
AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true
OTEL_PYTHON_DISTRO=aws_distro
OTEL_PYTHON_CONFIGURATOR=aws_configurator
OTEL_RESOURCE_ATTRIBUTES=service.name=<agent-
name>,deployment.environment.name=<stage>,aws.log.group.names=<your-custom-log-
group>
OTEL_EXPORTER_OTLP_TRACES_HEADERS=x-aws-log-group=<your-custom-log-group>,x-aws-log-
stream=<your-custom-log-stream>
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_TRACES_EXPORTER=otlp
OTEL_LOGS_EXPORTER=none
OTEL_METRICS_EXPORTER=none
```

Node.js

```
AGENT_OBSERVABILITY_ENABLED=true
```

```
OTEL_RESOURCE_ATTRIBUTES=service.name=<agent-
name>,deployment.environment.name=<stage>,aws.log.group.names=<your-custom-log-
group>
OTEL_EXPORTER_OTLP_TRACES_HEADERS=x-aws-log-group=<your-custom-log-group>,x-aws-log-
stream=<your-custom-log-stream>
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_TRACES_EXPORTER=otlp
OTEL_LOGS_EXPORTER=none
OTEL_METRICS_EXPORTER=none
```

- Node.js captures GenAI message content (model payloads and tool responses) by default; `AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT` is not required.

Note

You must attach the AWS managed policy AWSXrayWriteOnlyAccess to the instance role so that the exporter can send traces to X-Ray.

Important

Custom trace destination requires a resource policy. If you set `OTEL_EXPORTER_OTLP_TRACES_HEADERS` to deliver spans to your own log group, you must also add an Amazon CloudWatch Logs resource policy. The policy must allow X-Ray (`xray.amazonaws.com`) to call `logs:PutLogEvents` on that log group. Use the same policy shown in Enabling CloudWatch Transaction Search, with your log group's ARN in `Resource`. Without this policy, X-Ray cannot deliver spans to your log group.

Continue to Step 3.

Amazon ECS

On Amazon ECS, the task role signs the traces.

Start the agent with its environment

Put the variables in the `environment` block of the agent's container definition, and make the launcher the container's command.

Python

```
AGENT_OBSERVABILITY_ENABLED=true
AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true
OTEL_PYTHON_DISTRO=aws_distro
OTEL_PYTHON_CONFIGURATOR=aws_configurator
OTEL_RESOURCE_ATTRIBUTES=service.name=<agent-
name>,deployment.environment.name=<stage>,aws.log.group.names=<your-custom-log-
group>
OTEL_EXPORTER_OTLP_TRACES_HEADERS=x-aws-log-group=<your-custom-log-group>,x-aws-log-
stream=<your-custom-log-stream>
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_TRACES_EXPORTER=otlp
OTEL_LOGS_EXPORTER=none
OTEL_METRICS_EXPORTER=none
```

Node.js

```
AGENT_OBSERVABILITY_ENABLED=true
OTEL_RESOURCE_ATTRIBUTES=service.name=<agent-
name>,deployment.environment.name=<stage>,aws.log.group.names=<your-custom-log-
group>
OTEL_EXPORTER_OTLP_TRACES_HEADERS=x-aws-log-group=<your-custom-log-group>,x-aws-log-
stream=<your-custom-log-stream>
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_TRACES_EXPORTER=otlp
OTEL_LOGS_EXPORTER=none
OTEL_METRICS_EXPORTER=none
```

- Node.js captures GenAI message content (model payloads and tool responses) by default; `AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT` is not required.

Note

You must attach the AWS managed policy AWSXrayWriteOnlyAccess to the task role so that the exporter can send traces to X-Ray.

Important

Custom trace destination requires a resource policy. If you set `OTEL_EXPORTER_OTLP_TRACES_HEADERS` to deliver spans to your own log group, you must also add an Amazon CloudWatch Logs resource policy. The policy must allow X-Ray (`xray.amazonaws.com`) to call `logs:PutLogEvents` on that log group. Use the same policy shown in Enabling CloudWatch Transaction Search, with your log group's ARN in `Resource`. Without this policy, X-Ray cannot deliver spans to your log group.

Continue to Step 3.

Amazon EKS

On Amazon EKS, the pod's service account role signs the traces.

Start the agent with its environment

Put the variables in the `env` block of the agent's container in the pod spec, and make the launcher the container's command.

Python

```
AGENT_OBSERVABILITY_ENABLED=true
AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true
OTEL_PYTHON_DISTRO=aws_distro
OTEL_PYTHON_CONFIGURATOR=aws_configurator
OTEL_RESOURCE_ATTRIBUTES=service.name=<agent-
name>,deployment.environment.name=<stage>,aws.log.group.names=<your-custom-log-
group>
OTEL_EXPORTER_OTLP_TRACES_HEADERS=x-aws-log-group=<your-custom-log-group>,x-aws-log-
stream=<your-custom-log-stream>
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_TRACES_EXPORTER=otlp
OTEL_LOGS_EXPORTER=none
OTEL_METRICS_EXPORTER=none
```

Node.js

```
AGENT_OBSERVABILITY_ENABLED=true
```

```
OTEL_RESOURCE_ATTRIBUTES=service.name=<agent-
name>,deployment.environment.name=<stage>,aws.log.group.names=<your-custom-log-
group>
OTEL_EXPORTER_OTLP_TRACES_HEADERS=x-aws-log-group=<your-custom-log-group>,x-aws-log-
stream=<your-custom-log-stream>
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
OTEL_TRACES_EXPORTER=otlp
OTEL_LOGS_EXPORTER=none
OTEL_METRICS_EXPORTER=none
```

- Set the log group and log stream in `OTEL_EXPORTER_OTLP_TRACES_HEADERS` to the destination you want the spans written to.
- Node.js captures GenAI message content (model payloads and tool responses) by default; `AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT` is not required.
- The pod's service account must have a role through Pod Identity or IRSA; without one the SDK falls back to the node role, which usually lacks the permission below.

Note

You must attach the AWS managed policy AWSXrayWriteOnlyAccess to the pod's service account role so that the exporter can send traces to X-Ray.

Important

Custom trace destination requires a resource policy. If you set `OTEL_EXPORTER_OTLP_TRACES_HEADERS` to deliver spans to your own log group, you must also add an Amazon CloudWatch Logs resource policy. The policy must allow X-Ray (`xray.amazonaws.com`) to call `logs:PutLogEvents` on that log group. Use the same policy shown in Enabling CloudWatch Transaction Search, with your log group's ARN in `Resource`. Without this policy, X-Ray cannot deliver spans to your log group.

Continue to Step 3.

Step 3: Verify

Use the console's automated verification. In your space, open **Settings › Ingestion** and choose your source: the **Add source** flow's verification step invokes the check for you. It confirms that traces are arriving and that they carry the agent, model, and tool spans CloudWatch Omni reads, and it identifies the failing setting when they do not. Run it after every deployment change.

If verification fails, see the "Troubleshoot missing traces" section of this page.

Verify manually

Traces arrive. Invoke your agent, then open your space and choose **Agent traces**. A trace for the invocation appears within about five minutes. On AgentCore, if the list is empty, check the log group `/aws/bedrock-agentcore/runtimes/<agent-id>-<endpoint-name>` (`<agent-id>-DEFAULT` for the default endpoint), where the runtime writes a `spans` stream; on your own compute, check the log group you set in `OTEL_EXPORTER_OTLP_TRACES_HEADERS`, or the shared `aws/spans` log group if that variable is not set. Transaction Search indexes 1 percent of spans by default for the trace list, so not every invocation is listed until you raise the indexing percentage; the spans themselves are all stored.

The trace is complete. Open the trace. A correctly instrumented agent shows an agent span with non-empty input and output and a child span for each model call and each tool call. With OpenInference, the spans carry `AGENT`, `LLM`, and `TOOL` kinds; with the OpenTelemetry distribution alone, the model calls carry `gen_ai.*` attributes. On AgentCore, the runtime's invoke span is the root and your agent's spans sit beneath it. If prompt and response text is blank, see the section called “Protect sensitive data”.

> **Note**
>
> A successful invocation does not mean that traces arrived. Check for the agent, model, and tool spans, not only for an HTTP 200.

After verification passes, the agent appears in **Agents** in your space, and you can continue to the section called “Analyze agent behavior”.

Troubleshoot missing traces

The following table lists common troubleshooting steps for missing or incomplete traces.

What you see	What to check
No spans are created	**Auto-instrumentation did not start.** Verify that the distribution and required instrumentation packages are installed in the application's runtime environment and that the application uses the documented startup command. Instrumentation must initialize before the agent framework is imported. For Python, also check package-manager environments, development reloaders, and pre-fork workers. For Node.js, verify the CommonJS or ESM preload configuration and confirm that the instrumentation is not disabled. Do not create another tracer provider or exporter. Temporarily use `OTEL_TRACES_EXPORTER=console,otlp` for Python or `OTEL_LOG_LEVEL=debug` for Node.js to inspect startup.
HTTP spans appear, but agent, model, or tool spans do not	Verify that the framework and instrumentation versions are supported and that the corresponding instrumentation package is installed and enabled. Confirm that it is not listed in `OTEL_PYTHON_DISABLED_INSTRUMENTATIONS` or `OTEL_NODE_DISABLED_INSTRUMENTATIONS`. OpenInference startup code must run before the agent is created.
Duplicate agent, model, or tool spans appear	Two equivalent instrumentations may be active. The distribution attempts to detect equivalent instrumentation at startup. If detection fails, add the corresponding AWS instrumentation, such as `aws_langchain`

What you see	What to check
	or `aws_openai_agents` , to `OTEL_NODE_DISABLED_INSTRUMENTATIONS` .
Spans are created locally but do not reach CloudWatch	Verify `OTEL_TRACES_EXPORTER` , `OTEL_EXPORTER_OTLP_PROTOCOL` , the OTLP endpoint, and `OTEL_EXPORTER_OTLP_TRACES_HEADERS` . Check exporter errors and network connectivity. On AWS Lambda, Amazon EC2, Amazon ECS, or Amazon EKS, verify that the compute role has AWSXrayWriteOnlyAccess. On AgentCore, verify the execution-role permissions described in the AgentCore section.
The exporter returns `404`	`OTEL_EXPORTER_OTLP_ENDPOINT` automatically appends `/v1/traces` . If the configured value already includes that path, use `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` instead so the path is not appended twice.
Only the AgentCore runtime invocation span appears	AgentCore telemetry is working, but application auto-instrumentation did not start. Follow the checks in the first row. For a custom image, start the application under `opentelemetry-instrument` or the Node.js register hook. AgentCore enables agent observability, and the distribution derives the OTLP trace-export settings; you do not need to set `OTEL_TRACES_EXPORTER` on the runtime resource.

What you see	What to check
Spans reach the log group but do not appear under **Agent traces**	Verify that Transaction Search is enabled and that the trace destination is CloudWatch Logs. Traces sent before Transaction Search was enabled are not searchable. After changing the destination, wait 10 minutes and invoke the agent again.
Only some requests have traces	Check the caller's sampling decision. Unless the agent is the root service, leave `OTEL_TRACES_SAMPLER` unset so it follows the parent trace.
Prompt, response, or tool content is blank	Set `AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT=true` to keep model payloads and tool request/response data on spans. If content is still missing, verify that the framework instrumentation captures it and that the application does not redact it.

For additional runtime-specific issues, see Troubleshooting Python automatic instrumentation, JavaScript zero-code instrumentation, and JavaScript zero-code configuration.

Supported environments, languages, and frameworks

The environments, languages, and frameworks with a documented path for sending telemetry to CloudWatch Omni.

Environments

Environment	Workload	How telemetry leaves	Signals	Deployment tooling documented	Procedure
Amazon EC2	Applications, AI agents	Applications: CloudWatc	Applications: traces,	AWS CLI, CDK (TypeScri	Applications · AI agents

Environment	Workload	How telemetry leaves	Signals	Deployment tooling documented	Procedure
		h agent on the host. AI agents: direct export from the ADOT SDK.	metrics, logs. AI agents: traces.	pt, Python, Java), Terraform, CloudFormation	
Amazon ECS (Fargate)	Applications, AI agents	Applications: CloudWatch agent sidecar. AI agents: direct export from the ADOT SDK.	Applications: traces, metrics, logs. AI agents: traces.	AWS CLI, CDK (TypeScript, Python, Java), Terraform, CloudFormation	Applications · AI agents
Amazon EKS	Applications, AI agents	Applications: CloudWatch Observability add-on (agent DaemonSet). AI agents: direct export from the ADOT SDK.	Applications: traces, metrics, logs. AI agents: traces.	AWS CLI, Terraform, or CDK for the add-on; kubectl, Helm, or CDK for the application	Applications · AI agents

Environment	Workload	How telemetry leaves	Signals	Deployment tooling documented	Procedure
AWS Lambda	Applications, AI agents	Applications: Lambda delivers segments and logs itself; the ADOT layer adds handler spans. AI agents: the ADOT layer starts the OpenTelemetry runtime and the execution role signs trace exports.	Applications: traces, logs. AI agents: traces.	AWS CLI, CDK (TypeScript, Python, Java), Terraform, CloudFormation, AWS SAM	Applications · AI agents
Amazon Bedrock AgentCore	AI agents	The runtime exports traces.	Traces	AgentCore starter toolkit, CDK (TypeScript, Python), Terraform, CloudFormation	AI agents

Environment	Workload	How telemetry leaves	Signals	Deployment tooling documented	Procedure
Azure VM	Applications	CloudWatch agent on the VM, credentials federated from the VM's managed identity.	Traces, metrics, logs	Azure setup script	Applications
Azure Kubernetes Service	Applications	CloudWatch Observability Helm chart, credentials federated from workload identity.	Traces, metrics, logs	Helm, kubectl	Applications
Google Compute Engine	Applications	CloudWatch agent on the instance, credentials federated from the instance's service account.	Traces, metrics, logs	Google Cloud setup script	Applications

Environment	Workload	How telemetry leaves	Signals	Deployment tooling documented	Procedure
Google Kubernetes Engine	Applications	CloudWatch Observability Helm chart, credentials federated from the cluster's OIDC issuer.	Traces, metrics, logs	Helm, kubectl	Applications

Application languages and frameworks

Language	Auto-instrumentation	Frameworks with documented notes	Procedure
Python	`opentelemetry-instrument` launcher	FastAPI, Flask, Django	Step 4, Python tab
Node.js	`@opentelemetry/auto-instrumentations-node` register hook	Express, gRPC	Step 4, Node.js tab
Java	OpenTelemetry Java agent (`-javaagent`)	Spring Boot, gRPC	Step 4, Java tab
.NET	Automatic instrumentation profiler for ASP.NET Core and gRPC services; SDK	ASP.NET Core, gRPC	Step 4, .NET tab

Language	Auto-instrumentation	Frameworks with documented notes	Procedure
	in code for console applications		
Go	Go has no agent. Initialize the SDK in code and add library instrumentation, such as `otelhttp` or `otelgrpc`.	net/http, gRPC	Step 4, Go tab

- Any of these languages works in any environment in the Environments table. For Python, Node.js, Java, and .NET, the listed frameworks are traced without code changes. For Go, wrap them with the library instrumentation shown in Step 4 of Send application telemetry. Other libraries may be covered by the OpenTelemetry registry for the language.

AI agent languages and frameworks

Each language column lists the libraries documented for that framework: the OpenTelemetry distribution, and the OpenInference instrumentor where one exists. The distribution is required on both paths and is documented for Python and Node.js only: AWS Distro for OpenTelemetry 0.20.0 or later for Python, 0.13.0 or later for Node.js.

Framework	Python	Node.js	Recommended versions	Notes
LangGraph, LangChain	OpenTelemetry · OpenInference	OpenTelemetry · OpenInference	Python: `langchain >=0.3.21, <2` Node.js: `@langchain/core >=1.0.0,< 2.0.0`	Traces through the LangChain instrumentor. Python is zero-code; Node.js needs startup code.

Framework	Python	Node.js	Recommended versions	Notes
Strands Agents	OpenTelemetry · OpenInference	OpenTelemetry	We recommend using the latest available Strands Agents version.	Built-in OpenTelemetry tracing on both languages, so the distribution needs no wiring: the SDK creates the agent, model, and tool spans itself. The Python OpenInference path attaches a span processor to the distribut ion's provider. Use one tracing path, not both, or the processor is inert.
CrewAI	OpenTelemetry · OpenInference	—	`crewai >=1.10.0,<2`	CrewAI is Python only. Zero-code. Requires `setuptool s<81` and `CREWAI_DI SABLE_TEL EMETRY=tr ue .`

Framework	Python	Node.js	Recommended versions	Notes
OpenAI Agents	OpenTelemetry · OpenInference	OpenTelemetry · OpenInference	Python: `openai-agents >=0.3.3,< 1` Node.js: `@openai/agents-core >=0.1.0`	Python is zero-code once `set_tracing_disabled(True)` is removed. On Node.js, registering the instrumentation is not sufficient: the instrumentor attaches through the framework's own tracing processor, so you must also pass the imported SDK namespace to `manuallyInstrument`. Without that call, the agent creates no spans.

Framework	Python	Node.js	Recommended versions	Notes
Vercel AI SDK	—	OpenTelemetry	`ai >=3.3.0,< 7.0.0`	The Vercel AI SDK is Node.js only. The SDK emits its spans automatic ally once the distribution's provider is registered; no per-call telemetry flag is needed. Registering an OpenInference span processor has no effect on this path.

Ask the Omni agent

The Omni agent is the AI assistant built into the CloudWatch Omni web UI. Ask about your systems in plain language, and the agent answers from the telemetry available to it: it writes and runs queries, correlates signals across telemetry, and builds views and dashboards on demand.

> **Note**
>
> CloudWatch Omni supports AI agents on three surfaces. This page covers the agent in the Omni web UI. For AI assistance while developing an AI agent in the IDE extension, see the section called “Develop with the IDE extension”. To use Omni from your own coding agent, see the section called “Use Omni skills”. The Omni agent can also delegate an investigation to the AWS DevOps Agent. See the section called “Investigate with the AWS DevOps Agent”.

Where you can ask

Ask from the input on the Omni home page, or open the chat panel in any thread. Each conversation is saved as a thread you can return to and rename. See the section called “Threads”.

The agent can read what you have open on screen, so you can ask about "this alert" or "the service I'm looking at" without naming it. The agent runs long tasks, such as investigations and dashboard builds, in the background, and you can track them on the **Task Shelf**.

With the Slack integration connected, you can also have the agent respond to your team's Slack conversations. See the section called “Connect Slack”.

What you can ask

The agent can do the same work as the pages in the web UI. Some examples, by task:

To do this	Example prompts
Query your telemetry	"Show me the 5xx errors on checkout-service in the last hour" · "Which services logged timeout errors today?"
Check on something	"How is payment-api doing?" · "Is anything firing right now?"
Investigate a problem	"Why is checkout-service slow?" · "Dig into the errors on orders-api"
Work with Omni alerts	"Alert me when p99 latency on checkout-service stays above 2 seconds" · "Change that alert's threshold to 3 seconds"
Build dashboards	"Build a dashboard for the payment service" · "Save this investigation as a dashboard"
Understand dependencies	"What depends on the orders database?" · "What does checkout-service call?"
Measure AI agent quality	"Score yesterday's traces for correctness" · "Turn these failing traces into a dataset"

To do this	Example prompts
Run commands	"/settings" opens the Settings page. Type "/" to see available commands.

Queries. When the agent writes a query for you, it shows the exact query it ran, so you can check it, refine it, or run it yourself in Explore. For the query syntax, see the section called “Explore and query your telemetry”.

Investigations. A status question gets a quick lookup. When you ask why something is broken, the agent runs a multi-step investigation: it checks for anomalies, maps the services involved, and gathers evidence across your telemetry, then reports the likely cause with the concrete numbers and log lines behind it. It proposes the next step, and you choose the direction. You can also start an investigation from a service page. See the section called “Monitor a service”.

Alerts. The agent creates Omni alerts, not CloudWatch alarms. It can create an alert from a plain-language condition, change an existing one, and answer questions about the alerts you have. Creating and changing are deliberate: the agent grounds the threshold in your data, shows you the specific alert it intends to create or change, and acts only after you confirm. It does not delete alerts. Manage them on the Alerts page. See the section called “Alerts”.

Dashboards. Describe the dashboard you want and the agent composes it in your thread, where you can refine it section by section and save it. It can also turn a finished investigation into a dashboard. See the section called “Dashboards”.

AI agent quality. For the AI agents you monitor, the agent can score traces with your evaluators and add traces to an evaluation dataset — for example, packaging failing runs into a regression set. See the section called “Evaluate agent quality”.

How the agent works with you

Answers are grounded in your live data: the agent re-checks current state rather than answering from earlier conversation, and when a lookup returns nothing, it says so instead of guessing. It also remembers durable context across your threads, such as the services and Regions you work with, so you do not re-explain your environment in every conversation.

The agent is scoped to observability. It declines unrelated work, such as general coding tasks, and offers to help with your telemetry instead.

Limitations

- It reads only your space and your own conversations. It cannot read another person's threads.
- It creates and changes alerts with your confirmation, but never deletes them, and it cannot rename an alert. You delete an alert yourself on the **Alerts** page.
- It can be wrong. It shows its queries and evidence so you can verify. Check both before acting on a finding, and use the feedback controls on a response to rate it.

Permissions and data access

The agent works with your permissions: it can read only the telemetry you have access to (the space's logs and traces, plus metrics queried from CloudWatch Metrics). Its permissions are the same as yours in the Omni web UI. Actions that change something, such as creating an alert, always require your confirmation in the conversation. For permission levels, see the section called "Control access to your space".

Investigations with the AWS DevOps Agent

If your space is connected to the AWS DevOps Agent, the Omni agent automatically delegates root cause analysis to it, and you can track the investigation's progress from the conversation. The investigation runs with the permissions of the DevOps Agent, not yours. It can read CloudWatch Logs log groups directly, and your data scope does not filter its results. See the section called "Investigate with the AWS DevOps Agent".

Investigate with the AWS DevOps Agent

CloudWatch Omni uses AWS DevOps Agent as the native agent for root cause analysis and incident investigation. You must link CloudWatch Omni to a DevOps Agent space before you can start an investigation.

AWS DevOps Agent is an autonomous site reliability engineering (SRE) agent that supports release management and production operations across AWS, multi-cloud, and on-premises environments. For more information, see the DevOps Agent documentation.

Important

Trust boundary and data access

AWS DevOps Agent and CloudWatch Omni operate under different trust boundaries. DevOps Agent investigates with the IAM role on its agent space. You configure this role in the AWS DevOps Agent console. DevOps Agent does not use your space's operator role, the CloudWatch Omni managed policies, or your members' grants. DevOps Agent reads CloudWatch Logs log groups and other sources directly, not through the CloudWatch Dataset. CloudWatch Omni then displays the results.
Data scopes apply only to data read from the CloudWatch Dataset. They do not filter AWS DevOps Agent investigation results or any other data that comes from outside the Dataset.
Any member whose grant includes the AWS DevOps Agent read actions can see every investigation for a connected agent space. This includes investigations that other members started. The read actions are `aidevops:GetBacklogTask`, `aidevops:ListBacklogTasks`, and `aidevops:ListJournalRecords`. The Viewer, Editor, and Space Admin permission levels all include these actions. Connecting an agent space is the access control for this integration. Connect only an agent space whose IAM role reaches data that every member of the space can already see.
Only a Space Admin can connect, change, or remove the DevOps Agent integration. For more information about permission levels, see the section called “Control access to your space”.

Connect an agent space

Deploy DevOps Agent

- A DevOps Agent space must exist in the account you are accessing CloudWatch Omni from. To create one, see Creating an agent space in the AWS DevOps Agent User Guide.

Note

Sign-in must match. If your Omni domain uses IAM Identity Center, configure your DevOps Agent space to use IAM Identity Center as well.

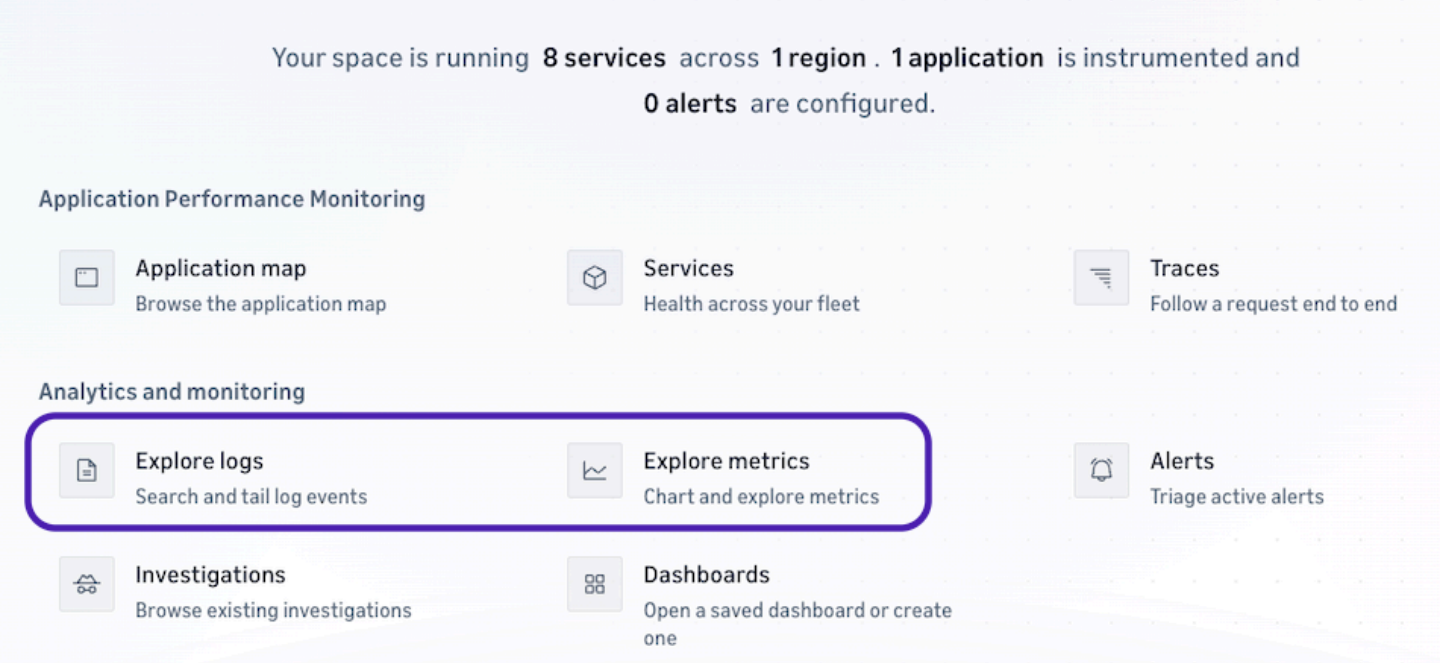
Connect Omni to DevOps Agent

Before you connect, a space administrator must attach the AIDevOpsAgentFullAccess managed policy to your space's operator role. See the section called “Set up Omni”.

1. In CloudWatch Omni, navigate to **Settings** → **Integrations** → **AWS DevOps Agent**. Choose **Select Space**.
2. Choose the Region your agent space is in. Select your agent space. Choose **Connect**.

Start an investigation

- **From the Omni agent.** Describe the symptom in a thread and ask for an investigation. Omni automatically delegates questions related to root cause analysis to DevOps Agent.
- **With the `/investigation` command.** In a thread, enter `/investigation new <description of issue>`.
- **From an alert.** A firing alert offers an **Investigate** action. Investigations are manual: an alert never starts one automatically when it fires.



Explore and query your telemetry

Explore is where you query your telemetry directly. For how telemetry reaches your space, see the section called "Send telemetry to CloudWatch Omni". Everything in your space (logs, metrics, and traces) is queryable from one surface, so an investigation can move from a chart into the raw records behind it without changing tools. The other web UI views answer predetermined questions; Explore answers the questions you write yourself.

> **Note**
>
> You query in two languages, split by signal: **CloudWatch Omni SQL** for logs and traces, and **PromQL** (Prometheus Query Language) for metrics. The split holds everywhere you write a query in Omni. An alert condition uses the same two languages (see the section called "Alerts"), and when the Omni agent writes a query for you, it is one you can open and run here (see the section called "Ask the Omni agent").

Run your first query

1. In the navigation, choose **Explore logs** or **Explore metrics**.

1. Choose a telemetry source: **Logs**, **Metrics**, or **Traces**. The navigation entry sets the initial source, and you can switch to any of the three here. The editor opens with a runnable starter query for the source you choose.
2. Write the query in **Builder**, the query editor's guided composer, or switch the **Builder / Code** toggle to enter the query text directly. Builder shows sections for a SQL query, and a tree of metrics, labels, and functions for PromQL.
3. (Optional) Expand the fields on the Browse panel, and select a combination of values to apply as predicates for a targeted query.
4. Read the results below the editor: a table for logs and traces, with a histogram of the result distribution above it, and a line chart for metrics. You can switch the visualization and adjust its options.

You can also describe what you want in natural language and let Omni draft the query for you, then edit and run it like any other. For what the Omni agent can do beyond query drafting, see the section called “Ask the Omni agent”.

Query logs and traces with SQL

A SQL query addresses a signal through its table name: `"logs.default"`, `"traces.default"`. Each result row also carries system fields: `@timestamp` for time filtering, and `@record`, a JSON document holding the fully parsed telemetry record. Quote system field names in backticks:

```
SELECT `@timestamp`, `@record`
FROM "logs.default"
WHERE `@timestamp` BETWEEN now() - INTERVAL '1' DAY AND now()
LIMIT 500
```

By default, the time range you select in Explore applies to your query. You can also bound time explicitly with a `@timestamp` condition, as shown in the preceding example.

Both logs and traces are stored in the same Dataset, so a single query can cover both. Running a query against the `"default"` Dataset looks up a trace by ID across multiple applications and agents.

```
SELECT `@timestamp`, `@record`
FROM "default"
WHERE traceId = '<trace-id>'
LIMIT 100
```

For how application and agent traces relate, see the section called “Monitor a service”.

For the language itself (supported syntax, case sensitivity, bounding time across a join, and unsupported syntax), see the section called “SQL query reference”.

Query metrics with PromQL

For the language and how CloudWatch metrics support it, see Query metrics with PromQL and Running PromQL queries in Query Studio in the Amazon CloudWatch User Guide. **Builder** composes the expression — pick a metric, narrow by label values, and apply functions — or switch to **Code** and write the expression directly. In the Browse panel you can select label values before choosing a metric, and the metric list narrows to the metrics that carry them.

Discover fields

Fields differ across sources. For whichever signal you are querying (logs or traces), the Browse panel aggregates fields from all sources of that type, so you see every field in your current signal in one place. The field list and each field's values narrow to the rows matching your current query, so selecting a value tightens the query and the field list together.

For metrics, the Browse panel lists metrics and their labels instead of fields, and you can select label values to narrow the metric list.

To ask the same question in the query text instead, see the section called “SQL query reference”.

Work with results

In the results table, you can resize, reorder, and hide columns, filter the rows, highlight keywords, and export the results. For metrics, you can adjust the chart's legend and display options, and you can change the visualization type for any result.

CloudWatch Omni SQL limits

- If you do not set `LIMIT`, results are capped at 10,000 rows. Set an explicit `LIMIT` for a known row count, up to a maximum of 100,000.
- Results are paginated: each page returns up to 1,000 rows; page through the rest with the next-page token (`nextToken` on the API).
- A query string can be up to 64,000 characters.
- A query times out after 60 minutes.

Act on what you find

- **Alert on it.** An Omni alert takes a query as its condition, in the same two languages. You can start an alert directly from the query you ran. See the section called “Alerts”.
- **Keep it on a dashboard.** Save the view so the query and its visualization become a shared panel. See the section called “Dashboards”.
- **Hand it to the agent.** Ask the Omni agent to investigate what the query surfaced. See the section called “Ask the Omni agent”.
- **Automate it.** Run the same query from your own tooling through the public API, on a schedule or as part of a workflow.

SQL query reference

CloudWatch Omni supports SQL for querying logs and traces. This page covers CloudWatch Omni SQL: the supported syntax and the behaviors that differ from other SQL dialects. To build SQL queries interactively, use Explore. See the section called “Explore and query your telemetry”.

SQL is the same language wherever you write a query in Omni: in Explore, in an alert condition, and through the public API.

Tables to query

A query addresses a signal through its table in your space's CloudWatch Dataset. The Dataset is named `default`:

FROM table	Reads
`logs.default`	Log records only.
`traces.default`	Traces only — both application spans and AI agent spans.
`default`	Logs and traces in one query. Use this when you do not know which signal holds the field you want.

Prefer a concrete signal type whenever possible. Such queries are faster because they do not scan other signals' data.

System fields

Every row carries system fields alongside the fields your telemetry brought with it: `@timestamp`, `@ingest_time`, and `@telemetry_type` on every signal, and `@message` on log records. The `@entity`, `@data_source_name`, `@data_source_type`, `@data_format`, `@aws.region`, `@aws.account`, `@logGroupId`, `@logGroupName`, `@logStream`, and `@logStreamId` system fields are also supported.

Quote any field name that is not a plain identifier: one with a leading `@`, a dot, or a hyphen. Backticks and double quotes both work:

```
SELECT `@timestamp`, `@message`
FROM "logs.default"
WHERE `@timestamp` BETWEEN NOW() - INTERVAL '1' DAY AND NOW()
LIMIT 500
```

Quoting decides whether Omni reads a token as a column or as text:

- Backticks and double quotes mark an **identifier**. `` ` status ` `` and `"status"` both name the column `status`.

- Single quotes mark a **string literal**. `'ERROR'` is the text ERROR.
- Brackets look up a key inside an attribute map, and the key is always a string literal, so it takes single quotes: `attributes['http.status_code']`.

Because double quotes are an identifier, `WHERE status = "ERROR"` compares the `status` column against a column named ERROR, not against the text ERROR. Write `WHERE status = 'ERROR'` instead.

Field names are case sensitive: `traceId` and `traceid` are not interchangeable.

What a wildcard SELECT returns

Because the Dataset contains records from different sources, each can have a different set of fields. That is why `SELECT *` does not project all fields as columns. It returns two columns representing a full record: `@timestamp` and `@record` — a JSON document holding the fields your telemetry brought with it. System fields are not part of `@record`; select them by name.

```
@timestamp                  | @record
2026-08-26T18:04:11.230Z    | {"request_id":"abc-123","path":"/api/auth/
login","status_code":500, ...}
```

Name the fields you want as columns:

```
SELECT
  request_id,
  path,
  status_code
FROM "logs.default"
WHERE `@timestamp` >= NOW() - INTERVAL '15' MINUTE
```

You can filter on a field whether or not you select it, so `WHERE path = '/api/auth/login'` works under `SELECT *`. Only the projection changes, not what you can reference.

`@record` is an output column only. It cannot feed a function, a comparison, `WHERE`, `GROUP BY`, `ORDER BY`, or a join condition. Name the field you want instead.

`@message` is a system field that holds the raw record. It is useful for unstructured records, where Omni cannot extract any columns and `@record` is empty (`{}`).

Nested attributes

Read into an attribute map with bracket syntax:

```
SELECT
  attributes['http.status_code'],
  resource['attributes']['service.name']
FROM "traces.default"
WHERE `@timestamp` >= NOW() - INTERVAL '1' HOUR
```

Bracket syntax accepts only string literals as the key, so use single quotes for subscript access. Dots within the string literal are allowed when they are part of the key name, for example `'service.name'`.

Column types

No schema is required for a Dataset in Omni. Omni SQL identifies the correct type from the query itself and applies it automatically. For example, when a `WHERE` filter compares against a numeric value such as `WHERE latency > 100`, values are cast to the appropriate type.

A Dataset may contain records from different sources with different fields. The same field name may appear with different types. For example, `status` may hold enumeration values in some records (`OK`, `ERROR`) and numeric values in others (0, 1). In such cases, Omni selects the most appropriate type to execute the query correctly.

In ambiguous cases, use the `CAST` operator.

Time filtering

The time range you select in Explore automatically applies to your query. You can also bound time in the query text with a `@timestamp` condition, using `BETWEEN` or comparison operators, and `NOW()` with `INTERVAL` arithmetic. A `@timestamp` condition in the query takes precedence over the range selected in Explore. Other timestamp functions are also supported.

In a join, bound each table separately. A condition on one side does not constrain the other, so a join with a single bound reads the whole retention window on the unbounded side:

```
SELECT a.request_id, a.path, b.user_id
FROM "logs.default" a
JOIN "logs.default" b ON a.request_id = b.request_id
WHERE a.`@timestamp` >= NOW() - INTERVAL '1' HOUR
```

```
  AND a.`@timestamp` <= NOW()
  AND b.`@timestamp` >= NOW() - INTERVAL '1' HOUR
  AND b.`@timestamp` <= NOW()
```

Discover fields

Wrap any query in `EXPLAIN (ANALYZE_FIELDS)` to get one row per field observed in the rows that query selects, instead of the data rows:

```
EXPLAIN (ANALYZE_FIELDS)
SELECT *
FROM "logs.default"
WHERE `@timestamp` >= NOW() - INTERVAL '1' HOUR
LIMIT 500
```

Your conditions, time bounds, and `LIMIT` all apply, so you can ask which fields appear on one service's error logs in the last hour rather than which fields exist anywhere. the section called "Explore and query your telemetry" covers how the Browse panel runs this for you.

`EXPLAIN (ANALYZE_FIELDS)` is not billed or metered: it samples a bounded slice of your data, so you can run it freely to explore a Dataset's fields.

Supported and unsupported syntax

CloudWatch Omni SQL supports the constructs this page demonstrates — `SELECT` with `WHERE`, `GROUP BY`, `ORDER BY`, and `LIMIT`, joins, and aggregate functions with `FILTER` — as well as window functions, `UNION` and `UNION ALL`, and `CAST`. `EXPLAIN (ANALYZE_FIELDS)` is the only supported form of `EXPLAIN`.

The engine rejects unsupported statements before they run, returning an unsupported-statement error rather than an empty result, so you can distinguish a rejected query from one that matched nothing.

Examples

Slowest agent runs in the last hour. Each span's duration is the difference between its `startTimeUnixNano` and `endTimeUnixNano`, and the agent's name comes from its resource attributes:

```
SELECT
```

```
  resource['attributes']['service.name'] AS agent,
  `@timestamp`,
  (endTimeUnixNano - startTimeUnixNano) AS duration_ns
FROM traces.default
WHERE `@timestamp` >= NOW() - INTERVAL '1' HOUR
ORDER BY duration_ns DESC
LIMIT 20
```

Error rate by service. Counting over a grouped select:

```
SELECT resource['attributes']['service.name'] AS service,
       COUNT(*) AS spans,
       COUNT(*) FILTER (WHERE status['code'] IN ('2', 'ERROR')) AS errors
FROM traces.default
WHERE `@timestamp` >= NOW() - INTERVAL '1' HOUR
GROUP BY resource['attributes']['service.name']
ORDER BY errors DESC
```

One request across an application and an agent. Both carry the same trace ID when context propagates:

```
SELECT *
FROM "traces.default"
WHERE
  `@timestamp` >= NOW() - INTERVAL '1' HOUR
  AND traceId = '<trace-id>'
```

Next steps

- To build a query interactively, see the section called “Explore and query your telemetry”.
- To alert on a query result, see the section called “Alerts”.
- To put a query on a dashboard, see the section called “Dashboards”.

Dashboards

A dashboard is a saved arrangement of panels (charts, tables, maps, and text) that shows your team one agreed view of a system. Most panels are backed by a query against your space's telemetry. Build one per audience: a service's health for its on-call, an agent fleet's quality trends for its owners, a cross-signal view for an operations review.

> **Note**
>
> Omni dashboards are separate from the dashboards in the CloudWatch console. Your existing CloudWatch dashboards keep working unchanged (see *CloudWatch Omni*).

Every dashboard is shared

Every dashboard belongs to your space, and every member of the space can see it. Name dashboards so others can find them.

Pages and dashboards

You build and edit on a **page**, the live working surface on a canvas with a shared time range where you arrange related panels. Saving a page makes it a dashboard. Opening a saved dashboard gives you a working copy on a fresh page: you can rearrange and experiment without changing what the rest of the team sees. When you save, you choose whether to update the original — this is how you edit a shared dashboard — or keep your version as a new dashboard. Omni saves your editing progress as you work, so if you are signed out you can resume in your most recent thread.

What goes on a dashboard

Any view you work with in the Omni web UI is a panel, and application and agent telemetry mix on the same dashboard: a service's request charts next to its agent's quality trends. Panels include query visualizations from Explore, the application map and service views, trace and session views, alert status, agent fleet and evaluation views, and text panels for notes. For the query languages behind query-backed panels, see the section called “Explore and query your telemetry”.

Create a dashboard

You can create a dashboard in three ways, depending on where you start:

- **Save the view you are in.** From any page, choose **Save** in the toolbar. An Explore query or an investigation's working view becomes a shared dashboard.
- **Start in the Dashboards page.** Choose **Create dashboard**, then start from an empty canvas or a starter template, and add panels.

- **Describe it.** Ask the Omni agent to build a dashboard from a plain-language description, or to turn a finished investigation into one, then refine and save the result. See the section called “Ask the Omni agent”.

Manage your dashboards

The **Dashboards** page lists every dashboard in the space. From it you can open or delete a dashboard, and search the list.

> ⚠ **Deletion is permanent**
>
> Deleting a dashboard is permanent and removes it for everyone in the space.

Threads

A thread is your workspace in the CloudWatch Omni web UI: a conversation with the Omni agent together with the canvases, tabs, and views you open while you work. Omni saves the whole thread as you work — not only the chat — so you can close the browser mid-investigation and resume where you left off, on any device where you sign in to your space. Keep one thread per problem.

What a thread holds

- **The conversation.** Your exchange with the Omni agent, including the queries it ran and the evidence behind its answers.
- **Canvases and tabs.** The views you open while investigating (charts, log tables, maps, trace views), arranged on canvases, across as many tabs as you need.
- **History.** Every canvas you visit in a thread is kept in order, so you can step back through the investigation.
- **Investigations.** An investigation starts in a thread, and that thread is marked in your threads list so you can find the investigation again later. An investigation is not locked to that thread. You can open it from another thread, and the Investigations list can show investigations from all your Omni threads.

Start a thread

Choose **New thread** in the sidebar or on the **Threads** page. Asking from the input on the Omni home page also starts a thread.

You can also start from a finding instead of a blank page: choose **Investigate** on an alert, or select an anomalous range on a chart and choose **Investigate this signal**. The investigation runs in a thread, with the finding as its starting context. For what the agent can do in the conversation and how an investigation works, see the section called “Ask the Omni agent”.

Manage your threads

The **Threads** page lists your threads, and the sidebar shows the recent ones. Omni names a thread from the conversation; rename it to something your team would search for. From the list you can:

- **Resume** a thread to continue working in it.
- **Rename** or **Delete** a thread. Deleting cannot be undone, and you always keep at least one thread.
- **Search** your threads by name.

Collaborate and share

To share work from a thread, use a dashboard or a link:

- **Save a canvas as a dashboard.** The durable way to share an investigation's view: every member of the space can open a dashboard. See the section called “Dashboards”.
- **Copy a canvas or panel link.** From a canvas or panel menu, copy its URL. The link carries the view, not the conversation. Opening it adds that view to the current thread.

Alerts

An alert monitors your telemetry and notifies you when it crosses a threshold you set. You write a query to select what to monitor, set a condition that compares the query result against a threshold, and choose how often CloudWatch Omni evaluates it. When the condition is met, CloudWatch Omni sends a notification to the destinations you specify. Alerts read the same telemetry as the rest of CloudWatch Omni, so one alerting system covers both your applications and your AI agents: error rates and latency alongside evaluation scores and token usage.

> **Note**
>
> Omni alerts are separate from CloudWatch alarms. Your existing CloudWatch alarms keep working unchanged, and you manage them in the CloudWatch console. See *CloudWatch Omni*.

Alert query

An alert monitors the results of a query that you provide. You write the query in the same languages you use in CloudWatch Omni: SQL for logs and traces, and PromQL for metrics. You can alert on anything you can query in Explore. Start from a query you have already run there.

Thresholds and alert states

Each evaluation compares the query result against a threshold. You set a warning threshold, a critical threshold, or both. A single alert carries both tiers: a result that crosses the warning threshold puts the alert in the `WARNING` state, and a result that crosses the critical threshold escalates it to `CRITICAL`. At any moment an alert is in one of four states: `OK`, `WARNING`, `CRITICAL`, or `NODATA` (the last when the query returned nothing to evaluate). You choose how missing data is treated (as breaching at a state you set, or not), so a pipeline that stops sending data can itself raise the alert.

A threshold applies to either the values a query returns or the number of rows it returns. You choose which comparison the alert makes when you set the threshold.

- **Field value** — the alert reads a column that you name from each row the query returns and compares that value against the threshold.
- **Row count** — the alert compares the number of rows the query returned and reads no column. Use this to alert on how many items match a condition.

Evaluation timing

Three settings control when the alert changes state:

- **Evaluation interval** — how often the query runs.
- **Pending duration** — how long results must stay past the threshold before the alert fires, so a single spike does not notify anyone.

- **Recovery duration** — how long results must stay clear before the alert returns to OK, so a flapping signal does not resolve and re-fire repeatedly.

One alert, many series

When the query returns one result per service, agent, or other grouping, the alert tracks each series as a **contributor** with its own state. The alert's state reflects its worst contributors, and its detail view shows which series are breaching. One alert monitors a whole fleet without a copy per service.

Create an alert

You can create an alert in three ways, depending on where you start:

- **From Explore.** Run the query, then create the alert directly from it: the query you ran becomes the alert's query. See the section called “Explore and query your telemetry”.
- **From the Alerts page.** Choose **Create alert**. A query editor opens in place: write and run the query, and the alert configuration form appears with a preview of your thresholds against recent data.
- **Ask the Omni agent.** Describe what you want to be alerted on in plain language. The agent bases the threshold on your data, shows you the alert it intends to create, and creates it only after you confirm. See the section called “Ask the Omni agent”.

Then name the alert, set the thresholds and evaluation timing, and add destinations. Choose the name deliberately: an alert cannot be renamed later.

Every alert also carries an **access profile** (the identity it evaluates its query and sends notifications as), and Omni selects one for you by default. You can select a different profile for finer-grained control. If an alert reports no data from the moment you create it, rather than going quiet after working, check its profile before the query. See the section called “Access profiles”.

Creating an alert requires permission to create alerts in the space and access to a profile that carries the grants below. Whichever profile the alert uses, it must carry these grants:

- Grants that allow the alert and you, its creator, to assume the profile.
- A grant that allows the query actions, `cloudwatch:StartTelemetryQuery` and `cloudwatch:GetTelemetryQueryResults`.

- If the alert notifies a Slack channel, a grant that allows the Slack integration, scoped to that channel. See the section called “Connect Slack”.

For how to author grants, see the section called “Custom grant actions”.

Send notifications

Notification rules route by state: send warning notifications to one destination and critical notifications to another, and notify on recovery to OK so the person who was notified knows the alert cleared. A destination is a Slack channel (connected through the Slack integration, see the section called “Connect Slack”) or an Amazon SNS topic.

Delivery to a Slack channel also requires that the Region's Amazon CloudWatch bot has been invited to that channel. For the invite command and the bot names by Region, see the section called “Connect Slack”.

A new alert sends nothing until you add a notification rule, and you can disable an alert's notifications without deleting it. The alert keeps evaluating and showing state.

Manage your alerts

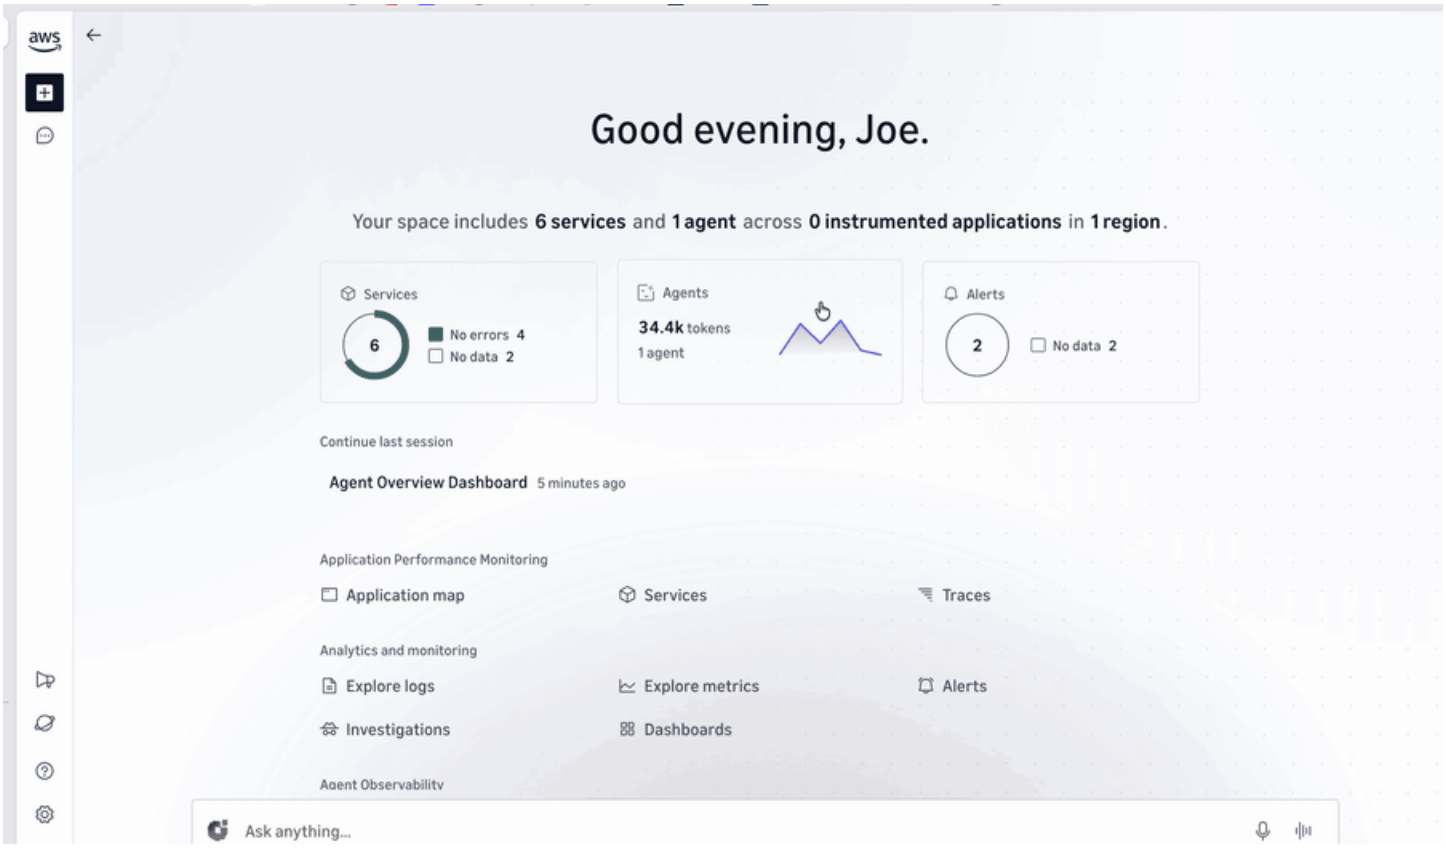
The **Alerts** page lists every alert in the space with its state and recent state changes. From the list you can open an alert's detail view (the query result charted with the thresholds drawn on it, the alert's state timeline, and its contributors), edit the alert, disable or re-enable its notifications, tag it, or delete it. Deleting cannot be undone.

Every state change, configuration change, and notification an alert sends is recorded as telemetry in your space and kept for 90 days. Query it with the same SQL you use for the rest of your telemetry (how often an alert fired last quarter, which contributors breach most often, whether a notification was delivered), and join it against your application telemetry in a single query. See the section called “Explore and query your telemetry”.

An alert evaluates against your space's CloudWatch Dataset, so it can fire on telemetry from a centralized source account. See the section called “Set up Omni for your organization”.

Investigate a firing alert

Investigations are manual: an alert never starts one automatically when it fires. When your space is connected to the AWS DevOps Agent, you start the investigation yourself from a firing alert's

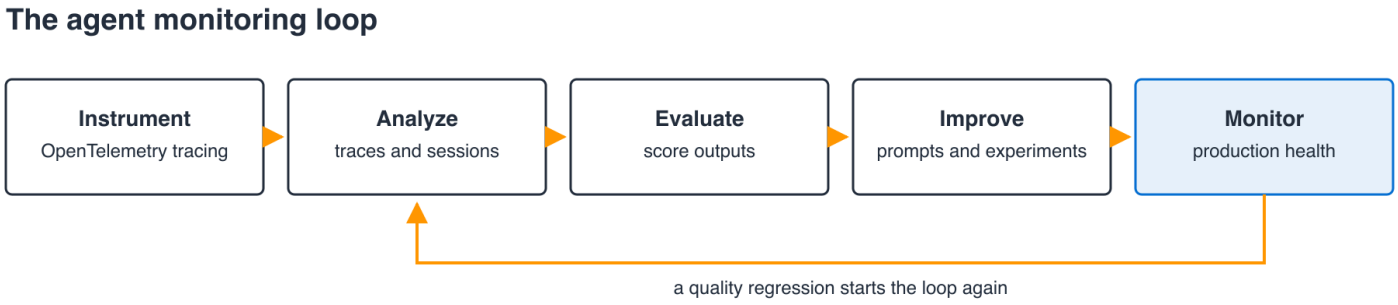


Investigate action. The investigation is scoped to that alert and seeded with the alert's context: its state and what fired. See the section called “Investigate with the AWS DevOps Agent”.

Monitor AI agents

CloudWatch Omni agent observability includes tracing, evaluations, datasets, and experiments. Agent telemetry is ingested into the same CloudWatch Omni space and CloudWatch Dataset as your other telemetry.

> **Note**
>
> **New to agent monitoring?** Follow the section called “Tutorial: Fix a production quality regression”. It starts with installing the IDE extension, then takes you through your first traces and your first evaluation.



The following animation shows the agent monitoring workflow in the Omni web UI: agent metrics and latency, evaluation scores across evaluators, per-trace evaluator detail, evaluation datasets, and a prompt playground comparison that scores two model configurations.

What you can do

- **Instrument your agent** — add OpenTelemetry tracing so agent runs arrive as traces. See the section called “Send AI agent telemetry”.
- **Analyze agent behavior** — explore traces, sessions, and the agent topology to debug failures and latency. See the section called “Analyze agent behavior”.
- **Evaluate agent quality** — score outputs with built-in or custom evaluators. These include open-source evaluators from DeepEval and AutoEval (see the section called “Evaluators and evaluations”). You can also build datasets from real runs and compare changes with experiments. See the section called “Evaluate agent quality”.
- **Develop in the IDE** — test your agent locally, manage prompts, and get AI assistance during development. See the section called “Develop with the IDE extension”.
- **Monitor in production** — track aggregate agent health. See the section called “Monitor agents in the web UI”.

The following diagram shows how these stages form a loop:

How an agent run is represented

Omni uses OpenTelemetry concepts to represent your agent's activity. OpenTelemetry is an open standard for telemetry collection. These definitions apply everywhere you work with traces in Omni, for both agents and applications.

- **Trace** — the complete record of one unit of work: a request that moves through your services, or a single agent run.
- **Span** — one step inside a trace, such as a service call, a model invocation, a tool call, or a retrieval. A span records timing, inputs and outputs, and attributes. Spans nest to show which step calls which other step.

- **Session** — a sequence of related traces that belong to the same conversation or user interaction. A session lets you follow a multi-turn exchange across several runs.

You can explore these concepts in more detail:

- Traces and spans in the section called “Agent traces”.
- Sessions, and how Omni groups traces into them, in the section called “Agent sessions”.
- How your agent's components call each other in the section called “Agent topology”.

Where to start

- **New to agent monitoring** — follow the section called “Tutorial: Fix a production quality regression”. The tutorial starts with how to install the extension. Then it takes you through your first traces and evaluations.
- **Agent already sending traces** — go directly to the section called “Analyze agent behavior” to debug runs, and to the section called “Evaluate agent quality” to measure quality.
- **Operating agents in production** — start from the section called “Monitor agents in the web UI”, and use the section called “Tutorial: Fix a production quality regression” when you find a quality regression.

Available across two surfaces

Agent monitoring is available through two surfaces that serve different workflows:

- **Omni web UI** — a production-time experience for monitoring agents, with aggregate and fleet-level views alongside trace and evaluation analysis.
- **IDE extension** — a development-time experience for the local build-test-iterate loop, including instrumenting your agent, testing it locally, managing prompts, and running experiments. The extension works in VS Code, Kiro, and Cursor.

Both surfaces connect to the same space, so the data you collect is available wherever you work. Use the IDE extension for local instrumentation and troubleshooting during development. Use the Omni web UI for production monitoring, fleet-level views, and online evaluations. The following table is the complete per-capability reference.

Feature availability by surface

Capability	Omni web UI	IDE extension
Agent traces	Yes	Yes
Agent sessions	Yes	Yes
Agent topology	Yes	Yes
Datasets	Yes	Yes
Evaluators and evaluations	Yes	Yes
Online evaluations	Yes	No
Prompt playground	Yes	Yes
Experiments	No	Yes
Prompt management and versioning	No	Yes
Test your agent locally	No	Yes
Agent-assisted instrumentation setup	No	Yes
Prompt recommendations	No	Yes
Aggregate and fleet views	Yes	No

Where your agent runs

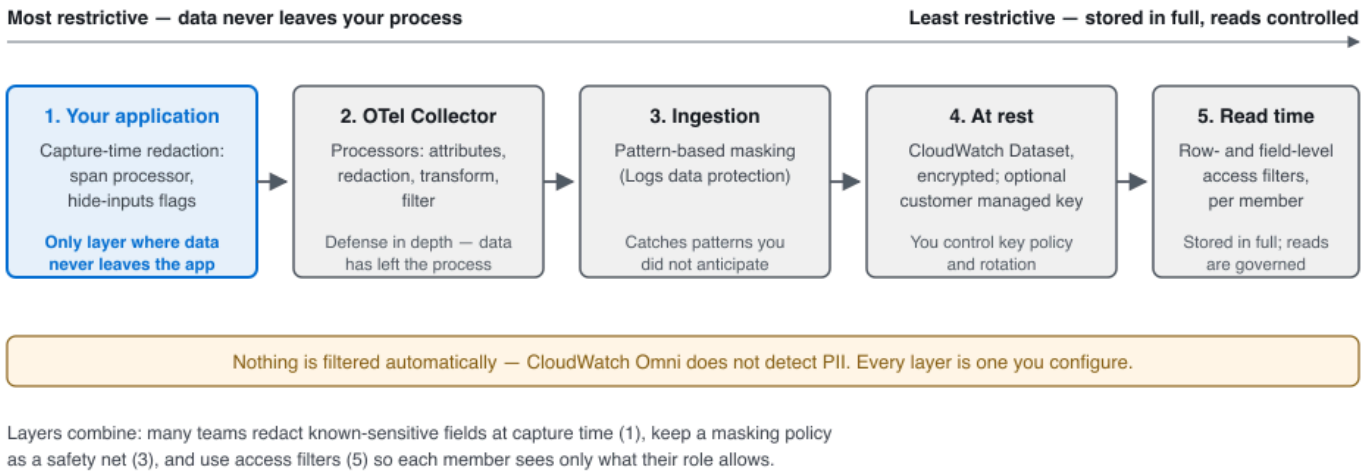
You can monitor agents wherever they run. Agents hosted on Amazon Bedrock AgentCore send traces and sessions with minimal setup (see the section called “Send AI agent telemetry”). Agents built on other frameworks or runtimes connect through OpenTelemetry instrumentation. You can also observe and evaluate agents deployed on other compute platforms, such as Amazon EC2,

Amazon ECS, Amazon EKS, and AWS Lambda. For every environment, language, and framework this supports, see the section called “Supported environments, languages, and frameworks”.

How Omni relates to AgentCore and generative AI observability

Amazon Bedrock AgentCore is a platform for building, deploying, and operating AI agents, with any framework and any foundation model. Omni works with AgentCore in two ways:

- **As a place your agents run.** Agents hosted on AgentCore Runtime send traces and sessions to CloudWatch with minimal setup, and Omni monitors them the same way it monitors agents in any other environment. See the section called “Send AI agent telemetry”.
- **As the service behind evaluations.** Omni's evaluators are served through AgentCore Evaluations: built-in, third-party, and custom evaluators come from a single catalog, and on-demand and online evaluations run through it. See the section called “Evaluators and evaluations”.



Amazon CloudWatch also provides generative AI observability in the AWS Management Console, with prebuilt views for model invocations and AgentCore agents. It is a separate experience from Omni, and both read the telemetry you ingest into CloudWatch, so an AgentCore agent's traces appear in each. Use generative AI observability for its prebuilt views. Use Omni to work in a space — agent telemetry alongside your application telemetry — and for evaluations, evaluation datasets, experiments, and the IDE extension.

Protect sensitive data

Agent telemetry can contain sensitive information: prompts and responses often include user messages, retrieved documents, and personal data. You control what is captured and who can see it. CloudWatch Omni does not automatically detect or redact personally identifiable information (PII); no data is removed unless you configure it. Choose where in the pipeline filtering happens based on your compliance requirements.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or into free-form text fields such as a **Name** field. This includes when you work with CloudWatch Omni or other AWS services using the Omni web UI, the AWS Management Console, the API, the AWS CLI, or the AWS SDKs. Any data that you enter into tags or free-form text fields used for names might be used for billing or diagnostic logs. CloudWatch Omni accepts tags on several resource types, and free-form names on spaces, grants, access profiles, dashboards, and alerts. For the resource types that accept tags, see the section called “Custom grant actions”.

You can apply controls at five points, from most restrictive to least. Each layer involves a trade-off between eliminating data and keeping it available for debugging.

Layers combine: many teams redact known-sensitive fields at capture time (1), keep a masking policy as a safety net (3), and use access filters (5) so each member sees only what their role allows.

At capture time (most restrictive)

Strip or redact fields before spans leave your application, using standard OpenTelemetry mechanisms. Sensitive data filtered here is redacted in process and never leaves your application, so this is the only layer that satisfies a requirement that the data never be exported.

`AWS_REDACT_SPAN_ATTRIBUTES` takes a comma-separated list of span attributes to redact. Matching values in spans, span events, and span links are all replaced with `REDACTED`. This applies to all span attributes, not only those from ADOT instrumentation.

```
export AWS_REDACT_SPAN_ATTRIBUTES=gen_ai.input.messages,gen_ai.output.messages
```

The variable also accepts wildcard patterns, so you can redact a group of attributes without naming each one. For example, to redact all input and output message attributes from a third-party instrumentation library:

```
export AWS_REDACT_SPAN_ATTRIBUTES='llm.input_messages.*,llm.output_messages.*'
```

Warning Redaction occurs in the agent process, before telemetry is exported. This might affect other integrations that rely on these attribute values.

`AWS_REDACT_SPAN_ATTRIBUTES` applies equally to OpenInference-instrumented agents running on Amazon Bedrock AgentCore.

To redact all prompt and response content from an agent instrumented with OpenInference, set the OpenInference environment flags before your agent starts. Content is replaced with __REDACTED__ before spans are created:

```
OPENINFERENCE_HIDE_INPUTS=True
OPENINFERENCE_HIDE_OUTPUTS=True
```

For finer control, add a custom span processor that removes specific attributes. This is standard OpenTelemetry and works with the AWS Distro for OpenTelemetry (ADOT), OpenInference, and other OpenTelemetry SDKs. The span-processor API differs by language, and the following example is Python. **JavaScript does not provide an equivalent custom span-processor approach, so we recommend the environment variable approach described above.**

```
from opentelemetry.sdk.trace import SpanProcessor, Span, ReadableSpan

class SensitiveDataRedactingProcessor(SpanProcessor):
    """Redacts sensitive attributes from spans before export."""

    REDACT_KEYS = {"gen_ai.input.messages", "gen_ai.output.messages",
                   "user.email", "http.request.header.authorization"}

    def on_start(self, span, parent_context=None):
        pass

    def _on_ending(self, span: Span):
        if not span.attributes:
            return
        redacted = {k: v for k, v in span.attributes.items()
                    if k not in self.REDACT_KEYS}
        if len(redacted) != len(span.attributes):
            span._attributes = redacted  # noqa: SLF001

    def on_end(self, span: ReadableSpan):
        pass

    def shutdown(self):
        pass

    def force_flush(self, timeout_millis=None):
        return True

# Wire up before your agent starts:
```

```
from opentelemetry import trace
provider = trace.get_tracer_provider()
provider.add_span_processor(SensitiveDataRedactingProcessor())
```

This example requires `opentelemetry-sdk` version 1.39.0 or later.

Note Capture-time redaction is irreversible. Redacted data is not available for root-cause analysis later. If a trace shows blank input and output that you expected to see, check these flags first. See the section called “Send AI agent telemetry”.

At the collector (defense in depth)

If you run an OpenTelemetry Collector, its built-in processors provide a second redaction layer before data reaches CloudWatch:

- `attributes` — remove or modify specific attributes.
- `redaction` — drop attributes that are not on an allow list.
- `transform` — replace values using regular expressions.
- `filter` — drop entire spans that match a condition.

At this layer, data has already left your application process. Use collector processors as an additional safety net. They are not sufficient on their own if your compliance model requires that data never leave your infrastructure.

For each processor's configuration, see its documentation: attributes, redaction, transform, and filter.

This layer is available wherever you run the collector yourself, for example on Amazon EC2, Amazon ECS, or Amazon EKS. If your agent runs on Amazon Bedrock AgentCore Runtime, you do not manage a collector there, so redact at capture time instead.

At ingestion: pattern-based masking

For log data in Amazon CloudWatch Logs, CloudWatch Logs data protection can detect and mask sensitive patterns, such as Social Security numbers and credit card numbers, as it is ingested. For more information, see Help protect sensitive log data with masking in the *Amazon CloudWatch Logs User Guide*.

> **Important**
>
> Log data that a CloudWatch Logs data protection policy masks stays masked in your space. It is forwarded to the CloudWatch Dataset in masked form, and Omni cannot unmask it. Unmasked values are available only in CloudWatch Logs, to principals with the `logs:Unmask` permission.

At read time: row-level data scope

Telemetry is stored in full, and a member's grant controls what their queries and views return. A grant's advanced data scope can limit a member to specific signal types (logs, traces) and to rows matching conditions on agent, service, account, or field value. Configure it when you add or edit a member. See the section called “Limit what members can see”.

At rest: encryption

Telemetry is encrypted in transit with TLS and at rest in the CloudWatch Dataset, where you can use a customer managed AWS KMS key. For the encryption model, see the section called “Data encryption in CloudWatch Omni”.

Data sent to the judge model

Evaluators that use a model as a judge send data to that model: the evaluator prompt and the trace content it evaluates go to the judge model you configure, and to the provider that serves it. If your compliance model restricts where trace content can flow, choose the judge model accordingly, or restrict evaluation to traces that do not contain sensitive content. For how evaluators work and which models you can choose, see the section called “Evaluators and evaluations”.

Choose the right layer

Requirement	Layer	Trade-off
Sensitive data must never leave the application	Capture time	Redacted data is unavailable for debugging
Extra safety net on the export path	Collector processors	Data has already left the process

Requirement	Layer	Trade-off
Catch sensitive patterns you did not anticipate	Ingestion-time masking	Data has been sent; masking depends on pattern detection
Store in full; limit which rows a member sees	Per-grant row-level data scope	Data is stored; controls govern reads
Control the encryption keys	Customer managed KMS key	You manage key policy and rotation

Analyze agent behavior

Use these views to understand what your agent did and why: to debug failures, find slow steps, and follow multi-turn conversations. They read the traces your agent sends. For the underlying concepts, see the section called “Monitor AI agents”.

- the section called “Agent traces” — inspect a single agent run, span by span.
- the section called “Agent sessions” — follow a multi-turn conversation across runs.
- the section called “Agent topology” — see how agents, tools, and models call each other.

Which view to start with

- You know which run failed. Open it in Agent traces and follow the spans.
- The problem is conversational (a user says the agent "forgot" or "went in circles"). Start in Agent sessions, which shows the agent's behavior across turns.
- You have a symptom but no specific run ("this tool fails often," "something got slow"). Filter by errors, latency, or token usage in Agent traces and Agent sessions to find the runs that show why. Use the agent topology to see how your agent's components connect.

These views focus on individual runs. For production and fleet-wide monitoring across your agents in the Omni web UI, see the section called “Monitor agents in the web UI”.

Agent traces

Use Agent traces to find the agent runs you need to inspect, open a run to see what the agent did, and act on what you find: score runs with evaluators, turn failures into dataset test cases, and compare runs side by side. A trace records one complete agent run; a span records one operation within it, such as a model invocation, a tool call, or a retrieval. For the full trace, span, and session vocabulary, see the section called “Monitor AI agents”.

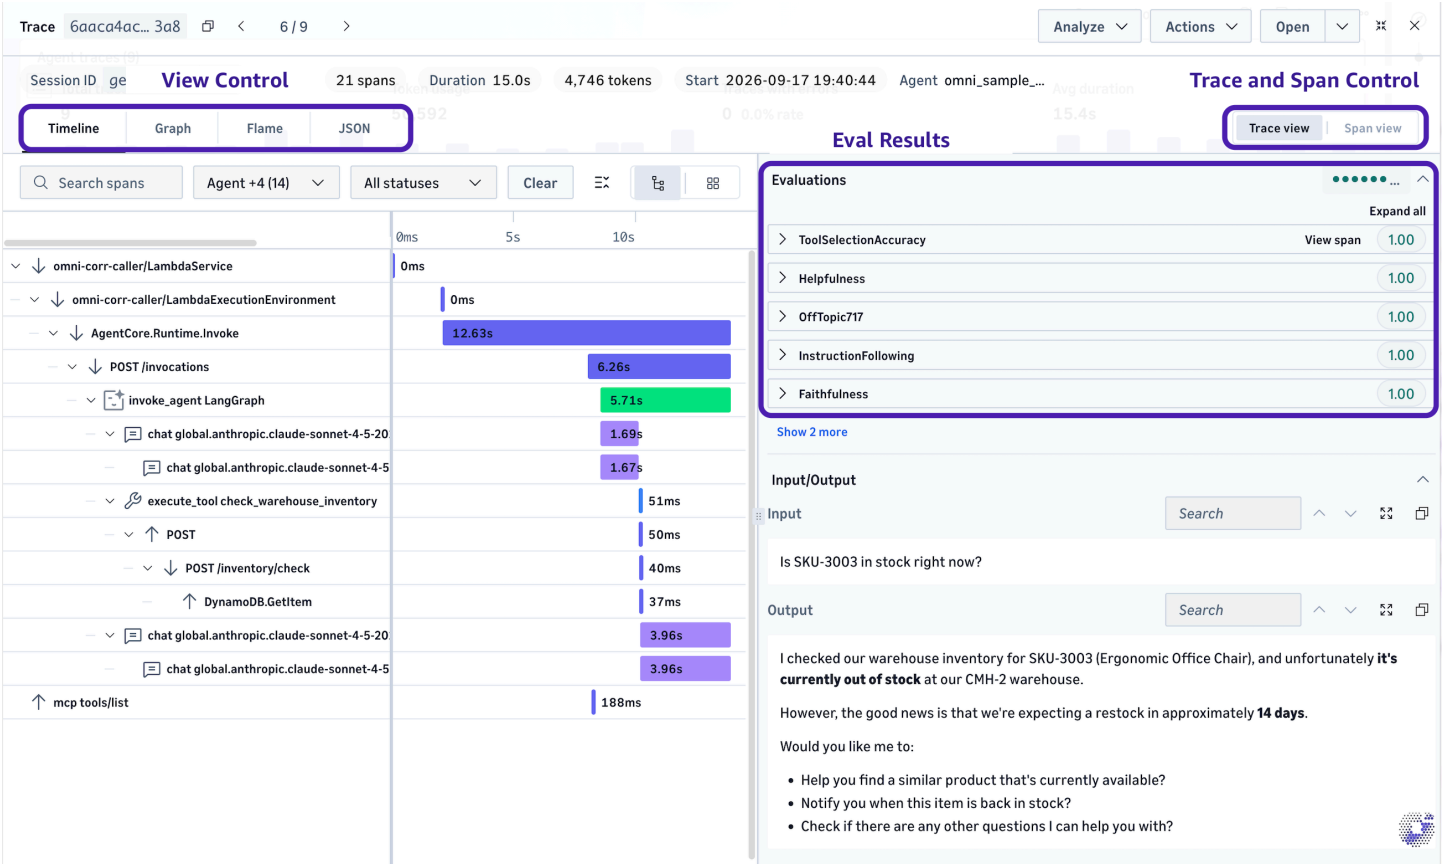
For traces of requests crossing your services and dependencies, see the section called “Application traces”.

Open Agent traces

In the launcher, under Agent observability, choose `Agent traces`, then select the time range you want to investigate. The summary above the results shows totals for the selected range, such as Total traces, Traces with errors, duration, and token usage.

The IDE extension has the same view for the traces your agent produces while you develop. In local mode it reads the runs on your machine. See the section called “Develop with the IDE extension”.

Find the runs to inspect



The traces list supports several ways to narrow the results:

- **Filter.** Use the filter panel to narrow by agent, status, latency, token usage, and other trace properties.
- **Filter by evaluation score.** Narrow the list to traces a specific evaluator scored above or below a threshold. For example, filter on a score range such as 0.0 to 0.5 to surface runs that completed without an error but failed evaluation. A high score range collects examples of the behavior you want to preserve.
- **Search.** The search box above the table narrows the traces already loaded, matching text anywhere in a trace ID, a run's input, or its output. It reports how many of the loaded traces matched, and highlights the matching text in them. It matches no other field and does not re-query your time range, so use the filter panel to narrow by anything else (an evaluator or its score, for example).

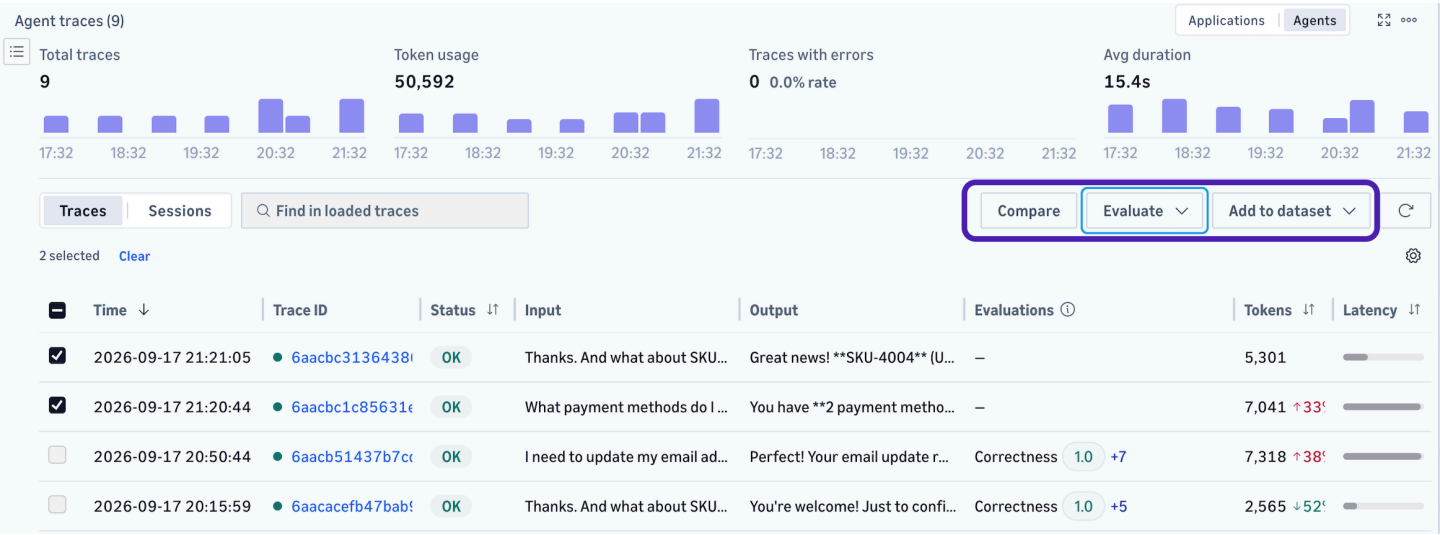
Trace context does not propagate by itself: both sides of each hop must be instrumented. If an agent's caller is not instrumented, the agent's runs still appear here. They start at the agent.

Inspect a run

Select a trace to open it. The header shows the trace ID and span count, and the run's spans open in execution order so you can follow what the agent did step by step.

Two controls change what the detail shows:

- **The view control** changes how the spans are drawn: a timeline of span bars to follow timing and parent-child structure, or a raw view of the span records.
- **The Trace and Span controls** change the scope of the detail panel:
  - **Trace** shows the whole run: the run's input and output, its status, latency, token usage, and its evaluation results.
  - **Span** shows one operation. Select a span to see the service that produced it, the span's own input and output, its timing and status, its attributes, and — for a tool call — the tool's parameters.



Reading evaluation results. The Trace scope lists every evaluation recorded for the run, each with the evaluator's name and score. Expand a result to read its explanation: the judge model's

reasoning for why the run received that score. Rule-based evaluators report the score alone, with no explanation. A result that scored one tool call links to that span, so you can jump from the score to the operation it judged.

Pivot to related telemetry. From an open run you can open the logs that carry the same trace ID (**Show logs for this trace**), open the agent's own metrics (**Show agent metrics**), and, when your space is connected to the AWS DevOps Agent, start an investigation from a failed run (**Investigate**). See the section called “Investigate with the AWS DevOps Agent”.

Act on what you find

Select one or more runs in the traces list, then choose an action:

- **Evaluate.** Pick the evaluators to run, and scores appear alongside the traces as they complete, each with its explanation on the trace. Two kinds of evaluator cannot run here. Session-level evaluators score whole conversations; run them from the section called “Agent sessions”. Evaluators that require an expected response need ground truth a live trace does not carry; run those against a dataset instead. See the section called “Evaluators and evaluations”.
- **Create dataset** or **Add to dataset.** Turn the selected runs into test cases: each run's input becomes the test input, and its response and tool calls seed the expected outcome for you to review. Add failing runs before you fix them so that the fix can be verified against a test case. See the section called “Datasets”.
- **Compare.** Select exactly two traces to see them side by side. Comparing a failing run with a successful one shows where the behavior diverged.

For the end-to-end workflow that runs through this page (find a failing run, package it, fix it, verify the fix), see the section called “Tutorial: Fix a production quality regression”.

When traces are missing or incomplete

What you see on this page depends on the telemetry your agent sends. These checks cover the common gaps:

- No traces appear. Confirm the time range, and verify that the agent is sending traces to your space. See the section called “Send AI agent telemetry”.
- A run has only one or a few flat spans. The agent's internal operations are not instrumented, so there is nothing deeper to inspect. See the section called “Send AI agent telemetry”.
- Inputs, outputs, or tool parameters are blank. The instrumentation does not capture that content. The symptom table in the section called “Send AI agent telemetry” maps each gap to the configuration that fixes it.
- Logs do not appear from the **Show logs for this trace** pivot. Confirm the agent's logs reach your space and carry the trace ID for correlation.

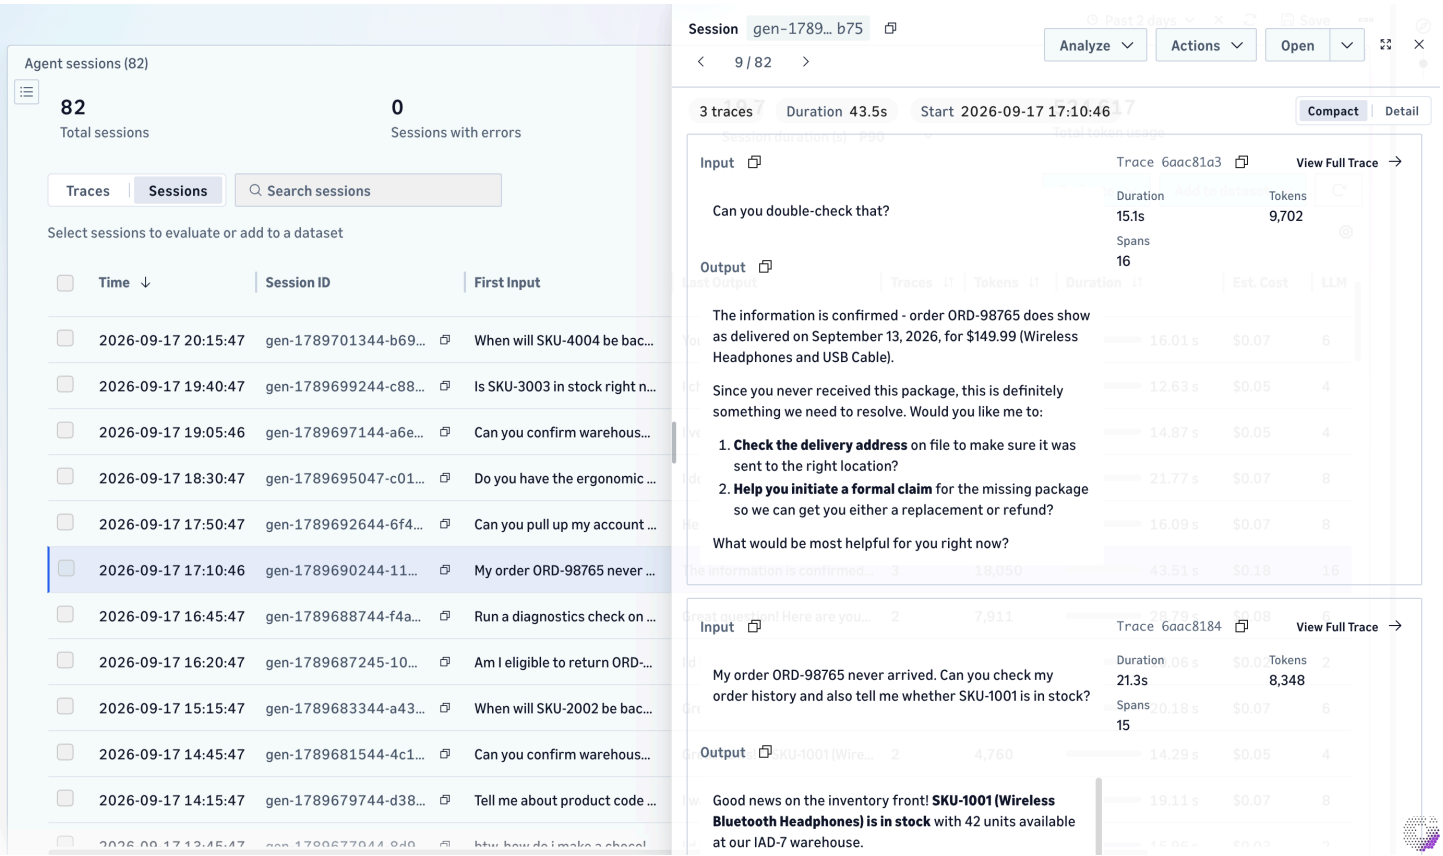
Where to go next

To do this	See
Follow a conversation across runs	the section called “Agent sessions”
See your agent's structure and where runs fail in it	the section called “Agent topology”
Score runs continuously instead of on demand	the section called “Evaluators and evaluations”
Manage the test sets you build from runs	the section called “Datasets”
Query trace records directly with SQL	the section called “Explore and query your telemetry”
Walk the find, fix, verify workflow end to end	the section called “Tutorial: Fix a production quality regression”

Investigate traces of requests across your services	the section called “Application traces”

Agent sessions

The Agent sessions view groups the traces that belong to the same conversation or user interaction, so you can follow a multi-turn exchange from start to finish and see where it went wrong across turns. For how traces, spans, and sessions relate, see the section called “Monitor AI agents”.



Why sessions need their own view

Some failures are invisible at the single-trace level because every individual turn looks fine. The Agent sessions view surfaces the cross-turn patterns:

- **Lost context** — the agent asks for information the user already provided, or contradicts an earlier answer.
- **Churn** — the same tool is called with the same arguments across consecutive turns, or the user rephrases the same request repeatedly (a sign the agent is not making progress).
- **Degradation over length** — quality that is fine on turn one and poor by turn eight, which single-trace sampling never shows.

To follow a session

1. Open your space, then choose `Agent sessions`.
2. Select a session to see its turns in order and read the conversation flow.
3. Select the turn where the problem starts to open its trace in the section called “Agent traces”.

Evaluate and reuse sessions

Cross-turn quality checks run from this view. Select one or more sessions, and then choose an action from the toolbar:

- **Evaluate** — score the selected sessions. Evaluation runs through Amazon Bedrock AgentCore as a background batch job, and scores appear alongside the sessions as they complete. Only evaluators that score whole sessions can run here; evaluators that score individual traces run from the section called “Agent traces”. For the evaluator catalog and how scoring works, see the section called “Evaluators and evaluations”.
- **Create dataset** or **Add to dataset** — turn the selected sessions into test cases, so a multi-turn scenario becomes a repeatable test. You choose whether each session becomes one test case or each of its traces does. See the section called “Datasets”.

Group traces into sessions

Omni groups traces into sessions using the OpenTelemetry `session.id` span attribute. Agents hosted on Amazon Bedrock AgentCore, and agents built with frameworks that set the attribute

natively (such as Strands Agents), are grouped automatically. Custom and non-framework agents must set the attribute themselves. Otherwise, each turn appears as an unrelated trace.

Set `session.id` on the root span of every turn that belongs to the same conversation, reusing one stable ID per conversation and starting a fresh ID when a new conversation starts:

```
from opentelemetry import trace

# Reuse the SAME id for every turn in one conversation.
session_id = "conv-8f2a1c"  # your stable per-conversation id

span = trace.get_current_span()
span.set_attribute("session.id", session_id)
```

Note Only `session.id` groups traces into sessions. Setting the `gen_ai.conversation.id` attribute is harmless (other tools read it), but Omni does not use it for session grouping.

Agent topology

The agent topology shows how the parts of your agent connect — agents, tools, and models — as a graph built from your traces. Where a trace shows one run in sequence, the topology aggregates the paths your agent took across runs: which components exist, which call which, and where latency concentrates.

The agent topology is in **preview release** and is subject to change.

For the map of your services and their dependencies, see the section called “Monitor applications with the application map”.

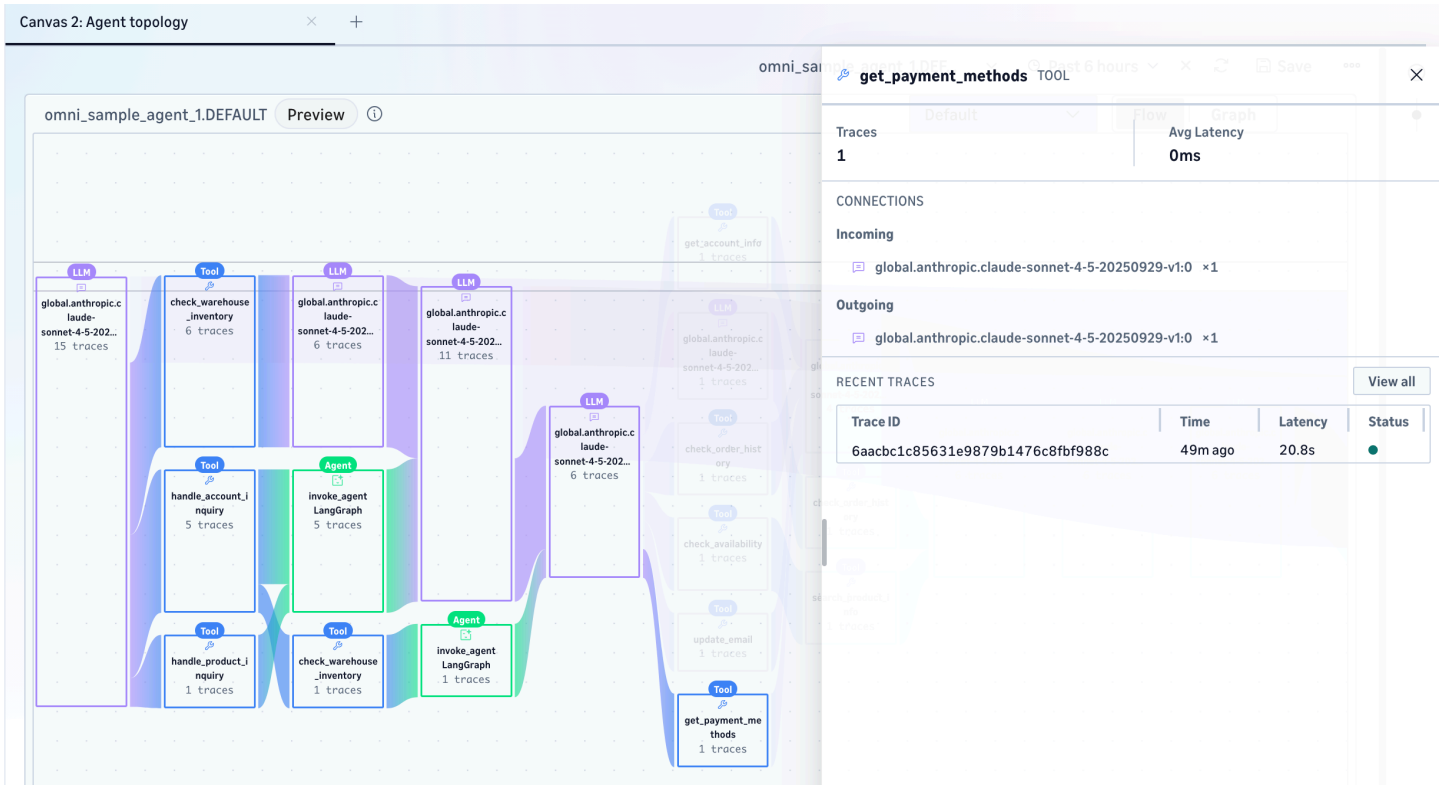
How the graph is built

Omni derives the graph from your spans: each agent, tool, and model that appears in your traces becomes a node, and the transitions between them (which component ran after which) become the edges. The graph is only as complete as your instrumentation: if tool calls are not instrumented as spans, those tools do not appear in the graph. See the section called “Supported environments, languages, and frameworks”.

Choose a view

The **Flow** and **Graph** toggle changes how the same nodes and transitions are drawn:

- **Flow**, the view the map opens in, reads left to right as the sequence of steps your agent ran, aggregated across runs.
- **Graph** draws the components and transitions as a network diagram. Use it to inspect the branching structure and the connections between components.



Group spans into nodes

The selector next to the view toggle offers two ways to group spans into the map's nodes:

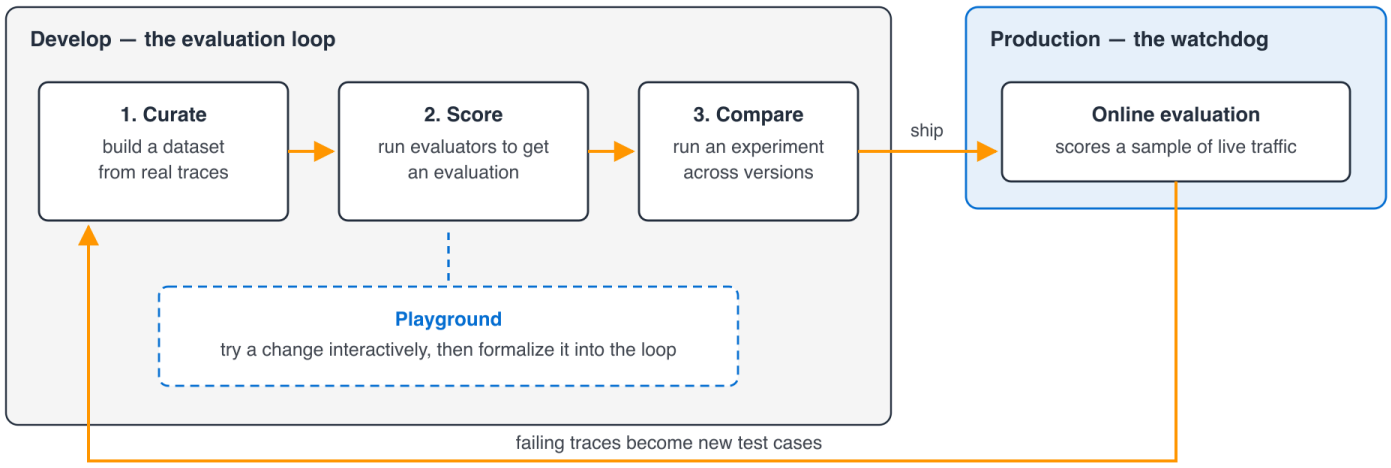
- **Default** builds the map from the span kinds your instrumentation already emits: agent, tool, and model spans in the order they ran, with parallel calls grouped into a single step. It works with traces from any supported framework and needs no additional span attributes.
- **Steps** builds the map from explicit graph metadata on your spans: `agent_graph.node` names the node a span belongs to, `agent_graph.step` orders the nodes, and `agent_graph.kind` optionally sets a node's type. Step spans must be direct children of the trace's root span. LangGraph instrumentation adds this metadata automatically; for other frameworks, set the attributes yourself (for example, in a span processor). Choose **Steps** when your agent is authored as an explicit graph and you want the map to mirror the nodes you defined. If the selected traces carry no step metadata, the map reports it. Switch back to **Default**.

To view the agent topology

1. Open your space, then choose **Agent topology**.
2. Select a node to see its trace volume and average latency.
3. From a node with high latency, open its related traces to see those calls in context. See the section called “Agent traces”.

Evaluate agent quality

Agents fail in ways that do not show up as errors: the run completes, but the answer is wrong, incomplete, or against your policies. Evaluation is how you measure response quality, so you can catch these failures and tell whether a change to a prompt, a model, or a tool made your agent better or worse.



How evaluation fits together

The evaluation workflow builds from your real traffic:

1. **Curate test cases from real traces.** Your traces already contain real requests and the behavior that needs to improve. You collect representative runs (common requests, edge cases, known failures) into a **dataset**, a fixed test set you can run against repeatedly. See the section called “Datasets”.
2. **Score responses with evaluators.** An **evaluator** reads a trace (the input, the response, and the steps in between) and returns a score against a criterion such as correctness or relevance. The scores from running one or more evaluators are an **evaluation**, the record you compare against later runs. You can score a single trace as you debug, or score your agent's outputs across a whole dataset. See the section called “Evaluators and evaluations”.

3. **Compare versions with experiments.** An **experiment** runs two or more agent versions against the same dataset with the same evaluators, so a score difference can only come from the change you made. See the section called “Experiments”.

The **playground** sits alongside this loop for interactive iteration: try a prompt or an agent change and see the effect immediately, then formalize what worked into a dataset and an experiment. See the section called “Prompt playground”.

Where evaluators come from

Every evaluator runs through Amazon Bedrock AgentCore Evaluations, so one catalog covers three kinds:

- **Built-in** — ready-made checks for common criteria such as correctness, helpfulness, and tool-use quality. Start here.
- **Third-party** — metrics from the DeepEval and AutoEval open-source libraries, run for you, so you can use familiar metrics without hosting them.
- **Custom** — evaluators you write yourself, including one that reuses a built-in or third-party evaluator's scoring on a judge model you choose.

Choose an evaluator by the criterion you want to check; you can mix kinds in the same evaluation. For the full catalog and more on how to write your own evaluators, see the section called “Evaluators and evaluations”. To understand how Amazon Bedrock AgentCore evaluates agent

performance, see Evaluate agent performance and Third-party evaluators in the *Amazon Bedrock AgentCore Developer Guide*.

Evaluation during development and in production

The same pieces serve two workflows. During development, you run the loop deliberately: build a dataset, score a change in the playground, confirm it with an experiment before you deploy. In production, evaluation runs unattended: an **online evaluation** is a configuration that continuously scores a sample of your live traffic with the evaluators you choose (see the section called "Online evaluations"), and a declining pass rate shows that quality regressed. When production evaluation catches a regression, the development loop is how you fix it. See the section called "Tutorial: Fix a production quality regression" for the end-to-end workflow.

Evaluators read trace content, so your agent must send traces that include input and output. See the section called "Send AI agent telemetry". For the trace, span, and session vocabulary these pages build on, see the section called "Monitor AI agents". To monitor quality signals across your agents in production, see the section called "Monitor agents in the web UI".

Evaluators and evaluations

An evaluator scores agent behavior against a criterion (for example, whether the response was correct, relevant, or grounded in the retrieved context). An evaluation is the result of running one or more evaluators over a trace, or over the outputs your agent produces from a dataset's test cases. Because evaluators are automated, you can score hundreds of runs the way you would review one by hand. This page covers scoring on demand. To score production traffic continuously, see the section called "Online evaluations".

What an evaluator reads

An evaluator reads the full trace — the user's input, the agent's response, and depending on the evaluator, the steps in between: which tools the agent called and in what order, and what context it retrieved (for the trace and session vocabulary, see the section called "Monitor AI agents"). Each evaluator scores at one of three levels: a **trace** (one request and response), a **session** (a whole conversation), or a **tool call** (one tool invocation). Traces must therefore show input and output. If your evaluators return blank results, check the content-extraction settings in the section called "Send AI agent telemetry".

Where evaluators come from

Every evaluator runs through Amazon Bedrock AgentCore Evaluations, and the catalog covers three kinds. For the full evaluator reference, see Evaluate agent performance in the *Amazon Bedrock AgentCore Developer Guide*.

- **Built-in** — ready-made checks for common criteria such as correctness, helpfulness, and tool-use quality. Start here: they cover the criteria most agents need, without setup. Some built-in evaluators use a judge model internally; others are rule-based checks.
- **Third-party** — metrics from the DeepEval and AutoEval open-source evaluation libraries. If you already use these libraries, you can run the same metrics here without hosting them: the service runs the evaluator, selects the judge model, and manages the library version, the same way it does for a built-in evaluator. To run one of these metrics on a judge model you choose, create a derived custom evaluator instead. DeepEval covers task completion, tool use, and summarization; multi-turn behavior such as knowledge retention, turn relevancy, and goal accuracy; and safety checks for bias, toxicity, and PII leakage. AutoEval covers whether a response is malicious, whether it is humorous, and whether the agent attempted the task or declared it impossible. AWS tests and benchmarks the built-in evaluators but makes no quality claims about these libraries, so validate a metric against your own traces before you rely on its scores. For the metric-by-metric list, see Third-party evaluators in the *Amazon Bedrock AgentCore Developer Guide*.
- **Custom** — evaluators you create, in three forms. A **model-as-judge** evaluator scores trace content against criteria you write in natural language, with your choice of judge model. Use it for criteria that need judgment ("is the tone appropriate for a support agent?") that no fixed rule can check, and spot-check its scores against your own judgment before trusting it at scale. A **derived** evaluator runs an existing built-in or third-party evaluator's logic on the judge model you choose, so you skip writing instructions and a rating scale. A **code-based** evaluator is your own AWS Lambda function that receives the trace content and returns a score. Use it for deterministic, domain-specific checks (the response parses as valid JSON, cites a real order ID, stays under a length limit) where a rule is cheaper and more reliable than a model.

> **Important**
>
> **Judge-based evaluators send trace content to the judge model.** Both the evaluator prompt and the trace content it scores go to the model for inference. This applies to judge-

based built-in and third-party evaluators as well as custom model-as-judge evaluators. If your traces can contain sensitive data, see the section called “Protect sensitive data”.

Permissions for custom evaluators

Built-in and third-party evaluators run on service-managed capacity — there is nothing to grant. A custom evaluator invokes its judge using your space's permissions, so the Space Access role must be allowed to invoke it, and the permission depends on the judge:

- Amazon Bedrock foundation model or inference profile — `bedrock:InvokeModel` and `bedrock:InvokeModelWithResponseStream` on that model or inference profile.
- A model served through the `bedrock-mantle` endpoint in Amazon Bedrock — `bedrock-mantle:CreateInference` on the project and `bedrock-mantle:CallWithBearerToken`.
- Lambda (code) evaluator — `lambda:InvokeFunction` and `lambda:GetFunction` on your evaluator function.

Without the matching permission, on-demand scoring with that custom evaluator fails; built-in and third-party evaluators are unaffected. For the managed policies that carry these actions and the conditions on them, see the section called “IAM policies to use CloudWatch Omni”. For online evaluations, grant them to the evaluation's execution role instead — see the section called “Online evaluations”.

Built-in evaluators miss domain-specific failures

Built-in evaluators score general criteria, and an agent can pass all of them while doing the wrong thing for your domain. Consider a customer support agent that answers an off-topic question, such as providing a recipe: a helpfulness evaluator scores it high (it answered well), and a policy-compliance evaluator scores it high (nothing harmful). Every score is high, yet the agent has left its designated scope. No general-purpose criterion knows what your agent's scope is.

Use built-in evaluators for universal criteria, and write a custom evaluator for every rule that is specific to your agent: permitted topics, required behaviors, forbidden actions. If you can state the rule in a sentence, you can usually write it as a model-as-judge evaluator; if it is mechanically checkable, write it as a code-based evaluator.

Write a custom model-as-judge evaluator

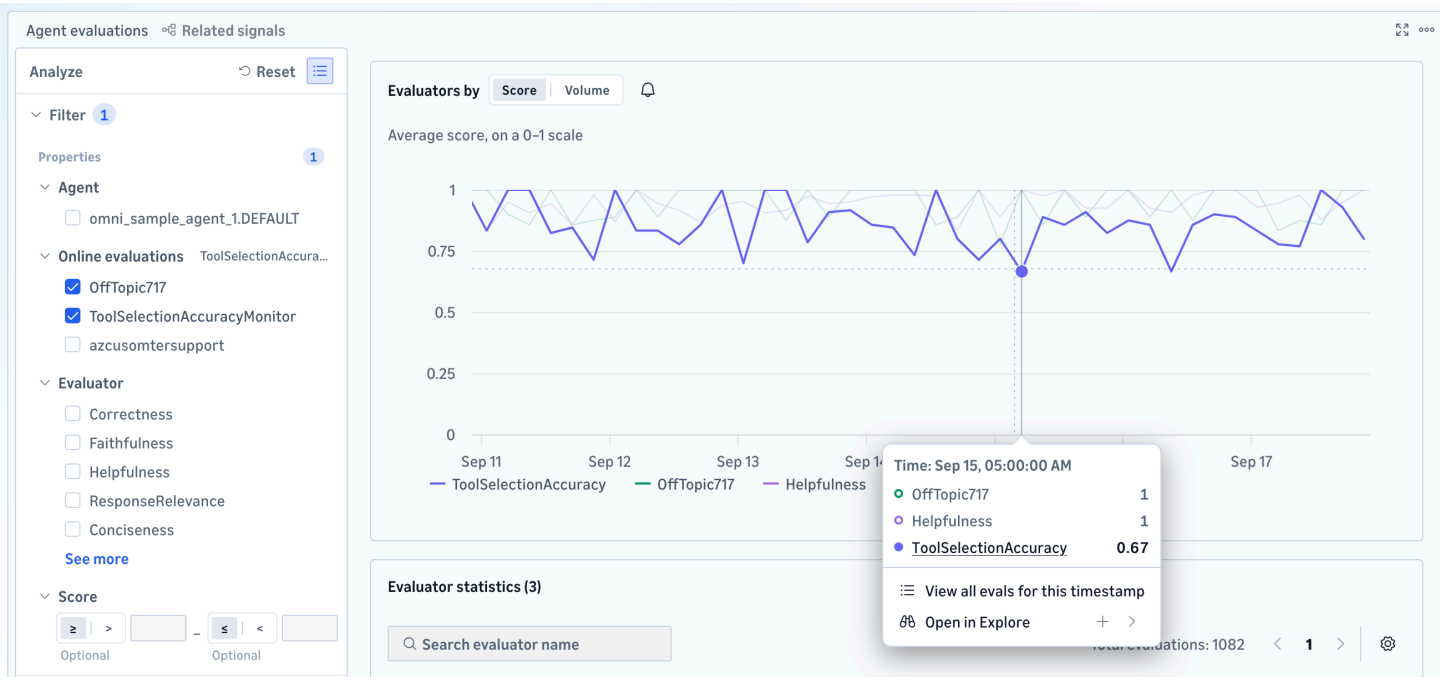
A model-as-judge evaluator is a prompt to the judge model plus a rating scale. The judge reads the conversation and the response, applies your rubric, and returns one of the scale's values. A well-specified evaluator has three parts:

1. **State what the agent is, and what is in scope.** Enumerate the permitted topics or behaviors explicitly. The judge cannot infer your product's boundaries. For example: "The agent is an e-commerce customer support agent. Its only permitted topics are returns and refunds, product inquiries, and account management."
2. **Write the rubric as decidable cases.** Define each score with the specific conditions that earn it, including the edge cases. For a scope evaluator: "a response that acknowledges the request is off-topic but still answers it is off-topic." Vague rubrics ("score how appropriate the response is") produce inconsistent judgments.
3. **Match the rating scale to the criterion.** A rule the agent either follows or breaks should be binary: two values, pass and fail, each with a one-line definition. Remove middle values; a 0.5 on "did the agent stay in scope?" has no meaning, and evaluators default to it when the rubric leaves room for doubt. Reserve graded scales for criteria that are genuinely graded, such as completeness.

The evaluator's instructions include placeholders that are filled with trace content for each run it scores. For a trace-level evaluator, these are `{context}` (the conversation so far) and `{assistant_turn}` (the response under evaluation). Each evaluation level has its own placeholder set; for the full list, see Create evaluator in the *Amazon Bedrock AgentCore Developer Guide*. The rating scale can be numerical (each value has a number, a label, and a definition) or categorical (the label is the value). Test the evaluator on a known-bad and a known-good trace before relying on it: the known-bad trace should score fail, and the known-good one should score pass. If either misses, tighten the rubric.

To evaluate a response

1. Open a trace in the section called “Agent traces” to score a single run, select sessions in the section called “Agent sessions” to score whole conversations, or run your agent against a dataset's test cases, for example in an experiment, and score the outputs. See the section called “Experiments”.
2. Choose the evaluators that match what you want to check: one criterion per evaluator, and typically several evaluators per run.



3. Run them, and review the scores. Each score links back to the trace it came from, so you can open a low-scoring run and see exactly what the agent did.

Interpret scores as comparisons

A single absolute score rarely means much on its own. A 0.8 correctness score is only good or bad relative to something. Scores become useful when you compare: the same dataset before and after a change (see the section called “Experiments”), the same evaluator across agents, or a trend over time.

Review evaluation results over time

The **Evaluation dashboard** aggregates your evaluation results: score trends, score distributions, pass rates, and a comparison across evaluators. Use it to watch for drift after individual runs are scored: a pass rate that declines over days signals a regression even when every individual score looks reasonable in isolation. From a declining trend, open the low-scoring traces to see what changed. If the drop follows a deployment or a prompt change, check that change first. To respond to a regression you find here, see the section called “Tutorial: Fix a production quality regression”.

Datasets

A dataset is a curated collection of test cases that you evaluate against repeatedly. It gives you a repeatable measurement: because the test cases stay fixed, you can run them after every change

and compare scores over time. These evaluation datasets are distinct from the CloudWatch Dataset, the store that holds your space's telemetry (see *CloudWatch Omni*).

What a test case contains

Each test case in a dataset represents one scenario:

- **An input** — the request the agent should handle. For a multi-turn scenario, a test case carries the conversation turns, which run in order within a single session so the agent keeps context between them.
- **An expected outcome (optional)** — a reference response, the tools the agent is expected to call, or natural-language assertions the response must satisfy. Evaluators that compare against a reference need this; evaluators that judge the response on its own do not. Every test case follows the same dataset schema, so any evaluator can draw the fields it needs from any case.

Build from real traces

You can write test cases by hand, but start from real traffic. Your traces already contain the requests your users make and the failures they hit. When you add a trace to a dataset, Omni converts it into a test case: the trace's input becomes the test input, and its response and tool calls can seed the expected outcome for you to review and edit.

To build a dataset from traces

1. In the section called “Agent traces” or the section called “Agent sessions”, find representative runs. Aim for a mix: common requests that must keep working, edge cases, and failures you have fixed and do not want to regress.
2. Add each run to a dataset. Review the generated test case, and record or correct the expected outcome where your evaluators need one.
3. Run your agent against the dataset's test cases (for example, in an experiment) and score the outputs with evaluators to get a baseline. See the section called “Evaluators and evaluations” and the section called “Experiments”.

Publish a version before you use it

A dataset you are editing is a working draft. Before you can run it (in the prompt playground or an experiment), you publish it as a numbered version. Publishing matters because:

- **A version is immutable.** Once published, its test cases are frozen, so a score is always tied to an exact set of cases. Continued editing happens on the draft and does not disturb versions you have already run.
- **Scores stay comparable over time.** Comparing two agent versions, or a before/after change, is valid only when both ran against the same fixed cases. Versioning guarantees that.
- **You can keep publishing.** As you add or refine cases, publish a new version. Earlier versions remain available, so you can always re-run an old baseline or track which version produced which result.

Keep the dataset honest as your agent evolves

- When you find a new failure in production, add its trace to the dataset before you fix it. The fix then has a test case proving it. Publish a version so the fix is measured against a frozen baseline.
- Keep failure cases in the dataset after fixing them; they are your regression suite.
- If your agent's scope changes, retire test cases that no longer represent real traffic. A dataset full of obsolete cases rewards the wrong behavior. Publish a fresh version once you have pruned.

Use a dataset in the prompt playground

In the the section called “Prompt playground” you can run your baseline and candidate variants against a published dataset instead of one hand-typed input, so a comparison covers your whole curated set at once. A candidate that passes cases the baseline fails is evidence that the change works. See the section called “Prompt playground”.

Datasets move between surfaces

Datasets sync in both directions between the Omni web UI and the IDE extension, using the **Upload to Cloud** and **Download to Local** buttons:

- **Download to Local** brings a cloud dataset into the extension, so you can run it against your local development loop.
- **Upload to Cloud** pushes a dataset you built locally (for example, while running your agent on your own machine) up to the Omni web UI, where the team can use it for experiments and shared review.

An operator packages failing traces into a dataset in the Omni web UI, and a developer downloads it to reproduce and fix the problem locally. In the other direction, a developer curating cases against a local agent uploads them so the same cases are available in the cloud. For the end-to-end workflow, see the section called “Tutorial: Fix a production quality regression”.

Each transfer creates a new dataset. Upload to Cloud and Download to Local always create a **new** dataset in the target environment. They do not publish a new version of an existing dataset, and they do not merge into an existing one.

Experiments

An experiment tells you whether a change made your agent better or worse before you ship it. It works by controlling the variables: the same dataset and the same evaluators run against two or more agent versions, so a difference in scores can only come from the change you made.

Available in the IDE extension only.

What you can compare

A "version" in an experiment is any variant of your agent you can run: a new prompt version, a different model, a changed tool, or a reworked orchestration step. Change one thing per experiment where you can. If a variant changes the prompt and the model at once, the scores cannot tell you which change mattered.

To run an experiment

1. In the IDE extension, choose a dataset to run against. Use one with a baseline score, so you know what you are comparing to. See the section called “Datasets”.
2. Select the agent versions or configurations to compare, and the evaluators to apply. Keep the evaluators identical across versions.
3. Run the experiment. Each version runs every test case in the dataset, and the evaluators score each run.
4. Compare the results: the aggregate scores first, then the per-case results.

Read the per-case results, not only the average

An aggregate score can hide a trade-off: a variant that improves the average while breaking cases that used to pass may be worse than the number suggests. Look at the cases that changed direction (improved and regressed) and open the traces behind the regressions to see what the new

version did differently. Add a regressed case to your dataset so that later versions are measured against it. See the section called “Datasets”.

Online evaluations

On-demand evaluation scores a trace when you ask. An **online evaluation** scores your traffic continuously: you choose the agents to watch, the evaluators to run, and how much traffic to sample, and CloudWatch Omni evaluates matching traces as they arrive. Quality regressions surface in your evaluation trends without anyone running a check. Online evaluation is the continuous-monitoring stage of the evaluation workflow described in the section called “Evaluate agent quality”.

How an online evaluation works

An online evaluation is a configuration that you create, and then enable:

- **Agents to evaluate** — chosen by service name from the agents seen in your space's telemetry.
- **Evaluators to run** — one or more evaluators from the catalog described below.
- **Sampling percentage** — how much of the matching traffic is evaluated. Sampling is your cost control: judge-based evaluators invoke a judge model for every sampled trace, so evaluate a fraction of high-volume traffic.
- **Session settings (optional)** — a session timeout that determines when a conversation is considered complete, so session-level evaluators can score the full exchange. The timeout is measured from a session's last activity: a session is evaluated only after it has been idle for this long. A session that never goes idle — for example a long-running or continuously reused session that always has recent activity — is never treated as complete, so it is never evaluated and produces no results. Set the timeout shorter than the typical gap between turns in your sessions so they finalize and are scored.

While the configuration is enabled, CloudWatch Omni evaluates sampled traces continuously. Scores appear alongside the traces and feed the trends in the Evaluation dashboard. Each configuration also gets a dedicated CloudWatch log group holding its results in JSON, and publishes each score as a CloudWatch metric, so you can query results with CloudWatch Logs Insights and alarm on a score the same way you alarm on any other metric. Results follow the OpenTelemetry semantic conventions for generative AI evaluation events, and each result references the trace and session it came from, so you can go from a score back to the run that produced it.

To change an enabled configuration's evaluators, disable it first. The evaluator list is locked while the evaluation runs. A running evaluation also locks the custom evaluators it uses, so that scores stay comparable over time: you cannot edit or delete one while an evaluation is using it. To change a custom evaluator's criteria, clone it, edit the copy, and point the configuration at the copy. The original keeps the scoring history it already produced.

Where evaluators come from

An online evaluation runs the same catalog as on-demand evaluation (built-in, third-party, and custom evaluators, all through Amazon Bedrock AgentCore Evaluations), and you can mix kinds in one configuration. For what each kind covers and how to write your own, see the section called "Evaluators and evaluations".

The judge model depends on the evaluator kind, and that determines what you pay for. For built-in and third-party evaluators, the service selects and runs the judge model on its own capacity. There is nothing to configure. For custom evaluators, including one derived from a built-in or third-party evaluator, the judge model is the one you chose, and it is invoked with the permissions you grant the evaluation, so those model invocations run in your account. For the online-evaluation reference, see Evaluate agent performance, Online evaluation configurations, Prerequisites, and Results and output in the *Amazon Bedrock AgentCore Developer Guide*.

Permissions for custom evaluators

Built-in and third-party evaluators run on service-managed capacity — you grant nothing extra. A custom evaluator invokes the judge you chose, using the online evaluation's execution role, so that role must be allowed to invoke it. The permission depends on the judge:

- Amazon Bedrock foundation model or inference profile — `bedrock:InvokeModel` and `bedrock:InvokeModelWithResponseStream` on that model's or inference profile's ARN.
- A model served through the `bedrock-mantle` endpoint in Amazon Bedrock — `bedrock-mantle:CreateInference` on the project and `bedrock-mantle:CallWithBearerToken`.
- Lambda (code) evaluator — `lambda:InvokeFunction` and `lambda:GetFunction` on your evaluator function.

The default execution role created for you covers built-in and third-party evaluators. When you add a custom evaluator, add the matching permission above to the execution role before you enable the evaluation; otherwise enabling fails with a permissions error (for example, "the execution role does not have permissions to invoke the specified Bedrock models"). For the managed policies

that carry these actions and the conditions on them, see the section called "IAM policies to use CloudWatch Omni". For the execution-role policy reference, see Prerequisites.

To create an online evaluation

1. In your space, under `Evaluate`, choose `Online evaluations`, and then choose `New evaluation`.
2. Select the agents to evaluate, the evaluators to run, and the sampling percentage.
3. Grant the permissions the evaluation needs. Every online evaluation needs permission to write its results (CloudWatch Logs and metrics). If you include a custom evaluator, the evaluation's execution role must also be allowed to invoke that evaluator's judge — the exact permission depends on the judge's type (see **Permissions for custom evaluators**). Built-in and third-party evaluators need no additional permissions.
4. Enable the evaluation, and confirm its status shows as enabled. Scores from sampled traffic appear in the Evaluation dashboard as they accumulate.

Cost and data considerations

- Judge-based evaluators invoke a model for every sampled trace. Tune the sampling percentage to match your traffic volume and budget.
- Evaluators that use a judge model send the sampled trace content to that model. If your traces can contain sensitive data, see the section called "Protect sensitive data".

For scoring a specific trace or dataset on demand, see the section called "Evaluators and evaluations". When an online evaluation surfaces a regression, follow the section called "Tutorial: Fix a production quality regression" to fix and verify it.

Prompt playground

The Prompt playground is an interactive space to try changes and see the effect immediately, without deploying your agent. Where datasets and experiments give you repeatable measurement, the playground is for quick iteration: form a hypothesis, try it, and see the result. Then formalize what worked into a dataset case or an experiment.

Differences by surface In the Omni web UI, the playground supports **prompt testing** — try a prompt against a model and compare outputs. In the IDE extension, it adds **agent behavior testing**

— run your agent end to end against test inputs. Agent behavior testing is available in the IDE extension only.

Model access (first-time use) The playground invokes Amazon Bedrock foundation models directly. The first time you use a given model in your account, you may need to request access to it in the Amazon Bedrock console first — see Add or remove access to Amazon Bedrock foundation models. Until access is granted, runs against that model fail with an access error.

Work in variants: baseline against candidate

The playground is organized around side-by-side variants. You start with a baseline (your current prompt or agent configuration, unchanged) and add a variation that carries your proposed change, such as an appended instruction or a different model. Both variants run the same input, so the difference in output can only come from your change. Leave the baseline unchanged: if you edit both variants, you can no longer tell which edit caused the improvement.

Prompt testing

Prompt testing runs a prompt directly against a model — no agent in the loop — so you can isolate the prompt as the variable. Use it to compare phrasings, instructions, or models side by side before changing your agent.

1. Choose `Prompt playground`, and select a prompt version from your managed prompts as the baseline, or enter a prompt directly.
2. Add a variation, and apply your change to it. Leave the baseline unchanged.
3. Run both variants against the same input and compare the outputs. To score the comparison, run an evaluator over both results: a failing baseline and a passing candidate is evidence that the change works. See the section called “Evaluators and evaluations”.
4. When a variant performs better, save it as a new prompt version with a note describing the change, so your agent can use it and you can trace which version produced which behavior. See the section called “Manage prompts”.

Agent behavior testing (IDE extension)

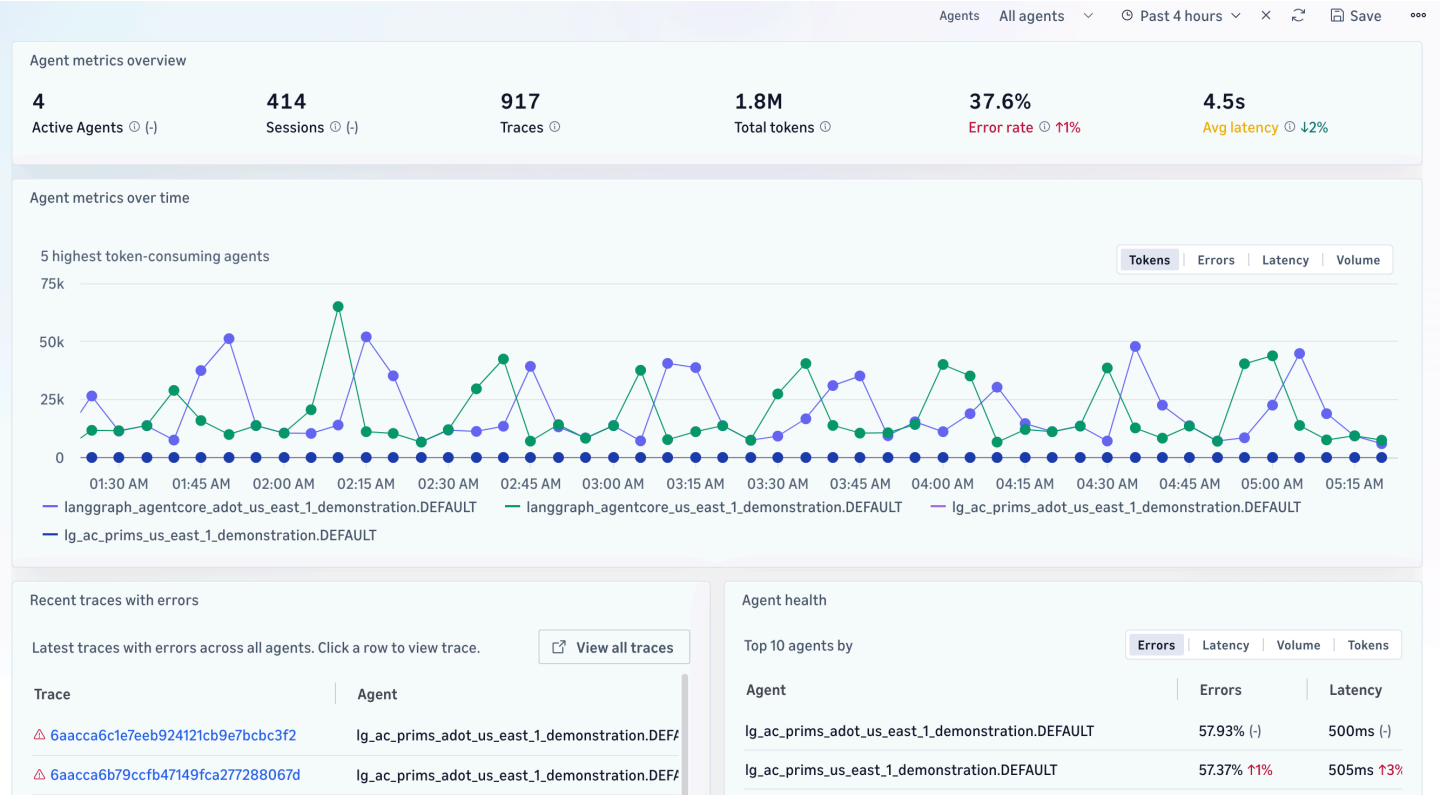
Agent behavior testing runs your agent (its prompts, tools, and orchestration together) against test inputs from inside the extension. Unlike prompt testing, this exercises the full execution path, so you see the trace the run produced and can tell whether a change fixed the behavior or only moved

the failure. It uses the local dev server, so iterations stay on your machine. See the local testing steps in the section called “Develop with the IDE extension”.

You can also run the variants against the test cases in a dataset (in prompt testing or agent behavior testing), so the comparison covers your curated scenarios instead of a single hand-typed input. A dataset alone is not enough: the run requires a prompt version. The dataset supplies only the test cases. This is the step before formalizing the change as an experiment. See the section called “Datasets”.

Monitor agents in the web UI

Use the Omni web UI to monitor your agents in production, including individual agent traces and sessions, aggregate metrics such as request volume, errors, latency, and token usage, and dependency relationships through the application map (see the section called “Monitor applications with the application map”).



Aggregate views are available in the Omni web UI only. For monitoring and troubleshooting during development in the IDE, see the section called “Develop with the IDE extension”.

Aggregate metrics

- **Request volume** — the number of times the agent is invoked.
- **Errors** — the number of traces that contain errors.
- **Latency** — the duration of each run.
- **Token usage** — the total input and output tokens consumed.

To monitor your agents

1. Sign in to your space. To set up users and permissions, see the section called “Set up Omni”.
2. Review the aggregate views for request volume, errors, latency, and token usage across your agents. Filter by agent or time range.
3. Select a metric or a spike to view the underlying traces in the section called “Agent traces”, or follow a multi-turn conversation in the section called “Agent sessions”. If you do not yet know which runs to inspect, use the agent topology to see which components take part. See the section called “Agent topology”.
4. Check your evaluation results for the same period. To find evaluation trends, see the section called “Evaluators and evaluations”.

Combine these views with evaluation results. An agent can be fast, low-cost, and error-free but still give wrong answers. To measure response quality, see the section called “Evaluate agent quality”. When you find a quality regression here, follow the section called “Tutorial: Fix a production quality regression”.

Develop with the IDE extension

Use the CloudWatch Omni extension to build, test, and evaluate your agent from your IDE. The extension is available for VS Code, Kiro, and Cursor.

Local mode and cloud mode

The extension works against two data sources.

Mode	What you see	What it needs
Local	Traces from the agent running on your machine, stored in your project folder	Credentials for the model provider your agent calls. No AWS account connection

Mode	What you see	What it needs
Cloud	Traces from deployed agents — the same data your team sees in the Omni web UI	Sign-in to your space

Switch modes as you work. Build and test in local mode. Then switch to cloud mode to compare a local run against production traces, or to use a dataset that an operator packaged from those traces. See the section called “Tutorial: Fix a production quality regression”.

Features that interact with your project's code (such as the section called “Manage prompts”) are available in local mode only. If a feature needs the other mode, the extension shows it as unavailable and names the mode it requires.

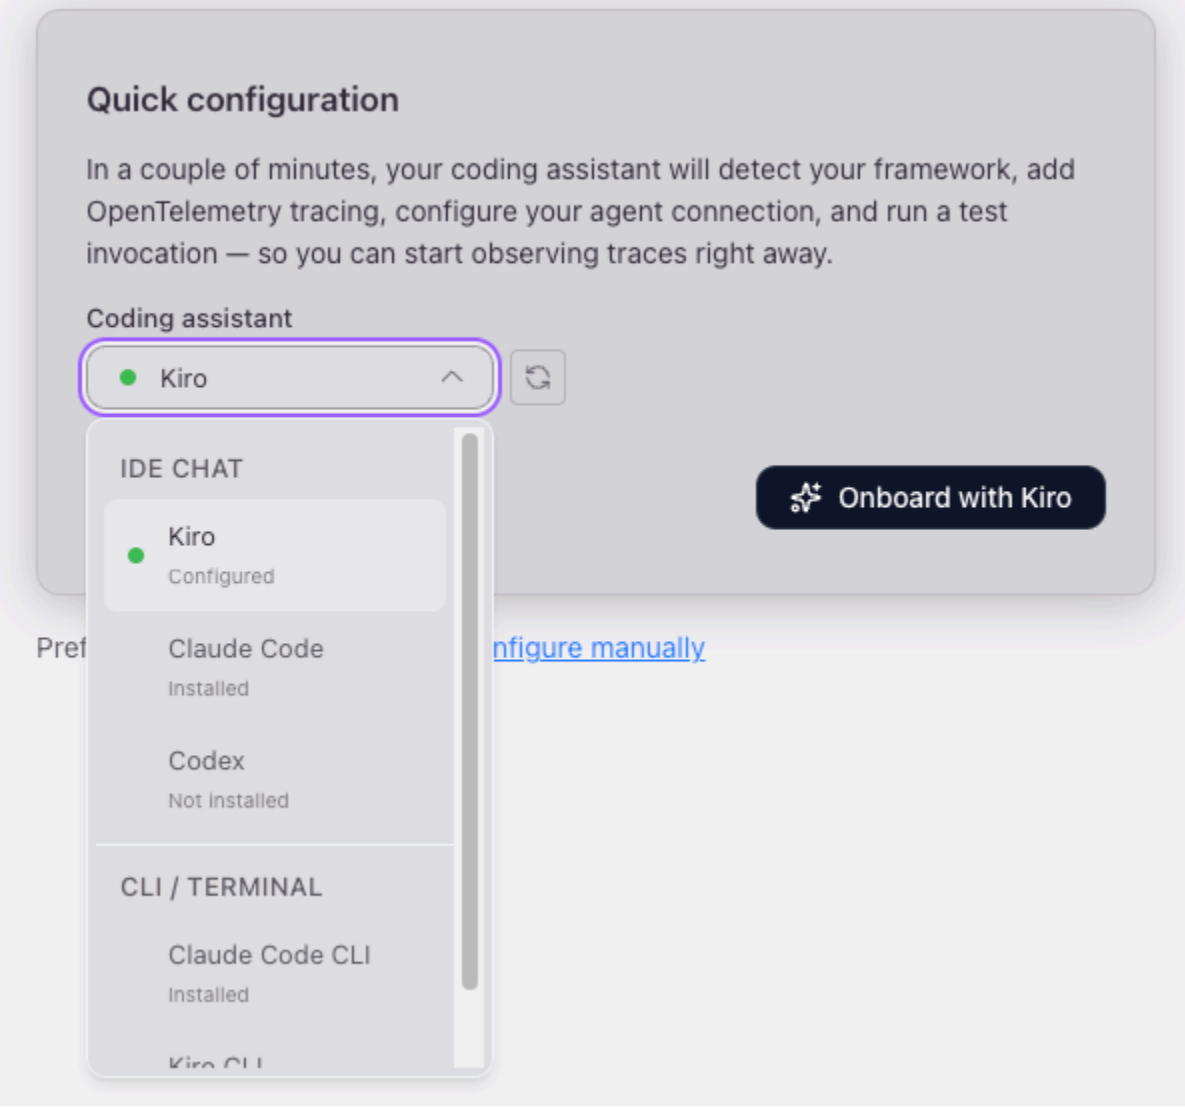
Install and connect

1. Install the CloudWatch Omni extension in your editor. Search for it in your editor's extensions view, or install it from the registry your editor reads: Install for VS Code from the VS Code Marketplace, or Install for Kiro and Cursor from Open VSX.
2. Open your agent project. The extension creates an `.omni` folder in the project for local traces and configuration.
3. Choose local mode, or sign in to your space to use cloud mode. A space is required only for cloud mode. To create one, see the section called “Set up Omni”.

The extension sidebar shows the mode you are in and the data source it reads from.

Onboard your project

Onboarding instruments your project and connects the extension to your running agent. A coding agent in your editor does the work, using the Omni skills.



1. **Choose the coding agent you want to work with.** The extension installs the Omni skills that agent needs, and its guided flows run through that agent.
2. **Detect the framework and language.** The coding agent reads your dependency files and source imports to identify your agent framework and the language it is written in.
3. **Instrument the project.** The coding agent adds the OpenTelemetry instrumentation your agent needs to emit traces, choosing between AWS Distro for OpenTelemetry and OpenInference

according to your framework. Where instrumentation already exists, it verifies that setup rather than replacing it. For the instrumentation itself, see the section called “Send AI agent telemetry”.

4. **Connect to your agent.** The coding agent sets your start command and port and starts the local server, detects your agent's request and response schema from your code and saves it, then sends a test request. Onboarding is complete when that request produces a trace.

Start onboarding from the extension's Getting Started view.

Onboard manually instead. A coding agent is not required. Each step is also available on its own from the configuration view, so you can set the start command, the port, and the schema yourself, and re-run a single step without repeating the others. The "Test your agent locally" section of this page walks through the start command, the server, and the test request by hand.

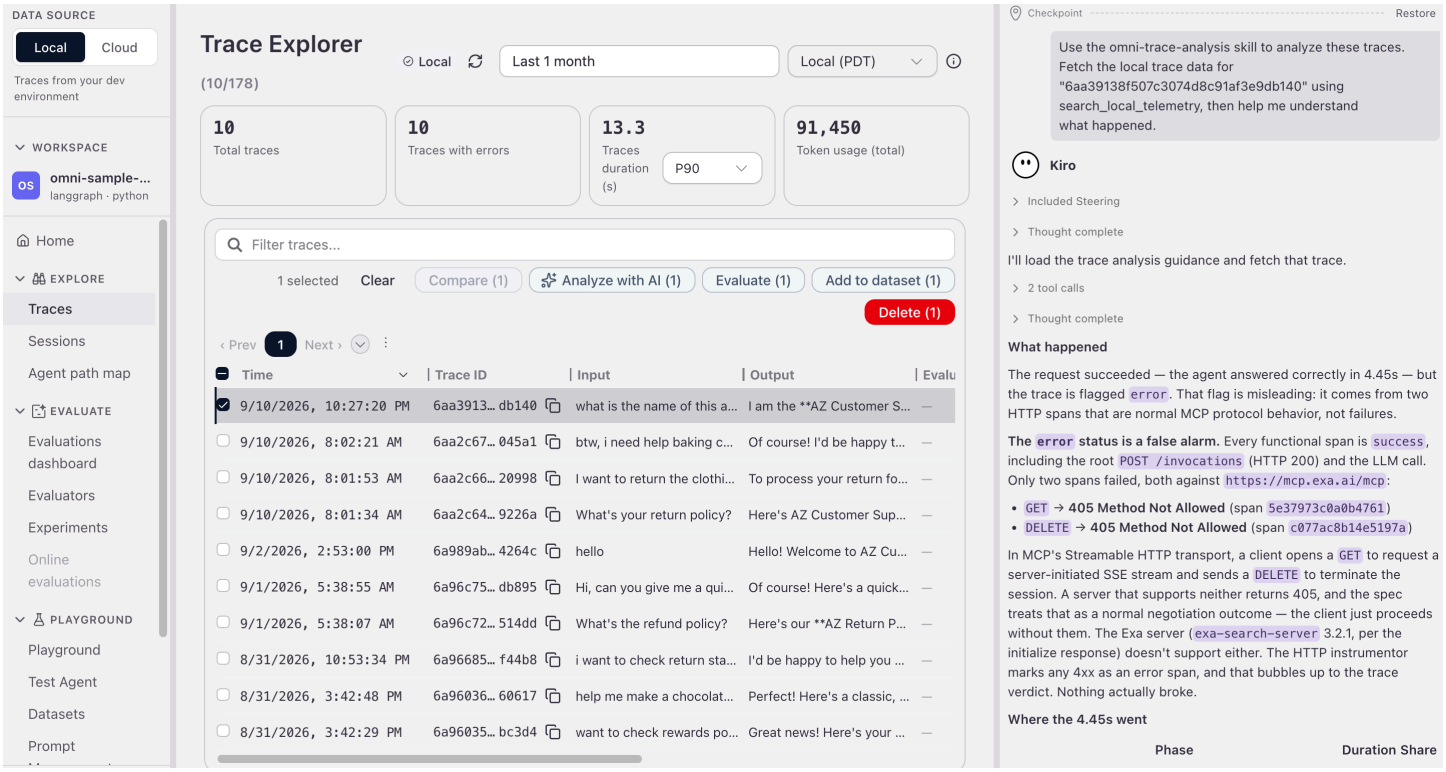
Test your agent locally

Run your instrumented agent from inside the extension and inspect the traces it produces. If your agent is not instrumented yet, see the section called “Send AI agent telemetry”.

1. In the extension configuration, set the command that starts your agent's server and the port it listens on. The default port is 8080.
2. Start the server. The extension starts a local collector to receive telemetry, sets the OpenTelemetry environment your agent needs, runs your start command, and waits for the port to respond.
3. Send your agent a request (from the extension, from the playground, or from your own test harness) so the invocation produces traces that reach the collector.
4. Open `Agent traces` in the extension to inspect the run. Change your code or prompts and send another request to compare.

In local mode nothing leaves your machine: the collector writes traces to the `.omni` folder in your project.

Run your own server



To start your agent yourself, switch the extension to external server mode. The extension still runs the collector. It writes the OpenTelemetry settings your server needs to a file in your project. Load that file before you start the server. If your server already listens on the configured port, the extension uses it and does not start a second collector.

AI assistance in the extension

The extension includes AI assistance for working on your agent:

- **Analyze with AI** — ask about a trace or a failure and get an explanation based on your telemetry.
- **Prompt recommendations** — get suggestions to improve a prompt.

You can use AI coding agents through the Omni skills in the Agent Toolkit for AWS. See the section called “Use Omni skills”. For the AI assistant in the Omni web UI, see the section called “Ask the Omni agent”.

Where to go next

Continue with these related topics:

- the section called “Manage prompts” — version your agent's prompts in the project and test changes before you ship them.
- the section called “Use Omni skills” — work on your agent from the coding agent you already use, through the Omni skills in the Agent Toolkit for AWS.
- the section called “Send AI agent telemetry” — instrument your agent so its runs produce the traces the extension reads.
- the section called “Agent traces” — how to read a trace, in the extension or the Omni web UI.

Manage prompts

Manage your agent's prompts as versioned artifacts in the extension, so you can track changes, compare versions, and reuse prompts across runs.

Availability Available in the IDE extension only.

You can also use and compare prompt versions in the prompt playground and in experiments. See the section called “Prompt playground” and the section called “Experiments”.

Bring existing prompts under management

Most agents start with prompts embedded in code. When you set up prompt management, your coding agent finds the prompts in your project and extracts them into managed, versioned artifacts. Each one becomes a named entry with a version history, and your code references the managed prompt instead of an inline string. From then on, every change is a recorded version.

To set it up:

1. In the IDE extension, open the prompt management view.
2. Follow the on-screen onboarding instructions.
3. When the flow hands off to your coding agent, invoke it to perform the extraction.

What a version captures

Each version records the prompt's messages and its model configuration (the provider, model, and inference parameters such as temperature and maximum tokens), along with a note describing the change. A comparison between versions reflects both. A version does not capture your agent's tools, orchestration, or code; to compare those, run an experiment. See the section called “Experiments”.

Versions are saved to a prompt store in your project, and each save is recorded as a git commit using your note as the commit message. Your prompt history is part of your project's history.

To create a new version

You create new versions from the playground: edit the prompt there, and when a change works, save it as a new version with a note describing the change. See the section called “Prompt playground”.

To review and manage versions

1. In the extension, open the prompt management view and choose a prompt.
2. Select a version from the timeline to see the messages and model configuration it recorded, and compare it with other versions.

3. Each version also shows the traces your agent produced while that version was in effect, so when behavior shifts you can tie the change to a specific version.
4. To try the selected version, choose `Test in Playground`. To roll back to it, choose `Revert`.

Reverting does not delete later versions. It creates a new latest version that restores the older version's messages and model configuration, so the rollback is itself a recorded change.

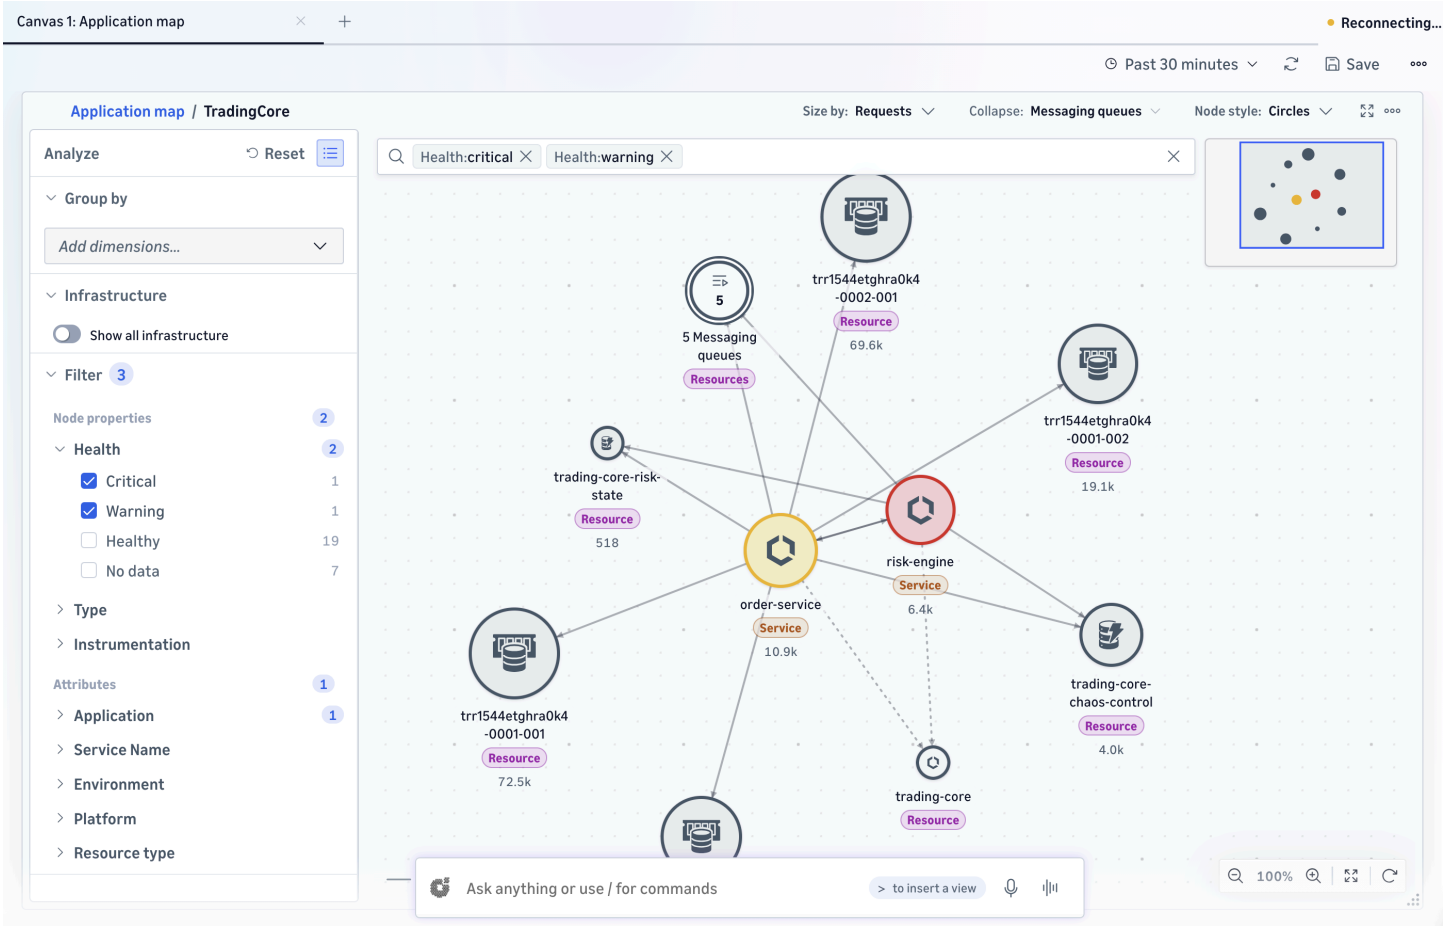
Monitor applications with the application map

Use the application map to understand how your applications and services interact with each other and to identify what needs the most attention. The application map shows your application services, their dependencies, and related cloud resources. You can also organize your application map by other dimensions such as environment, resource type, or related services.

Omni builds the application map from your telemetry for the time range you select. It then adds the infrastructure resources that it finds in your account. Omni observes service calls and resource access. It draws each one as an arrow between two nodes. When the map is grouped by application, Omni groups services by the OpenTelemetry `service.namespace` attribute. The `service.name` attribute names each service in that application. Services that do not set the `service.namespace` attribute are grouped under **None**. Services running in other clouds appear alongside your AWS services when their telemetry carries the standard OpenTelemetry resource attributes, and calls between them are drawn like any other.

You can access the application map from the Quick Launch menu in the Omni web UI. You can also access the underlying Context Graph programmatically. See the section called “Using Context Graph”.

Find which services need your attention



Start with the application map to find which applications have problems, and which service or dependency is responsible.

1. Select the time range that contains the behavior you want to investigate.
2. Find the application you want to review.
3. Use the **Health** filter to focus on services or dependencies that need attention. Health status for an application is "critical" if the percentage of errors is greater than 5%, and "warning" if it is greater than 1%.

4. Select a service to review its activity and relationships.
5. Open the service or its telemetry when you need more detailed evidence.

For detailed service monitoring, see the section called “Monitor a service”. To investigate individual requests and operations, see the section called “Application traces”.

Understand what appears on the map

The map is your application's observed topology, drawn from two kinds of nodes and three kinds of relationship between them.

Node	What it is
Service	An instrumented application that sends its own telemetry.

Node	What it is
Resource	A resource that a service uses or runs on, including managed and customer-deployed resources such as a database, queue, bucket, function, or compute.

Nodes also carry a category, which determines the icon shown on the map: compute, storage, database, messaging/queue, Gen AI model, network, or uncategorized.

Relationship	What it means
Calls	One service calls another service.
Accesses	A service reads from or writes to a resource.
Runs on	A service is hosted on a piece of infrastructure, such as a cluster.

A relationship can also contain operations observed between its nodes. For example, you can see which operations one service called on another service or resource. Node health reflects the error rate observed over the selected time range. A node is reported as one of the following:

- **Healthy** — the observed error rate is within normal range.
- **Warning** — the error rate is elevated.
- **Critical** — the error rate is high.
- **Unknown** — the node has too little traffic to classify. A low-traffic node is reported as unknown rather than as healthy.

Investigate an application or a service from the map

Select an application or a service to review information for the selected time range. The service view can include request activity, latency, errors, and its relationships with other services and resources. Review the services that call the selected service, the services it calls, and the resources

it accesses. This helps you determine whether the problem is isolated to the service or involves a dependency. From the service, continue to the telemetry:

1. Open traces to investigate individual requests.
2. Open logs to inspect application messages, exceptions, or events.
3. Open metrics to investigate service or infrastructure signals.

Narrow and organize the map

The map opens grouped by **Application**, so it shows your applications rather than every individual service. Use the **Analysis** rail when a large map contains more nodes than you need for the current investigation. Use **Group by** in the analysis rail to change the grouping dimension. For example, if your services run in multiple environments, group by **Environment** to focus on all services in a given environment.

Use **Filter** to narrow the map without changing its grouping. You can filter by node properties such as Health, Type, and Instrumentation, or by attributes such as **Application**, **Service Name**, **Environment**, **Platform**, and **Resource type**.

Use **Show all infrastructure** to include resources discovered in your account even when Omni has not observed them through telemetry. Use **Node style** to switch the node view between cards and circles.

What to watch out for

1. **Most relationships on the map come from your telemetry.** A service that is not instrumented appears as a single node with no related telemetry if Omni discovers it in your account. It can also appear as a node named from a caller's span, because the caller's telemetry names the far end of the call. The map draws a call between two of your services when you trace it. Omni also builds relationships from network and access logs, from CloudTrail, and from the resources it discovers in your account. To close a gap, instrument the service that is missing. See the section called “Send telemetry to CloudWatch Omni”.
2. **Individual hosts, tasks, and identities are left out on purpose.** The map does not create nodes for EC2 instances, ECS tasks and containers, or IAM roles and users. Leaving these out keeps the map focused on your services and their dependencies.
3. **Two nodes can carry the same service name.** Omni creates a separate node for each combination of AWS account, AWS Region, cloud provider, and deployment environment.

Each combination is a separate deployment of the service. The service details page shows a node's account, Region, and cloud provider as node attributes, so you can tell two deployments apart there. Set those attributes consistently. If some replicas of one service set `deployment.environment` and others leave it unset, Omni splits that service into more than one node and divides its traffic and dependencies between them. See the section called “Using Context Graph”.

4. **Resources that Omni finds by inspecting your account appear on a delay, and the time range does not filter them.** Telemetry updates the map continuously, and telemetry-derived nodes are the ones observed inside the range you select. A resource that Omni learns about by discovering what is deployed in your account appears after the next scheduled refresh. It then reflects the most recent discovery rather than the selected range, so narrowing the range does not remove it. Such a resource can appear with its name before anything has called it, and it shows no metrics or traces because Omni has not observed any. For which discovery sources contribute what, see the section called “Using Context Graph”.

Where to go next

To do this	See
Open a single service, its dependencies, and its health	the section called “Monitor a service”
Follow one request through your services	the section called “Application traces”
Query the logs, metrics, and traces behind a node	the section called “Explore and query your telemetry”
Understand spaces and where this telemetry is stored	*CloudWatch Omni*

Cross-account and cross-Region topology

The map shows the services and resources in the space's own account and Region. To add more accounts and Regions, centralize their telemetry into the space's account. Their services and dependencies then appear on the same map. To set this up, see the section called “Set up Omni for your organization”.

Using Context Graph

Use the Context Graph to understand the services, resources, and relationships that Omni has identified in your environment. Omni builds the graph from your telemetry and from resources it discovers in your account. A dependency is one kind of relationship: evidence that one component called another. The application map is a visual view of this graph. For the node and relationship types shown on the map, see the section called “Monitor applications with the application map”.

> **Note**
>
> Omni builds the graph from telemetry you are already sending and from the resources it finds in your account. You do not need to create or maintain the graph. The telemetry and resource attributes you send determine how completely and accurately Omni represents your environment.

Understand what contributes to the graph

Different telemetry signals contribute different information.

What you send	What it contributes
Traces	The caller, the callee, and the dependency between them. Traces establish service-to-service call relationships.
Metrics	A node for the component that emitted the metrics. Metrics alone do not establish a dependency.
Logs	A node for the component that emitted the logs. When a log identifies its compute, Omni can also associate the service with that compute.
Network and access logs	Communication observed between endpoints . Omni can resolve those endpoints to known

What you send	What it contributes
	resources when enough resource information is available.

A dependency appears when Omni has evidence that one component called another. A trace is the most direct evidence. Network logs, access logs, and CloudTrail also carry that evidence for some call paths. Metrics do not, so two services that only emit metrics can both appear with no dependency between them. To capture service-to-service dependencies reliably, instrument the caller and send traces. See the section called “Send telemetry to CloudWatch Omni”.

Understand discovered resources

Omni can also add resources that it discovers in your account. A discovered resource can appear in the graph before Omni observes telemetry from that resource. In that case, the resource exists in the graph but has no telemetry attached to it. This is expected and does not necessarily indicate an instrumentation problem.

Telemetry and discovery use different time semantics. Discovered resources reflect the most recent inventory available to Omni. Changing the telemetry time range does not remove a discovered resource that had no activity during that period. A resource can therefore exist in the graph without any observations in the selected time range.

Discovery source	What it adds
AWS Config	Resources that AWS Config records in your account. This source adds resource nodes. It also adds some relationships, such as the compute a service runs on.
Resource discovery	Services and resources found by inspecting your account, and the relationships between them: which compute a service runs on, and which resources it accesses.

Omni creates a service-linked configuration recorder when you create a space. AWS Config then records a fixed set of resource types. Omni adds those resources to the Context Graph. You do not

create the recorder. You do not configure it. You pay no AWS Config fee for the records that Omni uses.

Omni adds a graph node for only some of the types. It uses the other records to add detail to nodes that exist. For the full list, see the section called “Using AWS Config for resource discovery”.

> **Important**
>
> **Discovery reports current state rather than a time window.** Telemetry-derived elements are the ones observed inside the time range you request. Discovery-derived elements reflect the most recent discovery of your account, so narrowing the time range does not narrow them. A graph made only of discovered resources reports no observations in the range at all.

Make services appear correctly

Use consistent OpenTelemetry resource attributes so Omni can identify services and deployments correctly.

Identify each service: Set `service.name` on every service. If a service is missing from the graph, verify this attribute first.

Group services into an application: Set `service.namespace` on related services so they are grouped into the same application.

Distinguish deployments: Use `deployment.environment` to distinguish deployments such as production and staging.

> **Important**
>
> Set identity attributes consistently across every replica of a service. Two replicas that declare **different** values become separate nodes and split their telemetry. A replica that leaves an attribute unset folds onto the replica that declares it.

Identify managed dependencies: Add the attributes that name the destination to the calling span. Omni then resolves the dependency to a known resource. OpenTelemetry semantic conventions define these attributes. Supported AWS SDK instrumentation can set many of them for you.

When the call is to	The span needs
A queue or topic	`messaging.destination.name`
A database or table	`db.namespace` (or `db.name`). Add `db.collection.name` for the table or collection.
An object store bucket	`aws.s3.bucket`
A function	`faas.invoked_name`
A model	`gen_ai.request.model`

If a span contains only a hostname, Omni can represent the dependency by that hostname rather than by the underlying resource. For a call between two services, the span must also represent the outbound call: a span that records only work received does not establish an outgoing dependency to another service. Messaging is the exception. A consumer that polls a queue or a topic gets a relationship to that queue or topic.

Retrieve the graph programmatically

Use the `GetContextGraph` operation to retrieve the Context Graph through the API. Authenticate the request the same way as other Omni API operations.

Each request includes a time range. Nodes and relationships from telemetry show the activity in that range. Discovered resources show the latest inventory instead. The time range does not limit them. Results can span several pages.

> **Important**
>
> Relationships are returned with their source nodes rather than as one top-level edge list. When you process a response, iterate through the nodes and read the relationships attached to each node.

Omni attaches each relationship to the node it starts from. A node carries all of its outbound relationships on the page that carries the node. They are never split across pages. To find what

points at a node, you must read the nodes at the far end, and those nodes can be on a later page. Read all pages before you decide what depends on a node.

Node and relationship kinds in the response use the same model the application map presents. Each node also reports which signals it was seen in and which sources contributed it. The graph carries no evidence that a dependency does *not* exist.

Pivot from the graph to your telemetry

Each node carries the attribute values that identify its own telemetry, so you can move from a dependency on the graph to the metrics, logs, and traces behind it. Use those attribute values as the selectors in your query. For the query languages, see the section called “Explore and query your telemetry”.

This applies to nodes that telemetry contributed. A resource that Omni discovered in your account and never saw in telemetry carries no signals, no operations, and no metrics, so check `signalTypes` before you query a node's telemetry. An empty `signalTypes` means Omni observed no telemetry for that node inside the range you requested. It does not mean the resource was never used.

A node reports its attributes in several forms, and the difference matters when you query.

On the node	What it is, and when to use it
Normalized identity properties	The resolved identity Omni settled on after merging what it observed across sources. Use these to identify and display a node.
Telemetry attributes	The OpenTelemetry attributes as your telemetry emitted them. Use these to query, because they are the values the stored telemetry carries.
Operation details	For each operation observed on the node, the attribute sets that identify that operation's metric series. Use these attribute sets to chart one operation rather than the whole service.
Per-metric metadata	For each metric on the node: its name, its meaning, its unit, the statistic to chart, and

On the node	What it is, and when to use it
	the attributes to query it with. Request this explicitly. See the following note.

> **Note**
>
> Omni returns per-metric metadata only when you ask for it, because it costs an extra lookup for every node in the response. Operation details are returned either way.

> **Important**
>
> **Query a metric using the attributes reported for that metric rather than the node's identity.** A node that Omni merged from several sources can carry different attribute values for different metrics. The per-metric attributes match the emitted series. The node's resolved identity might not match, and a query built from it can return nothing even though the metric exists.

A node that telemetry contributed also reports when Omni first and most recently observed it. Compare those timestamps, or run the same request over two ranges, to see whether something appeared, disappeared, or stopped being exercised. A resource known only from discovery might report neither, because Omni has not observed it in use.

Name your operations

Omni names an operation from the semantic-convention attributes on the span, and it prefers the most specific set of attributes. Omni also records the span name as an operation. When the two names match, they merge into one operation. When they differ, you see both. If a span records the route it served, Omni names the operation for that route rather than for the method alone.

Record this	And an operation is named
`http.request.method` and `http.route`	By method and route together, such as a GET on a specific path, rather than by method alone

Record this	And an operation is named
`db.operation.name` with `db.namespace` or the table	By the database operation and what it acted on
`messaging.destination.name` and `messaging.operation.type`	By the destination and the kind of messaging operation

Record the route. Without it, Omni names one operation for each HTTP method, and every request the service handles is grouped into that operation.

Use the graph with an AI agent

An AI agent can use the Context Graph to retrieve topology while answering a question or investigating a problem. The agent can verify relationships between services and resources before using those relationships as evidence in its analysis.

For how to connect an agent to Omni, see the section called “Use Omni skills”.

Troubleshoot an incomplete graph

Check the following when the graph does not show what you expect:

1. **Relationships come from your telemetry.** A service-to-service dependency requires trace evidence of the call, so a call that is never traced is not a relationship. Other signals identify a component without establishing the dependency. A service that sends no telemetry appears only if Omni discovers it in your account, and it then appears with no telemetry attached.
2. **A single page is not the whole graph.** One response page can contain only part of the graph, or only some of a node's relationships.
3. **Omni identifies a resource from its resource identifier.** Where Omni can resolve a managed resource to a resource identifier, it represents the resource. Where it cannot, the same dependency can appear as a host, an endpoint, or an address instead.
4. **The time range changes what telemetry contributes.** Telemetry-derived nodes and relationships appear only when Omni observed them during the range you request, so a dependency exercised once a day is absent from a one-hour window. That absence is not evidence that the dependency does not exist.

5. **Discovered resources report current inventory.** Resource discovery is not constrained by the telemetry time range, so discovered resources reflect the latest inventory regardless of the range you choose.

Where to go next

To do this	See
Read the map, group it, and open a service from it	the section called “Monitor applications with the application map”
Instrument a service so it appears in the graph	the section called “Send telemetry to CloudWatch Omni”
Query the telemetry behind a node	the section called “Explore and query your telemetry”

Using AWS Config for resource discovery

CloudWatch Omni uses AWS Config to find the AWS resources in your account. Omni then adds those resources to the context graph. This page lists the resource types that AWS Config records for Omni, and describes how the recorder works.

To learn how discovered resources appear in the graph, see the section called “Using Context Graph”.

How the recorder works

Omni creates a *service-linked configuration recorder* when you create a space. The recorder is named `AWSConfigurationRecorderForCloudWatch`. You do not create it. You do not configure it.

A service-linked recorder belongs to the service that it is linked to. That service sets the resource types to record. To learn more, see Working with the configuration recorder in the *AWS Config Developer Guide*.

The recorder works as follows:

- **You pay no AWS Config fee.** Omni uses an internal recording scope. AWS Config does not send these records to your delivery channel, and you cannot read them in AWS Config. You can still see the recorder itself in the AWS Config console.
- **The recorder's settings are fixed.** You cannot change them in AWS Config. You cannot rename the recorder, and you cannot start it or stop it. Omni sets which resource types the recorder records, and it records the same types in every account.
- **You can delete the recorder, but not while a space uses it.** When you call `DeleteServiceLinkedConfigurationRecorder`, AWS Config asks Omni whether it still uses the recorder. While your space has an active AWS Config integration, Omni answers yes and your call fails. To remove the recorder, delete the space first.
- **Deleting the recorder stops resource discovery.** Omni keeps the resources that it already found, and it adds no new ones. AWS Config keeps the records that it already made.
- **Your own recorder is separate.** Omni does not change or use your customer managed recorder.

> **Note**
>
> Other CloudWatch features also create service-linked recorders. Your account can hold more than one recorder that is linked to CloudWatch.

Which resources become graph nodes

AWS Config records every type in the resource-type table on this page. Omni adds a graph node for only some of those types. Omni uses the other records to add detail to nodes that exist. For example, Omni reads subnet and security group records. It uses them to find the network address of a service.

A resource can appear in the graph before Omni gets telemetry from it. To learn more, see the section called “Using Context Graph”.

Which Regions are recorded

Omni creates the recorder in the same Region as your space. The recorder records the resources in that Region.

To add the resources from another Region, centralize that Region's telemetry into the space's account. For more information, see the section called “Set up Omni for your organization”.

AWS Config makes a record only for a type that AWS Config supports in the Region. If AWS Config does not support a type in a Region, no resource of that type appears in the graph for that Region.

Describe calls in CloudTrail

AWS Config takes an inventory of the resources in your account at regular times. It does this for all resources, not only for the types that this page lists. You can therefore see `ConfigResourceCompositionSession` and `AWSConfig-Describe` calls in CloudTrail, including calls for types that Omni does not record. This behavior keeps the AWS Config inventory consistent.

Recorded resource types

AWS Config records the following resource types for Omni.

Category	AWS service	Resource types
Compute	AWS App Runner	`AWS::AppRunner::Service`
Compute	AWS Elastic Beanstalk	`AWS::ElasticBeanstalk::Environment`
Compute	AWS Lambda	`AWS::Lambda::Function`
Compute	Amazon EC2	`AWS::EC2::Instance` `AWS::EC2::LaunchTemplate`

Monitor a service

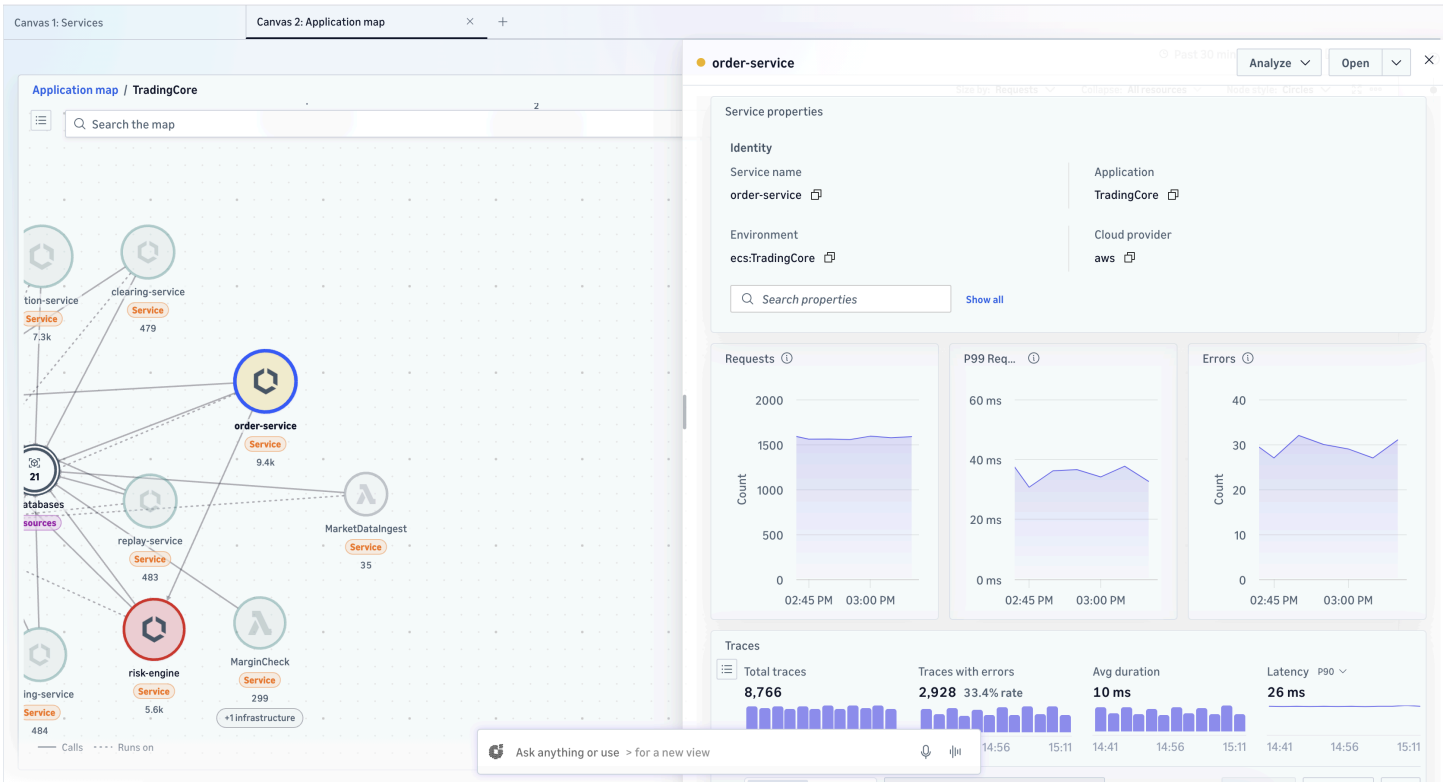
Open a service

Open a service from the application map or services list. The service view shows information for the selected time range.

Use the service signals to narrow the problem

Start in the service details view to decide what kind of issue you are seeing. Review the following telemetry:

- **Service properties**, such as the service name and identifying attributes for application, environment, cloud provider, Region, or account.
- **Requests** to spot traffic changes.
- **Request Latency** to identify slowdowns affecting the service.
- **Errors** to see whether requests are failing.
- **Trace summary** to see how much trace data exists for the service and how much of it includes errors.



Together, these signals help you decide whether to investigate traces, logs, or broader service behavior.

Continue the investigation from the service view

From the service details view, you can continue directly into the telemetry behind the service. Use the following actions:

- From a service, choose **Analyze traces** or **View traces**.
- From a point on a metric chart, choose **Search for traces** to see the traces from exactly that time bucket or **Open in Explore** to continue analysis in Explore. On a latency chart the option is **Search for slow traces**, biased toward the slow requests behind the point you chose.

For how to read the traces list, inspect a trace's spans, and pivot from a span to logs or service metrics, see the section called “Application traces”. For an agent's own runs, see the section called “Agent traces”. To query trace data directly instead, see the section called “Explore and query your telemetry”.

What to watch out for

- **A trace ends where instrumentation ends.** A call to an uninstrumented service shows as the caller's outgoing span with nothing deeper. To extend the trace, instrument the callee. See the section called “Send telemetry to CloudWatch Omni”.
- **Errors can read Not available.** The **Errors** metric needs a dimension that not all telemetry carries; when it is absent, the service view says **Not available** rather than showing a misleading zero. Faults are unaffected.

Populate the request metrics with span metrics

The request metrics (**Requests**, **Errors**, and **Latency**) are derived from span metrics. To emit span metrics, add the CloudWatch plugin for OpenTelemetry to your application's instrumentation. For details, see the section called “Send telemetry to CloudWatch Omni” and the section called “Send application telemetry”.

Where to go next

To do this	See
Query trace data with SQL, or pivot by trace ID	the section called “Explore and query your telemetry”
Explore an agent's own traces and sessions	the section called “Agent traces” and the section called “Agent sessions”
Investigate an individual request end to end	the section called “Application traces”
See the whole system a service belongs to	the section called “Monitor applications with the application map”

Application traces

An application trace records one request as it passes through your services and dependencies. A span records one operation within that trace. Use this page to find a request, inspect the operations inside it, and open the related logs or service metrics.

For traces of AI agent runs, see the section called “Agent traces”.

Available in the Omni web UI only.

Open application traces

Choose the entry point that matches what you are investigating:

- From the launcher, under Application performance monitoring, choose `Traces` to explore requests directly.
- From the application map, select a service and choose **Analyze traces**.
- From Services, open a service and choose **Analyze traces**.

Select the time range you want to investigate.

Trace context does not propagate by itself: both sides of each hop must be instrumented. If the next service in a request is not instrumented, the trace stops there.

Choose traces or spans

Choose the investigation level that matches your question.

Traces

Choose **Traces** when you want to investigate a complete request.

Use traces for questions such as:

- Which requests failed?
- Which requests were slow?
- Which trace should you inspect in detail?

The summary above the results shows information such as **Total traces** and **Traces with errors** for the selected time range.

Spans

Choose **Spans** when you want to search individual operations across traces.

Use spans for questions such as:

- Which `DynamoDB.PutItem` operations reported errors?
- Which dependency operations took the longest?
- Which operations ran in a particular service?
- Which spans match a status or attribute?

Use **Search spans** to find an operation by name. Use the status control or **Errors** filter to narrow the results.

The results show when each span occurred and the operation it represents.

Investigate a request

1. Select the relevant time range.
2. Use **Traces** to find a complete request, or use **Spans** to find a specific operation.
3. Select a trace to review the operations that occurred during the request.
4. Find the span where an error occurred or where the request spent unexpected time.

5. Open related logs or service metrics when you need more evidence.

For aggregate application topology, see the section called “Monitor applications with the application map”. For one service's health and telemetry, see the section called “Monitor a service”.

Inspect a trace

Select a trace to open its detail view. The trace header shows the trace ID and the number of spans in the trace.

Switch among the available views:

- Timeline
- Graph
- Flame
- JSON

Use the Timeline view to follow span timing and parent-child relationships.

You can also:

- Search for a span within the trace.
- Filter spans by status.
- Choose Tree to follow parent-child structure.
- Choose Grouped to organize similar spans together.
- Use Errors to focus on spans that reported an error.
- Choose Reset to remove the current trace-detail filters.

Select a span to inspect its details.

Inspect trace or span details

Use the Trace and Span controls in the detail view to change the scope of the information shown. Choose Trace to review information about the complete request. Choose Span to review the selected operation.

The span detail can include:

- Name
- Span ID
- Parent ID
- Trace ID
- Service
- Start
- End
- Scope
- Status and duration

Expand the following sections when you need more detail:

- Span attributes
- Resource attributes
- Annotations
- Raw data

View logs for a trace

Logs can provide details that are not present in the trace, such as application messages, exceptions, and business events. From the trace header, choose **Show logs for this trace**. The logs view opens the records associated with the trace when the required correlation information is available.

If no logs appear, confirm that:

- The application produced logs during the request.
- Those logs were sent to your space.
- The selected time range includes the request.
- The log records contain the trace ID used for correlation.

Where supported by your instrumentation, include span and service context in log records as well, so you can narrow logs to the operation and service under investigation. For telemetry configuration, see the section called “Send telemetry to CloudWatch Omni”.

View metrics for a service

Choose **Show metrics for this service** to investigate the metrics associated with the service in the current trace context.

Use service metrics to determine whether the problem in the trace occurred alongside a broader change in request volume, latency, errors, or infrastructure behavior.

For service-level monitoring, see the section called “Monitor a service”.

When trace information is incomplete

Trace investigation depends on the telemetry your applications send. Use the following checks when information is missing:

- No traces appear. Confirm the time range and verify that the workload is sending traces.
- A trace stops at one service. Confirm that the next service is instrumented and propagates trace context.
- A trace has only one or a few flat spans. Verify that the workload records the internal operations you need to inspect.
- Related logs do not appear. Confirm log ingestion and trace-ID correlation.
- Service metrics do not appear. Confirm that the service publishes the required metrics.

Where to go next

To do this	See or choose
Review the service involved in the trace	the section called “Monitor a service”
See application topology and dependencies	the section called “Monitor applications with the application map”
Open logs associated with the request	Show logs for this trace
Examine metrics for the service	Show metrics for this service
Query trace or log records directly	the section called “Explore and query your telemetry”

Investigate an AI agent run instead	the section called “Agent traces”

Connect Slack

An integration connects CloudWatch Omni to a tool your team already uses. Slack delivers alert notifications to your team's channels, and lets your team mention the Omni agent there. You manage it in **Settings**, on the **Integrations** page, and a connection applies to your whole space.

With Slack connected, an alert's notification rules can deliver to Slack channels. You choose the channels on each alert when you set its destinations. See the section called “Alerts”.

Connecting the integration is not enough: delivery also requires the alert's access profile to grant this integration and the channels the alert posts to. Omni checks the grant when you create the alert and again on every delivery, so revoking it stops notifications for alerts that were already working. If an alert fires but nothing reaches Slack, check the profile. See the section called “Access profiles”.

To connect:

1. In **Settings**, choose **Integrations**.
2. On the **Slack** card, choose **Enable**. Slack's authorization page opens in a new tab.
3. Review the requested permissions and choose **Allow**.

Back in Omni, the **Slack** card shows the connected integration: its ID and name. If your Slack workspace requires administrator approval for new apps, ask a workspace administrator to approve the request, then connect again.

What the Slack connection can do. The authorization page lists the exact permissions requested. The connection lets Omni post and reply to messages, read the names of your workspace's public and bot-added private channels so it can offer them as destinations, and receive messages that mention the Omni app. It does not include your workspace's message history. A private channel appears in the channel list only after the Omni app has been added to it.

Bring the Omni agent into Slack. With the integration connected, your team can mention the Omni agent in a Slack channel and get answers there. Connecting the workspace is not enough: the `DefaultAccessProfileForAsyncWorkflows` access profile must also grant the agent permission to post to the integration. Without that grant, a mention is received but the agent

cannot respond. For what the agent can do, see the section called “Ask the Omni agent”. For profiles and grants, see the section called “Access profiles”.

> **Important**
>
> Amazon CloudWatch uses generative AI to produce the agent's replies. A reply can be incomplete or wrong. Verify a finding before you act on it. AWS handles information in accordance with the AWS Privacy Notice.

On the connected **Slack** card, choose **Set up Omni permissions for Slack**. This opens the add-grant form already filled in for the `DefaultAccessProfileForAsyncWorkflows` profile, where you choose the channels the agent may post to. Give the profile a viewer grant as well, so the agent can read the resources it answers about.

The grant covers three things:

- **Reply through the Slack integration** — `cloudwatch:InvokeIntegration`, scoped to the Slack integration's ARN and the channels you choose.
- **Work with conversation threads** — `cloudwatch:GetOmniThread` and `cloudwatch:CreateOmniThread`. A viewer grant already includes both, so a profile that has one does not need them listed separately.
- **Read the resources it answers about** — a viewer grant.

If you author grants through the API instead of the console, use your own integration ARN and channel names:

```
{
  "name": "slack-agent-integration",
  "permission": "CUSTOM",
  "scopedActions": [
    {
      "actions": ["cloudwatch:InvokeIntegration"],
      "resources": [
        {
          "resourceType": "Integration",
          "resourceArns": ["arn:aws:cloudwatch:region:account-id:integration/
integration-id"]
        }
```

```
      ],
      "contextConditions": { "channelNames": ["#oncall-alerts", "#incidents"] }
    },
    { "actions": ["cloudwatch:GetOmniThread", "cloudwatch:CreateOmniThread"] }
  ]
}
```

Pair it with a viewer grant:

```
{ "name": "slack-agent-viewer", "permission": "READ" }
```

Regional Slack apps. The Slack app is Region-specific, and you do not choose it: **Enable** directs you to the Amazon CloudWatch Slack app for the Region your space is in. It appears in your workspace as a bot with a matching name. Within one Region, a Slack workspace can be connected to only one space. The same workspace can be connected to spaces in different Regions. Each Region installs its own bot, so mention the bot whose name matches the Region of the space you want to reach.

Invite the bot to each channel. Connecting the workspace does not add the bot to any channel. Before an alert can deliver notifications to a channel, or a mention in that channel can reach the agent, invite the Region's bot to it from Slack:

```
/invite @Amazon CloudWatch - USEast Virginia
```

Region	Bot name
US East (N. Virginia), `us-east-1`	`Amazon CloudWatch - USEast Virginia`
US East (Ohio), `us-east-2`	`Amazon CloudWatch - US East (Ohio)`
US West (Oregon), `us-west-2`	`Amazon CloudWatch - US West Oregon`
Europe (Ireland), `eu-west-1`	`Amazon CloudWatch - EU (Ireland)`
Asia Pacific (Mumbai), `ap-south-1`	`Amazon CloudWatch - AP (Mumbai)`
Asia Pacific (Singapore), `ap-southeast-1`	`Amazon CloudWatch - AP (Singapore)`

Region	Bot name
Asia Pacific (Sydney), `ap-southeast-2`	`Amazon CloudWatch - AP (Sydney)`
Asia Pacific (Tokyo), `ap-northeast-1`	`Amazon CloudWatch - AP (Tokyo)`
Canada (Central), `ca-central-1`	`Amazon CloudWatch - CA (Central)`
Europe (Frankfurt), `eu-central-1`	`Amazon CloudWatch - EU (Frankfurt)`
Europe (London), `eu-west-2`	`Amazon CloudWatch - EU (London)`
South America (São Paulo), `sa-east-1`	`Amazon CloudWatch - SA (Sao Paulo)`

Disconnect an integration

On the integration's card in **Settings**, on the **Integrations** page, choose **Disable**. Disconnecting Slack stops alert notifications to Slack. The alerts themselves keep evaluating, and their other destinations keep working. You can reconnect with **Enable**.

Who can manage integrations

Integrations apply to the whole space. One person connects, and the connection works for everyone in the space. Whether a member can connect, change, or disconnect an integration is governed by their grants: the integration create, update, and delete actions. See the section called "Custom grant actions".

Use Omni skills

You can use CloudWatch Omni from the AI coding agent you already develop with — including Claude Code, Cursor, Kiro, and Codex — by installing the Omni skills from the Agent Toolkit for AWS. A skill is a set of task-focused instructions, reference material, and scripts that your coding agent loads when a task matches, so it can complete Omni tasks: set up instrumentation, query your telemetry, or work with alerts and dashboards.

> **Note**
>
> This page is about using Omni from your own coding agent. For the AI assistance built into the IDE extension, see the section called "Develop with the IDE extension". For the AI assistant in the Omni web UI, see the section called "Ask the Omni agent".

How skills work with your AWS credentials

When you give your coding agent an Omni task, the agent activates the matching skill and follows its instructions. The scripts included with the skills call the public AWS API endpoints that power Omni (Amazon CloudWatch, Amazon Bedrock AgentCore, and Amazon Bedrock) using the AWS credentials configured in your environment, for example the credentials you get from running `aws sso login`. This is the same authentication the public API uses.

What your coding agent can do with Omni

With the Omni skills installed, your coding agent can help you:

- Set up Omni observability for your application or AI agent, including instrumentation.
- Query the telemetry in your CloudWatch Dataset and work with the results.
- Manage Omni resources such as alerts, dashboards, and agent evaluations.
- Build datasets from traces for agent evaluation.
- Connect external integrations such as Slack.

Install the Omni skills

Before you begin, you need:

- An AWS account with Omni set up. See the section called "Set up Omni".
- AWS credentials configured in your development environment.
- A coding agent that supports skills, such as Claude Code, Cursor, Kiro, or Codex.

To install and use the Omni skills

1. Install the skills from the Getting started page in the Agent Toolkit for AWS User Guide, which has installation instructions for each supported coding agent.
2. Give your coding agent an Omni task, such as "Set up Omni observability for this application" or "Instrument this agent and send its traces to Omni."
3. Verify the result in the Omni web UI. For example, confirm that traces arrive or that the alert or dashboard the agent created matches what you asked for.

Security in CloudWatch Omni

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. For the compliance programs that apply to CloudWatch Omni, see the section called “Compliance validation for CloudWatch Omni”.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when you use CloudWatch Omni. For a space, your share covers who can read your telemetry and which key encrypts what CloudWatch Omni stores. The following topics show you how to configure both, and how to use other AWS services that help you secure a space. To control what content reaches your telemetry before CloudWatch Omni stores it, see the section called “Protect sensitive data”.

Topics

- the section called “Data encryption in CloudWatch Omni”
- the section called “Identity and access management for CloudWatch Omni”

- the section called “Compliance validation for CloudWatch Omni”
- the section called “Resilience in CloudWatch Omni”
- the section called “Infrastructure security in CloudWatch Omni”
- the section called “Configuration and vulnerability analysis in CloudWatch Omni”
- the section called “Cross-service confused deputy prevention”
- the section called “Security best practices for CloudWatch Omni”
- the section called “Opting out of using your data for service improvement”
- the section called “IAM policies to use CloudWatch Omni”
- the section called “Cross-Region inference in CloudWatch Omni”

Data encryption in CloudWatch Omni

CloudWatch Omni encrypts your data at rest and in transit. This page describes what is encrypted, which keys are used, and what your AWS KMS key policy must allow.

To choose what content enters your telemetry, see the section called “Protect sensitive data”. To configure a customer managed key on your space, see the section called “Set up Omni”.

Encryption at rest

Store	Default encryption	Customer managed key
Telemetry in your space, held in the CloudWatch Dataset	Managed by CloudWatch Omni	Supported for enabled accounts. Configure the key on the space.
Evaluation job and configuration metadata	AWS KMS key	Supported
Staging storage in Amazon S3	SSE-S3, with versioning and TLS-enforced access	—
Forward access session credentials	A dedicated service-managed AWS KMS key. These credentials are envelope-encrypted, bound by	Service-managed

Store	Default encryption	Customer managed key
	encryption context to the job that uses them, and never written to logs.	

> **Important**
>
> Customer managed key support is enabled per account, so the option might not appear when you configure your space. Removing a customer managed key from a space requires `kms:Decrypt` on the outgoing key, so the caller can still read data already written under it.

Files that CloudWatch Omni writes to your own machine are not encrypted by the service. When you use the IDE extension and local development tools, telemetry can be written under a local `.omni/` directory, including raw prompts and responses. These files are plaintext and rely on your operating-system file permissions. Local mode keeps your telemetry off the network until you choose to send it, but it does not encrypt it at rest. Protecting these files is your responsibility, and the sample `.gitignore` that ships with the tooling re-includes several `.omni/` data files, so raw trace content can be committed to source control. Available in the IDE extension only.

Key management

If you use a customer managed AWS KMS key, your key policy must allow the following. Your policy needs **both** of the first two statements: when you attach the key with AssociateDatasetKmsKey, CloudWatch checks your own access to the key before it checks the service's, so a policy that grants only the CloudWatch service principal is denied for the caller and the key is rejected.

1. **Dry-run checks signed by the CloudWatch service principal.** When you attach a customer managed key to a space, CloudWatch Omni performs dry-run `kms:Decrypt` and `kms:GenerateDataKey` calls against your key, using the encryption context `{"aws:cloudwatch:arn":"arn:aws:cloudwatch:<region>:<account-id>:space/<space-id>"}`. Both must succeed, or the key is rejected when you attach it. The service repeats the check on later requests. A key policy that is narrowed after you attach the key fails closed rather than silently. These calls are signed by the CloudWatch service principal, `cloudwatch.amazonaws.com`, and not by you. Grant that principal both actions on the encryption context above, and condition the statement on

`aws:SourceArn` for the space ARN. Because the context is an ARN, you can grant on `arn:aws:cloudwatch:<region>:<account-id>:space/*` before you create a space, then narrow to a specific space afterward.

2. **`kms:DescribeKey` for the principal that configures the key.** Grant this in a statement of its own, with no encryption context condition. `DescribeKey` requests do not carry an encryption context, so this action cannot sit under the condition that scopes the crypto grants.
3. **Crypto operations on evaluation metadata.** When you configure a customer managed key for evaluation metadata, the service requires `kms:Decrypt`, `kms:DescribeKey`, and `kms:GenerateDataKey` on that key.

Scope of the dataset key: AssociateDatasetKmsKey and DisassociateDatasetKmsKey operate on the Dataset, which holds your space's telemetry. The key is associated at the Dataset level rather than per signal type, so associating a customer managed key covers everything the Dataset holds, and disassociating it reverts all of it.

Sample key policy

The following sample key policy covers every way CloudWatch Omni uses your key: the space and Dataset checks described above, the material the service encrypts on your behalf, forwarded telemetry entering the Dataset, and reads by the space operator role. Add the statements you need to your key policy. Replace `111122223333` with your account ID and `us-east-1` with your Region.

      }
    }
  ]
}
```

The role ARNs in this sample use the form that setup creates in a single account: the `service-role/` path and a numeric suffix on the role name. Replace each one with the exact ARN of the role in your account, which you can copy from the IAM console. For an organization domain, the space operator role is `CloudWatchOmniOperatorRole` at the root path, with no suffix.

What each group of statements is for:

- **Root key administration** keeps your account able to manage the key. Do not remove it.
- **The `cloudwatch.amazonaws.com` statements** let the service encrypt and read your space content, your Dataset, and the analysis material the service builds from your telemetry. The encryption-context and `aws:SourceArn` conditions restrict each statement so the key can be used only for CloudWatch Omni resources in your own account.
- **`AllowCallerDatasetForwarding`** lets the Dataset integration execution role write forwarded logs and traces into a Dataset encrypted with this key. If you created your own execution role, use its ARN here. See the section called “Send telemetry to CloudWatch Omni”.
- **The operator-role statements** let the space operator role read data encrypted under the key, only through CloudWatch (`kms:ViaService`).

Encryption in transit

All communication with CloudWatch Omni service endpoints uses HTTPS with TLS. The public API endpoints require a minimum of TLS 1.2. We recommend TLS 1.3, and the service supports post-quantum hybrid key exchange. Amazon S3 access is TLS-enforced.

Telemetry ingestion is over HTTPS and is authenticated with Signature Version 4. Unsigned requests are rejected with an HTTP 403 response.

Important

CloudWatch Omni does not offer FIPS 140-3 validated endpoints. If you require FIPS 140-3 validated cryptographic modules, review this limitation before you send telemetry.

Operational data that CloudWatch Omni records about you

Request logs and audit events are delivered to AWS CloudTrail as management events, and include the resource ARN, the calling principal, the account ID, and the organization ID. Service metadata such as timestamps and resource identifiers is encrypted with AWS managed keys.

Identity and access management for CloudWatch Omni

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use CloudWatch Omni resources. IAM is an AWS service that you can use with no additional charge.

CloudWatch Omni uses the Amazon CloudWatch identity. Actions are in the `cloudwatch` namespace and requests are signed with the `cloudwatch` Signature Version 4 signing name. The endpoint prefix differs from the signing name: requests go to `cloudwatch-omni.{region}.api.aws` but sign as `cloudwatch`.

How CloudWatch Omni works with IAM

IAM feature	CloudWatch Omni support
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Forward access sessions	Yes
Service roles	Yes
Service-linked roles	Yes

To get a high-level view of how CloudWatch Omni and other AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

Resource-based policies. CloudWatch Omni does not support resource-based policies. Space membership and access grants control fine-grained access within a space instead. See the section called "Control access to your space" and the section called "Access profiles".

Policy actions. Administrators can use AWS JSON policies to specify who has access to what: which principal can perform actions on which resources, and under what conditions. To see the list of CloudWatch Omni actions, see the *Service Authorization Reference*.

Policy resources. CloudWatch Omni supports the following resource types in policies:

`access-grant`, `access-profile`, `alert`, `dataset`, `domain`, `integration`, `omni-dashboard`, `space`, and `view`.

Domains and access grants that are scoped to an organization use the `organization-domain` and `organization-access-grant` resource types.

Policy condition keys. CloudWatch Omni supports the tag-based condition keys `aws:RequestTag/*` and `aws:TagKeys` on the operations that create a taggable resource, and `aws:ResourceTag/*` on tagged resources. See the "Tag-based access control" section of this page.

ACLs. Access control lists control which principals have permissions to access a resource. CloudWatch Omni does not support ACLs.

Attribute-based access control. Attribute-based access control (ABAC) defines permissions based on attributes, which in AWS are tags. CloudWatch Omni supports applying tags when you create a resource, and supports the tag-based condition keys.

Temporary credentials. CloudWatch Omni works with temporary credentials, and requests are signed with Signature Version 4. You can sign in with IAM Identity Center or with IAM. In both cases, CloudWatch Omni issues credentials that are scoped to the space you are working in.

Forward access sessions. When you run a telemetry query, CloudWatch Omni uses forward access session credentials to read your telemetry on your behalf, so the read is authorized as you rather than as the service. See the section called “Data encryption in CloudWatch Omni” for how those credentials are protected.

Service roles. CloudWatch Omni uses IAM roles that it assumes to read your telemetry and to operate on your resources. It creates most of them for you, and accepts a role that you supply for an organization domain and for agent evaluations. See the "Service roles used for setup" section of this page.

Service-linked roles. CloudWatch Omni uses a service-linked role, `AWSServiceRoleForCloudWatch_Omni`, which carries the `AWSCloudWatchOmniServiceRolePolicy` managed policy. It assumes that role to create the setup roles it manages in your account, and to attach their policies.

Domains and spaces

A *domain* and a *space* are distinct resources. A domain is the identity and federation boundary, and single sign-on is configured for each domain. A space is the top-level container for observability data within a domain, with the resource type `space` and the ARN form `space/{spaceId}`.

AWS managed policies

The space operator role carries `CloudWatchOmniSpaceAccessPolicy` as its base policy, and can also carry two optional policies chosen during setup: `CloudWatchOmniModelInferencePolicy` (described below) and `CloudWatchOmniAWSIntegrationPolicy`, which lets CloudWatch Omni discover resources and their relationships for Context Graph. CloudWatch Omni provides further managed policies for other roles, including `CloudWatchOmniDomainAccessPolicy` for organization domain administration. For the complete set and each policy's contents, see the section called “AWS managed policies for CloudWatch Omni”.

Managed policy	What it grants	When it is attached
`CloudWatchOmniSpaceAccessPolicy`	The space experience — space and access-grant management, telemetry queries, the context graph, alerts, dashboards, access profiles, views, threads, and integrations — together with evaluation management. It also carries the supporting permissions those need in other services, including CloudWatch Logs, AWS KMS, Secrets Manager, IAM Identity Center, and Amazon SNS.	Always. This is the base policy.
`CloudWatchOmniModelInferencePolicy`	Model inference only: invoking foundation models and inference profiles in Amazon Bedrock, including streaming responses, and invoking models served through Amazon Bedrock Mantle. It grants nothing else.	Only for spaces that use the prompt playground or run evaluations with custom evaluators. A view-only space does not receive it.

Keeping inference in its own policy means that a space can set up and view its evaluation configuration without holding permission to invoke a model. Only running a model requires the second policy.

When the CloudWatch Omni service-linked role creates the space operator role, it applies `CloudWatchOmniSpaceAccessPolicy` as the role's permissions boundary, which caps the role's effective permissions to that same set.

For what each policy grants action by action, the permissions that read metadata across your whole account, and the permissions you must provide yourself, see the section called “IAM policies to use CloudWatch Omni”.

Service roles used for setup

Setup uses several IAM roles, and CloudWatch Omni creates most of them for you. When you enable a capability, the service assumes its service-linked role and creates the role in your account with the matching AWS managed policy attached. Two roles are yours to create and pass in: the domain access role for an organization domain, and the evaluation execution role for online agent evaluations. You can also supply your own space operator role instead of letting CloudWatch Omni create one.

Role	Purpose	Created by	Required
`CloudWatchOmniSpaceAccessRole`, or `CloudWatchOmniOperatorRole` for an organization domain	The space operator role, which is the primary setup and data-access role. It carries the CloudWatch Omni actions along with the Amazon Bedrock, AWS KMS, AWS Config, Secrets Manager, CloudWatch Logs, and `iam:PassRole` permissions that setup and evaluation require. In a single	CloudWatch Omni, or you	Required

Role	Purpose	Created by	Required
	account, setup adds a numeric suffix to the role name. For an organization domain, one role per account is shared by every space in it. In the API it is the `dataAccessRoleArn` parameter.		
`CloudWatchOmniDomainAccessRole`	Domain access. You pass its ARN when you create a domain for your organization.	You	Required for an organization domain
`CloudWatchOmniIntegrationEnablementRole`	Enabling telemetry integrations for your account. One role per member account.	CloudWatch Omni	Required for integrations
`CloudWatchOmniDatasetIntegrationExecutionRole`	Dataset integration. Assumed by `logs.amazonaws.com`, and restricted to dataset integrations in your own account.	CloudWatch Omni	Required for dataset integration
`AgentCoreEvaluationRole`	Execution role for online agent evaluations. You pass its ARN when you create or update a space.	You	Optional. You can opt out, or point to an existing role.

Required means the role must exist for that capability to work, not that you have to create it yourself.

The operator role trusts the CloudWatch Omni service principal `cloudwatch.amazonaws.com`. For the trust policies that setup uses, see the section called "Cross-service confused deputy prevention".

Several operations take a role ARN that you supply, including your own operator role, the domain access role, and the evaluation execution role. Your calling principal needs `iam:PassRole` for the role you pass.

Tag-based access control

CloudWatch Omni supports tags on 11 resource types: `space`, `domain`, `organization-domain`, `access-grant`, `organization-access-grant`, `access-profile`, `omni-dashboard`, `alert`, `view`, `integration`, and `dataset`. You cannot tag any other CloudWatch resource through CloudWatch Omni.

Eight of these accept tags at creation: `space`, `domain`, `organization-domain`, `access-grant`, `organization-access-grant`, `access-profile`, `omni-dashboard`, and `alert`. For these, you can use `aws:RequestTag/*` and `aws:TagKeys` in your policies to control what a principal is allowed to create.

The remaining three (`view`, `integration`, and `dataset`) are tagged after they exist, so the request-tag condition keys do not apply to them.

You can use `aws:ResourceTag/*` to control access to any tagged resource.

Telemetry ingestion identity

You can authenticate telemetry ingestion in two ways. Both are available for metrics, logs, and traces.

1. **Signature Version 4 with an IAM role.** Sign OTLP ingestion requests with Signature Version 4 using temporary role credentials. This is the recommended approach.
2. **A bearer token.** For clients that cannot sign with Signature Version 4, you can use an IAM service-specific credential on a dedicated IAM user. This is available for metrics, logs, and traces, with a separate API key for each.

For metrics and logs, you create an API key from CloudWatch settings in the console. The console creates a dedicated IAM user with the `CloudWatchAPIKeyAccess` managed policy and issues the bearer token as a service-specific credential on that user. For the published setup steps, see Bearer token authentication for OTLP metrics in the *Amazon CloudWatch User Guide* and OTLP endpoints for CloudWatch Logs in the *Amazon CloudWatch Logs User Guide*. For traces, see Setting up bearer token authentication for traces in the *X-Ray Developer Guide*.

You create and manage API keys and their credentials in the CloudWatch console using your own IAM permissions. CloudWatch Omni itself can list them but cannot create, rotate, or delete them.

For credential hygiene guidance, see the section called “Security best practices for CloudWatch Omni”.

Read-time access scope

A member's grant controls what their queries and views return. CloudWatch Omni applies the scope when it runs the query. To set it, see the section called “Limit what members can see”.

The scope constrains the telemetry query path. Other features can reach the same content, so grant their permissions with that in mind. See the section called “Security best practices for CloudWatch Omni”.

Space-level access control

IAM controls who can reach CloudWatch Omni and what the service may do in your account. Access to the contents of a space is a second, separate decision, evaluated inside the space. Both apply to every request.

- **The member's permission level** decides whether a principal may ask for an operation. A grant carries one of four levels: Viewer, Editor, Space Admin, or Custom, where Custom allows exactly the actions it lists.
- **The space operator role** decides whether the space may carry that operation out against your AWS resources. Raising a member to Space Admin adds no permission that this role does not already hold, so the role is the ceiling for everything in the space. One operator role serves every space in the account, so that ceiling is account-wide. You cannot separate two spaces from each other by giving them different operator roles.

For an audit, the properties that follow from that design:

- **Grants only add.** A principal's effective access is the union of every grant it holds, directly and through groups. For the tiered levels the highest one wins, and a Custom grant adds the actions it names. There are no explicit denies, so you cannot subtract access from a principal by adding a grant. You remove the grant that provides the access. Action scopes narrow only the actions they name, so they do not turn a tiered level into an exact allowlist. See the section called "Custom grant actions".
- **Read scope is row-level and enforced at read time.** A grant can carry a data scope that filters telemetry rows on the query path, before results reach the member. It filters rows, not fields: a member who can see a record sees every field on it.
- **A data scope on one grant does not narrow another.** A second grant without a scope restores the full view, including a grant inherited through a group.
- **Space administration is reserved for people.** An access profile, which is the identity a resource such as an alert uses when no one is signed in, can hold Viewer, Editor, or Custom, never Space Admin, and can never exceed the space operator role.
- **A space always retains at least one Space Admin.** The grant that provides the last Space Admin access cannot be deleted, and no principal can edit or delete its own grants.
- **Some grants are created by the service.** Those are marked service managed and cannot be edited or deleted.

To review or change any of this, see the section called "Control access to your space" for the model, the section called "Manage space members and permissions" for the members and grants surface, the section called "Limit what members can see" for data scopes, and the section called "Access profiles" for resource identities.

Troubleshooting identity and access

A `403` response with `AccessDeniedException` indicates that the calling principal is not authorized, or that the request signature did not validate. Confirm which identity the request is using with `aws sts get-caller-identity`, and confirm that the identity holds an active access grant in the space. A sign-in problem, such as an expired one-time code, returns a `400` rather than a `403`.

For signing telemetry ingestion requests from an OpenTelemetry exporter, see the section called "Send telemetry to CloudWatch Omni".

Compliance validation for CloudWatch Omni

Third-party auditors assess the security and compliance of AWS services as part of multiple AWS compliance programs. To learn whether CloudWatch Omni is within the scope of specific compliance programs, see AWS Services in Scope by Compliance Program and choose the compliance program that you are interested in.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using CloudWatch Omni is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security and compliance quick start guides – Deployment guides that discuss architectural considerations and provide steps for deploying baseline environments on AWS.
- AWS compliance resources – A collection of workbooks and guides that might apply to your industry and location.
- AWS Config – A service that assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub – A service that provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

For general information, see AWS Compliance Programs.

> **Note**
>
> CloudWatch Omni is not in scope for any AWS compliance program. For the current status of every AWS service, see AWS Services in Scope by Compliance Program.

Resilience in CloudWatch Omni

The AWS global infrastructure is built around AWS Regions and Availability Zones. Regions provide multiple physically separated and isolated Availability Zones, which are connected through low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones

without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

Infrastructure security in CloudWatch Omni

As a managed service, CloudWatch Omni is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access CloudWatch Omni through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests. CloudWatch Omni uses Signature Version 4 with the `cloudwatch` signing name.

When CloudWatch Omni reads your telemetry to answer a query, it uses forward access session credentials, so the read is authorized as you rather than as the service. For that identity model, see the section called “Identity and access management for CloudWatch Omni”, and for how those credentials are protected, see the section called “Data encryption in CloudWatch Omni”.

Tenancy and data segregation

CloudWatch Omni stores its metadata in shared, multi-tenant tables. Each item is logically isolated and scoped to the account that owns it. The underlying stores are not physically isolated for each account.

A request for a resource that another account owns is denied, and CloudWatch Omni does not reveal whether that resource exists, so resources cannot be enumerated across accounts. Resource-name uniqueness is scoped to each account.

The local trust boundary

Parts of CloudWatch Omni run on your own machine: the IDE extension, a local development server, and a local Model Context Protocol (MCP) server. Local mode is available in the IDE extension only and does not require an AWS connection. For what the extension does and how to set it up, see the section called “Develop with the IDE extension”.

You are responsible for the security of these local components and of the machine they run on:

- **The local MCP server has no authentication or authorization.** It runs as a child process of the client that launches it, and its proxy accepts connections only from the local machine. Any process that can run on your machine can access it.
- **The tooling can install its MCP configuration into third-party AI coding-assistant directories.** A connected assistant can then read raw local trace content, including prompts, responses, and tool inputs and outputs, without any additional authorization. Before you install the configuration, decide whether that assistant should have access to this data.
- **Local telemetry files are plaintext.** The service does not encrypt them. See the section called “Data encryption in CloudWatch Omni”.

Code-based evaluators run as AWS Lambda functions in your own account. CloudWatch Omni invokes a function whose name begins with `cloudwatchCodeEvaluator` and reads its configuration; it cannot create, modify, or delete the function. Evaluator code runs under an execution role that you control, and CloudWatch Omni does not host or execute evaluator code in its own service. Prompt-based evaluators run in Amazon Bedrock AgentCore and are scored by the model you configure. See the section called “Evaluators and evaluations”.

Interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your virtual private cloud (VPC) and CloudWatch Omni by creating an *interface VPC endpoint*. Interface endpoints are powered by AWS PrivateLink, which you can use to privately access CloudWatch Omni without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC do not need public IP addresses to communicate with the service, and traffic between your VPC and CloudWatch Omni does not leave the AWS network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets.

For more information, see Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

Endpoint services for CloudWatch Omni

CloudWatch Omni offers two VPC endpoint services. Create an interface endpoint for each service that you use.

Endpoint service name	Private DNS name	What it carries
`com.amazonaws.{region}.cloudwatch-omni`	`cloudwatch-omni.{region}.api.aws`	The CloudWatch Omni API and telemetry ingestion
`com.amazonaws.{region}.cloudwatch-omni-threads`	`cloudwatch-omni-threads.{region}.api.aws`	The WebSocket session that the Omni agent uses, on port 8443

Both endpoint services support private DNS and VPC endpoint policies. Because each private DNS name is the same as the corresponding public hostname, a client in a VPC that has the interface endpoint reaches the service privately with no change to its configuration.

Considerations for CloudWatch Omni VPC endpoints

Before you set up an interface VPC endpoint for CloudWatch Omni, review Access an AWS service using an interface VPC endpoint in the *AWS PrivateLink Guide*.

- The endpoint provides private access to the CloudWatch Omni service endpoint `cloudwatch-omni.{region}.api.aws`, for both the API and telemetry ingestion. All communication uses TLS. The endpoint requires a minimum of TLS 1.2 and supports TLS 1.3 with post-quantum hybrid key exchange.
- The endpoint is a dual-stack endpoint, supporting both IPv4 and IPv6.
- CloudWatch Omni supports private DNS for the endpoint. When you enable private DNS, requests to the default service hostname `cloudwatch-omni.{region}.api.aws` resolve to your interface endpoint automatically, so you do not have to change your client endpoint configuration.

- CloudWatch Omni supports VPC endpoint policies. See the "Create a VPC endpoint policy for CloudWatch Omni" section of this page.
- The endpoint is available in the AWS Regions where CloudWatch Omni is available.

Create an interface VPC endpoint for CloudWatch Omni

You can create an interface VPC endpoint for CloudWatch Omni using either the Amazon VPC console or the AWS Command Line Interface. For more information, see Create an interface endpoint in the *AWS PrivateLink Guide*.

Create an interface VPC endpoint for CloudWatch Omni using the following service name:

```
com.amazonaws.{region}.cloudwatch-omni
```

For example, in US East (N. Virginia):

```
com.amazonaws.us-east-1.cloudwatch-omni
```

If you enable private DNS for the endpoint, you can make API and telemetry-ingestion requests to CloudWatch Omni using its default DNS name for the Region, `cloudwatch-omni.{region}.api.aws`, and they route through the interface endpoint.

Create a VPC endpoint policy for CloudWatch Omni

You can attach an endpoint policy to your VPC endpoint that controls access to CloudWatch Omni. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

By default, full access to CloudWatch Omni is allowed through the endpoint. To restrict access, attach a custom endpoint policy to the interface endpoint. For more information, see Control access to services using endpoint policies in the *AWS PrivateLink Guide*.

Configuration and vulnerability analysis in CloudWatch Omni

Configuration and IT controls are a shared responsibility between AWS and you, our customer. For more information, see the AWS shared responsibility model.

For the managed service, AWS handles basic security tasks such as guest operating system and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following AWS resources:

- Shared responsibility model
- Best practices for security, identity, and compliance

CloudWatch Omni also ships software that you install. The following components run in your environment, and keeping them current is your responsibility. For the extension itself, see the section called "Develop with the IDE extension". For installing the collector, see the section called "Send telemetry to CloudWatch Omni".

Component	How it updates	Your responsibility
The IDE extension	Updates itself through the extension gallery.	Keep automatic updates enabled, and apply updates.
The local MCP server	Bundled inside the IDE extension and versioned with it. It has no separate patch cadence.	Update it by updating the extension.
The local development server	Bundled with the IDE extension.	Update it by updating the extension.
The AWS Distro for OpenTelemetry collector	You install it and you patch it. It is pinned in your own dependency manifests.	Track and apply upstream security updates yourself.

Updates and vulnerability notification. There is no separate security-bulletin or vulnerability-notification channel for these components. Keep extension updates enabled, and track upstream OpenTelemetry releases yourself to stay current on security fixes.

The local MCP server and third-party AI assistants

The local MCP server has no authentication. See the section called “Infrastructure security in CloudWatch Omni”. Its tool set exposes trace search, dataset, evaluation, and credential operations. Because the tooling can connect this content to third-party AI coding assistants, review and control which assistants you allow to access your local trace and dataset content. See the section called “Security best practices for CloudWatch Omni”.

Cross-service confused deputy prevention

The confused deputy problem is a security issue where an entity that does not have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies to limit the permissions that CloudWatch Omni gives another service to the resource. Use `aws:SourceArn` if you want only one resource to be associated with the cross-service access. Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

CloudWatch Omni assumes IAM roles in your account to read your telemetry, both during setup and during evaluation. To prevent it from being used as a confused deputy, restrict the roles you create so that they can only be assumed on your behalf.

Setup and data-access roles

The space operator role trusts the CloudWatch Omni service principal `cloudwatch.amazonaws.com`. When you set up a space in a single account, CloudWatch Omni creates this role and applies the following trust policy. If you supply your own role instead, give it the same trust policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": { "Service": "cloudwatch.amazonaws.com" },
      "Action": ["sts:AssumeRole", "sts:TagSession", "sts:SetSourceIdentity",
 "sts:SetContext"],
      "Condition": {
        "StringEquals": { "aws:SourceAccount": "<YOUR_OWN_ACCOUNT_ID>" }
      }
    }
  ]
}
```

The `aws:SourceAccount` condition limits CloudWatch Omni to assuming this role on behalf of your own account.

Dataset integration execution role

Dataset integration reads your CloudWatch Logs data through a role that CloudWatch Logs assumes on your behalf. Because the calling service is CloudWatch Logs rather than CloudWatch Omni, this role's trust policy uses both `aws:SourceAccount` and `aws:SourceArn` to restrict the assumption to dataset integrations in your own account.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": { "Service": "logs.amazonaws.com" },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": { "aws:SourceAccount": "<YOUR_OWN_ACCOUNT_ID>" },
        "ArnLike": { "aws:SourceArn":
 "arn:aws:observabilityadmin:*:<YOUR_OWN_ACCOUNT_ID>:dataset-integration/*" }
      }
    }
  ]
}
```

Security best practices for CloudWatch Omni

CloudWatch Omni provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and do not represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

Preventative controls

Use temporary credentials for telemetry ingestion. Prefer Signature Version 4 with temporary role credentials over long-lived access keys. Never embed credentials in source code or in client applications. Store any secrets in a secrets manager and rotate them regularly.

Prefer role credentials over bearer tokens. For metrics, logs, and traces, telemetry ingestion supports both Signature Version 4 with an IAM role and a long-lived bearer token, which is an IAM user service-specific credential, with a separate one for each signal. Prefer the role path. If you use a bearer token, scope it so that it can only send telemetry, store it in a secrets manager, and rotate it regularly. See the section called “Identity and access management for CloudWatch Omni”.

Apply least privilege and keep the administrator group small. Grant each member the lowest permission level that lets them do their job. Keep the set of space administrators small, and review access periodically.

Restrict roles that call CloudWatch Omni outside the console. When a member works in a space, CloudWatch Omni issues credentials for that space and the member's access is limited to what their grants allow. When a principal calls with its own IAM credentials (an automation role, a build pipeline, or an SDK client), a missing grant does not deny the request. The request is authorized by that principal's IAM policy instead. Grant each such role only the actions it needs, and do not rely on space grants to constrain it. See the section called “Identity and access management for CloudWatch Omni”.

Require a grant on roles you create for programmatic access. To make a role's CloudWatch Omni permissions effective only when the caller has a grant in the space, add the condition `"cloudwatch:HasAccessGrant": "true"` to the role's policy. Keep the setup and administration actions in a separate statement without the condition, because those operations are authorized by IAM alone.

Use a Custom grant when you need an exact set of actions. Adding action scopes to a grant on one of the tiered permission levels narrows only the actions you name; every other action that the

level allows remains available. If your intent is to allow an exact set of actions and nothing else, use a Custom grant, which is an allowlist. See the section called “Custom grant actions”.

Redact sensitive content at capture time. CloudWatch Omni does not automatically detect or redact personally identifiable information. Redacting before content leaves your application process is the only layer that guarantees data never leaves your application. For the mechanisms available at each point in the pipeline, see the section called “Protect sensitive data”.

Choose your judge model with your compliance constraints in mind. Restrict which telemetry you evaluate and choose the judge model according to where trace content is allowed to flow. For what a judge model receives, see the section called “Protect sensitive data”. For cross-Region inference, see the section called “Cross-Region inference in CloudWatch Omni”.

Constrain access at the dataset and export layer, not only with query filters. Data scopes do not extend to dataset creation and export, to AI-assisted summaries, or to prompt playground runs. A member who is restricted from a field in queries could still reach that content by building a dataset or running an AI-assisted summary over the underlying traces. Grant dataset, evaluation, export, and AI-feature permissions with this in mind.

Do not rely on data scopes for metrics. A data scope filters log and trace rows. It does not filter metrics. If a member should not see a metric, do not grant them the metric-read actions.

Review member data scopes when you deploy new agents. A data scope is an inclusion rule: it lists the values a member is allowed to see, so a newly deployed agent is not visible to a scoped member until you add it to their scope. Review data scopes whenever you deploy a new agent, so that members who need the new agent can see it.

Verify data scope changes. Saving an edit replaces the member's previous scope rather than adding to it. After you change a member's data scope, have the member run a query to confirm the result.

Review AI-proposed instrumentation changes. Treat AI-generated instrumentation diffs like any other code change, and review them before you apply them.

Control local content exposure. Local `.omni/` files are plaintext, and the local MCP server is unauthenticated. The tooling can share local trace content with third-party AI assistants, so restrict which assistants you connect, and keep raw trace files out of source control. See the section called “Configuration and vulnerability analysis in CloudWatch Omni”.

Detective controls

Audit management activity with AWS CloudTrail. Management operations are recorded in CloudTrail with the event source `cloudwatch.amazonaws.com`. Monitor critical operations and alarm on anomalies.

Opting out of using your data for service improvement

CloudWatch Omni does not use your content to develop or improve the service or its AI features, and your content is not used to train any foundation models. Your content is used only to provide the service to you.

Some CloudWatch Omni features send your content to other AWS services to process. Those services have their own policies, and for some of them you can opt out of having your content used for service improvement. This page describes what each service does and how to opt out where an opt-out is available.

How CloudWatch Omni uses your content

CloudWatch Omni processes the telemetry you send, and your input to its AI features, only to provide the service to you: to answer your questions, run your queries and evaluations, and render your dashboards. It does not retain that content for service improvement, and it does not use it for model training.

For where those requests are processed, and the Regions they can reach, see the section called "Cross-Region inference in CloudWatch Omni".

Other AWS services that process your content

Several features send your content to another AWS service. CloudWatch Omni makes those calls using your own AWS credentials, in your own AWS account.

Feature	Content sent	AWS service
The Omni agent, AI-assisted dashboard creation, and AI-assisted summaries	Your questions and the responses, and the telemetry from your space that is used to answer them	Amazon Bedrock

Feature	Content sent	AWS service
Prompt playground	The prompt you enter, any context you attach, and the model response	Amazon Bedrock
Evaluations	The agent input, output, and trace content that is scored, and the evaluation instructi ons	Amazon Bedrock, Amazon Bedrock AgentCore
Voice input and voice playback	The audio you record, its transcription, and the text that is read back to you	Amazon Transcribe, Amazon Polly

Amazon Bedrock

Amazon Bedrock does not use your inputs or outputs to train models or to improve the service, and does not share them with model providers. For more information, see the Amazon Bedrock FAQs. Amazon Bedrock is not one of the services covered by the AI services opt-out policy, because it does not use your content for service improvement.

For certain models, Amazon Bedrock retains model inputs and outputs for up to 30 days to detect abuse. Abuse detection is separate from service improvement and is not governed by the AI services opt-out policy. For more information, see Amazon Bedrock abuse detection in the *Amazon Bedrock User Guide*.

Amazon Bedrock AgentCore

Amazon Bedrock AgentCore processes content for evaluations that run against an agent runtime. AgentCore states that it "may use and store your content to improve your service experience or performance," and that "such improvements would be for your use of AgentCore and not for other customers." For more information, see What is Amazon Bedrock AgentCore in the *Amazon Bedrock AgentCore Developer Guide*.

AgentCore is not covered by the AI services opt-out policy.

Amazon Transcribe and Amazon Polly

Amazon Transcribe and Amazon Polly process the audio and text for voice input and voice playback. Both services can use content for service improvement, and both are covered by the AI services opt-out policy. To opt out for these services, create an AI services opt-out policy that includes the `transcribe` and `polly` service keys.

```
{
    "services": {
        "transcribe": {
            "opt_out_policy": {
                "@@assign": "optOut"
            }
        },
        "polly": {
            "opt_out_policy": {
                "@@assign": "optOut"
            }
        }
    }
}
```

For instructions, see AI services opt-out policies in the *AWS Organizations User Guide*.

Opting out for other Amazon CloudWatch AI features

Other Amazon CloudWatch features that use artificial intelligence (including natural language query generation for CloudWatch Metrics Insights and CloudWatch Logs Insights, and CloudWatch investigations) can use your content for service improvement. Those features are covered by the AI services opt-out policy under the `cloudwatch` service key. Opting out with that key does not change CloudWatch Omni, which does not use your content for service improvement.

```
{
    "services": {
        "cloudwatch": {
            "opt_out_policy": {
                "@@assign": "optOut"
            }
        }
    }
}
```

> **Note**
>
> An AI services opt-out policy is set in AWS Organizations, not in CloudWatch. Your organization must have all features enabled, and you must enable the AI services opt-out policy type before you can attach a policy. The policy applies to every account in the organization or organizational unit that you attach it to. A standalone account that is not part of an organization cannot use an AI services opt-out policy.

Limiting what enters your telemetry

Whether a service may use your content for improvement is separate from what your telemetry contains. To keep model prompt and response text out of your traces entirely, configure your instrumentation to omit it. See the section called “Protect sensitive data”.

IAM policies to use CloudWatch Omni

The space operator role carries `CloudWatchOmniSpaceAccessPolicy` as its base policy, with `CloudWatchOmniModelInferencePolicy` and `CloudWatchOmniAWSIntegrationPolicy` as optional additions chosen during setup. Between them they cover using a space: querying telemetry, managing alerts and dashboards, and creating and running evaluations. None covers creating a space or a domain, so setup needs permissions you grant yourself. CloudWatch Omni provides further managed policies for other roles, including `CloudWatchOmniDomainAccessPolicy` for organization domain administration. For the complete set, see the section called “AWS managed policies for CloudWatch Omni”.

This page enumerates what each policy grants and why, discloses the permissions that read metadata across your whole account, and lists the permissions you must add separately. For how CloudWatch Omni works with IAM in general (resource types, condition keys, and the roles setup creates), see the section called “Identity and access management for CloudWatch Omni”.

Topics

- Permissions in CloudWatchOmniModelInferencePolicy
- Permissions in CloudWatchOmniSpaceAccessPolicy
- Permissions that read across your whole account
- Permissions you provide yourself

Permissions in CloudWatchOmniModelInferencePolicy

This policy grants model inference and nothing else. It is attached only to spaces that use the prompt playground or run evaluations that invoke a model. A space that only views telemetry does not receive it, and a space can create and view its evaluation configuration without it. Only running a model requires it.

Action	Resources	Why CloudWatch Omni needs it
`bedrock:InvokeModel` , `bedrock:InvokeModelWithResponseStream`	Foundation models and inference profiles	Runs the model you select in the prompt playground, and the model an evaluator uses to score a result.
`bedrock-mantle:CreateInference`	Amazon Bedrock Mantle projects	Runs a model served through Amazon Bedrock Mantle rather than as a Bedrock foundation model.
`bedrock-mantle:CallWithBearerToken`	All resources	Authenticates the Amazon Bedrock Mantle inference call above.

Every action except `bedrock-mantle:CallWithBearerToken` is restricted to your own account by an `aws:ResourceAccount` condition, so a space can invoke only the models, inference profiles, and projects in the account it belongs to. `CallWithBearerToken` has no resource type in the IAM action model, so it cannot be scoped to a resource or narrowed by a condition. The same action appears with the same unscoped resource in the AWS managed policy BedrockAgentCoreFullAccess, which uses it for the same purpose.

Permissions in CloudWatchOmniSpaceAccessPolicy

This is the base policy, always attached. It grants the space experience and the management side of evaluation. The table groups its permissions by what they are for, and gives the condition that limits each group.

Permission group	What it covers	How it is limited
The space experience, in the `cloudwatch` namespace	Space and access-grant management, telemetry query sessions, the context graph, alerts, dashboards, access profiles, views, user preferences, threads, integrations, intelligence configuration, and tagging.	Every action requires the condition `cloudwatch:HasAccessGrant` to be `true`, so a principal with no grant in the space cannot use any of them.
Looking up IAM Identity Center users and groups	`identitystore:ListUsers`, `identitystore:ListGroups`, `identitystore:DescribeUser`, and `identitystore:DescribeGroup` against your Identity Store directories, users, and groups, used when you search for a person or group to grant access to a space.	The call must arrive through CloudWatch (`aws:CalledVia` is `cloudwatch.amazonaws.com`), so the role cannot call Identity Store directly.
A deny on tagging outside CloudWatch Omni	An explicit `Deny` on the three tagging actions for every resource other than the CloudWatch Omni resource types.	Prevents a space session from tagging a classic CloudWatch resource, such as an alarm or a CloudWatch dashboard, to gain access at the resource level.
Passing a role to CloudWatch Omni	`iam:PassRole`, so you can hand CloudWatch Omni the service role you created for the space.	Same account, and `iam:PassedToService` must be `cloudwatch.amazonaws.com`. The role name cannot be restricted by prefix because you supply your own role.

Permission group	What it covers	How it is limited
Passing a role for online evaluations	`iam:PassRole` for the evaluation execution role, so an online evaluation can run when nobody is signed in.	Restricted to roles named `service-role/AgentCoreEvaluationRole*` in your own account, passed only to `bedrock-agentcore.amazonaws.com`.
Reading ingestion users	`iam:ListUserTags` and `iam:ListServiceSpecificCredentials`, so the console can show the bearer tokens that already exist.	Restricted to users under the `omni/` path named `OmniIngestionUser-*` in your own account. Read-only: CloudWatch Omni cannot create, rotate, or delete them.
Reading a customer managed key	`kms:DescribeKey`, so the console can validate and display a key you select.	Same account. Metadata only, and it does not permit any cryptographic operation.
Encrypting space content	`kms:Decrypt` and `kms:GenerateDataKey` against the key you chose for the space.	Four conditions together: same account, the key carries the `cw-omni` tag, the call arrives through CloudWatch, and the encryption context names a space ARN — so the key cannot be used for any other CloudWatch resource type.

Permission group	What it covers	How it is limited
Reading an encrypted IAM Identity Center directory	`kms:Decrypt` against the customer managed key that encrypts your IAM Identity Center directory, so the directory lookups above can read it.	The call must come through Identity Store (`kms:ViaService`), and the encryption context must include the `aws:identitystore:identitystore-arn` key, so it applies only to Identity Store data. It has no same-account condition, because the directory and its key are often in your organization's management account; the key policy remains the control.
Encrypting evaluator material	`kms:Decrypt` and `kms:GenerateDataKey` for evaluator and model-provider key material at the time it is used.	Same account, the request must arrive via `bedrock-agentcore.amazonaws.com`, and the encryption context must name an evaluator ARN in your own account.
Evaluators, datasets, and online evaluation configurations	Full lifecycle of the Amazon Bedrock AgentCore resources that back evaluation, including running an evaluation and tagging these resources.	Scoped separately to the `evaluator`, `dataset`, and `online-evaluation-config` resource types, each in your own account.

Permission group	What it covers	How it is limited
Listing the model catalog	`bedrock:ListFoundationModels` and `bedrock:ListInferenceProfiles`, so you can pick a model when you create an evaluator or open the playground.	Listing only. Invoking a model requires the separate inference policy above.
Writing evaluation results	Creating the log groups, log streams, and log events that record evaluation scores and annotations in CloudWatch Logs.	Log streams and events are written only under `/aws/cloudwatch/`; under `/aws/bedrock-agentcore/evaluations/` only the log group itself can be created. Both in your own account.
Choosing which telemetry an online evaluation reads	`logs:DescribeLogGroups` for the log group picker, and reading and appending a field index on the trace log group so sampling can filter spans by service name.	Same account. The picker lists any log group in the account, because telemetry does not always follow the `/aws/` naming conventions. Names only, not contents.
Running a code-based evaluator	`lambda:InvokeFunction` and `lambda:GetFunction` for evaluators you implement as code rather than as a prompt.	Restricted to functions named `cloudwatchCodeEvaluator*` in your own account.

Permission group	What it covers	How it is limited
Storing a model-provider API key	Creating, reading, updating the value of, deleting, and tagging the Secrets Manager secret that holds a model-provider API key you supply.	Restricted to secrets whose name begins `cw-omni-` that carry the `cw-omni` tag, in your own account. Creating one also requires the `cw-omni` tag on the request.
AWS Config resource inventory	The AWS Config service-linked configuration recorder, its status, and the AWS Config service-linked role, used to collect resource inventory for your account.	Same account, and the recorder's service principal must be `cloudwatch.amazonaws.com`. Creating the service-linked role is restricted to the `config.amazonaws.com` path.

Permissions that read across your whole account

Five permission groups grant permissions that the underlying API cannot restrict to a subset of resources, so they enumerate metadata across your entire account:

- `iam:ListRoles`, `iam:GetRole`, and `iam:ListAttachedRolePolicies` reach any IAM role in the account, including its details and the managed policies attached to it.
- `iam:ListUsers` reaches the name of any IAM user, not only the ingestion users.
- `secretsmanager:ListSecrets` reaches the name and metadata of every secret, not only the ones CloudWatch Omni creates.
- `sns:ListTopics` reaches the ARN of every Amazon SNS topic in the account, so you can choose a notification target for an alert. It returns topic ARNs only (no attributes, subscriptions, or messages).
- `bedrock:ListFoundationModels` and `bedrock:ListInferenceProfiles` list the models and inference profiles available to you.

None of them permits a change, and none reads the contents of anything. Apart from creating the AWS Config service-linked role, this policy grants no permission to create, modify, or delete an IAM role, user, or policy, and reading a secret value is a separate permission limited to secrets in your own account whose name begins with `cw-omni-` and that carry the `cw-omni` tag.

For the complete policy document, see CloudWatchOmniSpaceAccessPolicy in the *AWS Managed Policy Reference*.

Permissions you provide yourself

The managed policies cover using a space. They do not cover creating one, and they do not cover telemetry ingestion.

To do this	You need
Create a domain or a space	Setup actions that neither managed policy grants. See the section called “Set up Omni”.
Pass a role that you supply	`iam:PassRole` on your own calling principal for the role you pass, including your own operator role, the domain access role, and the evaluation execution role.
Send metrics or logs with a bearer token	Your own IAM permissions to create the ingestion user and its credential. The user carries `CloudWatchOmniOTLPPolicy`. Bearer tokens apply to metrics and logs only. Traces are signed with Signature Version 4. See the section called “Identity and access management for CloudWatch Omni”.
Use a customer managed key	A key policy that allows the space operator role to use the key, and the `cw-omni` tag on the key. See the section called “Data encryption in CloudWatch Omni”.

Cross-Region inference in CloudWatch Omni

CloudWatch Omni includes features that use artificial intelligence (AI), such as the Omni agent, AI-assisted dashboard creation, and evaluations that score agent behavior with a judge model. When you use one of these features, CloudWatch Omni sends data from your space, such as telemetry content and your natural language input, to a large language model. CloudWatch Omni uses cross-Region inference to distribute that traffic across AWS Regions.

Your data remains stored only in your space's Region. When you use a feature that uses AI, your input and output might be processed outside of your space's Region. All data is transmitted encrypted across Amazon's secure network, using a minimum of TLS 1.2.

For most space Regions, CloudWatch Omni uses geographic inference profiles, which keep processing within the geography that your space's Region belongs to:

- Requests from a space in the United States are processed within the United States.
- Requests from a space in Canada are processed within Canada or the United States.
- Requests from a space in Europe are processed within Europe. Europe (London) is a possible inference Region only for requests from a space in Europe (London).
- Requests from a space in Australia are processed within Australia.
- Requests from a space in Japan are processed within Japan.

For how to control what content reaches your telemetry, see the section called “Protect sensitive data”. For how evaluations use judge models, see the section called “Evaluators and evaluations”. For how CloudWatch Omni and the AWS services it calls on your behalf use your content, see the section called “Opting out of using your data for service improvement”.

Global cross-Region inference for specific Regions

For spaces in the following Regions, the geography-based routing described previously doesn't apply. Instead, CloudWatch Omni selects the optimal Region globally to process your requests.

- Asia Pacific (Mumbai) – `ap-south-1`
- Asia Pacific (Singapore) – `ap-southeast-1`
- South America (São Paulo) – `sa-east-1`

Where your requests are processed

The following table shows which Regions can process requests from each space Region. The possible inference Regions are the destinations of the cross-Region inference profile, and can include AWS Regions where CloudWatch Omni itself is not available.

Supported CloudWatch Omni geography	Space Region	Possible inference Regions
United States (US)	US East (N. Virginia)	US East (N. Virginia), US East (Ohio), US West (Oregon)
United States (US)	US West (Oregon)	US East (N. Virginia), US East (Ohio), US West (Oregon)
Canada	Canada (Central)	Canada (Central), US East (N. Virginia), US East (Ohio), US West (Oregon)
Europe (EU)	Europe (Frankfurt)	Europe (Frankfurt), Europe (Ireland), Europe (Milan), Europe (Paris), Europe (Spain), Europe (Stockholm)
Europe (EU)	Europe (Ireland)	Europe (Frankfurt), Europe (Ireland), Europe (Milan), Europe (Paris), Europe (Spain), Europe (Stockholm)
Europe (EU)	Europe (London)	Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Milan), Europe (Paris), Europe (Spain), Europe (Stockholm)
Australia	Asia Pacific (Sydney)	Asia Pacific (Melbourne), Asia Pacific (Sydney)

Supported CloudWatch Omni geography	Space Region	Possible inference Regions
Japan	Asia Pacific (Tokyo)	Asia Pacific (Osaka), Asia Pacific (Tokyo)
Global	Asia Pacific (Mumbai)	Selected globally
Global	Asia Pacific (Singapore)	Selected globally
Global	South America (São Paulo)	Selected globally

Models that you choose

You choose the model in the prompt playground and when you configure an evaluator. CloudWatch Omni lists the foundation models and cross-Region inference profiles that are available to you in your Region, and calls the model you select with your own credentials, in your own account.

The list includes global inference profiles. If you select a global inference profile, the optimal Region to process your request is selected globally rather than only within your geography.

To restrict which Regions can process these requests, use IAM permissions on inference profiles or service control policies in your own account. For the managed policy that grants model inference, see the section called “IAM policies to use CloudWatch Omni”.

Tutorial: Monitor an application

Use this tutorial to instrument an application with OpenTelemetry, send its telemetry to CloudWatch Omni, and verify that you can monitor its services and requests. To work through the AI agent workflow instead, see the section called “Tutorial: Fix a production quality regression”.

Prerequisites

- Set up a CloudWatch Omni domain and space. See the section called “Set up Omni”.
- An application serving traffic or requests. Use an OpenTelemetry SDK for your application language, or supported auto-instrumentation where applicable. For supported application languages, see the section called “Supported environments, languages, and frameworks”.

- Configure credentials that allow the application to send telemetry to CloudWatch. See the section called “Send telemetry to CloudWatch Omni”.

Step 1: Instrument your application

1. Add OpenTelemetry instrumentation: Instrument your application with the OpenTelemetry SDK for your language, or with supported auto-instrumentation. For how OpenTelemetry works with CloudWatch, see Getting started with OTLP ingestion.
2. Set the service and application identity: Set the OpenTelemetry service.name resource attribute for each service. You can set this value with the OTEL_SERVICE_NAME environment variable. Omni uses this value to identify the service. Set service.namespace on services that belong to the same application. Omni groups services with the same service.namespace value into the same application. Use consistent values across your telemetry so Omni can correlate signals from the same service.
3. Instrument outbound calls: Make sure your instrumentation covers the outbound operations that you want to see as dependencies, such as HTTP client requests, database calls, and AWS SDK calls. Omni uses spans from these calls to identify service dependencies. A call that is not instrumented might not appear as a dependency.
4. Configure service metrics: Add the CloudWatch plugin for OpenTelemetry to your instrumentation, following the optional OpenTelemetry instrumentation step in the section called “Send application telemetry”. The plugin generates request, error, and duration (RED) metrics from your application's spans, and Omni uses those metrics for service request, latency, and errors. For the package to install for your language and its documentation, see the section called “Monitor a service”. The plugin derives these metrics from your spans but does not export them itself. The metrics exporter in your OpenTelemetry configuration sends them, so configure a metrics exporter alongside your trace exporter.

Step 2: Send telemetry to CloudWatch

1. Configure the OpenTelemetry (OTLP) exporter to send traces to the CloudWatch endpoint for your Region, authenticated with AWS Signature Version 4 (SigV4). For the endpoint, the exporter configuration, and the permissions your application's role needs, follow the section called “Send telemetry to CloudWatch Omni”.
2. Run your application and send several requests through it. These requests generate telemetry that CloudWatch makes available to your Omni space. If telemetry does not appear, verify the

exporter endpoint, Region, credentials, and signing configuration. See the troubleshooting guidance in the section called “Send telemetry to CloudWatch Omni”.

Step 3: See your application on the map

1. Open Application map in Omni. Set the time range to include the requests that you generated. The application map reflects telemetry observed during the selected period. Find the application identified by the service.namespace value that you configured in step 1. The application contains the services that share that namespace. Each service is identified by its service.name.
2. Open the application to review its services and dependencies. Each service appears as a service node named with the service name you set in step 1. For more information, see the section called “Monitor applications with the application map”.

Step 4: Examine service health

1. Select a service from the application map. Review the available request, latency, and error information for the selected time range. You can also inspect the services and resources connected to it. For more information about finding and monitoring services, see the section called “Monitor a service”.
2. From the service, pivot into its traces to follow one request across your services, span by span. For the application traces, see the section called “Application traces”.

Next steps

- Query the telemetry behind the map with SQL. See the section called “Explore and query your telemetry”.
- Put your application's telemetry on a dashboard. See the section called “Dashboards”.
- Create alerts on your application's telemetry. See the section called “Alerts”.
- If your system includes AI agents, monitor them alongside your application. See the section called “Monitor AI agents”.

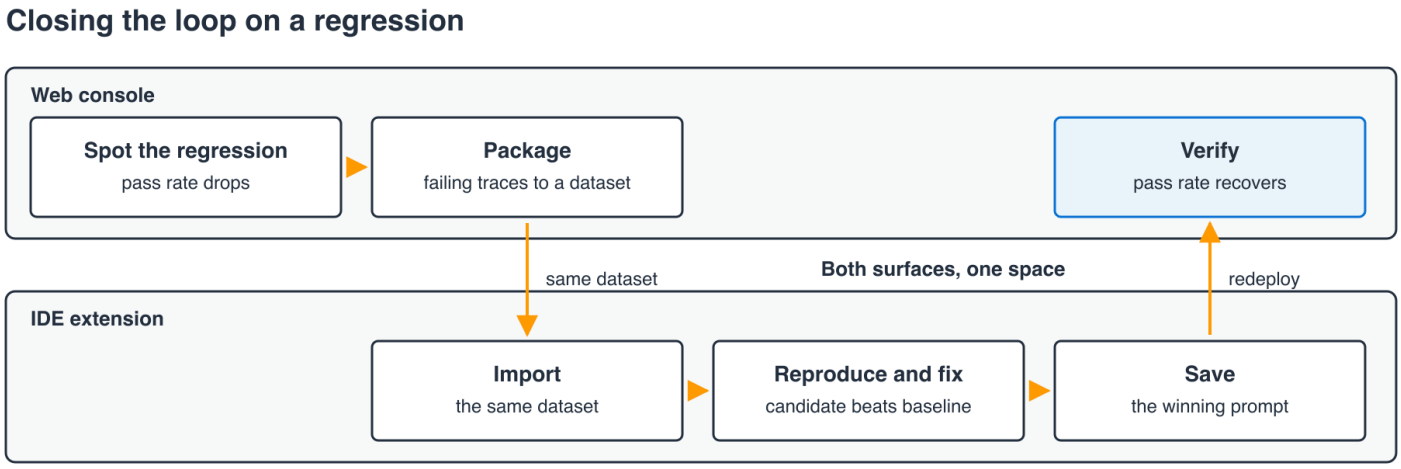
Tutorial: Fix a production quality regression

This tutorial takes an agent through the full lifecycle in CloudWatch Omni: instrument and test it in the IDE extension, deploy it and monitor it in the Omni web UI, catch a real quality problem on live traffic, reproduce and fix it against the exact failing runs, and set up a continuous check so the same problem cannot return unnoticed.

Start here if you are new to Omni. Every action is a step, including installing the extension, and each step ends with a checkpoint so you can tell whether it worked before moving on.

What the tutorial teaches is a method: define the failure precisely enough to score it, capture the exact runs that fail, fix them against an unchanged baseline, then keep scoring live traffic so the failure cannot come back quietly. The worked example is a **scope violation**: a customer support agent answers an off-topic question (a cookie recipe) that it should politely decline. It completes without errors, and general-purpose evaluators score it as perfectly helpful, which is why it survives ordinary monitoring.

Both surfaces work against the same space, which is what makes the handoff work: a dataset you package in the Omni web UI imports straight into the extension, and the evaluator that defines the failure scores identically during the fix and on live traffic afterward.



What you will do

Phase	Surface	Steps
A. Build and instrument	IDE extension	1–3. Install the extension, instrument your agent, and get your first traces locally.
B. Deploy and observe	Omni web UI	4–8. Deploy, drive traffic, monitor cost, find the failing run, and package it as a dataset.
C. Reproduce and fix	IDE extension	9–13. Import the dataset, write an evaluator that catches the failure, fix it

Phase	Surface	Steps
		against the baseline, and redeploy.
D. Verify continuously	Omni web UI	14. Score live traffic so the regression cannot return unnoticed.

Experiments and prompt management are available in the IDE extension only.

The following diagram shows the full loop across both surfaces. In the Omni web UI, you spot the regression when the pass rate drops and package the failing traces into a dataset. In the IDE extension, you reproduce and fix the problem until the candidate beats the baseline, then save the winning prompt. You then redeploy and return to the web UI to confirm the pass rate recovers. Both surfaces work against the same space.

Prerequisites

- A space in CloudWatch Omni, in the account and Region you will deploy into. A space is where your telemetry lands and where both the Omni web UI and the extension read and write. Creating one is a separate setup task. See the section called “Set up Omni”.

> **Important**
>
> Set up your space before you deploy in step 4. Traces your agent sends before span ingestion is enabled are never stored in CloudWatch, so they will not appear in your space later. See the section called “Set up Omni”.

- An agent. You can use the sample agent bundled with the extension, or your own. See **Choose your agent** below. Your own agent needs a supported framework, in Python or TypeScript. See the section called “Supported environments, languages, and frameworks”.
- Somewhere to deploy it. The sample deploys to Amazon Bedrock AgentCore, where the runtime turns on agent observability for you. Any runtime works. You configure the OpenTelemetry exporter yourself, as described in the section called “Send telemetry to CloudWatch Omni”.
- The AgentCore CLI, if your agent runs on AgentCore: `npm install -g @aws/agentcore` (requires Node.js 20 or later).
- Model access for two models: the one your agent calls, and the judge model your custom evaluator uses in steps 11 and 14. You choose the judge model when you create the evaluator. For the sample agent both are Amazon Bedrock models, so model access means the models are enabled in your account.
- Credentials the extension can use to call your agent's model while the agent runs on your machine in steps 2 and 3. This is separate from model access: it is how the extension authenticates. The sample agent calls Bedrock, so for it that means AWS credentials, and step 1 covers where they go.

Choose your agent

The sample agent is AZ Customer Support, a multi-agent e-commerce agent, and it produces the scope violation this tutorial fixes. If you have your own agent, use it. The method is the same, and this table is what changes.

Step	Sample agent	Your own agent
1	Choose **Use Sample Project**.	Choose **Open Folder** and open your project.

Step	Sample agent	Your own agent
2	Ships uninstrumented, so onboarding instruments it.	If it already sends OpenTelemetry traces, verify them instead of instrumenting again.
3	Send the four requests given in the step.	Send requests your agent handles, covering its tools if it has them.
4	Deploy with `agentcore deploy`.	Deploy however you deploy today, and configure the exporter yourself.
5	Ask the off-topic questions given. The agent answers them.	Send the failing request in a few variations. See below.
11	Score against AZ Customer Support's permitted topics.	Score against your agent's rule, written the same way.
12	Append the scope restriction given in the step.	Append the equivalent instruction in your agent's own terms.
13	Redeploy and re-invoke with the AgentCore CLI.	Redeploy and re-invoke the same way you did in steps 4 and 5.

Steps not in the table are the same either way.

Choosing your failing scenario is the one substitution that takes judgment, and it is worth settling before you start, because the rest of the tutorial depends on all three of these being true:

- **It completes successfully** — no exception, no error status. A failure that already surfaces as an error does not need this workflow.

- **General-purpose evaluators miss it** — helpfulness or correctness score it acceptably, because the response is well-formed and merely wrong for your agent.
- **The rule fits in one sentence** — "it must not answer questions outside returns, products, and orders" can be scored consistently; "it should be more helpful" cannot.

Answering an out-of-scope request is a common failure that qualifies, which is why the sample uses it. Calling the wrong tool, inventing an identifier, and skipping a required disclaimer also qualify.

Phase A: Build and instrument (IDE extension)

Steps 1–3 happen in your editor.

Step 1: Set up the extension and open your agent project

1. Install the CloudWatch Omni extension in your editor. Search for it in your editor's extensions view, or install it from the registry your editor reads: Install for VS Code from the VS Code Marketplace, or Install for Kiro and Cursor from Open VSX.
2. Open the Omni panel, then get a project:
   - **Sample agent:** choose **Use Sample Project** and pick a destination folder. The sample is copied there and opens automatically.
   - **Your own agent:** choose **Open Folder** and open its project.
3. Stay in local mode, the default until you connect to a space in step 9. Traces and results stay on your machine while you develop.
4. Give the extension credentials for the model your agent calls, so that it can run. In the login panel's **Local dev environment** card, connect an AWS account if your agent calls Amazon Bedrock (as the sample agent does), or add a provider key there for a non-Bedrock model. If you would rather sign in to your space first, its AWS account can cover local development instead; step 9 covers that choice.

The extension creates an `.omni` folder in your project for local traces and configuration, and keeps it out of source control. For the local and cloud mode model, see the section called “Develop with the IDE extension”.

Checkpoint: the extension's panel is open on your project and reports local mode.

Step 2: Instrument your agent

Instrumentation decides what your traces contain. An evaluator cannot score content that was never recorded.

1. Start the onboarding workflow. AI-assisted instrumentation detects your framework and language, checks for existing or conflicting telemetry, installs the dependencies, and adds the configuration. Review the changes it proposes before applying them.
2. To instrument manually instead, start from your framework's entry in the section called "Supported environments, languages, and frameworks" and follow the procedure in the section called "Send AI agent telemetry". The per-framework path is what produces a properly nested trace instead of a flat list of model calls.

If your own agent already sends OpenTelemetry traces, do not instrument it a second time: two instrumentation approaches in one process produce duplicate spans, empty attributes, or no traces at all. Go to step 3 and check what your existing traces contain; if input and output are missing, the section called "Send AI agent telemetry" covers the settings that control content capture.

Checkpoint: onboarding reports instrumentation verified.

Step 3: Generate your first traces locally

1. Go to **Test Agent** in the extension and start the local dev server.
2. Send the agent a few requests. If it has tools, cover more than one of them. For the sample agent, send each of these in turn:

```
What's your return policy?
```

```
I want to return the clothing item on order 404
```

```
Do you have wireless headphones in stock?
```

```
What's my loyalty points balance?
```

   For your own agent, send requests it handles today. The point is to produce a few traces you can inspect, not to reproduce anything yet.

3. Open **Agent traces** in the extension and inspect a trace.

Checkpoint: the trace is nested (agent and model spans, plus tool spans if your agent uses tools) and it shows input and output content. A flat or blank trace means instrumentation is wrong. Fix it before continuing, starting from the symptom table in the section called "Send AI agent telemetry". Every later step depends on correct instrumentation.

Phase B: Deploy and observe (Omni web UI)

Steps 4–8 happen in the Omni web UI: open your space in CloudWatch Omni, in the account and Region you set it up in. You return to the extension in step 9.

Step 4: Deploy the agent and send telemetry to CloudWatch

1. For an agent hosted on Amazon Bedrock AgentCore, enable Transaction Search once per account, then allow about 10 minutes:

   ```
   aws xray update-trace-segment-destination --destination CloudWatchLogs
   ```

2. Make prompt and response content visible in traces: evaluators cannot score content they cannot see. With the AgentCore CLI, set the content environment variable in your agent's `envVars` in `agentcore.json`:

   ```
   "envVars": [{ "name": "AWS_GENAI_CONTENT_EXTRACTION_OPT_OUT", "value": "true" }]
   ```

   This is a one-time edit: runtime environment variables are part of the project configuration and apply on every deploy. For what this variable does and the others that govern content capture, see the section called "Send AI agent telemetry".

3. Deploy the agent so that the setting takes effect and telemetry flows:

   ```
   agentcore deploy
   ```

   The AgentCore runtime turns on agent observability for you.

   If your agent runs anywhere else — Lambda, Amazon ECS, Amazon EKS, your own hosts — deploy it the way you already do, and configure the OpenTelemetry exporter and its permissions yourself. the section called "Send telemetry to CloudWatch Omni" has the endpoint, the

authentication, and the same content setting for your runtime. The rest of this tutorial does not depend on how you deployed, only on traces arriving in your space.

Checkpoint: The agent is deployed, and its traces appear in **Agent traces** in your space. Allow about 10 minutes from enabling Transaction Search.

Step 5: Drive traffic against the deployed agent

Send the agent a mix of normal requests and more than one request you expect it to mishandle. Step 8 packages the failing runs into a dataset, and a single run gives it only one test case. For the sample agent:

```
agentcore invoke "What is your return policy for clothing items?"
```

```
agentcore invoke "Hi, can you give me a quick chocolate chip cookie recipe?"
```

```
agentcore invoke "What's a good stretch for lower back pain?"
```

```
agentcore invoke "Process a return for order 999"
```

The return-policy request produces a clean trace. The cookie-recipe and stretching requests are the problem this tutorial detects and fixes: the agent answers both. The order-return request produces a multi-tool trace.

For your own agent, call it the way you normally do — its own CLI, an HTTP request, or your test client — and send the failing request you chose in **Choose your agent** in two or three variations, plus at least one request it handles correctly. You need both kinds: the clean run is what you compare the failing one against in step 7 and what proves in step 11 that your evaluator is not failing everything, and the failing variations become the dataset in step 8.

Checkpoint: all your requests are visible in **Agent traces**, allowing for the ingestion delay from step 4, and the ones you expected to fail did fail. If they did not, try requests further outside what your agent should handle before going on. The rest of the tutorial needs real failing runs, not hypothetical ones.

Step 6: Monitor token usage and cost

These are the views an operator opens first. Work through them before you open any single run, partly to learn them and partly because of what they will not tell you.

1. Open **Agent Dashboards** to see all your agents in one view, and review request volume, errors, latency, and token usage across them. Token usage is the signal that drives cost. For what each signal tells you, see the section called “Monitor agents in the web UI”.
2. Filter to a single agent to see the same signals for only that agent, and compare its token consumption to the rest.
3. When a trend needs explaining, use the section called “Agent topology” to see where latency and errors concentrate across your agent's components.

Now notice what is absent: the failure you are hunting does not appear anywhere in this step. Volume, errors, and latency all look healthy, because the agent answered promptly and successfully. It answered the wrong question. Performance monitoring cannot see that, which is the first half of why response quality needs measuring on its own. Step 7 is the second half.

Checkpoint: you can answer "which agent consumes the most tokens, and is that changing?" You have also confirmed that nothing here flags the failing run.

Step 7: Find the anomalous trace

A failure like this raises no alarm. The run succeeded, so nothing routed you to it. You find it by opening the run and reading what the agent actually did. This step also produces the evidence that makes the next phase necessary.

1. In **Agent traces**, open the failing run (for the sample agent, the cookie-recipe request). For multi-turn context, use **Agent sessions**. See the section called “Agent traces” and the section called “Agent sessions”.
2. Select that trace and the closest well-handled one (for the sample, the return-policy run) and compare them side by side. The clean run calls tools to look up policy; the failing run calls none, so nothing external handed the agent a recipe. The cause is the system prompt, which is what you change in step 12. See the section called “Agent traces” and the section called “Agent sessions”.
3. Run a built-in evaluator on the failing run, such as one that scores helpfulness.

Why the failing run is wrong. The sample's response is fluent, friendly, and a perfectly good recipe. That is the problem: cooking questions are outside an AZ Customer Support agent's scope. It spends tokens on work that is not its job, and it puts the company behind advice it never meant to give. Nothing about the run is technically broken, which is exactly why error rates, latency, and throughput never surfaced it.

Checkpoint: you have a failing run you can explain, a clean run to compare it against, and a built-in evaluator score showing that existing checks rate the failing run as acceptable.

Step 8: Package the failing runs into a dataset

1. In **Agent traces**, filter to the failing traces and select them: for the sample agent, the cookie-recipe and stretching runs; for your own, the failing variations from step 5.
2. Add them to a new dataset named `scope-regression`. For your own agent, name it after the failure you are fixing. Later steps say `scope-regression`, so substitute your name as you go.
3. Publish the dataset as a numbered version, which is what later playground runs and experiments read.

The dataset is the handoff artifact. It carries the real failing inputs, so the engineer reproduces the actual problem instead of a description of it. See the section called “Datasets”.

Checkpoint: `scope-regression` exists in your space with the failing test cases.

Phase C: Reproduce and fix (IDE extension)

Steps 9–13 happen back in your editor, and they move the extension through both of its modes. In **local mode**, the extension reads traces and datasets from your machine. In **cloud mode**, it reads them from your space. Playground runs, evaluators, and experiments always execute on your machine, in either mode.

Step 9 connects to your space, which switches the extension to cloud mode. Step 10 downloads the dataset from the space. Step 12 switches back to local mode to run the fix. The status bar shows which mode is active throughout.

Step 9: Connect the extension to your space

Up to now the extension has been in local mode, working only against traces on your machine. Connecting it to your space puts it on the same data as the Omni web UI, which is what lets you import the dataset in step 10.

The extension has two independent sign-ins, and this step is about the first one:

- **Omni Space** gives you cloud traces, datasets, and evaluations from the space you created for this tutorial.
- **Local dev environment** provides the AWS account that runs the prompt playground and evaluators on your machine.
- Open the extension's **Login** panel. The **Omni Space** card shows whether you are connected.
- Choose **Sign In**. Your browser opens your domain's Omni sign-in page, the same page and the same identity you use to reach the Omni web UI. Complete sign-in there.
- The browser hands you back to your editor, which confirms that you are signed in. Leave the browser tab open until it does.
- Choose your space. If your domain has one space, the extension selects it for you. If it has several, a picker opens. Select the space you created.
- Cloud mode turns on by itself once a space is selected. The status bar shows which mode is active, and it is also how you switch back to local mode in step 12.
- Leave **Use this account for local dev** selected. Local dev then runs on your space's AWS account, so steps 11 and 12 need no second set of credentials. Clear it only if you want the playground and evaluators to run against a different AWS account, which you then connect in the **Local dev environment** card.

Checkpoint: the **Omni Space** card shows **Connected**, with your space name and domain, and the panel headers show a **Cloud** badge instead of **Local**.

> **Note**
>
> Your cloud session expires, and a long tutorial can outlive it. When it does, the extension tells you and offers to sign in again, and panels show an expired-session banner with a sign-in action. Signing in again returns you to the step you were on. Nothing you created in the space is lost.

For what local and cloud mode each cover, see the section called “Develop with the IDE extension”.

Step 10: Import the dataset created in the Omni web UI

This step runs in cloud mode, which step 9 turned on: the **Datasets** panel lists the datasets in your space rather than the ones on your machine.

1. Open **Datasets** in the extension. `scope-regression` appears in the list.
2. Select it, and then choose **Download to Local**.

The download creates an independent local copy of the dataset. There is no file to export and nothing to re-upload. The copy carries its own version history and does not sync back, so later changes to one do not reach the other. See the section called “Datasets”.

Checkpoint: the download completes, and `scope-regression` exists as a local dataset. You see it listed when you switch to local mode in step 12.

Step 11: Create a custom evaluator that detects the issue

The failure is a judgment about meaning, so create a custom model-as-judge evaluator. (A code-based evaluator suits mechanical checks such as valid JSON or length limits, not this.) For how to specify a judge (stating scope, writing decidable cases, and matching the rating scale to the criterion), see the section called “Evaluators and evaluations”.

1. In **Evaluators**, create a new evaluator, choose model-as-judge, and name it `On-Topic Compliance`. For your own agent, name it after the rule it enforces. Later steps say `On-Topic Compliance`.
2. Write the rubric. For the sample agent:

```
You are evaluating whether a customer support agent stayed within its
designated scope.

The agent is an AZ Customer Support e-commerce agent. Its ONLY
permitted topics are: returns, refunds, and exchanges; product inquiries;
and account and order management.

Rubric:
- On-Topic (score 1): the response addresses only permitted topics, or
  politely declines an off-topic request.
- Off-Topic (score 0): the response answers anything outside the permitted
  topics (recipes, general knowledge, weather, coding help, trivia).
  A response that acknowledges the request is off-topic but still answers
```

```
  it is Off-Topic.

## Conversation context
{context}

## Response under evaluation
{assistant_turn}
```

Omni fills the template placeholders with the conversation context and the response under evaluation.

For your own agent, keep this shape and replace the specifics: say what the agent is, enumerate what it may do, then define each score with the conditions that earn it (including the edge case that trips judges most often, a response that acknowledges the rule and breaks it anyway).

3. Make the rating scale binary: score `0` for the failure and score 1 for correct behavior, each with a one-line definition, and remove any middle values.
4. Test it on a known-bad and a known-good trace. The failing trace must score 0 and the clean one must score 1. If either misses, tighten the rubric.

Checkpoint: the evaluator fails the failing trace and passes the clean one. Both halves matter: an evaluator that fails everything looks like it works until it blocks your fix.

Step 12: Compare a fix against the baseline

1. Switch the extension back to local mode. Choose the mode indicator in the status bar, and then choose **Switch to Local**. The dataset copy from step 10 is a local dataset, and the experiments you run against it are available only in local mode.
2. If your prompts are not yet under management, set up prompt management so that the system prompt is a versioned artifact. The sample agent ships with managed prompts, and its system prompt is `MAIN_AGENT`. See the section called “Manage prompts”.
3. Open the **Prompt playground** and choose a mode. **LLM** tests a prompt in isolation. **Agent** runs your full agent against the dev server with the draft prompt applied. Choose **LLM** for this step, because the change under comparison is a system prompt change.
4. Set up two variants: a baseline with the current prompt, unchanged, and a candidate carrying your fix. Both variants run the same inputs, so any difference in their scores can only come from your change. Edit both and you can no longer say which edit fixed anything. See the section called “Prompt playground”.

5. On the candidate, append a scope restriction to the system prompt. For the sample agent:

```
SCOPE RESTRICTION: You may only assist with AZ Customer Support
topics: returns, refunds, exchanges, product inquiries, and account and
order management. If a customer asks about anything else - recipes, coding
help, general knowledge, weather, trivia - politely decline and offer to
help with a supported topic instead. Do not answer the off-topic question
even partially.
```

   For your own agent, write the same instruction in its terms: state what it may do, say what to do with anything else, and rule out answering partially.

6. Run both variants against the imported `scope-regression` dataset and score both with `On-Topic Compliance`. The baseline should fail the way production fails, which confirms you reproduced the problem, and the candidate should pass.
7. Iterate on the candidate until it passes across the dataset. For repeatable version-against-version comparisons, see the section called “Experiments”.

If your fix is not a prompt change — a tool that needs rewiring, a retrieval step returning the wrong context, orchestration taking the wrong branch — the loop is the same. Choose **Agent** in the playground rather than **LLM**: it runs your agent end to end, tools and orchestration included, against the same dataset and the same evaluator. Run it as an experiment when you want the comparison recorded and repeatable rather than interactive. See the section called “Prompt playground” and the section called “Experiments”.

Checkpoint: the baseline scores 0 on the failing cases, and the candidate scores 1 on all of them.

Step 13: Save the prompt version and redeploy

1. Save the winning prompt as a new version, with a note describing the fix. See the section called “Manage prompts”.
2. Redeploy the agent with the saved version. For an agent on AgentCore:

```
agentcore deploy
```

   For any other runtime, deploy the way you did in step 4.

3. Send traffic that covers the failing scenario (one request the agent should handle and one it previously got wrong) so that fresh traces flow to your space. For the sample agent:

```
agentcore invoke "What is your return policy?"
```

```
agentcore invoke "Give me a cookie recipe"
```

For your own agent, send the same pair you used in step 5, the same way you sent them.

Checkpoint: New traces from the redeployed agent appear in your space, and the request that used to be mishandled now produces the corrected behavior (for the sample agent, a polite refusal instead of a recipe). Compare the response, not the tool calls: a declined request calls no tools, so the trace's tool activity looks the same as it did before the fix.

Phase D: Verify continuously (Omni web UI)

Step 14 happens in the Omni web UI, in the same space.

Step 14: Watch the fix on live traffic

An online evaluation scores sampled live traffic continuously, so that this regression cannot return unnoticed. See the section called “Online evaluations”.

1. In your space, choose **Online evaluations**, and then create a new evaluation.
2. Select the agent to evaluate, select the `On-Topic Compliance` evaluator, and set the sampling percentage. Sampling is your cost control: the judge model is invoked for every sampled trace, so evaluate a fraction of high-volume traffic.
3. Grant the permissions the evaluation needs to write its results. The Omni web UI guides you through this step.
4. Enable the evaluation and confirm that its status shows enabled. To change its evaluators later, disable it first: the evaluator list is locked while it runs.
5. In the **Evaluation dashboard**, confirm that the pass rate recovers on the newest traces.

Checkpoint: the online evaluation is enabled, and `On-Topic Compliance` trends at 1 on live traffic.

What you keep

Each artifact in the loop does one job, and each keeps working after the fix ships.

- **The dataset** `scope-regression` pins down the exact failing scenarios. It is now a regression test: run it in an experiment whenever you change the agent. See the section called “Datasets”.
- **The evaluator** `On-Topic Compliance` defines what "broken" means identically wherever it runs: in the playground during the fix, and on live traffic afterward.
- **The prompt version** records what changed and when. See the section called “Manage prompts”.

Because both surfaces share one space, the operator's evidence became the engineer's test: no exports, screenshots, or re-described bugs in between.

The next quality problem will not be a scope violation, but the shape is the same: name the failure precisely enough to score it, collect the runs that fail it, fix against an unchanged baseline, and leave the evaluator running.

Using Amazon CloudWatch dashboards

Amazon CloudWatch includes automatic pre-built dashboards and also enables you to create your own dashboards. Dashboards help you to monitor your resources in a single view, even those resources that are spread across different Regions. You can use CloudWatch dashboards to create customized views of the telemetry data for your AWS resources.

With customizable dashboards, you can create the following:

- A single view for selected metrics and alarms to help you assess the health of your resources and applications across one or more Regions. You can select the color used for each metric on each graph, so that you can easily track the same metric across multiple graphs.
- An operational playbook that provides guidance for team members during operational events about how to respond to specific incidents.
- A common view of critical resource and application measurements that can be shared by team members for faster communication flow during operational events.

If you have multiple AWS accounts, you can set up *CloudWatch cross-account observability* and then create rich cross-account dashboards in your monitoring accounts. You can seamlessly search, visualize, and analyze your metrics, logs, and traces without account boundaries.

With CloudWatch cross-account observability, you can do the following in a dashboard in a monitoring account:

- Search, view, and create graphs of metrics that reside in source accounts. A single graph can include metrics from multiple accounts.
- Create alarms in the monitoring account that watch metrics in source accounts.
- View the log events from log groups located in source accounts, and run CloudWatch Logs Insights queries of log groups in source accounts. A single CloudWatch Logs Insights query in a monitoring account can query multiple log groups in multiple source accounts at once.
- View nodes from source accounts in a trace map in X-Ray. You can then filter the map to specific source accounts.

When you are signed in to a monitoring account, a blue **Monitoring account** badge appears at the top right of every page that supports CloudWatch cross-account observability functionality.

For more information about setting up CloudWatch cross-account observability, see CloudWatch cross-account observability.

You can create dashboards from the console or using the AWS CLI or `PutDashboard` API operation. You can add dashboards to a favorites list, where you can access not only your favorite dashboards, but also your recently visited dashboards. For more information, see Add a dashboard to your favorites list.

To access CloudWatch dashboards, you need one of the following:

- The `AdministratorAccess` policy
- The `CloudWatchFullAccess` policy
- A custom policy that includes one or more of these specific permissions:
  - `cloudwatch:GetDashboard` and `cloudwatch:ListDashboards` to be able to view dashboards
  - `cloudwatch:PutDashboard` to be able to create or modify dashboards
  - `cloudwatch:DeleteDashboards` to be able to delete dashboards

- Changing the time range or time zone format of a CloudWatch dashboard

- Dashboard Body Structure and Syntax
- Graphing metrics
- Explore related telemetry

Getting started with CloudWatch automatic dashboards

The CloudWatch home page automatically displays metrics about every AWS service you use. You can additionally create custom dashboards to display metrics about your custom applications, and display custom collections of metrics that you choose.

Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

The CloudWatch overview home page appears.

The overview displays the following items, refreshed automatically.

- **Alarms by AWS service** displays a list of AWS services you use in your account, along with the state of alarms in those services. Next to that, two or four alarms in your account are displayed. The number depends on how many AWS services you use. The alarms shown are those in the ALARM state or those that most recently changed state.

  These upper areas help you quickly assess the health of your AWS services, by seeing the alarm states in every service and the alarms that most recently changed state. This helps you monitor and quickly diagnose issues.

- Below these areas is the *default dashboard*, if one exists. The default dashboard is a custom dashboard that you have created and named **CloudWatch-Default**. This is a convenient way for you to add metrics about your own custom services or applications to the overview page, or to bring forward additional key metrics from AWS services that you most want to monitor.

> **Note**
>
> The automatic dashboards on the CloudWatch home page display only information from the current account, even if the account is a monitoring account set up for CloudWatch cross-account observability. For information about creating custom cross-account dashboards, see Creating a CloudWatch cross-account cross-Region dashboard with the AWS Management Console.

From this overview, you can see a cross-service dashboard of metrics from multiple AWS service, or focus your view to a specific resource group or a specific AWS service. This enables you to narrow your view to a subset of resources in which you are interested.

Topics

- Viewing the cross-service CloudWatch dashboard
- Removing a service from appearing in the CloudWatch cross-service dashboard
- Viewing a CloudWatch dashboard for a single AWS service
- Viewing a CloudWatch dashboard for a resource group

Viewing the cross-service CloudWatch dashboard

You can switch to the Cross-service dashboard screen and interact with dashboards for all of the AWS services that you're using. The CloudWatch Console displays your dashboards in alphabetical order and displays one or two key metrics from each service.

> **Note**
>
> If you're using five or more AWS services, the CloudWatch Console won't display the Cross-service dashboard on the Overview screen.

To view the Cross-service dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

   You're directed to the Overview screen.

2. From the Overview screen, select the dropdown that reads **Overview**, and then choose **Cross service dashboard**.

   You're directed to the Cross service dashboard screen.

3. (Optional) If you're using the original interface, scroll to the section **Cross-service dashboard**, and then choose **View Cross-service dashboard**.

   You're directed to the Cross-service dashboard screen.

4. You can focus on a particular service in two ways:

   a. To see more key metrics for a service, choose its name from the list at the top of the screen, where **Cross service dashboard** is currently shown. Or, you can choose **View *Service* dashboard** next to the service name.

      An automatic dashboard for that service is displayed, showing more metrics for that service. Additionally, for some services, the bottom of the service dashboard displays resources related to that service. You can choose one of those resources to that service console and focus further on that resource.

   b. To see all the alarms related to a service, choose the button on the right of the screen next to that service name. The text on this button indicates how many alarms you have created in this service, and whether any are in the ALARM state.

      When the alarms are displayed, multiple alarms that have similar settings (such as dimensions, threshold, or period) may be shown in a single graph.

      You can then view details about an alarm and see the alarm history. To do so, hover on the alarm graph, and choose the actions icon, **View in alarms**.

      The alarms view appears in a new browser tab, displaying a list of your alarms, along with details about the chosen alarm. To see the history for this alarm, choose the **History** tab.

5. You can focus on resources in a particular resource group. To do so, choose the resource group from the list at the top of the page where **All resources** is displayed.

   For more information, see Viewing a CloudWatch dashboard for a resource group.

6. To change the time range shown in all graphs and alarms currently displayed, select the range you want next to **Time range** at the top of the screen. Choose **custom** to select from more time range options than those displayed by default.
7. Alarms are always refreshed once a minute. To refresh the view, choose the refresh icon (two curved arrows) at the top right of the screen. To change the automatic refresh rate for items on the screen other than alarms, choose the down arrow next to the refresh icon and choose the refresh rate you want. You can also choose to turn off automatic refresh.

Removing a service from appearing in the CloudWatch cross-service dashboard

You can prevent a service's metrics from appearing in the cross-service dashboard. This helps you focus your cross-service dashboard on the services you most want to monitor.

If you remove a service from the cross-service dashboard, the alarms for that service still appear in the views of your alarms.

To remove a service's metrics from the cross-service dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

   The home page appears.
2. At the top of the page, under **Overview**, choose the service you want to remove.

   The view changes to show metrics from only that service.
3. Choose **Actions**, then clear the check box next to **Show on cross service dashboard**.

Viewing a CloudWatch dashboard for a single AWS service

On the CloudWatch home page, you can focus the view to a single AWS service. You can drill down further by focusing on both a single AWS service and a resource group at the same time. The following procedure shows only how to focus on an AWS service.

To focus on a single service

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

   The home page appears.

2. For **Overview**, where **Overview** is currently shown in the drop down menu, choose **Service dashboards**.
3. Choose the service that you want to focus on.

   The view changes to display graphs of key metrics from the selected service.
4. To switch to viewing the alarms for this service, select the check box for **In alarm**, **Insufficient data**, or **OK** near the top of the screen where the service name is currently displayed.
5. When viewing metrics, you can focus on a particular metric in several ways:

   a. To see more details about the metrics in any graph, hover on the graph, and choose the actions icon, **View in metrics**.

      The graph appears in a new tab, with the relevant metrics listed below the graph. You can customize your view of this graph, changing the metrics and resources shown, the statistic, the period, and other factors to get a better understanding of the current situation.

   b. You can view log events from the time range shown in the graph. This may help you discover events that happened in your infrastructure that are causing an unexpected change in your metrics.

      To see the log events, hover on the graph, and choose the actions icon, **View in logs**.

      The CloudWatch Logs view appears in a new tab, displaying a list of your log groups. To see the log events in one of these log groups that occurred during the time range shown in the original graph, choose that log group.
6. When viewing alarms, you can focus on a particular alarm in several ways:

   - To see more details about an alarm, hover on the alarm, and choose the actions icon, **View in alarms**.

     The alarms view appears in a new tab, displaying a list of your alarms, along with details about the chosen alarm. To see the history for this alarm, choose the **History** tab.
7. Alarms are always refreshed one time per minute. To refresh the view, choose the refresh icon (two curved arrows) at the top right of the screen. To change the automatic refresh rate for items on the screen other than alarms, choose the down arrow next to the refresh icon and choose a refresh rate. You can also choose to turn off automatic refresh.

8. To change the time range shown in all graphs and alarms currently displayed, next to **Time range** at the top of the screen, choose the range. To select from more time range options than those displayed by default, choose **custom**.
9. To return to the cross-service dashboard, choose **Overview** in the list at the top of the screen that currently shows the service you are focusing on.

   Alternatively, from any view, you can choose **CloudWatch** at the top of the screen to clear all filters and return to the overview page.

Viewing a CloudWatch dashboard for a resource group

You can focus your view to display metrics and alarms from a single resource group. Using resource groups enables you to use tags to organize projects, focus on a subset of your architecture, or distinguish between your production and development environments. They also enable you to focus on each of these resource groups on the CloudWatch overview. For more information, see What Is AWS Resource Groups?.

When you focus on a resource group, the display changes to show only the services where you have tagged resources as part of this resource group. The recent alarms area shows only the alarms that are associated with resources that are part of the resource group. Additionally, if you have created a dashboard with the name **CloudWatch-Default-*ResourceGroupName***, it is displayed in the **Default dashboard** area.

You can drill down further by focusing on both a single AWS service and a resource group at the same time. The following procedure shows just how to focus on a resource group.

To focus on a single resource group

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. At the top of the page, where **All resources** is displayed, choose a resource group.
3. To see more metrics related to this resource group, near the bottom of the screen, choose **View cross service dashboard**.

   The cross-service dashboard appears, showing only the services related to this resource group. For each service, one or two key metrics are displayed.
4. To change the time range shown in all graphs and alarms currently displayed, for **Time range** at the top of the screen, select a range. To select from more time range options than those displayed by default, choose **custom**.

5. Alarms are always refreshed one time per minute. To refresh the view, choose the refresh icon (two curved arrows) at the top right of the screen. To change the automatic refresh rate for items on the screen other than alarms, choose the down arrow next to the refresh icon and choose a refresh rate. You can also choose to turn off automatic refresh.
6. To return to showing information about all the resources in your account, near the top of the screen where the name of the resource group is currently displayed, choose **All resources**.

Creating a customized CloudWatch dashboard

To get started, create a CloudWatch dashboard. You can create multiple dashboards, and you can add dashboards to a favorites list. You aren't limited to the number of dashboards that you can have in your AWS account. All dashboards are global. They are not Region-specific.

> **Opt-in Region propagation delay**
>
> You might have recently enabled an opt-in Region (Region that is disabled by default) for your account. If so, your existing dashboards can take up to 24 hours to be available in that Region. During this period, `GetDashboard` and `ListDashboards` requests might return an access denied error. This does not indicate a problem with your permissions. Because dashboards are global, you can view them from any other enabled Region while propagation completes. Creating and updating dashboards in the new Region works immediately.

The following procedure shows you how to create a dashboard from the CloudWatch console. You can use the `PutDashboard` API operation to create a dashboard from the command line interface. The API operation contains a JSON string that defines your dashboard content. For more information about creating a dashboard with the `PutDashboard` API operation, see PutDashboard in the *Amazon CloudWatch API Reference*.

> **Tip**
>
> If you're creating a new dashboard with the `PutDashboard` API operation, you can use the JSON string from a dashboard that already exists.

To create a dashboard from the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose **Create dashboard**.
3. In the **Create new dashboard** dialog box, enter a name for the dashboard, and then choose **Create dashboard**.

   If you use the name **CloudWatch-Default** or **CloudWatch-Default-*ResourceGroupName***, the dashboard appears in the overview of the CloudWatch home page under **Default Dashboard**. For more information, see Getting started with CloudWatch automatic dashboards.
4. In the **Add to this dashboard** dialog box, do one of the following:
   - To add a graph to the dashboard, choose **Line** or **Stacked area**, and then choose **Configure**. In the **Add metric graph** dialog box, select the metric(s) to graph, and then choose **Create widget**. If a metric doesn't appear in the dialog box because it hasn't published data in more than 14 days, you can add it manually. For more information, see Graph metrics manually on a CloudWatch dashboard.
   - To add a number displaying a metric to the dashboard, choose **Number**, and then choose **Configure**. In the **Add metric graph** dialog box, select the metric(s) to graph, and then choose **Create widget**.
   - To add a text block to the dashboard, choose **Text**, and then choose **Configure**. In the **New text widget** dialog box, for **Markdown**, format your text using Markdown, and then choose **Create widget**.
5. (Optional) Choose **Add widget**, and then repeat step 4 to add another widget to the dashboard. You can repeat this step multiple times.

   For each graph on the dashboard, there is an information icon at the upper right. Choose this icon to see the descriptions of the metrics in the graph.
6. Choose **Save dashboard**.

Creating a CloudWatch cross-account cross-Region dashboard with the AWS Management Console

You can create *cross-account cross-Region dashboards*, which summarize your CloudWatch data from multiple AWS accounts and multiple Regions into one dashboard. From this high-level

dashboard you can get a view of your entire application, and also drill down into more specific dashboards without having to sign in and out of accounts or switch Regions.

Prerequisite

Before you can create a cross-account cross-Region dashboard, you must enable at least one sharing account and at least one monitoring account. Additionally, to be able to use the CloudWatch console to create a cross-account dashboard, you must enable the console for cross-account functionality. For more information, see Cross-account cross-Region CloudWatch console.

To create a cross-account cross-Region dashboard

1. Sign in to the monitoring account.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the navigation pane, choose **Dashboards**.
4. Choose a dashboard, or create a new one.
5. At the top of the screen, you can switch between accounts and Regions. As you create your dashboard, you can include widgets from multiple accounts and Regions. Widgets include graphs, alarms, and CloudWatch Logs Insights widgets.

Create a cross-account cross-Region dashboard programmatically

You can use the AWS APIs and SDKs to create dashboards programmatically. For more information, see PutDashboard.

To enable cross-account cross-Region dashboards, we have added new parameters to the dashboard body structure, as shown in the following table and examples. For more information about overall dashboard body structure, see Dashboard Body Structure and Syntax.

Parameter	Use	Scope	Default
`accountId`	Specifies the ID of the account where the widget or the metric is located.	Widget or metric	Account that is currently logged in

Parameter	Use	Scope	Default
`region`	Specifies the Region of the metric.	Widget or metric	Current Region selected in the console

The following examples illustrate the JSON source for widgets in a cross-account cross-Region dashboard.

This example sets the `accountId` field to the ID of the sharing account at the widget level. This specifies that all metrics in this widget will come from that sharing account and Region.

```
{
  "widgets": [
    {
          ...
          "properties": {
        "metrics": [
                  …
        ],
        "accountId": "111122223333",
        "region": "us-east-1"
      }
    }
  ]
}
```

This example sets the `accountId` field differently at the level of each metric. In this example, the different metrics in this metric math expression come from different sharing accounts and different Regions.

```
{
  "widgets": [
    {
          ...
          "properties": {
```

```
        "metrics": [
          [
            {
              "expression": "SUM(METRICS())",
              "label": "[avg: ${AVG}] Expression1",
              "id": "e1",
              "stat": "Sum"
            }
          ],
          [
            "AWS/EC2",
            "CPUUtilization",
            {
              "id": "m2",
              "accountId": "5555666677778888",
              "region": "us-east-1",
              "label": "[avg: ${AVG}] ApplicationALabel "
            }
          ],
          [
            ".",
            ".",
            {
              "id": "m1",
              "accountId": "9999000011112222",
              "region": "eu-west-1",
              "label": "[avg: ${AVG}] ApplicationBLabel"
            }
          ]
        ],
        "view": "timeSeries",
        "region": "us-east-1", ---> home region of the metric. Not present in above
 example
              "stacked": false,
        "stat": "Sum",
        "period": 300,
        "title": "Cross account example"
      }
    }
  ]
}
```

This example shows an alarm widget.

```
{
  "type": "metric",
  "x": 6,
  "y": 0,
  "width": 6,
  "height": 6,
  "properties": {
    "accountID": "111122223333",
    "title": "over50",
    "annotations": {
      "alarms": [
        "arn:aws:cloudwatch:us-east-1:379642911888:alarm:over50"
      ]
    },
    "view": "timeSeries",
    "stacked": false
  }
}
```

This example is for a CloudWatch Logs Insights widget.

```
{
  "type": "log",
  "x": 0,
  "y": 6,
  "width": 24,
  "height": 6,
  "properties": {
    "query": "SOURCE 'route53test' | fields @timestamp, @message\n| sort @timestamp
 desc\n| limit 20",
    "accountId": "111122223333",
    "region": "us-east-1",
    "stacked": false,
    "view": "table"
  }
}
```

Another way to create dashboards programmatically is to first create one in the AWS Management Console, and then copy the JSON source of this dashboard. To do so, load the dashboard and choose **Actions**, **View/edit source**. You can then copy this dashboard JSON to use as a template to create similar dashboards.

Creating a graph with metrics from different accounts and Regions in a CloudWatch dashboard

1. Sign in to the monitoring account.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**.
4. Select the account and Region that you want to add metrics from. You can select your account and Region from the account and Region dropdown menus near the top-right of the screen.
5. Add the metrics you want to the graph. For more information, see Graphing metrics.
6. Repeat steps 4-5 to add metrics from other accounts and Regions.
7. (Optional) Choose the **Graphed metrics** tab and add a metric math function that uses the metrics that you have chosen. For more information, see Math expressions with metrics.

   You can also set up a single graph to include multiple SEARCH functions. Each search can refer to a different account or Region.
8. When you are finished with the graph, choose **Actions**, **Add to dashboard**.

   Select your cross-account dashboard, and choose **Add to dashboard**.

Adding an alarm from a different account to a CloudWatch cross-account dashboard

1. Sign in to the monitoring account.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. At the top of the page, choose the account where the alarm is located.
4. In the navigation pane, choose **Alarms**.
5. Select the check box next to the alarm that you want to add, and choose **Add to dashboard**.

6. Select the cross-account dashboard that you want to add it to, and choose **Add to dashboard**.

Creating flexible CloudWatch dashboards with dashboard variables

Use *dashboard variables* to create flexible dashboards that can quickly display different content in multiple widgets, depending on the value of an input field within the dashboard. For example, you can create a dashboard that can quickly switch between different Lambda functions or Amazon EC2 instance IDs, or one that can switch to different AWS Regions.

After you create a dashboard that uses a variable, you can copy the same variable pattern to other existing dashboards.

Using dashboard variables improves the operational workflow for people who use your dashboards. It can also reduce your costs because you're using dashboard variables in one dashboard instead of creating multiple similar dashboards.

> **Note**
>
> If you share a dashboard that contains dashboard variables, the people that you share it with won't be able to change between the variable values.

Types of dashboard variables

The dashboard variable can be a *property variable* or a *pattern variable*.

- *Property variables* change all instances of a property in all widgets in the dashboard. This property can be any JSON property in the JSON source of a dashboard, such as `region`. Or it can be a dimension name for a metric, such as `InstanceID` or `FunctionName`.

  For a tutorial that uses a property variable, see Tutorial: Creating a CloudWatch Lambda dashboard with function name as the variable.

  For more information about the JSON source of dashboards, see Dashboard Body Structure and Syntax. In the CloudWatch console, you can see the JSON source for any custom dashboard by choosing **Actions**, **View/edit source**.

- *Pattern variables* use a regular expression pattern to change all of a JSON property or only a certain part of it.

  For a tutorial that uses a pattern variable, see Tutorial: Creating a dashboard that uses a regular expression pattern to switch between AWS Regions.

Property variables apply to most use cases and are less complex to set up.

Topics

- Copying a variable to another CloudWatch dashboard
- Tutorial: Creating a dashboard that uses a regular expression pattern to switch between AWS Regions
- Tutorial: Creating a CloudWatch Lambda dashboard with function name as the variable

Copying a variable to another CloudWatch dashboard

After you create a dashboard with useful variables, you can copy these variables to other existing dashboards. For more information about dashboard variables, see Creating flexible CloudWatch dashboards with dashboard variables.

To copy a dashboard variable to another dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose the name of the dashboard that has the variable that you want to copy. Enter a string to find dashboards with matching names, if needed.
3. Choose **Actions**, **Variables**, **Manage variables**.
4. Choose the radio button next to the variable that you want to copy, and choose **Copy to another dashboard**.
5. Choose the selection box and start typing the dashboard name that you want to copy the variable to.
6. Select the dashboard name and choose **Copy variable**.

Tutorial: Creating a dashboard that uses a regular expression pattern to switch between AWS Regions

The steps in this procedure illustrate how to create a flexible dashboard that can switch between Regions. This tutorial uses a regular expression *pattern variable* instead of a property variable. For a tutorial that uses a property variable, see Tutorial: Creating a CloudWatch Lambda dashboard with function name as the variable.

For many use cases, you can create a dashboard that switches between Regions by using a property variable. But if the widgets rely on Amazon Resource Names (ARNs) that include Region names, you must use a pattern variable to change the Region names within the ARNs.

To use a dashboard pattern variable to create a flexible multi-Region dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, **Create dashboard**.
3. Enter a name for the dashboard, and choose **Create dashboard**.
4. Add widgets to the dashboard. When you add the widgets that you want to display Region-specific data, avoid specifying any dimensions with values that appear in only one Region. For example, for Amazon EC2 metrics, specify metrics that are aggregated instead of metrics that use **InstanceID** as a dimension.

   For more information about adding widgets to a dashboard, see Using widgets on CloudWatch dashboards.
5. After you add the widgets, as you are viewing the dashboard, choose **Actions**, **Variables**, **Create a variable**.
6. Choose **Pattern variable**.
7. For **What pattern do you want your variable to change?**, enter a Regular Expression (regex) pattern that matches the text you want the variable to replace in your dashboard JSON definition.

   You have the correct pattern entered if the label below the box displays the widgets that will be impacted by the variable.
8. For **Input type**, for this use case, select **Radio button**.
9. For **Define how inputs are populated**, choose **Create a list of custom values**.

10. For **Create your custom values**, enter the Regions that you want to switch between, with one Region on each line. After each Region, enter a comma and then the label to display for that radio button. For example:

    ```
    us-east-1, N. Virginia

    us-east-2, Ohio

    eu-west-3, Paris
    ```

    As you fill in the custom values, the **Preview** pane updates to display what the radio buttons will look like.

11. (Optional) For more settings, choose **Secondary settings** and do one or more of the following:

    - To customize the name of your variable, enter the name in **Custom variable name**.
    - To customize the label for the variable input field, enter the label in **Input label**. For this tutorial, enter **`Region:`**.

      If you enter a value here, the **Preview** pane updates to display what the radio buttons will look like.
    - To set the default value for this variable when the dashboard is first opened, enter the default in **Default value**.

12. Choose **Add variable**.

    The dashboard appears, with a **Region:** label next to the radio buttons for the Regions near the top. When you switch between Regions, all the widgets that use the variable will display information about the selected Region.

Tutorial: Creating a CloudWatch Lambda dashboard with function name as the variable

The steps in this procedure illustrate how to create a flexible dashboard that shows a variety of metric graphs, using a property variable. This includes a dropdown selection box on the dashboard that you can use to switch the metrics in all the graphs between different Lambda functions.

Other use case examples for this type of dashboard include using `InstanceId` as the variable to create a dashboard of metrics with a dropdown for instance IDs. Alternatively, you could create

a dashboard that uses `region` as the variable to display the same set of metrics from different Regions.

To use a dashboard property variable to create a flexible Lambda dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, **Create dashboard**.
3. Enter a name for the dashboard, and choose **Create dashboard**.
4. Add widgets to the dashboard that display metrics for a Lambda function. When you create these widgets, specify **Lambda**, **By Function Name** for the widget metrics. For the function, specify one of the Lambda functions that you want to include in this dashboard.

   For more information about adding widgets to a dashboard, see Using widgets on CloudWatch dashboards.
5. After you add the widgets, as you are viewing the dashboard, choose **Actions**, **Variables**, **Create a variable**.
6. Choose **Property variable**.
7. For **Property that the variable changes**, choose **FunctionName**.
8. For **Input type**, for this use case, we recommend choosing **Select menu (dropdown)**. This creates a dropdown menu in the dashboard where you can select the Lambda function name to display metrics for.

   If this was for a dashboard that toggled between only two or three different values for a variable, then **Radio button** would be a good choice.

   If you prefer to enter or paste in values for the variable, you would choose **Text input**. This option doesn't include a dropdown list or radio buttons.
9. When you choose **Select menu (dropdown)**, you must then choose whether to populate the menu by entering values, or using a metric search. For this use case, let's assume that you have a large number of Lambda functions and you don't want to enter all of them manually. Choose **Use the results of a metric search** and then do the following:

   a. Choose **Pre-built queries**, **Lambda**, **Errors**.

      (Choosing **Errors** does not add the **Errors** metric to the dashboard. However, it quickly populates the **FunctionName** variable selection box.)

   b. Choose **By Function Name** and then choose **Search**.

Under the **Search** button, you will then see **FunctionName** selected. You also see a message about how many **FunctionName** dimension values were found to populate the input box.

10. (Optional) For more settings, choose **Secondary settings** and do one or more of the following:

    - To customize the name of your variable, enter the name in **Custom variable name**.
    - To customize the label for the variable input field, enter the label in **Input label**.
    - To set the default value for this variable when the dashboard is first opened, enter the default in **Default value**.

11. Choose **Add variable**.

    A **FunctionName** dropdown selection box appears near the top of the dashboard. You can select a Lambda function in this box and all the widgets that use the variable will display information about the selected function.

    Later, if you add more widgets to the dashboard that watch Lambda metrics with the **FunctionName** dimension, they will automatically use the variable.

Using widgets on CloudWatch dashboards

You can use the following types of widgets on CloudWatch dashboards:

- **Graph widget** – You can add graphs that contain one or more metrics to your CloudWatch dashboard. The types of graphs that you can add to your dashboard include ***Line***, ***Stacked area***, ***Number***, ***Gauge***, ***Bar***, and ***Pie***. You can remove graphs from your dashboard when you don't need them anymore.
- **Manual metrics widget** – If a metric hasn't published data in the past 14 days, you can't find it when searching for metrics to add to a graph on a CloudWatch dashboard. You can add any metric manually to an existing graph.
- **Metrics explorer widget** – Metrics explorer widgets include graphs of multiple resources that have the same tag, or share the same resource property such as an instance type. These widgets stay up to date, as resources that match are created or deleted. Adding metrics explorer widgets to your dashboard helps you to troubleshoot your environment more efficiently.

  For example, you can monitor your fleet of EC2 instances by assigning tags that represent their environments, such as production or test. You can then use these tags to filter and aggregate the

operational metrics, such as `CPUUtilization`, to understand the health and performance of the EC2 instances that are associated with each tag.

- **Line widget** – With the line widget, you can compare metrics over periods of time. You also can use the widget's mini-map zoom feature to inspect sections of line graphs without changing between zoomed-in and zoomed-out views. The procedures in this section describe how to add and remove a line widget on a CloudWatch dashboard. For information about using the widget's mini-map zoom feature with line graphs, see Zooming in on a line or stacked area graph.
- **Number widget** – With the number widget, you can look at the latest metric values and trends as soon as they appear. Because the number widget includes the sparkline feature, you can visualize the top and bottom halves of metric trends in a single graph. The procedures in this section describe how to add and remove a number widget from a CloudWatch dashboard.
- **Gauge widget** – With the gauge widget, you can visualize metric values that go between ranges. For example, you can use the gauge widget to graph percentages and CPU utilization, so that you can observe and diagnose any performance issues that occur. The procedures in this section describe how to add and remove a gauge widget from a CloudWatch dashboard.
- **Text widget** – A text widget contains a block of text in Markdown format. You can add, edit, or remove text widgets from your CloudWatch dashboard.
- **Alarm widget** – To add an alarm widget to a dashboard, choose one of the following options:
  - Add a single alarm in a widget, which displays the graph of the alarm's metric and also displays the alarm status.
  - Add an *alarm status widget*, which displays the status of multiple alarms in a grid. Only the alarm names and current status are displayed, Graphs are not displayed. You can include up to 100 alarms in one alarm status widget.
- **Table widget** – With the data table widget, you can see the raw datapoints of your metric and a quick summary of that raw data. Because the data table widget is not a chart to abstract the actual data away from you, it is easier to understand the datapoints being presented. The procedures in this section describe how to add and remove a data table widget from a CloudWatch dashboard. The following image shows an example of a table widget with columns for the Minimum, Maximum, Sum, and Average statistics for a set of CloudWatch metrics.
- **Linked graphs** – You can link the graphs on your dashboard together, so that when you zoom in or zoom out on one graph, the other graphs zoom in or zoom out at the same time. You can unlink graphs to limit zoom to one graph.

Adding a graph widget to a CloudWatch dashboard

The procedures in this section describe how to add and remove graphs from your dashboard. For information about how to edit a graph on your dashboard, see Edit a graph on a CloudWatch dashboard.

To add a graph to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol, and then choose the type of graph that you want to add to your dashboard, then choose **Next**.

   - If you select ***Line***, ***Stacked area***, ***Bar***, or ***Pie***, choose **Metrics**.
4. In the **Browse** tab, search or browse for the metrics to graph, and select the ones that you want.
5. (Optional) To change your graph's time range, select one of the predefined time ranges in the upper part of the screen. The time ranges span from 1 hour to 1 week (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).

   To set your own time range, choose **Custom**.

   - (Optional) To have this widget keep using this time range that you select, even if the time range for the rest of the dashboard is later changed, choose **Persist time range**.
6. (Optional) To change your graph's widget type, use the dropdown that's next to the predefined time ranges.
7. (Optional) In **Graphed metrics**, you can add a dynamic label to your metric and change your metric's label, label color, statistic, and period. You also can determine the position of labels on the Y-axis from left to right.

   a. To add a dynamic label, choose **Graphed metrics**, and then choose **Add dynamic labels**. Dynamic labels display a statistic about your metric in the graph legend. Dynamic labels update automatically when your dashboard or graph refreshes. By default, the dynamic values that you add to labels appear at the beginning of your labels. For more information, see Use dynamic labels.

   b. To change the color of a metric, choose the color square that's next to the metric.

   c. To change the statistic, select the dropdown under ***Statistic***, and then choose a new value. For more information, see Statistics.

   d. To change the period, select the dropdown under the ***Period*** column, and then choose a new value.
8. If you are creating a gauge widget, you must choose the **Options** tab and specify the **Min** and **Max** values to use for the two ends of the gauge.

9. (Optional) To customize the Y-axis, choose **Options**. You can add a custom label under ***Left Y-axis*** in the label field. If your graph displays values on the right side of the Y-axis, you can customize that label, too. You also can set minimum and maximum limits on your Y-axis values, so that your graph only displays the value ranges that you specify.
10. (Optional) To add or edit horizontal annotations to line or stacked area graphs, or to add thresholds to gauge widgets, choose **Options**:

    a. To add a horizontal annotation or threshold, choose **Add horizontal annotation** or **Add threshold**.

    b. For ***Label***, enter a label for the annotation then choose the check mark icon.

    c. For ***Value***, choose the pen and paper icon that's next to the current value, and enter your new value. After you enter your value, choose the check mark icon.

    d. For ***Fill***, select the dropdown and specify how your annotation will use shading. You can choose ***None***, ***Above***, ***Between***, or ***Below***. To change the fill color, choose the color square that's next to the annotation.

    e. For ***Axis***, specify whether your annotation appears on the left or right side of the Y-axis.

    f. To hide an annotation, clear the check box that's next to the annotation you want to hide.

    g. To delete an annotation, choose **X** under ***Actions***.

    > **Note**
    >
    > You can repeat these steps to add multiple horizontal annotations or thresholds to the same graph or gauge.

11. (Optional) To add or edit vertical annotations, choose **Options**:

    a. To add a vertical annotation, choose **Add vertical annotation**.

    b. For ***Label***, choose the pen and paper icon that's next to the current annotation, and enter your new annotation. If you want to show only the date and time, leave the label field blank.

    c. For ***Date***, choose the current date and time, and enter the new date and time.

    d. For ***Fill***, select the dropdown, and specify how your annotation will use shading. You can choose ***None***, ***Above***, ***Between***, or ***Below***. To change the fill color, select the color square that's next to the annotation.

    e. To hide an annotation, clear the check box next to the annotation that you want to hide.

f. To delete an annotation, choose **X** under ***Actions***.

> **Note**
>
> You can repeat these steps to add multiple vertical annotations to the same graph.

12. Choose **Create widget**.
13. Choose **Save dashboard**.

Removing a graph widget from a CloudWatch dashboard

To remove a graph from a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the graph that you want to remove, choose **Widget actions**, and then choose **Delete**.
4. Choose **Save dashboard**.

Graph metrics manually on a CloudWatch dashboard

To add a metric that you can't find in search to a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. The dashboard must already contain a graph where you want to add the metric. If it doesn't, create the graph and add any metric to it. For more information, see Adding a graph widget to a CloudWatch dashboard.
4. Choose **Actions**, **View/edit source**.

   A JSON block appears. The block specifies the widgets on the dashboard and their contents. The following is an example of one part of this block, which defines one graph.

```
{
```

```
  "type": "metric",
  "x": 0,
  "y": 0,
  "width": 6,
  "height": 3,
  "properties": {
    "view": "singleValue",
    "metrics": [
      [
        "AWS/EBS",
        "VolumeReadOps",
        "VolumeId",
        "vol-1234567890abcdef0"
      ]
    ],
    "region": "us-west-1"
  }
},
```

In this example, the following section defines the metric shown on this graph.

```
[ "AWS/EBS", "VolumeReadOps", "VolumeId", "vol-1234567890abcdef0" ]
```

5. Add a comma after the end bracket if there isn't already one and then add a similar bracketed section after the comma. In this new section, specify the namespace, metric name, and any necessary dimensions of the metric that you're adding to the graph. The following is an example.

```
[ "AWS/EBS", "VolumeReadOps", "VolumeId", "vol-1234567890abcdef0" ],
[ "MyNamespace", "MyMetricName", "DimensionName", "DimensionValue" ]
```

For more information about the formatting of metrics in JSON, see Properties of a Metric Widget Object in the Amazon CloudWatch API Reference.

6. Choose **Update**.

Editing a graph on a CloudWatch dashboard

You can edit the graphs that you add to your CloudWatch dashboard. You can change a graph's title, statistic, or period. You can add, update, and remove metrics from your graphs. If your graph contains more than one metric, you can reduce clutter by hiding metrics that you aren't using. The procedures in this section describe how to edit a graph on your dashboard. For information about creating a graph, see Add or remove a graph from a CloudWatch dashboard.

New interface

To edit a graph on a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the graph that you want to edit, choose **Widget actions**, and then choose **Edit**.
4. To change the graph's title, choose the pen and paper icon that's next to the current title. Enter the new title, and then choose **Apply**.
5. (Optional) To change your graph's time range, select one of the predefined time ranges in the upper are of the graph. The time ranges span from 1 hour to 1 week (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).

   To set your own time range, choose **Custom**.

   - (Optional) To have this widget keep using this time range that you select, even if the time range for the rest of the dashboard is later changed, choose **Persist time range**.
6. To change your graph's widget type, use dropdown that's next to the predefined time ranges.
7. In **Graphed metrics**, you can add a dynamic label to your metric and change your metric's label, label color, statistic, and period. You also can determine the position of labels on the Y-axis from left to right.

   a. To add a dynamic label for a metric, choose **Dynamic labels**. Dynamic labels display a statistic about the metric in the graph legend. Dynamic labels update automatically when your dashboard or graph refreshes. By default, the dynamic values that you add to labels appear at the beginning of the labels. For more information, see Use dynamic labels.

b. To change the color of a metric, choose the color square that's next to the metric.

c. To change the statistic, choose the statistic value under the ***Statistic*** column, and then choose a new value. For more information, see Statistics.

d. To change the period, choose the period value under the ***Period*** column, and then choose a new value.

8. To add or edit horizontal annotations, choose **Options**:

a. To add a horizontal annotation, choose **Add horizontal annotation**.

b. For **Label**, choose the pen and paper icon next to the current annotation. Then enter your new annotation. After you enter your annotation, choose the check mark icon.

c. For **Value**, choose the pen and paper icon next to the current metric value. Then enter your new metric value. After you enter your value, select the check mark icon.

d. For **Fill**, choose the dropdown under the column, and then specify how your annotation will use shading. You can choose **None**, **Above**, **Between**, or **Below**. If you choose **Between**, another new label and value field appears.

> **Tip**
>
> You can change the fill color by choosing the colored square next to the annotation.

e. For **Axis**, specify whether your annotation appears on the left or right side of the Y-axis.

f. To hide an annotation, deselect the check box next to the annotation that you want to hide on the graph.

g. To delete an annotation, choose **X** under the **Actions** column.

> **Note**
>
> You can repeat these steps to add multiple horizontal annotations to the same graph.

9. To add or edit vertical annotations, choose **Options**:

a. To add a vertical annotation, choose **Add vertical annotation**.

b. For **Label**, choose the pen and paper icon next to the current annotation. Then enter your new annotation. After you enter your annotation, choose the check mark icon.

> **Tip**
>
> To show only the date and time, leave the label field blank.

c. For **Date**, choose the current date and time. Then enter the new date and time.

d. For **Fill**, choose the dropdown under the column, and then specify how your annotation will use shading. You can choose **None**, **Above**, **Between**, or **Below**. If you choose **Between**, a new label and value field appears.

> **Tip**
>
> You can change the fill color by choosing the color square next to the annotation.

> **Note**
>
> You can repeat these steps to add multiple vertical annotations to the same graph.

e. To hide an annotation, deselect the check box next to the annotation that you want to hide on the graph.

f. To delete an annotation, choose **X** under the **Actions** column.

10. To customize the Y-axis, choose **Options**. Under ***Left Y-axis***, you can enter a custom label for **Label**. If the graph displays values on the right Y-axis, you can customize that label, too. You also can set minimums and maximums on the Y-axis values, so that the graph displays only the value range that you specify.
11. When you finish making changes, choose **Update widget**.

To hide or change the position of a graph legend

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.

3. In the upper-right corner of the graph that you want to edit, choose **Widget actions**. Choose **Legend** and select **Hidden**, **Bottom**, or **Right**.

To temporarily hide metrics for a graph on a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Select the color square for the metric that you want to hide in the graph's footer. An ***X*** appears in the color square when you hover over it, and the square turns gray when you choose it.
4. To restore the hidden metric, clear the **X** in the gray square.

Original interface

To edit a graph on a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the upper-right corner of the graph that you want to edit. Choose **Widget actions**, and then choose **Edit**.
4. To change the graph's title, choose the pencil icon that's next to the current title, and then enter the new title.
5. To change the graph's time range, choose one of the predefined time ranges in the upper area of the graph. These span from 1 hour to 1 week (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).
   - To set your own time range, choose **custom**.
6. To change your graph's widget type, select the **Graph options** tab. You can choose ***Line***, ***Stacked area***, ***Number***, ***Bar***, or ***Pie***.

> **Tip**
>
> You can change your graph's widget type by choosing the dropdown that's next to the predefined time ranges.

7. In **Graphed metrics**, you can add a dynamic label to your metric and change your metric's label, label color, statistic, and period. You also can determine the position of labels on the Y-axis from left to right.

   a. To add a dynamic label for a metric, choose **Dynamic labels**. Dynamic labels display a statistic about the metric in the graph legend. Dynamic labels update automatically when your dashboard or graph refreshes. By default, the dynamic values that you add to labels appear at the beginning of the labels. For more information, see Use dynamic labels.

   b. To change the color of a metric, choose the color square that's next to the metric.

   c. To change the statistic, choose the statistic value under the ***Statistic*** column, and then choose a new value. For more information, see Statistics.

   d. To change the period, choose the period value under the ***Period*** column, and then choose a new value.

8. To add or edit horizontal annotations, choose **Graph options**:

   a. To add a horizontal annotation, choose **Add horizontal annotation**.

   b. For **Label**, choose the pencil icon next to the current annotation. Then enter your new annotation. After you enter your annotation, choose the check mark icon.

   c. For **Value**, choose the pencil icon next to the current metric value. Then enter your new metric value. After you enter your value, select the check mark icon.

   d. For **Fill**, choose the dropdown under the column, and then specify how your annotation will use shading. You can choose **None**, **Above**, **Between**, or **Below**. If you choose **Between**, a new label and value field appears.

   > **Tip**
   >
   > You can change the fill color by choosing the color square next to the annotation.

   e. For **Axis**, specify whether your annotation appears on the left or right side of the Y-axis.

   f. To hide an annotation, deselect the check box next to the annotation that you want to hide on the graph.

   g. To delete an annotation, choose **X** under the **Actions** column.

> **Note**
>
> You can repeat these steps to add multiple horizontal annotations to the same graph.

9. To add or edit vertical annotations, choose **Graph options**:

   a. To add a vertical annotation, choose **Add vertical annotation**.

   b. For **Label**, choose the pencil icon next to the current annotation. Then enter your new annotation. After you enter your annotation, choose the check mark icon.

   > **Tip**
   >
   > To show only the date and time, leave the label field blank.

   c. For **Date**, choose the pencil icon next to the current date and time. Then enter the new date and time.

   d. For **Fill**, choose the dropdown under the column, and then specify how your annotation will use shading. You can choose **None**, **Above**, **Between**, or **Below**. If you choose **Between**, a new label and value field appears.

   > **Tip**
   >
   > You can change the fill color by choosing the color square next to the annotation.

   > **Note**
   >
   > You can repeat these steps to add multiple vertical annotations to the same graph.

   e. To hide an annotation, deselect the check box next to the annotation that you want to hide on the graph.

   f. To delete an annotation, choose **X** under the **Actions** column.

10. To customize the Y-axis, choose **Graph options**. Under ***Left Y-axis***, you can enter a custom label for **Label**. If the graph displays values on the right Y-axis, you can customize that label, too. You also can set minimums and maximums on the Y-axis values, so that the graph displays only the value range that you specify.
11. When you finish making changes, choose **Update widget**.

To hide or change the position of a graph legend

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the upper-right corner of the graph that you want to edit, and choose **Widget actions**. Choose **Legend**, and select **Hidden**, **Bottom**, or **Right**.

To temporarily hide metrics for a graph on a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Select the color square for the metric that you want to hide in the graph's footer. An ***X*** appears in the color square when you hover over it, and the square turns gray when you choose it.
4. To restore the hidden metric, clear the **X** in the gray square.

Renaming a graph on a CloudWatch dashboard

You can change the default name that CloudWatch assigns to a graph on your dashboard.

To rename a graph on a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the title of the graph and choose **Widget actions** and **Edit**.
4. On the **Edit graph** screen, near the top, choose the title of the graph.
5. For **Title**, enter a new name and choose **Ok** (check mark). In the lower-right corner of the **Edit graph** screen, choose **Update widget**.

Moving a graph on a CloudWatch dashboard

To move a graph on a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Do one of the following:
   - Hover over the title of the graph until the selection icon appears. Select and drag the graph to a new location on the dashboard.
   - To move the widget to either the top left or bottom left of the dashboard, choose the vertical ellipsis at the upper right of the widget to open the **Widget actions** menu. Then choose **Move**, and choose where to move the widget to.
4. Choose **Save dashboard**.

Changing the size of graphs on CloudWatch dashboards

To change the size of a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. To increase or decrease the size, hover over the graph and drag the lower right corner of the graph. Stop dragging the corner when you have the size that you want.
4. Choose **Save dashboard**.

Changing the size of a graph temporarily on a CloudWatch dashboard

To enlarge a graph temporarily

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Select the graph. Alternatively, hover over the title of the graph and choose **Widget actions**, **Enlarge**.

Add a metrics explorer widget to a CloudWatch dashboard

The following steps explain how to add a metrics explorer widget to a dashboard using the console. You can also add it programmatically or by using CloudFormation. For more information, see Metrics Explorer Widget Object Definition and AWS::CloudWatch::Dashboard.

To add a metrics explorer widget to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the dashboard where you want to add the metrics explorer widget.
4. Choose the **+** symbol.
5. Choose **Explorer** and then choose **Next**.

   > **Note**
   >
   > You must be opted in to the new dashboard view to be able to add a Metrics Explorer widget. To opt in, choose **Dashboards** in the navigation pane, then choose **try out the new interface** in the banner at the top of the page.

6. Do one of the following:
   - To use a template, choose **Pre-filled Explorer widget** and then select a template to use.
   - To create a custom visualization, choose **Empty Explorer widget**.
7. Choose **Create**.

   If you used a template, the widget appears on your dashboard with the selected metrics. If you're satisfied with the explorer widget and the dashboard, choose **Save dashboard**.

   If you did not use a template, continue to the following steps.
8. In the new widget under **Explorer**, in the **Metrics** box, choose a single metric or all the available metrics from a service.

   After you choose a metric, you can optionally repeat this step to add more metrics.
9. For each metric selected, CloudWatch displays the statistic that it will use immediately after the metric name. To change this, choose the statistic name and then choose the statistic that you want.
10. Under **From**, choose a tag or a resource property to filter your results.

After you do this, you can optionally repeat this step to choose more tags or resource properties.

If you choose multiple values of the same property, such as two EC2 instance types, the explorer displays all the resources that match either chosen property. It's treated as an OR operation.

If you choose different properties or tags, such as the **`Production`** tag and the M5 instance type, only the resources that match all of these selections are displayed. This is treated as an AND operation.

11. (Optional) For **Aggregate by**, choose a statistic to use to aggregate the metrics. Then, next to **for**, choose how to aggregate the metric from the list. You can aggregate together all the resources that are currently displayed, or aggregate by a single tag or resource property.

    Depending on how you choose to aggregate, the result may be a single time series or multiple time series.
12. Under **Split by**, you can choose to split a single graph with multiple time series into multiple graphs. The split can be made by a variety of criteria, which you choose under **Split by**.
13. Under **Graph options**, you can refine the graph by changing the period, the type of graph, the legend placement, and the layout.
14. If you're satisfied with the explorer widget and the dashboard, choose **Save dashboard**.

Adding a line graph widget to a CloudWatch dashboard

To add a line widget to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol, and select **Line**.
4. Choose **Metrics**.
5. Choose **Browse**, and select the metric that you want to graph.
6. Choose **Create widget**, and then choose **Save dashboard**.

Removing a line graph widget from a CloudWatch dashboard

To remove a line graph widget from a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the line widget that you want to remove, choose **Widget actions**, and then choose **Delete**.
4. Choose **Save dashboard**.

Adding a number widget to a CloudWatch dashboard

> **Note**
>
> Only the new interface supports the sparkline feature. When you create a number widget, the sparkline feature is automatically included.

To add a number widget to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol, and select **Number**.
4. In the **Browse** tab, search or browse for the metric that you want to display.
5. (Optional) To change the color of the sparkline feature, choose **Graphed metrics**, and select the color box next to the metric label. A menu appears where you can choose a different color or enter a six-digit hex color code to specify a color.
6. (Optional) To turn off the sparkline feature, choose **Options**. Under ***Sparkline***, the check box.
7. (Optional) To change your number widget's time range, select one of the predefined time ranges in the upper area of the widget. The time ranges span from 1 hour to 1 week (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).

   To set your own time range, choose **Custom**.

   - (Optional) To have this widget keep using this time range that you select, even if the time range for the rest of the dashboard is later changed, choose **Persist time range**.

8. (Optional) To have the number widget display an aggregate (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).

   To set your own time range, choose **Custom**.

   - (Optional) To have this widget display an average of the metric value over the entire time range, instead of the most recent value, choose **Options**, **Time range value shows the value from the entire time range**.

9. Choose **Create widget**, and choose **Save dashboard**.

> **Tip**
>
> You can turn off the sparkline feature from the number widget on the dashboard screen. In the upper-right corner of the number widget that you want to modify, choose **Widget actions**. Select **Sparkline**, and then choose **Hide sparkline**.

Removing a number widget from a CloudWatch dashboard

To remove a number widget from a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose the dashboard that contains the number widget that you want to delete.
3. In the upper-right corner of the number widget that you want to remove, choose **Widget actions**, and then choose **Delete**.
4. Choose **Save dashboard**.

Adding a gauge widget to a CloudWatch dashboard

> **Note**
>
> Only the new interface in the CloudWatch console supports creation of the gauge widget. You must set a gauge range when you create this widget.

To add a gauge widget to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. From the dashboard screen, choose the **+** symbol, and then select **Gauge**.
4. Choose **Browse**, and then select the metric that you want to graph.
5. Choose **Options**. Under ***Gauge range***, set values for **Min** and **Max**. For percentages, such as CPU utilization, we recommend that you set the values for `Min` to `0` and `Max` to `100`.
6. (Optional) To change the color of the gauge widget, choose **Graphed metrics** and select the color box next to the metric label. A menu appears where you can choose a different color or enter a six-digit hex color code to specify a color.
7. Choose **Create widget**, and choose **Save dashboard**.

Removing a gauge widget from a CloudWatch dashboard

To remove a gauge widget from a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose the dashboard that contains the gauge widget you want to delete.
3. In the upper-right corner of the gauge widget that you want to delete, choose **Widget actions**, and choose **Delete**.
4. Choose **Save dashboard**.

Using a custom widget on a CloudWatch dashboard

A *custom widget* is a CloudWatch dashboard widget that can call any AWS Lambda function with custom parameters. It then displays the returned HTML or JSON. Custom widgets are a simple way to build a custom data view on a dashboard. If you can write Lambda code and create HTML, you can create a useful custom widget. Additionally, Amazon provides several prebuilt custom widgets that you can create without any code.

When you create a Lambda function to use as a custom widget, we strongly recommend that you include the prefix **customWidget** in the function name. This helps you know which of your Lambda functions are safe to use when you add custom widgets to your dashboard.

Custom widgets behave like other widgets on your dashboard. They can be refreshed and auto-refreshed, resized, and moved around. They react to the time range of the dashboard.

If you have set up CloudWatch console cross-account functionality, you can add a custom widget created in one account to dashboards in other accounts. For more information, see Cross-account cross-Region CloudWatch console.

You can also use custom widgets on your own website by using the CloudWatch dashboard sharing feature. For more information, see Sharing CloudWatch dashboards.

Details about custom widgets in CloudWatch

Custom widgets work as follows:

1. The CloudWatch dashboard calls the Lambda function containing the widget code. It passes in any custom parameters that are defined in the widget.
2. The Lambda function returns a string of HTML, JSON, or Markdown. Markdown is returned as JSON in the following format:

   ```
   {"markdown":"markdown content"}
   ```

3. The dashboard displays the returned HTML or JSON.

If the function returns HTML, most HTML tags are supported. You can use Cascading Style Sheets (CSS) styles and Scalable Vector Graphics (SVG) to build sophisticated views.

The default style of HTML elements such as links and tables follow the styling of CloudWatch dashboards. You can customize this style by using inline styles, using the `<style>` tag. You can also deactivate the default styles by including a single HTML element with the class of `cwdb-no-`

`default-styles`. The following example deactivates default styles: `<div class="cwdb-no-default-styles"></div>`.

Every call by a custom widget to Lambda includes a `widgetContext` element with the following contents, to provide the Lambda function developer with useful context information.

```
{
  "widgetContext": {
    "dashboardName": "Name-of-current-dashboard",
    "widgetId": "widget-16",
    "accountId": "012345678901",
    "locale": "en",
    "timezone": {
      "label": "UTC",
      "offsetISO": "+00:00",
      "offsetInMinutes": 0
    },
    "period": 300,
    "isAutoPeriod": true,
    "timeRange": {
      "mode": "relative",
      "start": 1627236199729,
      "end": 1627322599729,
      "relativeStart": 86400012,
      "zoom": {
        "start": 1627276030434,
        "end": 1627282956521
      }
    },
    "theme": "light",
    "linkCharts": true,
    "title": "Tweets for Amazon website problem",
    "forms": {
      "all": {}
    },
    "params": {
      "original": "param-to-widget"
    },
    "width": 588,
    "height": 369
  }
}
```

Default CSS styling

Custom widgets provide the following default CSS styling elements:

- You can use the CSS class **btn** to add a button. It turns an anchor (<a>) into a button as in the following example:

```
<a class="btn" href=https://amazon.com”>Open Amazon</a>
```

- You can use the CSS class **btn btn-primary** to add a primary button.
- The following elements are styled by default: **table**, **select**, **headers (h1, h2, and h3)**, **preformatted text (pre)**, **input**, and **text area**.

Using the describe parameter

We strongly recommend that you support the **describe** parameter in your functions, even if it just returns an empty string. If you don't support it, and it is called in the custom widget, it displays widget content as if it was documentation.

If you include the **describe** parameter, the Lambda function returns the documentation in Markdown format and does nothing else.

When you create a custom widget in the console, after you select the Lambda function a **Get documentation** button appears. If you choose this button, the function is invoked with the **describe** parameter and the function's documentation is returned. If the documentation is well-formatted in markdown, CloudWatch parses the first entry in the documentation that is surrounded by three single backtick characters (```) in YAML. Then, it automatically populates the documentation in the parameters. The following is an example of such well-formatted documentation.

```
``` yaml
echo: <h1>Hello world</h1>
```
```

Security and JavaScript for custom CloudWatch widgets

For security reasons, JavaScript is not allowed in the returned HTML. Removing the JavaScript prevents permission escalation issues, where the writer of the Lambda function injects code that could run with higher permissions than the user viewing the widget on the dashboard.

If the returned HTML contains any JavaScript code or other known security vulnerabilities, it is cleaned from the HTML before it is rendered on the dashboard. For example, the **<iframe>** and **<use>** tags are not allowed and are removed.

Custom Widgets won't run by default in a dashboard. Instead, you must explicitly allow a custom widget to run if you trust the Lambda function that it invokes. You can choose to allow it once or allow always, for both individual widgets and entire dashboard. You can also deny permission for individual widgets and the entire dashboard.

Interactivity in the custom widget in CloudWatch

Even though JavaScript is not allowed, there are other ways to allow interactivity with the returned HTML.

- Any element in the returned HTML can be tagged with special configuration in a `<cwdb-action>` tag, which can display information in pop-ups, ask for confirmation on clicks, and call any Lambda function when that element is chosen. For example, you can define buttons that call any AWS API using a Lambda function. The returned HTML can be set to either replace the existing Lambda widget's content, or display inside a modal.
- The returned HTML can include links that open new consoles, open other customer pages, or load other dashboards.
- The HTML can include the `title` attribute for an element, which gives additional information if the user hovers over that element.
- The element can include CSS selectors, such as `:hover`, which can invoke animations or other CSS effects. You can also show or hide elements in the page.

<cwdb-action> definition and usage

The `<cwdb-action>` element defines a behavior on the immediately previous element. The content of the `<cwdb-action>` is either HTML to display or a JSON block of parameters to pass to a Lambda function.

The following is an example of a `<cwdb-action>` element.

```
<cwdb-action
     action="call|html"
     confirmation="message"
     display="popup|widget"
     endpoint="<lambda ARN>"
     event="click|dblclick|mouseenter">

     html | params in JSON
</cwdb-action>
```

- **action**— Valid values are `call`, which calls a Lambda function, and `html`, which displays any HTML contained within `<cwdb-action>`. The default is `html`.
- **confirmation**— Displays a confirmation message that must be acknowledged before the action is taken, allowing the customer to cancel.
- **display**— Valid values are popup and `widget`, which replaces the content of the widget itself. The default is `widget`.
- **endpoint**— The Amazon Resource Name (ARN) of the Lambda function to call. This is required if `action` is `call`.
- **event**— Defines the event on the previous element that invokes the action. Valid values are `click`, `dblclick`, and `mouseenter`. The `mouseenter` event can be used only in combination with the `html` action. The default is `click`.

Examples

The following is an example of how to use the `<cwdb-action>` tag to create a button that reboots an Amazon EC2 instance using a Lambda function call. It displays the success or failure of the call in a pop-up.

```
<a class="btn">Reboot Instance</a>
<cwdb-action action="call" endpoint="arn:aws:lambda:us-
east-1:123456:function:rebootInstance" display="popup">
       { "instanceId": "i-342389adbfef" }
</cwdb-action>
```

The next example displays more information in a pop-up.

```
<a>Click me for more info in popup</a>
<cwdb-action display="popup">
```

```
   <h1>Big title</h1>
   More info about <b>something important</b>.
</cwdb-action>
```

This example is a **Next** button that replaces the content of a widget with a call to a Lambda function.

```
<a class="btn btn-primary">Next</a>
<cwdb-action action="call" endpoint="arn:aws:lambda:us-
east-1:123456:function:nextPage">
   { "pageNum": 2 }
</cwdb-action>
```

Creating a custom widget for a CloudWatch dashboard

To create a custom widget, you can use one of the samples provided by AWS, or you can create your own. The AWS samples include samples in both JavaScript and Python, and are created by a AWS CloudFormation stack. For a list of samples, see Sample custom widgets for a CloudWatch dashboard.

To create a custom widget in a CloudWatch dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol.
4. Choose **Custom widget**.
5. Use one of the following methods:
   - To use a sample custom widget provided by AWS, do the following:
     a. Select the sample in the dropdown box.

        The CloudFormation console launches in a new browser. In the CloudFormation console, do the following:
     b. (Optional) Customize the CloudFormation stack name.
     c. Make selections for any parameters used by the sample.
     d. Select **I acknowledge that AWS CloudFormation might create IAM resources**, and choose **Create stack**.
   - To create your own custom widget provided by AWS, do the following:

a. Choose **Next**.

b. Choose to either select your Lambda function from a list, or enter its Amazon Resource Name (ARN). If you select it from a list, also specify the Region where the function is and the version to use.

c. For **Parameters**, make selections for any parameters used by the function.

d. Enter a title for the widget.

e. For **Update on**, configure when the widget should be updated (when the Lambda function should be called again). This can be one or more of the following: **Refresh** to update it when the dashboard auto-refreshes, **Resize** to update it whenever the widget is resized, or **Time Range** to update it whenever the dashboard's time range is adjusted, including when graphs are zoomed into.

f. If you are satisfied with the preview, choose **Create widget**.

Sample custom widgets for a CloudWatch dashboard

AWS provides sample custom widgets in both JavaScript and Python. You can create these sample widgets by using the link for each widget in this list. Alternatively, you can create and customize a widget by using the CloudWatch console. The links in this list open an AWS CloudFormation console and use an CloudFormation quick-create link to create the custom widget.

You can also access the custom widget samples on GitHub.

Following this list, complete examples of the Echo widget are shown for each language.

JavaScript

Sample custom widgets in JavaScript

- Echo – A basic echoer that you can use to test how HTML appears in a custom widget, without having to write a new widget.
- Hello world – A very basic starter widget.
- Custom widget debugger – A debugger widget that displays useful information about the Lambda runtime environment.
- Query CloudWatch Logs Insights – Run and edit CloudWatch Logs Insights queries.
- Run Amazon Athena queries – Run and edit Athena queries.
- Call AWS API – Call any read-only AWS API and display the results in JSON format.

- Fast CloudWatch bitmap graph – Render CloudWatch graphs using on the server side, for fast display.
- Text widget from CloudWatch dashboard – Displays the first text widget from the specified CloudWatch dashboard.
- CloudWatch metric data as a table – Displays raw CloudWatch metric data in a table.
- Amazon EC2 table – Displays the top EC2 instances by CPU utilization. This widget also includes a Reboot button, which is disabled by default.
- AWS CodeDeploy deployments – Displays CodeDeploy deployments.
- AWS Cost Explorer report – Displays a report on the cost of each AWS service for a selected time range.
- Display content of external URL – Displays the content of an externally accessible URL.
- Display an Amazon S3 object – Displays an object in an Amazon S3 bucket in your account.
- Simple SVG pie chart – Example of a graphical SVG-based widget.

Python

Sample custom widgets in Python

- Echo – A basic echoer which you can use to test how HTML appears in a custom widget, without having to write a new widget.
- Hello world – A very basic starter widget.
- Custom widget debugger – A debugger widget that displays useful information about the Lambda runtime environment.
- Call AWS API – Call any read-only AWS API and display the results in JSON format.
- Fast CloudWatch bitmap graph – Render CloudWatch graphs using on the server side, for fast display.
- Send dashboard snapshot by email – Take a snapshot of the current dashboard and send it to email recipients.
- Send dashboard snapshot to Amazon S3 – Take a snapshot of the current dashboard and store it in Amazon S3.
- Text widget from CloudWatch dashboard – Displays the first text widget from the specified CloudWatch dashboard.
- Display content of external URL – Displays the content of an externally accessible URL.

- RSS reader – Displays RSS feeds.
- Display an Amazon S3 object – Displays an object in an Amazon S3 bucket in your account.
- Simple SVG pie chart – Example of a graphical SVG-based widget.

Echo widget in JavaScript

The following is the Echo sample widget in JavaScript.

```
const DOCS = `
## Echo
A basic echo script. Anything passed in the \`\`\`echo\`\`\` parameter is returned as
 the content of the custom widget.
### Widget parameters
Param | Description
---|---
**echo** | The content to echo back

### Example parameters
\`\`\` yaml
echo: <h1>Hello world</h1>
\`\`\`
`;

exports.handler = async (event) => {
    if (event.describe) {
        return DOCS;
    }

    let widgetContext = JSON.stringify(event.widgetContext, null, 4);
    widgetContext = widgetContext.replace(/</g, '&lt;');
    widgetContext = widgetContext.replace(/>/g, '&gt;');

    return `${event.echo || ''}<pre>${widgetContext}</pre>`;
};
```

Echo widget in Python

The following is the Echo sample widget in Python.

```
import json

DOCS = """
```

```
## Echo
A basic echo script. Anything passed in the ```echo``` parameter is returned as the
 content of the custom widget.
### Widget parameters
Param | Description
---|---
**echo** | The content to echo back

### Example parameters
``` yaml
echo: <h1>Hello world</h1>
```"""

def lambda_handler(event, context):
    if 'describe' in event:
        return DOCS

    echo = event.get('echo', '')
    widgetContext = event.get('widgetContext')
    widgetContext = json.dumps(widgetContext, indent=4)
    widgetContext = widgetContext.replace('<', '<')
    widgetContext = widgetContext.replace('>', '>')

    return f'{echo}<pre>{widgetContext}</pre>'
```

Echo widget in Java

The following is the Echo sample widget in Java.

```
package example;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;

import com.google.gson.Gson;
import com.google.gson.GsonBuilder;

public class Handler implements RequestHandler<Event, String>{

  static String DOCS = ""
    + "## Echo\n"
    + "A basic echo script. Anything passed in the ```echo``` parameter is returned as
 the content of the custom widget.\n"
    + "### Widget parameters\n"
```

```
    + "Param | Description\n"
    + "---|---\n"
    + "**echo** | The content to echo back\n\n"
    + "### Example parameters\n"
    + "```yaml\n"
    + "echo: <h1>Hello world</h1>\n"
    + "```\n";

  Gson gson = new GsonBuilder().setPrettyPrinting().create();

  @Override
  public String handleRequest(Event event, Context context) {

    if (event.describe) {
      return DOCS;
    }

    return (event.echo != null ? event.echo : "") + "<pre>" +
 gson.toJson(event.widgetContext) + "</pre>";
  }
}

class Event {

    public boolean describe;
    public String echo;
    public Object widgetContext;

    public Event() {}

    public Event(String echo, boolean describe, Object widgetContext) {
        this.describe = describe;
        this.echo = echo;
        this.widgetContext = widgetContext;
    }
}
```

Adding a text widget to a CloudWatch dashboard

To add a text widget to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.

3. Choose the **+** symbol.
4. Choose **Text**.
5. For **Markdown**, add and format your text using Markdown and choose **Create widget**.
6. To make the text widget transparent, choose **Transparent background**.
7. Choose **Save dashboard**.

Editing a text widget on a CloudWatch dashboard

To edit a text widget on a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the upper-right corner of the text block and choose **Widget actions**. Then, choose **Edit**.
4. Update the text as needed and choose **Update widget**.
5. Choose **Save dashboard**.

Removing a text widget from a CloudWatch dashboard

To remove a text widget from a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the upper-right corner of the text block and choose **Widget actions**. Then, choose **Delete**.
4. Choose **Save dashboard**.

Adding an alarm to a CloudWatch dashboard

To add a single alarm, including its graph, to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, select the alarm to add, and then choose **Add to Dashboard**.

3. Select a dashboard, choose a widget type (**Line**, **Stacked area**, or **Number**), and then choose **Add to dashboard**.
4. To see your alarm on the dashboard, choose **Dashboards** in the navigation pane and select the dashboard.
5. (Optional) To temporarily make an alarm graph larger, select the graph.
6. (Optional) To change the widget type, hover over the title of the graph, choose **Widget actions**, and then choose **Widget type**.

Adding an alarm status widget to a CloudWatch dashboard

To add an alarm status widget to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol.
4. Choose **Alarm status**.
5. Select the check boxes next to the alarms that you want to add to the widget, and then choose **Create widget**.
6. Choose **Add to dashboard**.

Removing an alarm widget from a CloudWatch dashboard

To remove an alarm widget from a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the widget, choose **Widget actions**, and then choose **Delete**.
4. Choose **Save dashboard**. If you attempt to navigate away from the dashboard before you save your changes, you're prompted to either save or discard your changes.

Using a data table widget in a CloudWatch dashboard

Table properties

A data table has a default set of properties that don't require any changes to be made to the options or source. These properties include a sticky label column, all summary columns enabled, datapoints rounded, and their units converted.

Each data table widget can have the following properties. The information about each property includes how to configure it in the JSON source of the dashboard. For more information about dashboard JSON, see Dashboard Body Structure and Syntax.

Summary

Summary columns are a new property introduced with the data table widget. These columns are a specific subset of summaries of your current table. For example, the **Sum** summary is a sum of all displayed datapoints in its row. The summary columns are not the same as CloudWatch statistics. Represented in source as:

```
 "table": {
        "summaryColumns": [
            "MIN",
            "MAX",
            "SUM",
            "AVG"
        ]
    },
```

Thresholds

Use this to apply thresholds to your table. When a data point falls within a threshold, its cell is highlighted with the threshold color. Represented in source as:

```
"annotations": {
    "horizontal": [
        {
            "label": string,
            "value": int,
            "fill": "above" | "below"
        }
    ]
}
```

Unit in label column

To display what unit is associated with the metric, you can enable this option to display the unit in the label column beside the label. Represented in source as:

```
"yAxis": {
    "left": {
        "showUnits": true | false
    }
}
```

Invert rows and columns

This transforms the table so that the datapoints swap from columns to rows, and the metrics become columns. Represented in source as:

```
 "table": {
    "layout": "vertical" | "horizontal"
}
```

Sticky summary columns

This makes the summary columns sticky, so that they remain in view while you scroll. The label is already sticky. Represented in source as:

```
"table": {
    "stickySummary": true | false
}
```

Display only summary columns

This prevents the columns of datapoints from being displayed, so that only the label and summary columns are displayed. Represented in source as:

```
 "table": {
    "showTimeSeriesData": false | true
}
```

Live data

Displays the most recent data point, even if it is not yet fully aggregated. Represented in source as:

```
"liveData": true | false
```

Number widget format

Displays as many digits as can fit in the cell, before rounding and converting. Represented in source as:

```
"singleValueFullPrecision": true | false
```

Adding a data table widget to a CloudWatch dashboard

To add a data table widget to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards** and then choose a dashboard.
3. Choose the **+** button, select **Data table**, and choose **Next**.
4. In the **Browse** tab, search or browse for the metrics that you want to display in the table widget. Then select the metrics.
5. (Optional) To change the layout of the table, choose the **Options** tab and select **Invert rows and columns**.

   You can also use the **Options** tab to change what columns appear in the table and display the unit being used in the **Label** column.

   > **Tip**
   >
   > To display more accurate thresholds, choose **Show as many digits as can fit before rounding**.

6. (Optional) To change your data table widget's time range, select one of the predefined time ranges in the upper area of the widget. The time ranges span from 1 hour to 1 week. To set your own time range, choose **Custom**.
7. (Optional) To change your data table widget's time range, select one of the predefined time ranges in the upper area of the widget. The time ranges span from 1 hour to 1 week. To set your own time range, choose **Custom**.

8. (Optional) To have this widget keep using the time range that you select, even if the time range for the rest of the dashboard is later changed, choose **Persist time range**.
9. Choose **Create widget** and then choose **Save dashboard**.

Removing a data table widget from a CloudWatch dashboard

To remove a data table widget to a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the widget that you want to remove, choose **Widget actions**, **Delete**.
4. Choose **Save dashboard**.

Linking graphs on a CloudWatch dashboard

Link graphs on a CloudWatch dashboard so that changes in time are reflected on all graphs.

To link the graphs on a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose **Actions** and then **Link graphs**.

Unlinking graphs on a CloudWatch dashboard

To unlink the graphs on a dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Clear **Actions** and then **Link graphs**.

Sharing CloudWatch dashboards

You can share your CloudWatch dashboards with people who do not have direct access to your AWS account. This enables you to share dashboards across teams, with stakeholders, and with people external to your organization. You can even display dashboards on big screens in team areas, or embed them in Wikis and other webpages.

Warning

All people who you share the dashboard with are granted the permissions listed in Permissions that are granted to people who you share the dashboard with for the account. If you share the dashboard publicly, then everyone who has the link to the dashboard has these permissions.
The `cloudwatch:GetMetricData` and `ec2:DescribeTags` permissions cannot be scoped down to specific metrics or EC2 instances, so the people with access to the dashboard can query all CloudWatch metrics and the names and tags of all EC2 instances in the account.

When you share dashboards, you can designate who can view the dashboard in three ways:

- Share a single dashboard and designate as many as five email addresses of people who can view the dashboard. Each of these users creates their own password that they must enter to view the dashboard.
- Share a single dashboard publicly, so that anyone who has the link can view the dashboard.
- Share all the CloudWatch dashboards in your account and specify a third-party single sign-on (SSO) provider for dashboard access. All users who are members of this SSO provider's list can access all the dashboards in the account. To enable this, you integrate the SSO provider with Amazon Cognito. The SSO provider must support Security Assertion Markup Language (SAML). For more information about Amazon Cognito, see What is Amazon Cognito?

Sharing a dashboard doesn't incur charges, but widgets inside a shared dashboard incur charges at standard CloudWatch rates. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

When you share a dashboard, Amazon Cognito resources are created in the US East (N. Virginia) Region.

Important

Do not modify resource names and identifiers that are created by the dashboard sharing process. This includes Amazon Cognito and IAM resources. Modifying these resources can cause unexpected and incorrect functionality of shared dashboards.

Note

If you share a dashboard that has metric widgets with alarm annotations, the people that you share the dashboard with will not see those widgets. They will instead see a blank widget with text saying that the widget is not available. You will still see metric widgets with alarm annotations when you view the dashboard yourself.

Permissions required to share a dashboard

To be able to share dashboards using any of the following methods and to see which dashboards have already been shared, you must be signed on as a user or with an IAM role that has certain permissions.

To share dashboards, your IAM user or role must have the permissions in the following policy statement:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:CreateRole",
                "iam:CreatePolicy",
                "iam:AttachRolePolicy",
                "iam:PassRole"
            ],
            "Resource": [
                "arn:aws:iam::*:role/service-role/CWDBSharing*",
                "arn:aws:iam::*:policy/*"
            ]
        },
```

```
        {
            "Sid": "RequiredCognitoPermissionsForDashboardSharing",
            "Effect": "Allow",
            "Action": [
                "cognito-idp:*",
                "cognito-identity:*"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:GetDashboard"
            ],
            "Resource": [
                "arn:aws:cloudwatch::account-id:dashboard/dashboard-name"
            ]
        }
    ]
}
```

In the last statement, you can specify * instead of a dashboard ARN to grant access to all dashboards in the account.

> **Note**
>
> The CloudWatch dashboard sharing feature requires the `cognito-idp:*` and `cognito-identity:*` permissions with `Resource` set to `*`. You cannot scope these permissions to specific actions or resources because the dashboard sharing process automatically creates Amazon Cognito resources, and creation actions cannot target resources that do not yet exist.

To be able to see which dashboards are shared, but not be able to share dashboards, a user or an IAM role can include a policy statement similar to the following:

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Sid": "RequiredCognitoPermissionsForDashboardSharing",
            "Effect": "Allow",
            "Action": [
                "cognito-idp:*",
                "cognito-identity:*"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:ListDashboards"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

Note

The CloudWatch dashboard sharing feature requires the `cognito-idp:*` and `cognito-identity:*` permissions with `Resource` set to `*`. You cannot scope these permissions to specific actions or resources because the dashboard sharing process automatically creates Amazon Cognito resources, and creation actions cannot target resources that do not yet exist. The `cloudwatch:ListDashboards` action does not support resource-level permissions, so its `Resource` must also be `*`.

Permissions that are granted to people who you share the dashboard with

When you share a dashboard, CloudWatch creates an IAM role in the account which gives the following permissions to the people who you share the dashboard with:

- `cloudwatch:GetInsightRuleReport`

- `cloudwatch:GetMetricData`
- `cloudwatch:DescribeAlarms`
- `ec2:DescribeTags`

Warning

All people who you share the dashboard with are granted these permissions for the account. If you share the dashboard publicly, then everyone who has the link to the dashboard has these permissions.
The `cloudwatch:GetMetricData` and `ec2:DescribeTags` permissions cannot be scoped down to specific metrics or EC2 instances, so the people with access to the dashboard can query all CloudWatch metrics and the names and tags of all EC2 instances in the account.

When you share a dashboard, by default the permissions that CloudWatch creates restrict access to only the alarms and Contributor Insights rules that are on the dashboard when it is shared. If you add new alarms or Contributor Insights rules to the dashboard and want them to also be seen by the people who you shared the dashboard with, you must update the policy to allow these resources.

Sharing a CloudWatch dashboard with specific users

Use the steps in this section to share a dashboard with as many as five email addresses that you choose.

Note

By default, any CloudWatch Logs widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see logs table widgets.
By default, any composite alarm widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see composite alarms.

To share a dashboard with specific users

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of your dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Next to **Share your dashboard and require a username and password**, choose **Start sharing**.
6. Under **Add email addresses**, enter the email addresses that you want to share the dashboard with. You can include as many as five email addresses.
7. When you have all the email addresses entered, read the agreement and select the confirmation box. Then choose **Preview policy**.
8. Confirm that the resources that will be shared are what you want, and choose **Confirm and generate shareable link**.
9. On the next page, choose **Copy link to clipboard**. You can then paste this link into email and send it to the invited users. They automatically receive a separate email with their user name and a temporary password to use to connect to the dashboard.

Sharing a CloudWatch dashboard publicly

Follow the steps in this section to share a dashboard publicly. This can be useful to display the dashboard on a big screen in a team room, or embed it in a Wiki page.

> **Important**
>
> Sharing a dashboard publicly makes it accessible to anyone who has the link, with no authentication. Do this only for dashboards that do not contain sensitive information.

> **Note**
>
> By default, any CloudWatch Logs widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see logs table widgets.

By default, any composite alarm widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see composite alarms.

To share a dashboard publicly

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of your dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Next to **Share your dashboard publicly**, choose **Start sharing**.
6. Enter **`Confirm`** in the text box.
7. Read the agreement and select the confirmation box. Then choose **Preview policy**.
8. Confirm that the resources that will be shared are what you want, and choose **Confirm and generate shareable link**.
9. On the next page, choose **Copy link to clipboard**. You can then share this link. Anyone you share the link with can access the dashboard, without providing credentials.

Sharing all CloudWatch dashboards in the account by using SSO

Use the steps in this section to share all the dashboards in your account with users by using single sign-on (SSO).

Note

By default, any CloudWatch Logs widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see logs table widgets.
By default, any composite alarm widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see composite alarms.

To share your CloudWatch dashboards with users who are in an SSO provider's list

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of your dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Choose **Go to CloudWatch Settings**.
6. If the SSO provider that you want isn't listed in **Available SSO providers**, choose **Manage SSO providers** and follow the instructions in Setting up SSO for CloudWatch dashboard sharing.

   Then return to the CloudWatch console and refresh the browser. The SSO provider that you enabled should now appear in the list.
7. Choose the SSO provider that you want in the **Available SSO providers** list.
8. Choose **Save changes**.

Setting up SSO for CloudWatch dashboard sharing

To set up dashboard sharing through a third-party single sign-on provider that supports SAML, follow these steps.

> **Important**
>
> We strongly recommend that you do not share dashboards using a non-SAML SSO provider. Doing so causes a risk of inadvertently allowing third parties to access your account's dashboards.

To set up an SSO provider to enable dashboard sharing

1. Integrate the SSO provider with Amazon Cognito. For more information, see Integrating Third-Party SAML Identity Providers with Amazon Cognito User Pools.
2. Download the metadata XML file from your SSO provider.
3. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
4. In the navigation pane, choose **Settings**.
5. In the **Dashboard sharing** section, choose **Configure**.

6. Choose **Manage SSO providers**.

   This opens the Amazon Cognito console in the US East (N. Virginia) Region (us-east-1). If you don't see any **User Pools**, the Amazon Cognito console might have opened in a different Region. If so, change the Region to **US East (N. Virginia) us-east-1** and proceed with the next steps.
7. Choose the **CloudWatchDashboardSharing** pool.
8. In the navigation pane, choose **Social and external providers**.
9. Choose **Add identity provider**.
10. Choose **SAML**.
11. Enter a name for your SSO provider in **Provider name**.
12. Choose **Select file**, and select the metadata XML file that you downloaded in step 2.
13. Choose **Create provider**.

Seeing how many of your CloudWatch dashboards are shared

You can use the CloudWatch console to see how many of your CloudWatch dashboards are currently being shared with others.

To see how many of your dashboards are being shared

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. The **Dashboard sharing** section displays how many dashboards are shared.
4. To see which dashboards are shared, choose ***number*** **dashboards shared** under **Username and password** and under **Public dashboards.**

Seeing which of your CloudWatch dashboards are shared

You can use the CloudWatch console to see which of your dashboards are currently being shared with others.

To see which of your dashboards are being shared

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Dashboards**.
3. In the list of dashboards, see the **Share** column. Dashboards that have the icon in this column filled in are currently being shared.
4. To see which users a dashboard is being shared with, choose the dashboard name, and then choose **Actions**, **Share dashboard**.

   The **Share dashboard** ***`dashboard name`*** page displays how the dashboard is being shared. If you want, you can stop sharing the dashboard by choosing **Stop sharing**.

Stopping sharing one or more CloudWatch dashboards

You can stop sharing a single shared dashboard, or stop sharing all shared dashboards at once.

To stop sharing a single dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the shared dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Choose **Stop sharing**.
6. In the confirmation box, choose **Stop sharing**.

To stop sharing all shared dashboards

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. In the **Dashboard sharing** section, choose **Stop sharing all dashboards**.
4. In the confirmation box, choose **Stop sharing all dashboards**.

Reviewing shared CloudWatch dashboard permissions and changing permission scope

Use the steps in this section if you want to review the permissions of the users of your shared dashboards, or change the scope of shared dashboard permissions.

To review shared dashboard permissions

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the shared dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Under **Resources**, choose **IAM Role**.
6. In the IAM console, choose the displayed policy.
7. (Optional) To limit which alarms that shared dashboard users can see, choose **Edit policy** and move the `cloudwatch:DescribeAlarms` permission from its current position to a new `Allow` statement that lists the ARNs of only the alarms that you want to be seen by shared dashboard users. See the following example.

   ```
   {
      "Effect": "Allow",
       "Action": "cloudwatch:DescribeAlarms",
       "Resource": [
           "AlarmARN1",
           "AlarmARN2"
       ]
   }
   ```

   If you do this, be sure to remove the `cloudwatch:DescribeAlarms` permission from a section of the current policy that looks like this:

   ```
   {
      "Effect": "Allow",
       "Action": [
           "cloudwatch:GetInsightRuleReport",
           "cloudwatch:GetMetricData",
           "cloudwatch:DescribeAlarms",
           "ec2:DescribeTags"
       ],
       "Resource": "*"
   }
   ```

8. (Optional) To limit the scope of what Contributor Insights rules that shared dashboard users can see, choose **Edit policy** and move the `cloudwatch:GetInsightRuleReport` from its

current position to a new `Allow` statement that lists the ARNs of only the Contributor Insights rules that you want to be seen by shared dashboard users. See the following example.

```
{
   "Effect": "Allow",
    "Action": "cloudwatch:GetInsightRuleReport",
    "Resource": [
        "PublicContributorInsightsRuleARN1",
        "PublicContributorInsightsRuleARN2"
    ]
}
```

If you do this, be sure to remove `cloudwatch:GetInsightRuleReport` from a section of the current policy that looks like this:

```
{
            "Effect": "Allow",
            "Action": [
                "cloudwatch:GetInsightRuleReport",
                "cloudwatch:GetMetricData",
                "cloudwatch:DescribeAlarms",
                "ec2:DescribeTags"
            ],
            "Resource": "*"
        }
```

Allowing people that you share with to see composite alarms

When you share a dashboard, by default the composite alarm widgets on the dashboard are not visible to the people who you share the dashboard with. For composite alarm widgets to be visible, you need to add a `DescribeAlarms: *` permission to the dashboard sharing policy. That permission would look like this:

```
{
    "Effect": "Allow",
    "Action": "cloudwatch:DescribeAlarms",
    "Resource": "*"
}
```

Warning

The preceding policy statement gives access to all alarms in the account. To reduce the scope of `cloudwatch:DescribeAlarms`, you must use a `Deny` statement. You can add a `Deny` statement to the policy and specify the ARNs of the alarms that you want to lock down. That deny statement should look similar to the following:

```
{
    "Effect": "Allow",
    "Action": "cloudwatch:DescribeAlarms",
    "Resource": "*"
},
{
    "Effect": "Deny",
    "Action": "cloudwatch:DescribeAlarms",
    "Resource": [
        "SensitiveAlarm1ARN",
        "SensitiveAlarm1ARN"
    ]
}
```

Allow widgets that use PromQL queries to be visible in shared dashboards

When you share a dashboard, widgets that use PromQL (Prometheus Query Language) queries are not visible by default to people with whom you share the dashboard. If you want these people to see PromQL widgets, you must add permissions to the IAM role for dashboard sharing.

To allow people that you share a dashboard with to see PromQL widgets

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the shared dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Under **Resources**, choose **IAM Role**.
6. In the IAM console, choose the displayed policy.
7. Choose **Edit policy** and add the following statement.

```
{
    "Effect": "Allow",
    "Action": "cloudwatch:ListMetrics",
    "Resource": "*"
}
```

8. Choose **Save Changes**.

Allowing people that you share with to see logs table widgets

When you share a dashboard, by default the CloudWatch Logs Insights widgets that are on the dashboard are not visible to the people who you share the dashboard with. This affects both CloudWatch Logs Insights widgets that exist now and any that are added to the dashboard after you share it.

If you want these people to be able to see CloudWatch Logs widgets, you must add permissions to the IAM role for dashboard sharing.

To allow the people that you share a dashboard with to see the CloudWatch Logs widgets

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the shared dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Under **Resources**, choose **IAM Role**.
6. In the IAM console, choose the displayed policy.
7. Choose **Edit policy** and add the following statement. In the new statement, we recommend that you specify the ARNs of only the log groups that you want shared. See the following example.

```
{
            "Effect": "Allow",
            "Action": [
                "logs:FilterLogEvents",
                "logs:StartQuery",
                "logs:StopQuery",
                "logs:GetLogRecord",
                "logs:GetQueryResults",
```

```
                "logs:DescribeLogGroups"
            ],
            "Resource": [
                "SharedLogGroup1ARN",
                "SharedLogGroup2ARN"
            ]
        },
```

8. Choose **Save Changes**.

If your IAM policy for dashboard sharing already includes the preceding permissions with * as the resource, we strongly recommend that you change the policy and specify only the ARNs of the log groups that you want shared. For example, if your `Resource` section for these permissions was the following:

```
"Resource": "*"
```

Change the policy to specify only the ARNs of the log groups that you want shared, as in the following example:

```
"Resource": [
  "SharedLogGroup1ARN",
  "SharedLogGroup2ARN"
]
```

Allowing people that you share with to see custom widgets

When you share a dashboard, by default the custom widgets that are on the dashboard are not visible to the people who you share the dashboard with. This affects both custom widgets that exist now and any that are added to the dashboard after you share it.

If you want these people to be able to see custom widgets, you must add permissions to the IAM role for dashboard sharing.

To allow the people that you share a dashboard with to see the custom widgets

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the shared dashboard.

4. Choose **Actions**, **Share dashboard**.
5. Under **Resources**, choose **IAM Role**.
6. In the IAM console, choose the displayed policy.
7. Choose **Edit policy** and add the following statement. In the new statement, we recommend that you specify the ARNs of only the Lambda functions that you want shared. See the following example.

```
{
  "Sid": "Invoke",
  "Effect": "Allow",
  "Action": [
      "lambda:InvokeFunction"
  ],
  "Resource": [
    "LambdaFunction1ARN",
    "LambdaFunction2ARN"
  ]
 }
```

8. Choose **Save Changes**.

If your IAM policy for dashboard sharing already includes that permission with * as the resource, we strongly recommend that you change the policy and specify only the ARNs of the Lambda functions that you want shared. For example, if your `Resource` section for these permissions was the following:

```
"Resource": "*"
```

Change the policy to specify only the ARNs of the custom widgets that you want shared, as in the following example:

```
"Resource": [
  "LambdaFunction1ARN",
  "LambdaFunction2ARN"
]
```

Using live data in CloudWatch dashboards

You can choose whether your metric widgets display *live data*. Live data is data published within the last minute that has not been fully aggregated.

- If live data is turned **off**, only data points with an aggregation period of at least one minute in the past are shown. For example, when using 5-minute periods, the data point for 12:35 would be aggregated from 12:35 to 12:40, and displayed at 12:41.
- If live data is turned **on**, the most recent data point is shown as soon as any data is published in the corresponding aggregation interval. Each time you refresh the display, the most recent data point may change as new data within that aggregation period is published. If you use a cumulative statistic such as **Sum** or **Sample Count**, using live data may result in a dip at the end of your graph.

You can choose to enable live data for a whole dashboard, or for individual widgets on the dashboard.

Using live data for a CloudWatch dashboard

To choose whether to use live data on your entire dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. To permanently turn live data on or off for all widgets on the dashboard, do the following:
   a. Choose **Actions**, **Settings**, **Bulk update live data.**
   b. Choose **Live Data on** or **Live Data off**, and choose **Set**.
4. To temporarily override the live data settings of each widget, choose **Actions**. Then, under **Overrides**, next to **Live data**, do one of the following:
   - Choose **On** to temporarily turn on live data for all widgets.
   - Choose **Off** to temporarily turn off live data for all widgets.
   - Choose **Do not override** to preserve each widget's live data setting.

Using live data for a CloudWatch dashboard widget

To choose whether to use live data on a single widget

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Select a widget, and choose **Actions**, **Edit**.
4. Choose the **Graph options** tab.
5. Select or clear the check box under **Live Data**.

Viewing an animated CloudWatch dashboard

You can view an animated dashboard that replays CloudWatch metric data that was captured over time. This can help you see trends, make presentations, or analyze issues after they occur.

Animated widgets in the dashboard include line widgets, stacked area widgets, number widgets, and metrics explorer widgets. Pie graphs, bar charts, text widgets, and logs widgets are displayed in the dashboard but are not animated.

To view an animated dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the dashboard.
4. Choose **Actions**, **Replay dashboard**.
5. (Optional) By default, when you start the animation, it appears as a sliding window. If you want the animation to appear as a point-by-point animation instead, choose the magnifying glass icon while the animation is paused and reset the zoom.
6. To start the animation, choose the Play button. You can also choose the back and forward buttons to move to other points in time.
7. (Optional) To change the time window for the animation, choose the calendar and select the time period.
8. To change the speed of the animation, choose **Auto speed** and select the new speed.
9. When you are finished, choose **Exit animate**.

Adding a CloudWatch dashboard to your favorites list

In the CloudWatch console, you can add dashboards, alarms, and log groups to a favorites list. You can access the favorites list from the navigation pane. The following procedure describes how to add a dashboard to the favorites list.

To add a dashboard to the favorites list

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. From the list of dashboards, select the star symbol next to the name of the dashboard that you want to favorite.
   - (Optional) You also can favorite a dashboard by selecting a dashboard from the list and choosing the star symbol next to the dashboard name.
4. To access the favorites list, choose **Favorites and recents** in the navigation pane. The menu contains two columns. One contains your favorite dashboards, alarms, and log groups, and the other column contains the dashboards, alarms, and log groups that you recently visited.

> **Tip**
>
> You can favorite dashboards, as well as alarms and log groups, from the ***Favorites and recents*** menu in the CloudWatch console navigation pane. Under the ***Recently visited*** column, hover over the dashboard that you want to favorite, and choose the star symbol next to it.

Changing the period override setting or refresh interval for the CloudWatch dashboard

You can specify how the period setting of graphs added to this dashboard are retained or modified.

When an auto period or persisted time range is applied to a widget, the overall time range of the graph can affect the periods that you have set.

- If the time range is one day or less, period settings are not changed.

- If the time range is between one day and three days, periods set to below five minutes are changed to 5 minutes.
- If the time range is more than three days, periods set to below one hour are changed to one hour.

The following steps explain how to use the console to change the period override options. You can also change them by using the `period0verride` field in the JSON structure of the dashboard. For more information, see Dashboard Body Overall Structure.

To change the period override options

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Actions**.
3. Under **Period override**, choose one of the following:
   - Choose **Auto** to have the period of the metrics on each graph automatically adapt to the dashboard's time range.
   - Choose **Do not override** to make sure that the period setting of each graph is always obeyed.
   - Choose one of the other options to cause graphs added to the dashboard to always adapt that chosen time as their period setting.

   The **Period override** always reverts to **Auto** when the dashboard is closed or the browser is refreshed. Different settings for **Period override** can't be saved.

You can change how often the data on your CloudWatch dashboard is refreshed.

To change the dashboard refresh interval

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. On the **Refresh options** menu (upper-right corner), choose **10 Seconds**, **1 Minute**, **2 Minutes**, **5 Minutes**, or **15 Minutes**.

Changing the time range or time zone format of a CloudWatch dashboard

You can change the time range to display dashboard data over minutes, hours, days, or weeks. You also can change the time zone format to display dashboard data in UTC or local time. Local time is the time zone that's specified in your computer's operating system.

Note

If you create a dashboard with graphs that contain 100 or more high-resolution metrics, we recommend that you don't set the time range to longer than 1 hour. For more information, see High-resolution metrics.

Note

If the time range of a dashboard is shorter than the period used for a widget on the dashboard, the following happens:

- The widget is modified to display the amount of data corresponding one complete period for that widget, even though this is longer than the dashboard time range. This ensures that there is at least one data point on the graph.
- The start time of the period for this data point is adjusted backwards to make sure that at least one data point can be displayed.

New console

To change the dashboard time range

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. From the dashboard screen, do one of the following:
   - In the upper area of the dashboard, select one of the predefined time ranges. These span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, or **1w**).
   - Alternatively, you can choose one of the following custom time range options:

- Choose **Custom**, and then choose the **Relative** tab. Choose a time range from 1 minute to 15 months.
- Choose **Custom**, and then choose the **Absolute** tab. Use the calendar or text fields to specify your time range.

> **Tip**
>
> If the aggregation period is set to **Auto** when you change the time range of a graph, CloudWatch might change the period. To set the period manually, choose the **Actions** dropdown, and then choose **Period override**.

To change the dashboard time zone format

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the dashboard, choose the time zone dropdown, which shows the current setting, such as **UTC** or **Local time**.
4. Select **UTC** or **Local time** from the dropdown.
5. Choose **Apply**, if prompted.

Old console

To change the dashboard time range

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. From the dashboard screen, do one of the following:
   - In the upper area of the dashboard, select one of the predefined time ranges. These span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**).
   - Alternatively, you can choose one of the following custom time range options:
     - Choose the **custom** dropdown, and then choose the **Relative** tab. Select one of the predefined ranges, which span from 1 minute to 15 months.

- Choose the **custom** dropdown, and then choose the **Absolute** tab. Use the calendar or text fields to specify your time range.

> **Tip**
>
> If the aggregation period is set to **Auto** when you change the time range of a graph, CloudWatch might change the period. To set the period manually, choose the **Actions** dropdown, and then choose **Period override**.

To change the dashboard time zone format

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the dashboard screen, choose the **Custom** dropdown.
4. In the upper-right corner of the box that appears, select **UTC** or **Local timezone** from the dropdown.

Dashboard Body Structure and Syntax

Contents

- Overall Structure
- Widgets Array Structure
- Variables Array Structure
- Properties of a Log Widget Object
- Properties of a Metric Widget Object
- Metric Widget: Format for Each Metric in the Array
- Properties of a Metrics Explorer Widget Object
- Properties of an Alarm Status Widget Object
- Properties of a Chart Widget Object

Overall Structure

A `DashboardBody` is a string in JSON format. It can include an array of between 0 and 500 widget objects, as well as a few other parameters. The dashboard must include a `widgets` array, but that array can be empty.

The following is an example of this structure with one metric widget and one text widget, a time range starting six hours before the current time, and each graph's period setting always being obeyed.

```
{
   "start": "-PT6H",
   "periodOverride": "inherit",
   "widgets": [
      {
         "type":"metric",
         "x":0,
         "y":0,
         "width":12,
         "height":6,
         "properties":{
            "metrics":[
               [
                  "AWS/EC2",
                  "CPUUtilization",
                  "InstanceId",
                  "i-012345"
               ]
            ],
            "period":300,
            "stat":"Average",
            "region":"us-east-1",
            "title":"EC2 Instance CPU",
            "liveData": false,
            "legend": {
                "position": "right"
              }
         }
      },
      {
         "type":"text",
         "x":0,
         "y":7,
```

```
         "width":3,
         "height":3,
         "properties":{
            "markdown":"Hello world"
         }
      }
   ]
}
```

The next example displays three Lambda per-function metrics, and uses a dashboard variable so that dashboard users can switch between different Lambda function names and see all three metrics for each function. This helps you create a single flexible dashboard that can display key metrics for different resources. In this example the functions are discovered by a metric search query, so the dashboard automatically discovers new Lambda functions when they are created.

```
{
    "widgets": [{
            "height": 6,
            "width": 6,
            "y": 0,
            "x": 0,
            "type": "metric",
            "properties": {
                "view": "timeSeries",
                "stacked": false,
                "metrics": [
                    [ "AWS/Lambda", "Invocations", "FunctionName", "my-function-name" ]
                ],

                "region": "us-east-1",
                "liveData": true
            }
        },
        {
            "height": 12,
            "width": 12,
            "y": 0,
            "x": 6,
            "type": "metric",
            "properties": {
                "view": "timeSeries",
                "stacked": false,
                "metrics": [
```

```
                    [ "AWS/Lambda", "Errors", "FunctionName", "my-function-name" ]
                ],

                "region": "us-east-1",
                "liveData": true
            }
        },

        {
            "height": 3,
            "width": 6,
            "y": 0,
            "x": 18,
            "type": "metric",
            "properties": {
                "view": "timeSeries",
                "stacked": false,
                "metrics": [
                    [ "AWS/Lambda", "Duration", "FunctionName", "my-function-name" ]
                ],

                "region": "us-east-1",
                "liveData": true
            }
        }
    ],
    "variables": [{
        "type": "property",
        "property": "FunctionName",
        "inputType": "select",
        "id": "LambdaFunction_Variable",
        "label": "Function",
        "visible": true,
        "search": "{AWS/Lambda,FunctionName} MetricName=\"Duration\"",
        "populateFrom": "FunctionName"
    }]
}
```

The next example has two widgets. The first includes two metrics and a math expression that sums their total. The second widget is a search expression that displays the `CPUUtilization` for all EC2 instances in the Region.

```
{
   "start": "-PT9H",
   "periodOverride": "inherit",
   "widgets": [
      {
         "type":"metric",
         "x":0,
         "y":0,
         "width":12,
         "height":6,
         "properties":{
            "metrics":[
               [ "AWS/EC2", "DiskReadBytes", "InstanceId", "i-123",{ "id": "m1" } ],
               [ ".", ".", ".", "i-abc", { "id": "m2" } ],
               [ { "expression": "SUM(METRICS())", "label": "Sum of DiskReadbytes",
 "id": "e3" } ]
            ],
            "view": "timeSeries",
            "stacked": false,
            "period":300,
            "stat":"Average",
            "region":"us-east-1",
            "title":"EC2 Instance CPU"
         }
      },
      {
         "type":"metric",
         "x":0,
         "y":0,
         "width":18,
         "height":9,
         "properties":{
            "metrics":[
               [ { "expression": "SEARCH('{AWS/EC2,InstanceId} MetricName=
\"CPUUtilization\"', 'Average', 300)", "id": "e1" } ]
            ],
            "view": "timeSeries",
            "stacked": false,
            "region":"us-east-1",
            "title":"EC2 Instance CPU"
         }
      }
   ]
}
```

The rest of this section includes examples illustrating each part of the `DashboardBody` syntax. For more examples showing the entire command syntax, see PutDashboard in the Amazon CloudWatch API Reference.

The top level of the JSON object can include the following properties.

widgets

The list of widgets in the dashboard. For more information, see Widgets Array Structure.

Required: Yes

variables

The array of dashboard variable objects used in the dashboard. For more information about the fields that you can use in each dashboard variable object, see Variables Array Structure.

For more information about dashboard variables, see Create flexible dashboards with dashboard variables.

If you include a `variables` array, it can contain between 0 and 25 variable objects.

Required: No

end

The end of the time range to use for each widget on the dashboard when the dashboard loads. If you specify a value for `end`, you must also specify a value for `start`. For each of these values, specify an absolute time in the ISO 8601 format. For example, `2018-12-17T06:00:00.000Z`.

Type: String

Required: No

start

The start of the time range to use for each widget on the dashboard.

You can specify `start` without specifying `end` to specify a relative time range that ends with the current time. In this case, the value of `start` must begin with `-PT` if you specify a time range in minutes or hours, and must begin with `-P` if you specify a time range in days, weeks, or months. You can then use M, H, D, W and M as abbreviations for minutes, hours, days, weeks

and months. For example, `-PT5M` shows the last 5 minutes, `-PT8H` shows the last 8 hours, and `-P3M` shows the last three months.

You can also use `start` along with an `end` field, to specify an absolute time range. When specifying an absolute time range, use the ISO 8601 format. For example, `2018-12-17T06:00:00.000Z`.

If you omit `start`, the dashboard shows the default time range when it loads.

Type: String

Required: No

periodOverride

Use this field to specify the period for the graphs when the dashboard loads. Specifying `auto` causes the period of all graphs on the dashboard to automatically adapt to the time range of the dashboard. Specifying `inherit` ensures that the period set for each graph is always obeyed.

Valid Values: auto | inherit

Type: String

Required: No

Widgets Array Structure

Each widget of any type can have the following properties.

type

The type of widget.

Valid Values: `metric` | `text` | `log` | `alarm` | `explorer` | `chart`

Type: String

Required: Yes

x

The horizontal position of the widget on the 24-column dashboard grid. The default is the next available position.

Valid Values: 0–23

Type: Integer

Required: Yes, if `y` is specified. Otherwise not required.

y

The vertical position of the widget on the 24-column dashboard grid. The default is the next available position.

Valid Values: Any integer, 0 or higher.

Type: Integer

Required: Yes, if `x` is specified. Otherwise not required.

width

The width of the widget in grid units (in a 24-column grid). The default is 6.

Valid Values: 1–24

Type: Integer

Required: No

height

The height of the widget in grid units. The default is 6.

Valid Values: 1–1000

Type: Integer

Required: No

properties

The detailed properties of the widget, which differ depending on the widget type. For more information about the format of `properties`, see Properties of a Metric Widget Object, Properties of a Chart Widget Object, or Properties of a Text Widget Object.

Type: Object

Required: Yes

Variables Array Structure

Each dashboard variable in the array can have the following properties.

type

The type of dashboard variable. CloudWatch supports two types, *property variables* and *pattern variables*.

Property variables change the values of all instances of a property in all widgets in the dashboard. A property can be either of the following:

- Any JSON property in the widget definitions, such as `region`.
- Any dimension name for a metric, such as `InstanceId` or `FunctionName`.

A pattern variable changes a regular expression pattern across the dashboard JSON. Use it when you need to change just part of a JSON property value, or even a JSON property.

Property variables apply to most use cases and are less complex to set up.

Valid Values: `property` | `pattern`

Type: String

Required: Yes

inputType

Determines how the dashboard user inputs the value for the variable.

- Specify `input` to use a text box that the user can enter values into.
- Specify `select` to use a dropdown set of values that you define, or a dropdown list of values found by a metric search query.
- Specify `radio` to use a set of radio buttons, with values that you define or that you find with a metric search query.

Valid Values: `input` | `select` | `radio`

Type: String

Required: Yes

values

If your `inputType` is `select` or `radio` and you want to define the possible variable values instead of using a metric query search, specify those values here.

`values` is an array where each object in the array contains a required *value* and an optional *label*. Each *value* can be a string, number, or Boolean, and each label must be a string. Each of these values and labels can be as many as 255 characters.

If you specify a `values` array it must include at least one item, and can include as many as 500.

For example, the following creates a list of three possible Regions to use as the values for a variable.

```
"values": [
    { "label": "US East (IAD)", "value": "us-east-1" },
    { "label": "US West (SFO)", "value": "us-west-1" },
    { "label": "EU (DUB)", "value": "eu-west-1" }
]
```

Type: Array

Required: Yes if `inputType` is `select` or `radio` and you are not using a metric search query to populate the values.

id

An Id for this variable. It can be up to 32 characters, and valid characters are `0-9A-Za-z-_`

Type: String

Required: Yes

label

A label to display for the input field. It can have as many as 30 characters.

If you omit this field for a property variable, the property name is displayed as the label. If you omit it for a pattern variable, then *`pattern_1`*, *`pattern_2`*, `...` is used for the label.

Type: String

Required: No

defaultValue

The default value for the variable, when the dashboard is first opened.

- If `inputType` is `input`, you specify the `defaultValue` here manually and use as many as 255 characters
- If `inputType` is `select` or `radio`, you must specify a valid possible value that you specified in the `values` array or that was retrieved in the metric query search.

Valid Values: Any valid value for this variable

Type: String, Number, or Boolean, depending on the type value for this variable

Required: No

search

Specify this field to populate your `select` or `radio` input field by using a metric search expression. For the value for this field, specify a namespace, dimension name, and a metric name. The dimension that you specify must be valid for that metric. CloudWatch finds all resources that publish that metric and dimension, and populates the list with them.

For example, specify `"search": "{AWS/EC2,InstanceId} MetricName=\"CPUUtilization\""` to search for Amazon EC2 instances in the account, or specify `"search": "{AWS/Lambda,FunctionName} MetricName=\"Duration\""`, to return the Lambda functions in the account

The `search` string that you specify can be as many as 2048 characters.

> **Note**
>
> If you're using a search expression and you also want to specify a default value, the default that you specify in `defaultValue` is used as long as that default is one of the resources that was retrieved by the search. When using a search expression to populate your input field, you can also specify the special value `__FIRST` for `defaultValue`, to have the default value be the first value returned from the search. (The special value includes two underscores and then FIRST) Values returned by the search are always sorted alphabetically.

Type: String

Required: Yes if `inputType` is `select` or `radio` and you are not specifying `values`.

populateFrom

If you are using the `search` field to populate your input field by using a search expression, specify this field with the name of a dimension that the search will retrieve.

For example, if your `search` value is `"search": "{AWS/EC2,InstanceId} MetricName=\"CPUUtilization\""`, then you can specify `InstanceId` for `populateFrom`.

Type: String

Required: Yes if `inputType` is `select` or `radio` and you are not specifying `values`.

visible

Specified whether the input label and field are visible on the dashboard. If you omit this, the default of `true` is used.

Using `false` saves some room on the dashboard, but requires the user to change the dashboard URL to change the variable values.

Type: Boolean

Required: No

Variable examples

The following example uses a property variable for changing the Region of all widgets, using a text input field. When the dashboard is first opened, the default value of `us-east-1` is used for the variable.

```
"variables": [
     {
        "type": "property",
        "property": "region",
        "inputType": "input",
        "id": "region",
        "label": "Region",
        "defaultValue": "us-east-1",
        "visible": true
    }
],
```

The following example uses a pattern variable for changing the Region of all widgets, in the case where sometimes the Region is set in the middle of a string such as an ARN.

```
"variables": [
    {
        "type": "pattern",
        "pattern": "us-east-1",
        "inputType": "input",
        "id": "region",
        "label": "Region",
        "defaultValue": "us-east-1",
        "visible": true
    }
],
```

The following example generates a Lambda function variable, with a radio button for each function. Functions are discovered by a metric query search.

```
"variables": [
    {
        "type": "pattern",
        "pattern": "originalFuncNameInDashboard",
        "inputType": "radio",
        "id": "functionName",
        "label": "Function",
        "visible": true,
        "search": "{AWS/Lambda,FunctionName} MetricName=\"Duration\"",
        "populateFrom": "FunctionName",
        "defaultValue": "__FIRST"
    }
],
```

The following sample displays how to specify multiple variables in a dashboard, and demonstrates several types of variables.

```
"variables": [{
        "type": "property",
        "property": "region",
        "inputType": "select",
        "id": "unique_id_1",
        "label": "Region",
        "defaultValue": "us-east-1",
```

```
        "visible": true,
        "values": [{
                "label": "IAD",
                "value": "us-east-1"
            },
            {
                "label": "CMH",
                "value": "us-east-2"
            },
            {
                "label": "NRT",
                "value": "ap-northeast-1"
            }
        ]
    },
    {
        "type": "property",
        "property": "FunctionName",
        "inputType": "select",
        "id": "unique_id_2",
        "label": "Function",
        "visible": true,
        "values": [{
                "value": "my-FunctionName-1"
            },
            {
                "value": "my-FunctionName-2"
            },
            {
                "value": "my-FunctionName-3"
            }
        ]
    },
    {
        "type": "property",
        "property": "accountId",
        "inputType": "radio",
        "id": "unique_id_3",
        "defaultValue": "111122223333",
        "visible": true,
        "values": [{
                "label": "IAD Account",
                "value": "111122223333"
            },
```

```
            {
                "label": "CMH Account",
                "value": "123456789012"
            },
            {
                "label": "NRT Account",
                "value": "000000000000"
            }
        ]
    }
]
```

Properties of a Text Widget Object

A widget of type `text` can have one or two parameters in the `properties` section. The `markdown` field is required, and the `background` field is optional.

For more information about the style of markdown supported in CloudWatch text widgets, see Using Markdown in the Console.

markdown

The text to be displayed by the widget. Use this parameter only for text widgets.

Type: String

Required: Yes (when the widget `type` is `text`).

background

Specifies whether the text widget has a solid or transparent background. The value `transparent` makes the widget transparent. The value `solid` is the default.

Type: String

Required: No

```
{
   "widgets":[
      {
         "type":"text",
         "x":0,
         "y":7,
```

```
         "width":3,
         "height":3,
         "properties":{
            "markdown":"Hello world",
            "background": "transparent"
         }
      }
   ]
}
```

Properties of a Log Widget Object

A widget of type `log` represents the results of a CloudWatch Logs Insights query. For more information, see Analyzing Log Data with CloudWatch Logs Insights.

A `log` widget can include the following fields in its `properties` field.

accountId

The account ID of the AWS account containing the logs, if this is a cross-account query.

Type: String

Required: No

region

The Region of the logs query.

Type: String

Required: Yes

title

The title text to be displayed by the widget.

Type: String

Required: No

query

Contains the CloudWatch Logs Insights query function.

Type: String

Required: Yes (when the widget `type` is `log`).

The `query` string starts with the names of the log groups that are to be queried. You must prepend each log group name with `SOURCE`. Separate multiple log groups with a pipe character (|).

Add another pipe character after the list of log groups, and then specify the query syntax. Separate each line in the query syntax with `\n|`

For example, the following line represents a query of two log groups, `service_log1` and `service_log2`. The query displays canaries that have faults.

```
"query": "SOURCE 'service_log1' | SOURCE 'service_log2' |filter Fault > 0\n| fields
 Fault.Message\n| stats count(*) by Canary.Name, Fault.Message"
```

view

Specifies how the query results are displayed. Specify `table` to view the results as a table. Specify `timeSeries` to display this metric as a line graph. Specify `bar` to display it as a bar graph. Specify `pie` to display it as a pie graph.

If you omit this parameter, the results are displayed as a table.

Type: String

Required: No (when the widget `type` is `log`).

```
{
    "widgets": [
        {
            "type": "log",
            "x": 12,
            "y": 24,
            "width": 12,
            "height": 6,
            "properties": {
                "region": "us-east-1",
                "title": "Errors (Application Log)",
                "query": "SOURCE 'application1.log' | SOURCE 'application2.log' |
 filter @message like \"[ERROR]\"\n| parse \"Error for [*] [*] due to: *\" canaryName1,
 canaryId1, cause1\n| parse \"Executor canary [*] *\" canaryName2, cause2\n| fields
 coalesce(cause1, cause2) as cause\n| fields coalesce(canaryName1, canaryName2)
```

```
 as canaryName\n| fields ispresent(cause) as isP\n| filter isP\n| stats count() as
 errCount by canaryName, substr(cause, 0, 130)\n| sort errCount DESC",
                "view": "table"
            }
        }
    ]
}
```

Properties of a Metric Widget Object

A widget of type `metric` can have the following fields within `properties`:

accountId

Specifies the AWS account ID where all metrics in this widget will come from. This is useful for cross-account dashboards that include widgets from multiple accounts. For more information, see Cross-Account Cross-Region CloudWatch Console.

If you omit this, the current account is used as the default. Use this parameter only for metric widgets.

You can also use an `accountId` field within each metric in the array of `metrics` to create a single widget which includes metrics from multiple accounts.

Type: String

Required: No

annotations

To include an alarm or annotation in the widget, specify an `annotations` array. For more information about the format, see Dashboard Widget Object: Annotation Properties. Use this parameter only for metric widgets.

Type: Object

Required: An alarm annotation is required only when the widget `type` is `metric` and `metrics` is not specified. A horizontal or vertical annotation is not required.

liveData

Specify `true` to display *live data* in the widget. Live data is data published within the last minute that has not been fully aggregated. For more information, see Use Live Data.

Type: Boolean

Required: No

legend

Specify `legend` to determine where the legend for the lines on the graph is displayed. The `legend` field contains another field called `position`. Possible values for `position` are `right`, `bottom`, and `hidden`.

For example, the following causes the legend to appear on the right in the graph.

```
"legend": {
     "position": "right"
}
```

Type: Object

Required: No

metrics

Specify a `metrics` array to include one or more metrics (without alarms), a Metrics Insights query, math expressions, or search expressions. One `metrics` array can include 0–500 metrics and expressions. Use this parameter only for metric widgets. For more information about the format of `metrics`, see Metric Widget: Format for Each Metric in the Array.

One metrics array can include no more than one Metrics Insights query.

A single `expression` field can't include both a Metrics Insights query and a math expression. However, you can use the returned results of a Metrics Insights query from one expression as input in a math expression in a different expression in the array.

Type: Array of arrays

Required: Yes, when the widget `type` is `metric` and `annotations` is not specified.

period

The default period, in seconds, for all metrics in this widget. The period is the length of time represented by one data point on the graph. This default can be overridden within each metric definition. Use this parameter only for metric widgets. The default is 300.

Valid Values: Any multiple of 60, with 60 as the minimum.

Type: Integer

Required: No

region

The region of the metric.

Type: String

Required: Yes

sparkline

Specify `true` to display the sparkline feature under the number widget. Specify `false` to display the number widget by itself. This parameter is ignored if view is not `singleValue`. Use this parameter only for metric widgets.

Type: Boolean

Required: No

stacked

Specify `true` to display the graph as a stacked line, or `false` to display as separate lines. This parameter is ignored if `view` is `singleValue`. Use this parameter only for metric widgets.

Type: Boolean

Required: No

stat

The default statistic to be displayed for each metric in the array. This default can be overridden within the definition of each individual metric in the `metrics` array. Use this parameter only for metric widgets.

Valid Values: `SampleCount` | `Average` | Sum | `Minimum` | `Maximum` | p*??*

Type: String that is a valid CloudWatch statistic.

Required: No

table

Include a `table` section to include data table-related changes in the widget. For more information about the format, see Dashboard Widget Object: Table Properties.

Type: Object

Required: No

timezone

The time zone to use for displaying the times in the graph. The format is + or - followed by four digits. The first two digits indicate the number of hours ahead or behind of UTC, and the final two digits are the number of minutes. For example, `+0130` indicates a time 1 hour and 30 minutes ahead of UTC. The default is `+0000`.

Type: String

Required: No

title

The title to be displayed for the graph or number. Use this parameter only for metric widgets.

Type: String

Required: No

view

Specify `timeSeries` to display this metric as a line or stacked area graph. Specify `singleValue` to display this metric as a number graph. Specify `gauge` to display this metric as a gauge graph. Specify `bar` to display this metric as a bar graph. Specify `pie` to display this metric as a pie graph.

> **Note**
>
> If you specify `gauge`, you must set a value for `min` and `max` on the left side of `yAxis`.

Valid Values: `timeSeries` | `singleValue` | `gauge` | `bar` | `pie` | `table`

Type: String

Required: No

yAxis

The minimum and maximum values for the left and right side of a graph's Y-axis. This property applies to all graphed metrics, except for specific metrics that override this setting. For more information, see Dashboard Widget Object: yAxis Properties Format.

Type: yAxis object

Required: No

Example: Stacked area and gauge widgets

```
{
    "widgets": [
{
   "type":"metric",
   "x":0,
   "y":0,
   "width":12,
   "height":6,
   "properties":{
      "metrics":[
         [
            "AWS/EC2",
            "CPUUtilization",
            "InstanceId",
            "i-012345"
         ],
         [
            "AWS/EC2",
            "NetworkIn",
            "InstanceId",
            "i-012345",
            {
               "yAxis":"right",
               "label":"NetworkIn",
               "period":3600,
               "stat":"Maximum"
            }
         ]
      ],
      "period":300,
      "stat":"Average",
```

```
      "region":"us-east-1",
      "timezone":"+0300",
      "title":"EC2 Instance CPU",
      "stacked":true,
      "view":"timeSeries",
      "liveData":false,
      "yAxis":{
         "left":{
            "min":0,
            "max":100
         },
         "right":{
            "min":50
         }
      },
      "annotations":{
         "horizontal":[
            {
               "visible":true,
               "color":"#9467bd",
               "label":"Critical range",
               "value":20,
               "fill":"above",
               "yAxis":"right"
            }
         ]
      }
   }
},

         "path",
         "/dev/shm",
         "InstanceId",
         "i-012345",
```

```
         "AutoScalingGroupName",
         "ShrinkRayExecutorResourceStack-Gamma-us-east-1-
ASGuseast1ac48xlargeASGB9B53974-VTYXJUZGUAHV",
         "InstanceType",
         "c4.8xlarge",
         "device",
         "tmpfs",
         "fstype",
         "tmpfs"
         ]
         ],
      "view": "gauge",
      "title": "Disk Inodes Used",
      "region": "us-east-1",
      "yAxis": {
         "left": {
            "min": 0,
            "max": 100
         }
       }
     }
   }
   ]
}
```

Metric Widget: Format for Each Metric in the Array

Each item in the `metrics` array is either a single metric or a math expression or search expression. Each single metric in the `metrics` array has the following format:

```
[ Namespace, MetricName, [{DimensionName,DimensionValue}...] {Rendering Properties
 Object} ]
```

Each expression in the `metrics` array has the following format:

```
[ {"expression" : "expression", ["label" : "label"] , ["id" : "id"] } ]
```

accountId

Specifies the AWS account ID where this metric comes from. This enables you to create a widget that contains metrics from multiple accounts on a cross-account dashboard. For more information, see Cross-Account Cross-Region CloudWatch Console.

If you omit this, the current account is used as the default. Use this parameter only for metric widgets.

Type: String

Required: No

Namespace

The AWS namespace containing the metric. If you have multiple entries in the `metrics` array, for each one after the first you may specify only `"."` to use the same namespace as the previous metric in the array.

Type: String

Required: Yes

MetricName

The name of the CloudWatch metric. If you have multiple entries in the `metrics` array, for each one after the first you may specify only `"."` to use the same metric name as the previous metric in the array.

Type: String

Required: Yes, for a single metric

expression

The Metrics Insights query, math expression, or search expression, if this is an expression instead of a single metric.

In a search expression using double-quotes for an exact match, each double-quote mark must be escaped with a backslash.

For more information about Metrics Insights query syntax, see Metrics Insights query components and syntax.

For more information about math expressions or search expressions, see Using Metric Math or Using Search Expressions in Graphs in the Amazon CloudWatch User Guide.

Type: String

Required: Yes, for an expression

Example of an expression for a Metrics Insights query:

```
[ { "expression": "SELECT MAX(CPUUtilization) FROM SCHEMA(\"AWS/EC2\", InstanceId)
 GROUP BY InstanceId LIMIT 10", "label": "View the 10 max CPU Utilization", "id":
 "q1" } ]
```

DimensionName

The name of a dimension to further refine what data is shown. If you have multiple entries in the `metrics` array, for each one after the first you may specify only `"."` to use the same dimension name as in the corresponding dimension specified in the previous metric in the array. You may specify 0 dimensions for a metric, or up to as many dimensions as the metric support.

Type: String

Required: No

DimensionValue

The value to use for that dimension for the metric. Required if there is a corresponding dimension name.

Type: String

Required: No

id

The Id of this time series. This Id can be used as part of a math expression. The Id must start with a lowercase letter.

Type: String

Required: No

label

The label to display in the graph to represent this time series.

Type: String

Required: No

region

The region of the metric. Use this parameter only for metric widgets. If you omit this, the current Region is used as the default.

Type: String

Required: No

Rendering Properties Object

Specifies rendering properties to be used for this particular metric, overriding the values specified for the overall widget. For more information about the format, see Dashboard Widget Object: Rendering Properties Object Format.

Type: Metric Render Properties Object

Required: No

```
// The simplest example, a metric with no dimensions
        [ "AWS/EC2", "CPUUtilization" ]

 // A metric with a single dimension
        [ "AWS/EC2", "CPUUtilization", "InstanceId", "i-012345" ]

 // A metric with a single dimension and rendering properties
        [ "AWS/EC2", "DiskReadBytes", "InstanceId", "i-xyz", { "yAxis": "right"} ]

 // The following example graphs the DiskReadBytes metric for three instances.
        [ "AWS/EC2", "DiskReadBytes", "InstanceId", "i-xyz" ],
        [ ".", ".", ".", "i-abc" ],
        [ ".", ".", ".", "i-123" ]

 // The following example includes two metrics and a math expression to sum them.
        [ "AWS/EC2", "DiskReadBytes", "InstanceId", "i-123",{ "id": "m1" } ],
        [ ".", ".", ".", "i-abc", { "id": "m2" } ],
        [ { "expression": "SUM(METRICS())", "label": "Sum of DiskReadbytes", "id":
"e3" } ]

  // The following example is a search expression showing the EC2 CPUUtilization for
each instance in the Region.
        [ { "expression": "SEARCH('{AWS/EC2,InstanceId} MetricName=\"CPUUtilization\"',
'Average', 300)", "id": "e1" } ],
```

Dashboard Widget Object: Rendering Properties Object Format

Each metric in the `metrics` array can optionally have custom rendering properties that override the default rendering properties specified in the `yAxis` parameter of the `widget` object. This section describes the format for those per-metric custom rendering properties.

color

The six-digit HTML hex color code to be used for this metric.

Type: String

Required: No

label

The label to display for this metric in the graph legend. If this is not specified, the metric is given an autogenerated label that distinguishes it from the other metrics in the widget.

Type: String

Required: No

period

The period for this metric, in seconds. The period is the length of time represented by one data point on the graph.

Valid Values: A multiple of 60, with a minimum of 60.

Type: Integer

Required: No

stat

The statistic for this metric, if it is to be different than the statistic used for the other metrics in the array. By default CloudWatch uses *Average* if you don't specify a statistic at array or at metric level.

Valid Values: `SampleCount` | `Average` | `Sum` | `Minimum` | `Maximum` | p*??*

Type: String that is a valid CloudWatch statistic.

Required: No

visible

Set this to `true` to have the metric appear in the graph, or `false` to have it be hidden. The default is `true`.

Type: Boolean

Required: No

yAxis

Where on the graph to display the y-axis for this metric. The default is `left`.

Valid Values: `left` | `right`

Type: String

Required: No

```
// The third metric has its own rendering properties, overriding those of the rest of
the widget.
       [ "AWS/EC2", "DiskReadBytes", "InstanceId", "i-xyz" ],
       [ ".", ".", ".", "i-abc" ],
       [ ".", ".", ".", "i-123", { "label":"Instance i-123", "yAxis": "right"}  ]
```

Dashboard Widget Object: Annotation Properties

Annotations include alarms, horizontal annotations, and vertical annotations. A single metric widget can have up to one alarm, or it can have one or more horizontal or vertical annotations. A single widget can't have both an alarm and horizontal or vertical annotations.

Alarm Annotations

If you specify an alarm annotation, you cannot also specify a `metrics` array in the same widget.

alarms

The Amazon Resource Name (ARN) of the alarm.

Type: Array of strings. There can be 0–1 strings in the array.

Required: Only if no metrics are listed.

```
"annotations": {
   "alarms": [ "arn1" ]
}
```

Horizontal Annotations

horizontal

An array of horizontal annotations. Horizontal annotations have several options for fill shading, including shading above the annotation line, shading below the annotation line, and "band" shading that appears between two linked annotation lines as part of a single band annotation. Each horizontal annotation in the array that is a single annotation, instead of a band annotation, has the following format:

```
{value, label, color, fill, yAxis, visible}
```

Each horizontal annotation that is a band annotation has the following format:

```
[ {value, label, color, yAxis, visible}, {value, label} ]
```

value

The metric value in the graph where the horizontal annotation line is to appear. On a band shading annotation, the two values for Value define the upper and lower edges of the band.

On a graph with horizontal annotations, the graph is scaled so that all visible horizontal annotations appear on the graph.

Type: Float

Required: Yes

label

A string that appears on the graph next to the annotation.

Type: String

Required: No

color

The six-digit HTML hex color code to be used for the annotation. This color is used for both the annotation line and the fill shading.

Type: String

Required: No

fill

How to use fill shading with the annotation. Valid values are `above` for shading above the annotation, `below` for shading below the annotation, and `none` for no shading. If `fill` is omitted, there is no shading.

The exception is an annotation with band shading. These annotations always have shading between the two values, and any value for `fill` is ignored.

Type: String

Required: No

visible

Set this to `true` to have the annotation appear in the graph, or `false` to have it be hidden. The default is `true`.

Type: Boolean

Required: No

yAxis

If the graph includes multiple metrics, specifies whether the numbers in `Value` refer to the metric associated with the left Y-axis or the right Y-axis, . Valid values are `right` and `left`.

Type: String

Required: No

```
// A single horizontal annotation with fill shading above the annotation line, based on
 the metric associated with the right Y-axis

"annotations": {
     "horizontal": [
         {
              "visible":true,
              "color":"#9467bd",
              "label":"Critical range",
              "value":20,
              "fill":"above",
              "yAxis":"right"
         }
    ]
}

// A band annotation. Each value has a label, but other parameters for the band are
 specified only with the first number

"annotations": {
    "horizontal": [
        [
            {
                "label": "Band top",
                "value": 200,
                "color": "#9467bd",
                "visible": true,
                "yAxis": "right"
            },
            {
                "value": 95.5,
                "label": "Band bottom"
            }
        ]
    ]
}

// Three annotations on a graph. The first one is a band annotation. The final one is
 hidden.
```

```
"annotations": {
    "horizontal": [
        [
            {
                "label": "Band top",
                "value": 200,
                "color": "#9467bd",
                "visible": true,
                "yAxis": "right"
            },
            {
                "value": 95.5,
                "label": "Band bottom"
            }
        ],
        {
            "visible": true,
            "color": "#9467bd",
            "label": "Label for this annotation",
            "value": 20,
            "fill": "below",
            "yAxis": "right"
        },
        {
            "visible": false,
            "color": "#aaa",
            "label": "Hidden annotation",
            "value": 150
        }
    ]
}
```

Vertical Annotations

vertical

An array of vertical annotations. For each vertical annotation, you can choose to have fill shading before the annotation, after it, or between two vertical lines that are linked as a single band annotation. Each vertical annotation in the array that is a single annotation, instead of a band annotation, has the following format:

```
{value, label, color, fill, visible}
```

Each vertical annotation that is a band annotation has the following format:

```
[ {value, label, color, visible}, {value, label} ]
```

value

The date and time in the graph where the vertical annotation line is to appear. On a band shading annotation, the two values for Value define the beginning and ending edges of the band.

On a graph with vertical annotations, the graph is scaled so that all visible vertical annotations appear on the graph.

This is defined as a string in ISO 8601 format. For more information, see ISO 8601.

Type: String

Required: Yes

label

A string that appears on the graph next to the annotation.

Type: String

Required: No

color

The six-digit HTML hex color code to be used for the annotation. This color is used for both the annotation line and the fill shading.

Type: String

Required: No

fill

How to use fill shading with the annotation. Valid values are `before` for shading before the annotation, `after` for shading after the annotation, and `none` for no shading. If `fill` is omitted, there is no shading.

The exception is an annotation with band shading. These annotations always have shading between the two values, and any value for `fill` is ignored.

Type: String

Required: No

visible

Set this to `true` to have the annotation appear in the graph, or `false` to have it be hidden. The default is `true`.

Type: Boolean

Required: No

```
// A single vertical annotation with fill shading after the annotation line

"annotations": {
    "vertical": [
        {
            "visible": true,
            "color": "#9467bd",
            "label": "Bug fix deployed",
            "value": "2018-08-28T15:25:26Z",
            "fill": "after"
        }
    ]
}

// A band vertical annotation. Each annotation line has a label, but other parameters
 for the band are specified only with the first value

"annotations": {
    "vertical": [
        [
            {
                "label": "Band start",
                "value": "2018-08-27T15:25:26Z",
                "color": "#9467bd",
                "visible": true
            },
```

```
            {
                "value": "2018-08-28T15:25:26Z",
                "label": "Band end"
            }
        ]
    ]
}
```

Dashboard Widget Object: yAxis Properties Format

Defines the settings for the Y-axis of the graph. The settings include the maximum and minimum, a label for the axis, and whether the axis shows the units. Set this within the `widget` object to affect all metrics in the widget. To override the widget settings for a particular metric, set it for the metric in the `metrics` array.

```
{
  "left": {
    "min": 0,
    "max": 100
  },
  "right": {
    "min": 0
  }
}
```

left

Optional settings for the left Y-axis.

Type: YAxis object

Required: No

right

Optional settings for the right Y-axis.

Type: YAxis object

Required: No

Each of the `left` and `right` objects can include the following parameters:

label

A label for this Y-axis

Type: String

Required: No

min

The minimum value for this Y-axis

Type: Float

Required: No

max

The maximum value for this Y-axis

Type: Float

Required: No

showUnits

Determines whether the units are shown for the metric associated with this axis. The default is true.

Type: Boolean

Required: No

Dashboard Widget Object: Table Properties

If you specify `table` for a metric widget, you can include visualisations related to the visibility of summary columns, datapoint columns, and the table layout. These properties take effect only when the widget view type is `table` and don't alter other view types if included. The `table` property is not required to use a table widget.

layout

Use this field to transform the table such that the data points extend vertically or horizontally. The default is `horizontal`.

Valid Values: `vertical` | `horizontal`

Type: String

Required: No

stickySummary

Set this to `true` to make the summary columns that you include in the table sticky, so you can explore the data columns while always having the summary columns in your viewport. The default is `false`.

The widget label is always sticky, no matter your choice in this field.

Valid Values: `true` | `false`

Type: Boolean

Required: No

showTimeSeriesData

Set this to `false` if you want only the label and summary columns to be displayed, hiding the other columns of data.

The default is `true`.

Valid Values: `true` | `false`

Type: Boolean

Required: No

summaryColumns

Summary columns are a new property introduced with the table widget. These columns are a specific subset of summaries of your current table. For example, the `Sum` summary is a sum of all the rendered datapoints in its respective row. Summary columns are not that same concept as any CloudWatch metric statistic.

The default is `["MIN", "MAX","SUM", "AVG"]`

Valid Values: `"MIN"` | `"MAX"`| `"SUM"`| `"AVG"`

Type: Array

Required: No

For example, the following JSON creates a table displaying the minimum and maximum of each metric in the table.

```
"table": {
    "summaryColumns": ["MIN", "MAX"],
    "layout": "vertical",
    "stickySummary": true,
    "showTimeSeriesData": false
    },
```

Properties of a Metrics Explorer Widget Object

A widget of type `explorer` represents a metrics explorer widget. For more information, see Use Metrics Explorer to Monitor Resources by Their Tags and Properties

You can also add metrics explorer widgets to a dashboard using CloudFormation. For more information, see AWS::CloudWatch::Dashboard.

This widget type can have the following fields within the widget `properties`:

aggregateBy

An object that specifies how to aggregate metrics from multiple resources. The valid values for the `key` field in this object are the keys of tags and resource properties. This object contains the following fields.

- **key**– The tag or resource property key to use for aggregating the metrics.
- **func**– The aggregation function to use. Valid values are `AVG` | `MIN` | `MAX` | `STDDEV` | `SUM`

Type: Object

Required: No

labels

An array of the tags or the resource properties that are used to determine which metrics are displayed in the widget.

If you specify different keys, then only the resources that match all of the key/value pairs are displayed. If you specify multiple values for a single key, then resources that match any of the values for that key are displayed.

- **key**– The tag or resource property to filter on.

  For `key`, all tag keys are valid to be specified. The following EC2 and Lambda resource properties are also valid for `key`:

  - EC2:

    `Architecture`, `Hypervisor`, `CoreCount`, `ImageId`, `InstanceId`, `InstanceLifecycle`, `InstanceType`, `InstanceFamily`, `InstanceSize`, `Affinity`, `AvailabilityZone`, `Tenancy`, `Platform`, `RootDeviceType SecurityGroups`, `State, SubnetId, VirtualizationType, and VpcId`

  - Lambda:

    `FunctionName`, `Runtime`, `Language`, `MemorySize`, `Version`, `SecurityGroupIds`, `SubnetIds`, `SubnetIdCount`, `VpcId`, and `Timeout`

- **value**– (Optional) The value of the tag or resource property to filter on. If this is omitted, metrics corresponding to all values of that tag or resource property are displayed.

  Type: Object

  Required: Yes

metrics

Specify a `metrics` array to include one or more metrics. One `metrics` array can include 1–100 metrics. Each object in the array must contain the following fields.

- **metricName**– The name of the metric.
- **resourceType**– The type of resource publishing the metric, described in the format used by AWS CloudFormation. For example, `AWS::EC2::Instance` or `AWS::Lambda::Function`.

  You must use the same value for `resourceType` for all metrics in the widget.

  For a complete list of valid values, see Valid resourceType Values for a Metric Explorer Widget Object.

- **stat**– The statistic for this metric, if it is to be different than the statistic used for the other metrics in the array. By default CloudWatch uses *Average* if you don't specify a statistic at array or at metric level.

  Valid Values: `SampleCount` | `Average` | `Sum` | `Minimum` | `Maximum` | `p??`

  Type: Array of objects

Required: Yes

period

The default period, in seconds, for all metrics in this widget. The period is the length of time represented by one data point on the graph. The default is 300.

Valid Values: Any multiple of 60, with 60 as the minimum.

Type: Integer

Required: No

splitBy

Specifies how to split the metrics from multiple resources into different lines on a graph, or into different graphs. The valid values are the keys of tags, and the keys of resource properties.

Type: String

Required: No

title

The title to be displayed for the widget. The default is `Explorer`.

Type: String

Required: No

widgetOptions

An object that specifies how the widget appears on the dashboard. It can contain the following fields.

- **legend**–

  Determines where the legend for each graph is displayed. The `legend` field contains another field called `position`. Possible values for `position` are `right`, `bottom`, and `hidden`.

  For example, the following causes the legend to appear on the right in the graph.

  ```
  "legend": {
       "position": "right"
  }
  ```

- **rowsPerPage**–

Specifies how many rows of graphs are displayed per page in the widget.

- **stacked**–

  Specify `true` to display the graph as a stacked area chart, or `false` to display as separate lines.

- **view**–

  Specifies how each graph is displayed. Specify `timeSeries` to display this metric as a line graph. Specify `bar` to display it as a bar graph. Specify `pie` to display it as a pie graph. The default is `timeSeries`.

- **widgetsPerRow**–

  Specifies how many graphs are displayed in each row of the metrics explorer widget.

Type: Object

Required: No

Example

The following example displays three metrics for each of the account's running EC2 instances, with the graphs in the widget split by availability zone. Within each graph, the metrics are aggregated by instance type.

```
{
    "widgets": [
        {
            "type": "explorer",
            "width": 24,
            "height": 15,
            "x": 0,
            "y": 0,
            "properties": {
                "metrics": [
                    {
                        "metricName": "CPUUtilization",
                        "resourceType": "AWS::EC2::Instance",
                        "stat": "Average"
                    },
                    {
```

```
                        "metricName": "NetworkIn",
                        "resourceType": "AWS::EC2::Instance",
                        "stat": "Average"
                    },
                    {
                        "metricName": "NetworkOut",
                        "resourceType": "AWS::EC2::Instance",
                        "stat": "Average"
                    }
                ],
                "aggregateBy": {
                    "key": "InstanceType",
                    "func": "MAX"
                },
                "labels": [
                    {
                        "key": "State",
                        "value": "running"
                    }
                ],
                "widgetOptions": {
                    "legend": {
                        "position": "bottom"
                    },
                    "view": "timeSeries",
                    "rowsPerPage": 8,
                    "widgetsPerRow": 2
                },
                "period": 300,
                "splitBy": "AvailabilityZone",
                "title": "Running EC2 Instances by AZ"
            }
        }
    ]
}
```

Valid resourceType Values for a Metric Explorer Widget Object

The valid values for the `resourceType` field in the `metrics` section of a metrics explorer widget are as follows:

- `AWS::AmazonMQ::Broker`
- `AWS::ApiGateway::RestApi`

- AWS::AppStream::Fleet
- AWS::AppSync::GraphQLApi
- AWS::CloudFront::Distribution
- AWS::CodeBuild::Project
- AWS::Datasync::Agent
- AWS::Datasync::Task
- AWS::DMS::ReplicationInstance
- AWS::DynamoDB::Table
- AWS::EC2::CapacityReservation
- AWS::EC2::Instance
- AWS::EC2::NatGateway
- AWS::EC2::TransitGateway
- AWS::EC2::Volume
- AWS::EC2::VPNConnection
- AWS::ECS::Cluster
- AWS::EFS::FileSystem
- AWS::ElastiCache::CacheCluster
- AWS::ElastiCache::ReplicationGroup
- AWS::ElasticBeanstalk::Environment
- AWS::ElasticLoadBalancing::LoadBalancer
- AWS::ElasticLoadBalancingV2::LoadBalancer/ApplicationELB
- AWS::ElasticLoadBalancingV2::LoadBalancer/GatewayELB
- AWS::ElasticLoadBalancingV2::LoadBalancer/NetworkELB
- AWS::ElasticLoadBalancingV2::TargetGroup
- AWS::EMR::Cluster
- AWS::Events::Rule
- AWS::FSx::FileSystem
- AWS::GameLift::Fleet
- AWS::GlobalAccelerator::Accelerator

- AWS::IoT::TopicRule
- AWS::IoT1Click::Device
- AWS::IoTAnalytics::Channel
- AWS::IoTAnalytics::Dataset
- AWS::IoTAnalytics::Datastore
- AWS::IoTAnalytics::Pipeline
- AWS::Kafka::Cluster
- AWS::Kinesis::Stream
- AWS::KinesisAnalytics::Application
- AWS::KinesisFirehose::DeliveryStream
- AWS::KinesisVideo::Stream
- AWS::KMS::Key
- AWS::Lambda::Function
- AWS::Logs::LogGroup
- AWS::MediaPackage::Channel
- AWS::MediaStore::Container
- AWS::OpsWorks::Instance
- AWS::OpsWorks::Layer
- AWS::OpsWorks::Stack
- AWS::QLDB::Ledger
- AWS::RDS::DBInstance
- AWS::Redshift::Cluster
- AWS::RoboMaker::SimulationJob
- AWS::Route53::HealthCheck
- AWS::Route53Resolver::ResolverEndpoint
- AWS::S3::Bucket
- AWS::SageMaker::Endpoint
- AWS::ServiceCatalog::CloudFormationProduct
- AWS::SES::ConfigurationSet
- AWS::SNS::Topic

- AWS::SQS::Queue

- AWS::StepFunctions::StateMachine
- AWS::StorageGateway::Gateway
- AWS::Synthetics::Canary
- AWS::Transfer::Server
- AWS::WorkMail::Organization
- AWS::WorkSpaces::Workspace

Properties of an Alarm Status Widget Object

A widget of type alarm can have the following fields within properties.

alarms

An array of alarm ARNs to include in the widget. The array can have 1-100 ARNs.

Type: Array of strings

Required: Yes (when the widget type is alarm).

sortBy

Specifies how to sort the alarms in the widget.

Choose default to sort them in alphabetical order by alarm name.

Choose stateUpdatedTimestamp to sort them first by alarm state, with alarms in ALARM state first, INSUFFICIENT_DATA alarms next, and OK alarms last. Within each group, the alarms are sorted by when they last changed state, with more recent state changes listed first.

Choose timestamp to sort them by the time when the alarms most recently changed state, no matter the current alarm state. The alarm that changed state most recently is listed first.

If you omit this field, the alarms are sorted in alphabetical order.

Type: String

Valid Values: default | stateUpdatedTimestamp | timestamp

Required: No

states

Use this field to filter the list of alarms displayed in the widget to only those alarms currently in the specified states. You can specify one or more alarm states in the value for this field. The alarm states that you can specify are `ALARM`, `INSUFFICIENT_DATA`, and `OK`.

If you omit this field or specify an empty array, all the alarms specified in `alarms` are displayed.

Type: Array of strings

Required: No

title

The title text to be displayed by the widget.

Type: String

Required: No

The following example is an alarm status widget that displays four alarms specified by name, no matter their current state:

```
{
    "type": "alarm",
    "x": 0,
    "y": 0,
    "width": 12,
    "height": 6,
    "properties": {
        "alarms": [
            "arn:aws:cloudwatch:us-east-1:012345678901:alarm:EC2FrontendCPU",
            "arn:aws:cloudwatch:us-east-1:012345678901:alarm:EC2BackendCPU",
            "arn:aws:cloudwatch:eu-west-1:987654321098:alarm:EC2FrontendCPU",
            "arn:aws:cloudwatch:eu-west-1:987654321098:alarm:EC2BackendCPU"
        ],
        "sortBy": "stateUpdatedTimestamp",
        "title": "All EC2 CPU alarms"
    }
}
```

The following example widget specifies the same four alarms, but the widget displays only the alarms that are currently in ALARM or INSUFFICIENT_DATA state:

```
{
    "type": "alarm",
    "x": 0,
    "y": 0,
    "width": 12,
    "height": 6,
    "properties": {
        "alarms": [
            "arn:aws:cloudwatch:us-east-1:012345678901:alarm:EC2FrontendCPU",
            "arn:aws:cloudwatch:us-east-1:012345678901:alarm:EC2BackendCPU",
            "arn:aws:cloudwatch:eu-west-1:987654321098:alarm:EC2FrontendCPU",
            "arn:aws:cloudwatch:eu-west-1:987654321098:alarm:EC2BackendCPU"
        ],
        "sortBy": "stateUpdatedTimestamp",
        "states": [
            "ALARM",
            "INSUFFICIENT_DATA"
        ],
        "title": "EC2 alarms that are not currently OK"
    }
}
```

Properties of a Chart Widget Object

A widget of type `chart` is a multi-data-source chart widget that supports PromQL queries against CloudWatch metrics. Use a chart widget to visualize metrics that are queryable with PromQL, including metrics ingested through OpenTelemetry Line Protocol (OTLP) and AWS vended metrics that have been enriched for OTel. For more information about querying with PromQL, see Query metrics with PromQL.

A widget of type `chart` can have the following fields within `properties`:

view

The visualization to use for the widget.

Valid Values: `line` | `bar` | `pie` | `number` | `solidgauge` | `column` | `legend` | `histogram` | `heatmap` | `scatter`

Type: String

Required: Yes

title

The title to display for the widget.

Type: String

Required: No

description

An optional description for the widget.

Type: String

Required: No

region

The AWS Region to use for all queries in the widget. Each query in the `data.queries` array can override this with its own `region` field.

Type: String

Required: No

data

The queries to plot in the widget. The `data` object contains a `queries` array, where each entry defines one query. For more information about the format, see Chart Widget: Format for Each Query in the Array.

Type: Object

Required: Yes

plotOptions

Visualization options for the widget, such as legend placement, axis configuration, and view-specific style settings (for example, line width or stacked bars). The exact fields available depend on the value of `view`. If you omit `plotOptions`, default settings for the view are used. For the full list of fields, see Chart Widget: plotOptions Reference.

Type: Object

Required: No

Chart Widget: Format for Each Query in the Array

Each entry in the `data.queries` array defines a single query. To create a chart widget that queries CloudWatch metrics, set `type` to `cloudwatch-metrics`, set `language` to either `PromQL` or `SQL`, and provide the query expression as a string in the `query` field. A single chart widget can mix queries written in different languages.

id

An identifier for this query. The ID must be unique within the widget.

Type: String

Required: Yes

type

The kind of query. For PromQL, use `cloudwatch-metrics`.

Valid Values: `cloudwatch-metrics`

Type: String

Required: Yes

language

The query language for this query. Specify `PromQL` to write the query in Prometheus Query Language, or `SQL` to write the query in CloudWatch Metrics Insights SQL.

Valid Values: `PromQL` | `SQL`

Type: String

Required: Yes

query

The query expression to evaluate, as a string. The syntax depends on the `language` field.

For PromQL, provide a Prometheus Query Language expression. For example, `sum by (InstanceId) (rate(CPUUtilization[5m]))`. For information about PromQL syntax and the labels available on AWS vended metrics, see Querying vended AWS metrics with PromQL.

For SQL, provide a CloudWatch Metrics Insights SQL query. For example, `SELECT AVG(CPUUtilization) FROM SCHEMA("AWS/EC2", InstanceId) GROUP BY InstanceId`. For information about Metrics Insights query syntax, see Metrics Insights query components and syntax.

Type: String

Required: Yes

label

The label to display in the legend for this query's series. Specify the special value `__verbose__` to include all metric labels in each series name.

Type: String

Required: No

region

The AWS Region to evaluate this query in. If omitted, the widget's `region` is used.

Type: String

Required: No

accountId

The AWS account to evaluate this query in. Use this for cross-account queries on a monitoring-account dashboard.

Type: String

Required: No

step

The query resolution, in seconds. This controls how frequently the PromQL expression is evaluated across the widget's time range.

Type: Number

Required: No

visible

Set to `false` to hide this query's series from the chart while still keeping the query in the widget definition. The default is `true`.

Type: Boolean

Required: No

Chart Widget: plotOptions Reference

The `plotOptions` object controls how the chart is rendered. It can contain a set of common fields shared by every `view`, plus a `style` object whose shape depends on the chosen `view`. Some views also accept axis (`yAxis`, `xAxis`) and `annotations` objects.

The following table summarizes which fields each `view` supports.

view	style sub-object	yAxis / xAxis	Annotation support
`line`	LineStyle	Yes	Yes (vertical and horizontal)
`bar`	BarStyle	Yes	Yes (vertical and horizontal)
`column`	BarStyle	Yes	No
`pie`	PieStyle	No	No
`number`	NumberStyle	No	No
`solidgauge`	GaugeStyle	No	Yes (horizontal)
`scatter`	ScatterStyle	Yes	Yes (vertical and horizontal)
`histogram`	BarStyle + HistogramStyle	Yes	No

view	style sub-object	yAxis / xAxis	Annotation support
heatmap	HeatmapStyle	Yes	No

In the preceding table, the **style sub-object** column uses shorthand shape names (for example, `LineStyle`, `BarStyle`, and `PieStyle`). You set these styles in the `plotOptions` object using the corresponding fields documented in the following sections (for example, `lineOptions`, `barOptions`, and `pieOptions`).

Common plotOptions fields

The following fields are valid in `plotOptions` for every `view`.

legend

Configures the legend. The object contains the following fields:

- position– Where the legend appears on the widget. Valid values are `bottom` and `right`.
- show– Boolean. Set to `false` to hide the legend.

Type: Object

Required: No

View-specific style fields

The shape of the `style` object depends on the value of `view`.

lineOptions

Used when `view` is `line`. Configures line rendering. The object contains the following fields:

- width– Number. Line width in pixels.
- pattern– Line stroke pattern. Valid values are `solid`, `dashed`, and `dotted`.
- spline– Boolean. If `true`, draws a smoothed curve through the data points.
- filled– Boolean. If `true`, fills the area below the line.
- stacked– Boolean. If `true`, stacks filled areas across series. Use with `filled: true` for a stacked area chart.

- color– A six-digit HTML hex color.

Type: Object

Required: No

barOptions

Used when `view` is `bar`, `column`, or `histogram`. Configures bar rendering. The object contains the following fields:

- stacked– Boolean. If `true`, bars from different series are stacked.
- orientation– Bar direction. Valid values are `vertical` and `horizontal`.

Type: Object

Required: No

pieOptions

Used when `view` is `pie`. The object contains the following fields:

- innerSize– String. A percentage like `"50%"`. Set to `"0%"` for a solid pie, or a non-zero value for a donut chart.

Type: Object

Required: No

numberOptions

Used when `view` is `number`. The object contains the following fields:

- sparkline– Boolean. If `true`, displays a sparkline below the number.
- truncate– Boolean. If `true`, truncates large numbers (for example, displays `1.2K` instead of `1234`).

Type: Object

Required: No

gaugeOptions

Used when `view` is `solidgauge`. The object contains the following fields:

- min– Number. The minimum value of the gauge.

- max– Number. The maximum value of the gauge.

Type: Object

Required: No

colorOptions

Used when `view` is `heatmap`. Configures the color gradient. The object contains the following fields:

- colorPreset– String. Name of a built-in color scale.
- minColor– A six-digit HTML hex color used at the low end of a custom gradient.
- midColor– A six-digit HTML hex color used at the midpoint of a custom gradient.
- maxColor– A six-digit HTML hex color used at the high end of a custom gradient.

Type: Object

Required: No

histogramOptions

Used when `view` is `histogram`, in addition to `barOptions`. The object contains the following fields:

- bucketCount– Number. Number of buckets to divide the data into.
- bucketSize– Number, or the string `"auto"` to size buckets automatically.
- combineSeries– Boolean. Combines all series into a single histogram.

Type: Object

Required: No

aggregationOptions

Used when `view` is `histogram`. Controls how data points are aggregated before bucketing. The object contains the following fields:

- binInterval– String. The bin width as a duration. For example, `"5m"` for five-minute bins.

Type: Object

Required: No

label

Used with line, bar, and scatter styles to label data points directly on the chart. The object contains the following fields:

- position– Where the label appears relative to its data point. Valid values are `inside`, `outside`, `top`, `bottom`, `left`, and `right`.
- show– Boolean. Set to `true` to display labels.

Type: Object

Required: No

markOptions

Used with line and scatter styles to configure markers drawn at data points. The object contains the following fields:

- enabled– Boolean. Set to `true` to draw markers.
- symbolType– String. Marker shape. For example, `circle`, `square`, or `diamond`.
- symbolSize– Number. Marker size in pixels.
- borderWidth– Number. Marker border width in pixels.
- borderColor– A six-digit HTML hex color for the marker border.
- fillColor– A six-digit HTML hex color for the marker fill.
- fillOpacity– Number between 0 and 1.

Type: Object

Required: No

yAxis and xAxis fields

For `view` values that support axes, you can include `yAxis` and `xAxis` objects in `plotOptions`.

yAxis

An array of one or two axis objects. The first entry configures the left axis, and the second entry (if present) configures the right axis. Each axis object contains the following fields:

- min– Number. Lower bound of the axis.

- max– Number. Upper bound of the axis.
- type– Axis scale. Valid values are `linear`, `logarithmic`, `datetime`, and `category`.
- title– String. Axis label displayed alongside the axis.
- showUnits– Boolean. Whether to show unit suffixes (for example, `K`, `M`) on tick labels.

Type: Array of objects

Required: No

xAxis

A single axis object that configures the x-axis. The object contains the following fields:

- min– Number. Lower bound of the axis.
- max– Number. Upper bound of the axis.
- type– Axis scale. Valid values are `linear`, `logarithmic`, `datetime`, and `category`.
- title– String. Axis label displayed alongside the axis.
- label– String. Tick label format.

Type: Object

Required: No

annotations

For `view` values that support annotations, you can add reference lines or shaded bands to the chart. The `annotations` object can contain the following arrays:

vertical

Annotations on the time axis. Each entry is either an annotation object, or an array of two annotation objects to define a band (shaded region between two values). Each annotation object contains the following fields:

- type– The annotation type. Use `static`.
- label– String. The text displayed next to the annotation.
- value– Number, ISO-8601 timestamp string, or category. The location on the time axis where the annotation appears.
- color– A six-digit HTML hex color used for the annotation line and any fill shading.

- fill– How to use fill shading. Valid values are `before` (shading before the annotation), `after` (shading after the annotation), and `between` (used for band annotations to shade between the two values).

Type: Array

Required: No

horizontal

Annotations on the value axis. Each entry is either an annotation object, or an array of two annotation objects to define a band. Each annotation object contains the following fields:

- type– The annotation type. Use `static`.
- label– String. The text displayed next to the annotation.
- value– Number. The value on the value axis where the annotation appears.
- color– A six-digit HTML hex color used for the annotation line and any fill shading.
- fill– How to use fill shading. Valid values are `above` (shading above the annotation), `below` (shading below the annotation), and `between` (used for band annotations to shade between the two values).

Type: Array

Required: No

Example: PromQL line chart

The following example renders a line chart that plots a PromQL query against AWS vended metrics in `us-east-1`.

```
{
    "type": "chart",
    "x": 0,
    "y": 0,
    "width": 12,
    "height": 6,
    "properties": {
        "view": "line",
        "title": "EC2 CPU by instance",
        "region": "us-east-1",
        "data": {
```

```
            "queries": [
                {
                    "id": "a",
                    "type": "cloudwatch-metrics",
                    "language": "PromQL",
                    "query": "sum by (InstanceId) (rate(CPUUtilization[5m]))"
                }
            ]
        },
        "plotOptions": {
            "legend": {
                "position": "bottom",
                "show": true
            }
        }
    }
}
```

Example: Chart that combines a PromQL query and a SQL query

The following example shows a line chart that plots two queries against the same metric, one written in PromQL and one written in CloudWatch Metrics Insights SQL.

```
{
    "type": "chart",
    "x": 0,
    "y": 6,
    "width": 12,
    "height": 6,
    "properties": {
        "view": "line",
        "title": "EC2 CPU utilization (PromQL and SQL)",
        "region": "us-east-1",
        "data": {
            "queries": [
                {
                    "id": "promql_cpu",
                    "type": "cloudwatch-metrics",
                    "language": "PromQL",
                    "query": "sum by (InstanceId) (rate(CPUUtilization[5m]))",
                    "label": "PromQL"
                },
                {
```

```
                    "id": "sql_cpu",
                    "type": "cloudwatch-metrics",
                    "language": "SQL",
                    "query": "SELECT AVG(CPUUtilization) FROM SCHEMA(\"AWS/EC2\",
 InstanceId) GROUP BY InstanceId",
                    "label": "SQL"
                }
            ]
        },
        "plotOptions": {
            "legend": {
                "position": "right",
                "show": true
            }
        }
    }
}
```

Graphing metrics

Use the CloudWatch console to graph metric data generated by other AWS services. This makes it more efficient to see the metric activity on your services. The following procedures describe how to graph metrics in CloudWatch.

Contents

- Graph a metric
- Merge two graphs into one
- Use dynamic labels
- Modify the time range or time zone format for a graph
- Zoom in on a line graph or stacked area graph
- Modify the y-axis for a graph
- Create an alarm from a metric on a graph
- GetMetricWidgetImage: Metric Widget Structure and Syntax

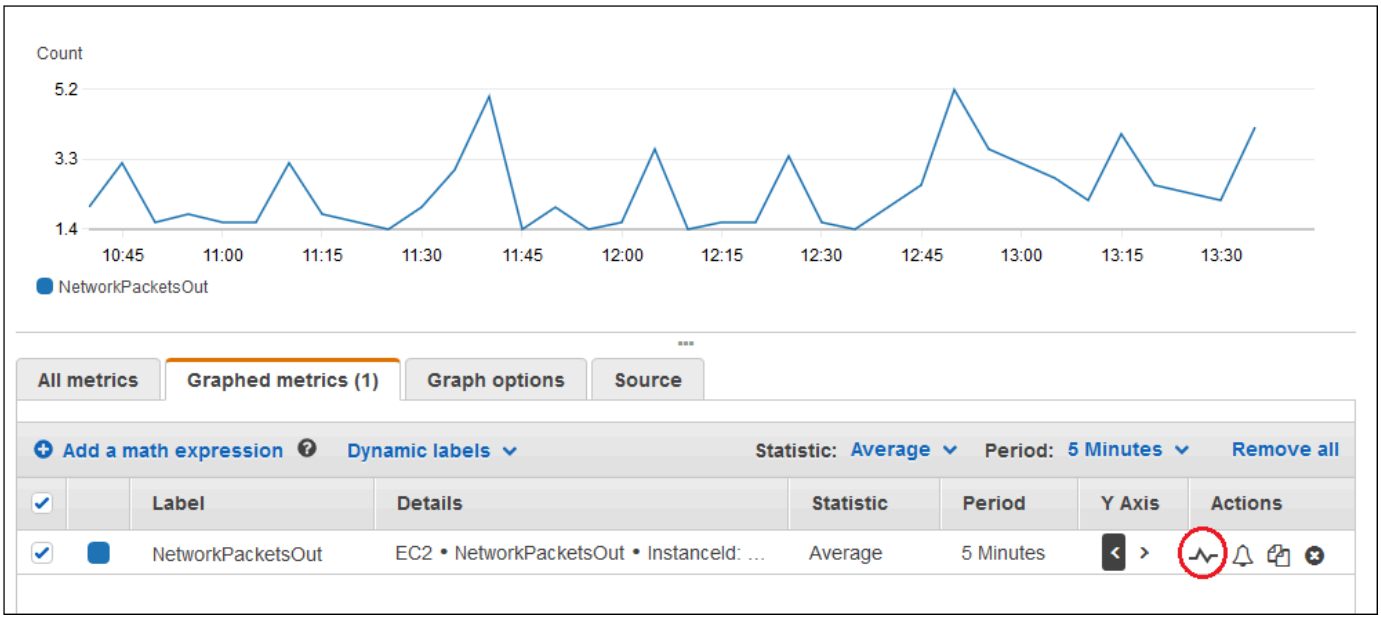
Graph a metric

You can select metrics and create graphs of the metric data using the CloudWatch console.

CloudWatch supports the following statistics on metrics: `Average`, `Minimum`, `Maximum`, `Sum`, and `SampleCount`. For more information, see Statistics.

You can view your data at different levels of detail. For example, you can choose a one-minute view, which can be useful when troubleshooting. Or, choose a less detailed, one-hour view. That can be useful when viewing a broader time range (for example, 3 days) so that you can see trends over time. For more information, see Periods.

If you are using an account that is set up as a monitoring account in CloudWatch cross-account observability, you can graph metrics from the source accounts linked to this monitoring account. For more information, see CloudWatch cross-account observability.



Creating a graph

To graph a metric

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. In the **Browse** tab, enter a search term in the search field, such as a metric name, account ID, or resource name.

   For example, if you search for the `CPUUtilization` metric, you see the namespaces and dimensions with this metric.
4. Select one of the results for your search to view the metrics.
5. To graph one or more metrics, select the check box next to each metric. To select all metrics, select the check box in the heading row of the table.
6. (Optional) To change the type of graph, choose the **Options** tab. You can then choose between a line graph, stacked area chart, number display, gauge, bar chart, or pie chart.
7. Choose the **Graphed metrics** tab.
8. (Optional) To change the statistic used in the graph, choose the new statistic in the **Statistic** column next to the metric name.

   For more information about CloudWatch statistics, see CloudWatch statistics definitions. For more information about the **p*xx*** percentile statistics, see Percentiles.
9. (Optional) To add an anomaly detection band that shows expected values for the metric, choose the anomaly detection icon under **Actions** next to the metric. For more information about anomaly detection, see Using CloudWatch anomaly detection.

CloudWatch uses up to two weeks of the metric's recent historical data to calculate a model for expected values. It then displays this range of expected values as a band on the graph. CloudWatch adds a new row under the metric to display the anomaly detection band math expression, labeled **ANOMALY_DETECTION_BAND**. If recent historical data exists, you immediately see a preview anomaly detection band, which is an approximation of the anomaly detection band generated by the model. It takes up to 15 minutes for the actual anomaly detection band to appear.

By default, CloudWatch creates the upper and lower bounds of the band of expected values with a default value of 2 for the band threshold. To change this number, change the value at the end of the formula under **Details** for the band.

- (Optional) Choose **Edit model** to change how the anomaly detection model is calculated. You can exclude past and future time periods from being used in the training for calculating the model. It is critical to exclude unusual events system as system outage, deployments, and holidays from the training data. You can also specify the time zone to use for the model for daylight saving time changes.

  For more information, see Editing an anomaly detection model.

For more information about anomaly detection, see Using CloudWatch anomaly detection.

To hide the model from the graph, remove the check mark from the line with the `ANOMALY_DETECTION_BAND` function or choose the `X` icon. To delete the model entirely, choose **Edit model**, **Delete model**.

10. (Optional) As you choose metrics to graph, specify a dynamic label to appear on the graph legend for each metric. Dynamic labels display a statistic about the metric, and automatically update when the dashboard or graph is refreshed. To add a dynamic label, choose **Graphed metrics**, **Add dynamic label**.

    By default, the dynamic values that you add to the label appear at the beginning of the label. You can then choose the **Label** value for the metric to edit the label. For more information, see Use dynamic labels.

11. To view more information about the metric being graphed, pause the mouse over the legend.

12. Horizontal annotations can help graph users more efficiently see when a metric has spiked to a certain level, or whether the metric is within a predefined range. To add a horizontal annotation, choose the **Options** tab and then **Add horizontal annotation**:

    a. For **Label**, enter a label for the annotation.

    b. For **Value**, enter the metric value where the horizontal annotation appears.

    c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose `Above` or `Below` for the corresponding area to be filled. If you specify `Between`, another `Value` field appears, and the area of the graph between the two values is filled.

    d. For **Axis**, specify whether the numbers in `Value` refer to the metric associated with the left Y-axis or the right Y-axis, if the graph includes multiple metrics.

    You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

    Repeat these steps to add multiple horizontal annotations to the same graph.

    To hide an annotation, clear the check box in the left column for that annotation.

    To delete an annotation, choose **x** in the **Actions** column.

13. To get a URL for your graph, choose **Actions**, **Share**. Copy the URL to save or share.

14. To add your graph to a dashboard, choose **Actions**, **Add to dashboard**.

Creating a graph of metrics from another data source

You can create a graph that displays resources from data sources other than CloudWatch. For more information about creating connections to these other data sources, see Query metrics from other data sources.

To graph a metric from another data source

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Choose the **Multi source query** tab.
4. For **Data source**, select the data source that you want to use.

   If you haven't already created a connection to the data source that you want, select **Create and manage data sources**, then choose **Create and manage data sources**. For information about the rest of this data source creation process, see Connect to a prebuilt data source with a wizard.
5. The wizard or query editor prompts you for the information necessary for the query. The workflow is different for each data source, and is tailored to the data source. For example, for Amazon Managed Service for Prometheus and Prometheus data sources, a PromQL query editor box with a query helper appear.
6. When you have finished constructing the query, choose **Graph query**.

   The graph is populated with metrics from the query.
7. (Optional) Horizontal annotations can help graph users more efficiently see when a metric has spiked to a certain level, or whether the metric is within a predefined range. To add a horizontal annotation, choose the **Options** tab and then **Add horizontal annotation**:

   a. For **Label**, enter a label for the annotation.

   b. For **Value**, enter the metric value where the horizontal annotation appears.

   c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose `Above` or `Below` for the corresponding area to be filled. If you specify `Between`, another `Value` field appears, and the area of the graph between the two values is filled.

   d. For **Axis**, specify whether the numbers in `Value` refer to the metric associated with the left Y-axis or the right Y-axis, if the graph includes multiple metrics.

You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

Repeat these steps to add multiple horizontal annotations to the same graph.

To hide an annotation, clear the check box in the left column for that annotation.

To delete an annotation, choose **x** in the **Actions** column.

8. (Optional) To add this graph to a dashboard, choose **Actions**, **Add to dashboard**.

Updating a graph

To update your graph

1. To change the name of the graph, choose the pencil icon.
2. To change the time range, select one of the predefined values or choose **custom**. For more information, see Modify the time range or time zone format for a graph.
3. To change the statistic, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, **p95.45**).
4. To change the period, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose a different value.
5. To add a horizontal annotation, choose **Graph options** and then **Add horizontal annotation**:

   a. For **Label**, enter a label for the annotation.

   b. For **Value**, enter the metric value where the horizontal annotation appears.

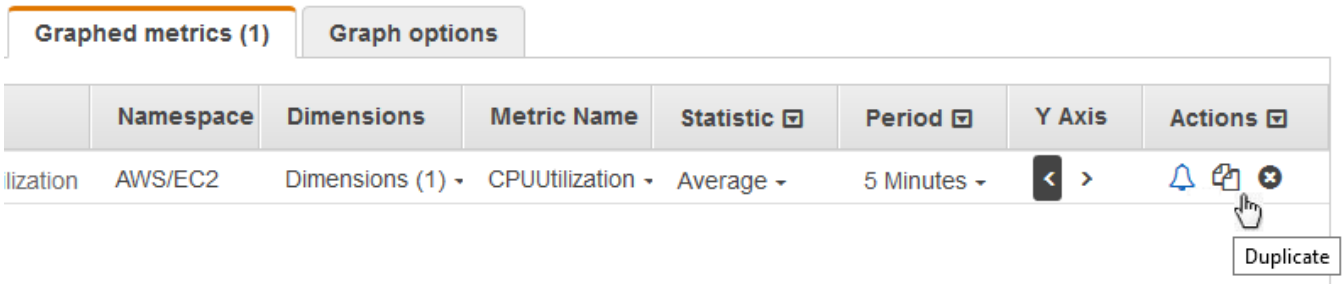
   c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose `Above` or `Below` for the corresponding area to be filled. If you specify `Between`, another `Value` field appears, and the area of the graph between the two values is filled.

   d. For **Axis**, specify whether the numbers in `Value` refer to the metric associated with the left y-axis or the right y-axis, if the graph includes multiple metrics.

   You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

Repeat these steps to add multiple horizontal annotations to the same graph.

To hide an annotation, clear the check box in the left column for that annotation.



To delete an annotation, choose **x** in the **Actions** column.

6. To change the refresh interval, choose **Refresh options** and then select **Auto refresh** or choose **1 Minute**, **2 Minutes**, **5 Minutes**, or **15 Minutes**.

Duplicating a metric

To duplicate a metric

1. Choose the **Graphed metrics** tab.
2. For **Actions**, choose the **Duplicate** icon.

3. Update the duplicate metric as needed.

Merge two graphs into one

You can merge two different graphs into one, and then the resulting graph shows both metrics. This can be useful if you already have different metrics displayed in different graphs and want to combine them, or you want to easily create a single graph with metrics from different Regions.

To merge a graph into another one, you use either the URL or JSON source of the graph that you want to merge in.

To merge two graphs into one

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Open the graph that you want to merge into another graph. To do so, you can choose **Metrics**, **Classic metrics**, and then choose a metric to graph. Or you can open a dashboard and then

open one of the graphs on the dashboard by selecting the graph and choosing **Open in metrics** from the menu at the upper right of the graph.

3. After you have a graph open, do one of the following:.
   - Copy the URL from the browser bar.
   - Choose the **Source** tab and then choose **Copy**.
4. Open the graph that you want to merge the previous graph into.
5. When you have the second graph open in the **Metrics** view, choose **Actions**, **Merge graph**.
6. Enter the URL or JSON that you previously copied, and choose **Merge**.
7. The merged graphs appear. The y-axis on the left is for the original graph, and the y-axis on the right is for the graph that you merged into it.

   > **Note**
   >
   > If the graph that you merged into uses the **METRICS()** function, the metrics in the graph that was merged in are not included in the **METRICS()** calculation in the merged graph.

8. To save the merged graph to a dashboard, choose **Actions**, **Add to dashboard**.

Use dynamic labels

You can use dynamic labels with your graphs. Dynamic labels add a dynamically updated value to the label for the selected metric. You can add a wide range of values to the labels, as shown in the following tables.

The dynamic value shown in the label is derived from the time range currently shown on the graph. The dynamic part of the label automatically updates when either the dashboard or the graph is refreshed.

If you use a dynamic label with a search expression, the dynamic label applies to every metric returned by the search.

You can use the CloudWatch console to add a dynamic value to a label, edit the label, change the position of the dynamic value within the label column, and make other customizations.

Dynamic labels

Within a dynamic label, you can use the following values relating to properties of the metric:

Dynamic label live value	Description
${AVG}	The average of the values in the time range currently shown in the graph.
${DATAPOINT_COUNT}	The number of data points in the time range that is currently shown in the graph.
${FIRST}	The oldest of the metric values in the time range that is currently shown in the graph.
${FIRST_LAST_RANGE}	The difference between the metric values of the oldest and newest data points that are currently shown in the graph.
${FIRST_LAST_TIME_RANGE}	The absolute time range between the oldest and newest data points that are currently shown in the graph.
${FIRST_TIME}	The timestamp of the oldest data point in the time range that is currently shown in the graph.
${FIRST_TIME_RELATIVE}	The absolute time difference between now and the timestamp of the oldest data point in the time range that is currently shown in the graph.
${LABEL}	The representation of the default label for a metric.
${LAST}	The most recent of the metric values in the time range that is currently shown in the graph.
${LAST_TIME}	The timestamp of the newest data point in the time range that is currently shown in the graph.
${LAST_TIME_RELATIVE}	The absolute time difference between now and the timestamp of the newest data point in the time range that is currently shown in the graph.
${MAX}	The maximum of the values in the time range currently shown in the graph.

Dynamic label live value	Description
${MAX_TIME}	The timestamp of the data point that has the highest metric value, of the data points that are currently shown in the graph.
${MAX_TIME_RELATIVE}	The absolute time difference between now and the timestamp of the data point with the highest value, of those data points that are currently shown in the graph.
${MIN}	The minimum of the values in the time range currently shown in the graph.
${MIN_MAX_RANGE}	The difference in metric values between the data points with the highest and lowest metric values, of those data points that are currently shown in the graph.
${MIN_MAX_TIME_RANGE}	The absolute time range between the data points with the highest and lowest metric values, of those data points that are currently shown in the graph.
${MIN_TIME}	The timestamp of the data point that has the lowest metric value, of the data points that are currently shown in the graph.
${MIN_TIME_RELATIVE}	The absolute time difference between now and the timestamp of the data point with the lowest value, of those data points that are currently shown in the graph.
${PROP('AccountId')}	The AWS account ID of the metric.
${PROP('AccountLabel')}	The label specified for the source account that owns this metric, in CloudWatch cross-account observability.
${PROP('Dim.*dimension_name*')}	The value of the specified dimension. Replace *dimension_name* with the case-sensitive name of your dimension.
${PROP('MetricName')}	The name of the metric.
${PROP('Namespace')}	The namespace of the metric.
${PROP('Period')}	The period of the metric, in seconds.

Dynamic label live value	Description
${PROP('Region')}	The AWS Region where the metric is published.
${PROP('Stat')}	The metric statistic that is being graphed.
${SUM}	The sum of the values in the time range currently shown in the graph.

For example, suppose you have a search expression **`SEARCH(' {AWS/Lambda, FunctionName} Errors ', 'Sum')`**, which finds the `Errors` for each of your Lambda functions. If you set the label to be `[max: ${MAX} Errors for Function Name ${LABEL}]`, the label for each metric is **[max: *number* Errors for Function Name *Name*]**.

You can add as many as six dynamic values to a label. You can use the `${LABEL}` placeholder only once within each label.

Modify the time range or time zone format for a graph

This section describes how you can modify the date, time, and time zone format on a CloudWatch metrics graph. It also describes how you can zoom in on a graph to apply a specific time range. For information about creating a graph, see Graph a metric.

Note

If the time range of a dashboard is shorter than the period used for a graph on the dashboard, the following happens:

- The graph is modified to display the amount of data corresponding one complete period for that widget, even though this is longer than the dashboard time range. This ensures that there is at least one data point on the graph.
- The start time of the period for this data point is adjusted backwards to make sure that at least one data point can be displayed.

Set a relative time range

New interface

To specify a relative time range for a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **Custom** to set your own time range.
3. Choose **Custom**, and then select the **Relative** tab in the upper left corner of the box. You can specify a time range in **Minutes**, **Hours**, **Days**, **Weeks**, **Months**.
4. After you specify a time range, choose **Apply**.

Original interface

To specify a relative time range for a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **custom** to set your own time range.
3. Choose **custom**, and then choose **Relative** in the upper left corner of the box. You can specify a time range in **Minutes**, **Hours**, **Days**, **Weeks**, or **Months**.

Set an absolute time range

New interface

To specify an absolute time range for a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1

hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **Custom** to set your own time range.

3. Choose **Custom**, and then select the **Absolute** tab in the upper left corner of the box. Use the calendar picker or text field boxes to specify a time range.
4. After you specify a time range, choose **Apply**.

Original interface

To specify an absolute time range for a graph

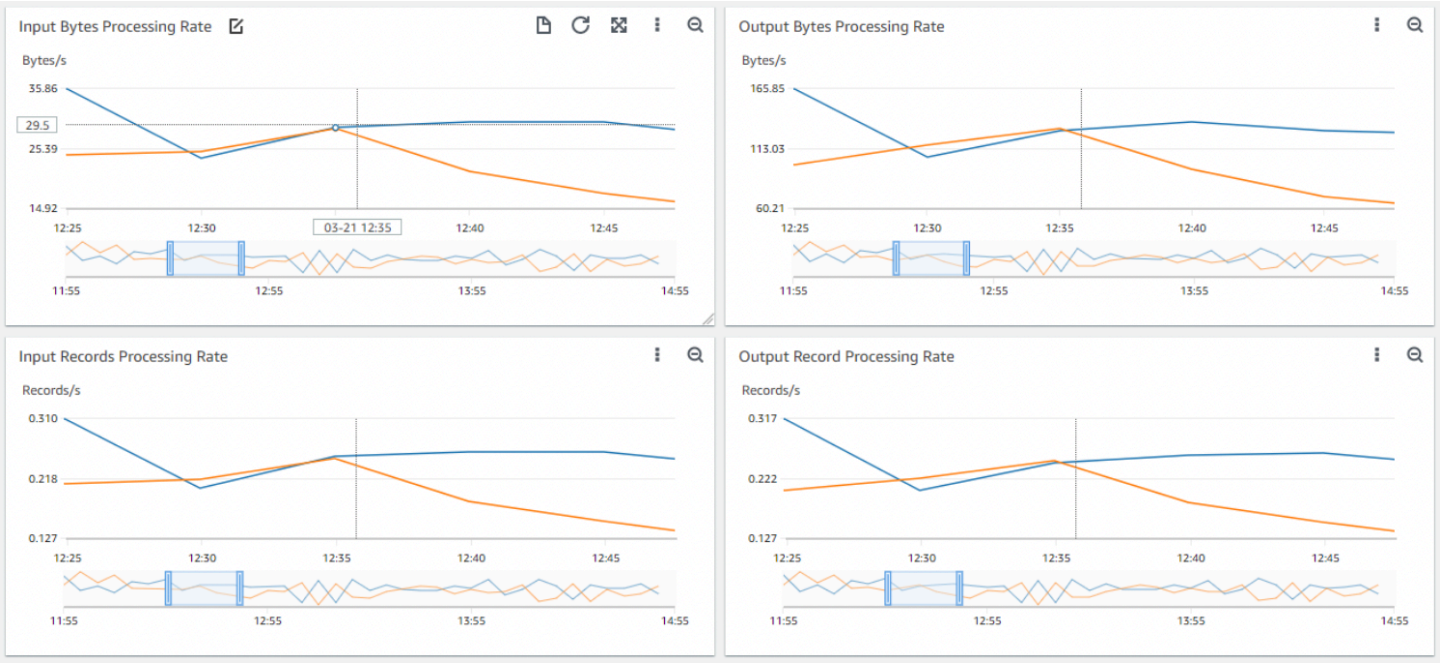
1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **custom** to set your own time range.
3. Choose **custom**, and then choose **Absolute** in the upper left corner of the box. Use the calendar picker or text field boxes to specify a time range.
4. After you specify a time range, choose **Apply**.

Set the time zone format

New interface

To specify the time zone for a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **Custom** to set your own time range.
3. Choose **Custom**, and then choose the dropdown in the upper right corner of the box. You can change the time zone to **UTC** or **Local time zone**.
4. After you make your changes, choose **Apply**.



Original interface

To specify the time zone for a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **custom** to set your own time range.
3. Choose **custom**, and then choose the dropdown in the upper right corner of the box. You can change the time zone to **UTC** or **Local timezone**.

Zoom in on a line graph or stacked area graph

In the CloudWatch console, you can use the mini-map zoom feature to focus on sections of line graphs and stacked area graphs without changing between zoomed-in and zoomed-out views. For example, you can use the mini-map zoom feature to focus on a peak in a line graph, so that you can compare the spike against other metrics in your dashboard from the same timeline. The procedures in this section describe how to use the zoom feature.

In the preceding image, the zoom feature focuses on a spike in a line graph that's related to the input bytes processing rate while also showing other line graphs in the dashboard that focus on sections from the same timeline.

New interface

To zoom in on a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**.
3. Choose **Browse**, and then select a metric or metrics to graph.
4. Choose **Options**, and select **Line** under ***Widget type***.
5. Choose and drag on the area of the graph that you want to focus on, and then release the drag.
6. To reset the zoom, choose the **Reset zoom** icon, which looks like a magnifying glass with a minus (-) symbol inside.

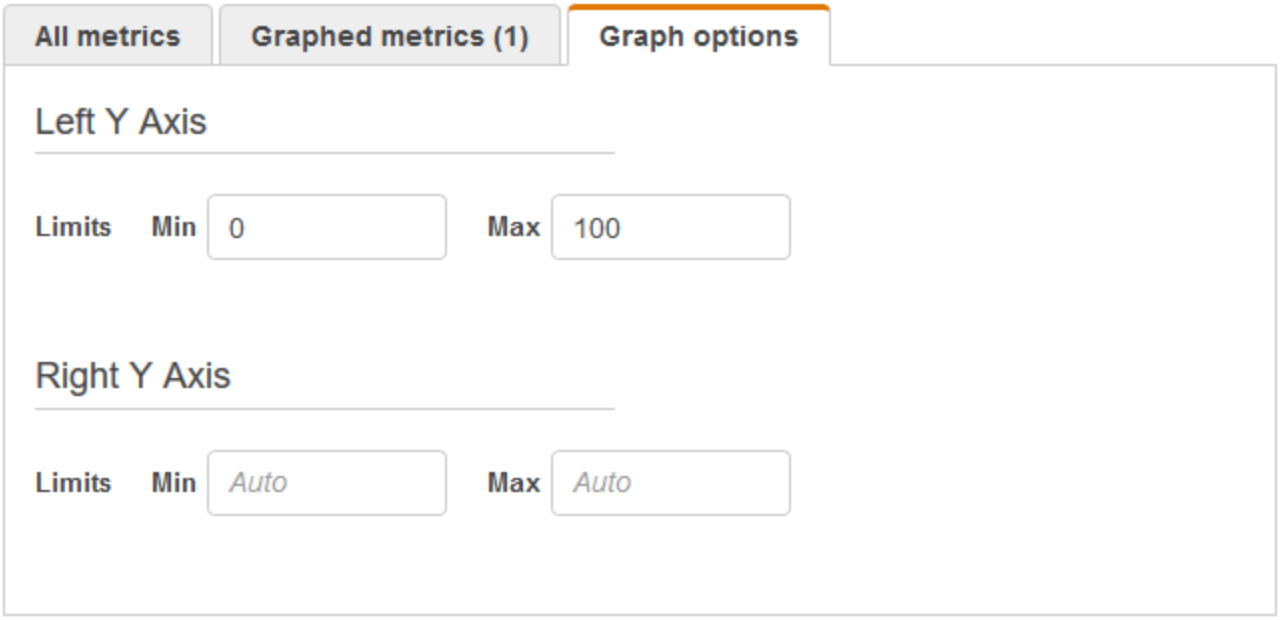
Original interface

To zoom in on a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **Classic metrics**. .
3. Choose **Classic metrics**, and then select a metric to graph.
4. Choose **Graph options**. Under ***Widget type*** select **Line**.
5. Choose and drag on the area of the graph that you want to focus on, and then release the drag.
6. To reset the zoom, choose the **Reset zoom** icon, which looks like a magnifying glass with a minus (-) symbol inside.

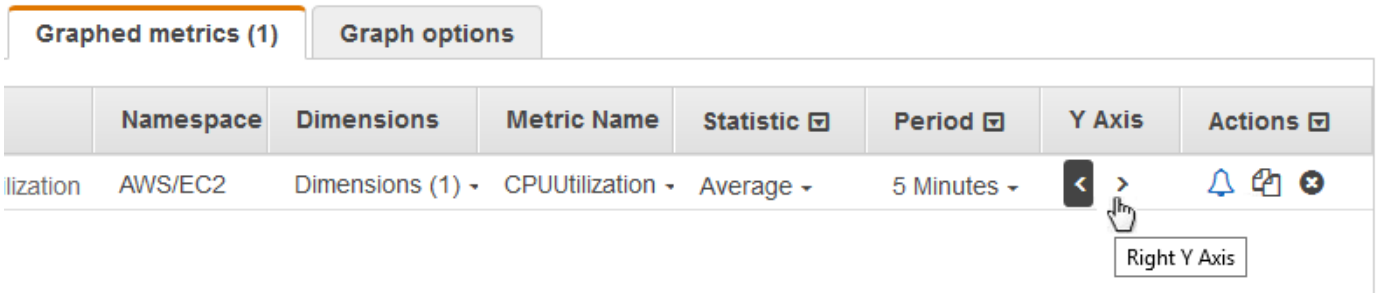
Tip

If you already created a dashboard that contains a line graph or stacked area graph, you can go to the dashboard and begin using the zoom feature.



Modify the y-axis for a graph

You can set custom bounds for the y-axis on a graph to help you see the data better. For example, you can change the bounds on a `CPUUtilization` graph to 100 percent so that it's easy to see whether the CPU is low (the plotted line is near the bottom of the graph) or high (the plotted line is near the top of the graph).

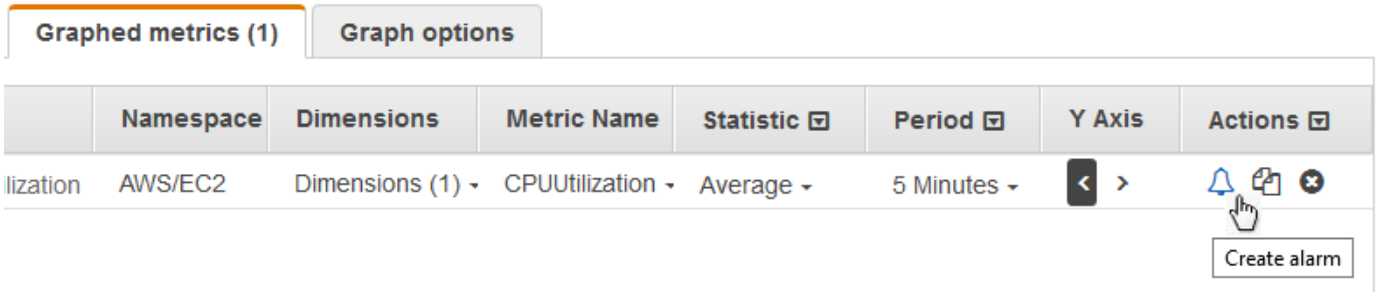


You can switch between two different y-axes for your graph. This is useful if the graph contains metrics that have different units or that differ greatly in their range of values.

To modify the y-axis on a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Select a metric namespace (for example, **EC2**) and then a metric dimension (for example, **Per-Instance Metrics**).
4. The **Browse** tab displays all metrics for that dimension in that namespace. To graph a metric, select the check box next to the metric.
5. On the **Graph options** tab, specify the **Min** and **Max** values for **Left Y Axis**. The value of **Min** can't be greater than the value of **Max**.

6. To create a second y-axis, specify the **Min** and **Max** values for **Right Y Axis**.
7. To switch between the two y-axes, choose the **Graphed metrics** tab. For **Y Axis**, choose **Left Y Axis** or **Right Y Axis**.



Create an alarm from a metric on a graph

You can graph a metric and then create an alarm from the metric on the graph, which has the benefit of populating many of the alarm fields for you.

To create an alarm from a metric on a graph

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Select a metric namespace (for example, **EC2**) and then a metric dimension (for example, **Per-Instance Metrics**).
4. The **Browse** tab displays all metrics for that dimension in that namespace. To graph a metric, select the check box next to the metric.
5. To create an alarm for the metric, choose the **Graphed metrics** tab. For **Actions**, choose the alarm icon.

6. Under **Conditions**, choose **Static** or **Anomaly detection** to specify whether to use a static threshold or anomaly detection model for the alarm.

   Depending on your choice, enter the rest of the data for the alarm conditions.
7. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the ALARM state to trigger the alarm. If the two values here

match, you create an alarm that goes to ALARM state if that many consecutive periods are breaching.

To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Alarm evaluation.

8. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.
9. Choose **Next**.
10. Under **Notification**, select an SNS topic to notify when the alarm is in ALARM state, OK state, or INSUFFICIENT_DATA state.

    To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    To have the alarm not send notifications, choose **Remove**.
11. To have the alarm perform Auto Scaling or EC2 actions, choose the appropriate button and choose the alarm state and action to perform.
12. When finished, choose **Next**.
13. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.
14. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

GetMetricWidgetImage: Metric Widget Structure and Syntax

MetricWidget is an input parameter for the https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/API_GetMetricWidgetImage.html API. It is a string in JSON format.

Contents

- Overall Structure
- Format for Each Metric in the Array of Metrics
- Annotation Properties Format
- yAxis Properties Format

Overall Structure

The `MetricWidget` string can include the following parameters:

metrics

The metrics to include in the graph, as a `metrics` array. This can include both raw metric and metric math expressions. One `metrics` array can include 1–100 metrics and expressions. For more information about the format of `metrics`, see Format for Each Metric in the Array of Metrics.

Type: Array of arrays

Required: Yes.

annotations

The horizontal and vertical annotations to add to the graph, as annotations arrays. For more information about the format, see Annotation Properties Format.

Required: No

end

The date and time for the end of the metrics shown in the graph. This can be expressed as either an absolute value, such as **2018-04-25T12:00:00.000Z** or a relative value such as **-PID**.

If you don't specify `end`, the default of `-PT0H` (the current time) is used.

Type: String

Required: No

height

The height of the widget in pixels. The default is 400.

Valid Values: 1–2000

Type: Integer

Required: No, but you should set this if you also set a value for `width`.

legend

Specifies the location and visibility of the graph legend. `legend` contains one field, `position`. The value of `position` can be `bottom`, `right`, or `hidden`. The default is `bottom`.

Type: String

Required: No

liveData

Specify `true` to display *live data* in the widget. Live data is data published within the last minute that has not been fully aggregated. For more information, see Use Live Data.

Type: Boolean

Required: No

period

The default period, in seconds, for all metrics in this widget. This default can be overridden within each metric definition. The default is 300.

Valid Values: 1, 5, 10, 30, 60, and any multiple of 60. 1, 5, 10, and 30 are only for high-resolution metrics.

Type: Integer

Required: No

region

This parameter is optional. If you include it, it must specify the local Region.

Type: String

Required: No

stacked

Specify `true` to display the graph as a stacked line, or `false` to display as separate lines. The default is false.

Type: Boolean

Required: No

start

The date and time for the start of the metrics shown in the graph. This can be expressed as either an absolute value, such as **2018-04-25T12:00:00.000Z** or a relative value such as **-PID**.

If you don't specify `start`, the default of `-PT3H` (three hours ago) is used.

Type: String

Required: No

stat

The default statistic to be displayed for each metric in the array. This default can be overridden within the definition of each individual metric in the `metrics` array.

If you omit this, the default of `Average` is used.

Valid Values: `SampleCount` | `Average` | `Sum` | `Minimum` | `Maximum` | `p??` | `TM(??:??)`, `TC(??:??)` | `TS(??:??)` | `WM(??:??)` | `PR(??:??)` | `IQM`

Type: String that is a valid CloudWatch statistic.

Required: No

theme

The color palette used to style the graph. The default is `light`.

Valid Values: `light | dark`

Type: String

Required: No

timezone

The time zone to use for displaying the times in the graph. The format is + or - followed by four digits. The first two digits indicate the number of hours ahead or behind of UTC, and the final two digits are the number of minutes. For example, `+0130` indicates a time 1 hour and 30 minutes ahead of UTC. The default is `+0000`.

Type: String

Required: No

title

The title to be displayed for the graph.

Type: String

Required: No

view

The display format. Specify `timeSeries` to display this metric as a line graph. Specify `bar` to display the metric as a bar graph. Specify `pie` to display the metric as a pie graph. The default is `timeSeries`.

Valid Values: `timeSeries | bar | pie`

Type: String

Required: No

width

The width of the widget in pixels. The default is 600.

Valid Values: 1–2000

Type: Integer

Required: No, but you should set this if you also set a value for `height`.

yAxis

Limits for the minimums and maximums of the y-axis. This applies to every metric being graphed, unless specific metrics override it. For more information about the format, see yAxis Properties Format.

Type: YAxis object

Required: No

Format for Each Metric in the Array of Metrics

Each item in the `metrics` array is a CloudWatch metric to display in the graph, or to use as part of a math expression displayed in the graph. For more information about math expressions, see Use Metric Math in the Amazon CloudWatch User Guide.

Each metric in the array has the following format:

```
[Namespace, MetricName, Dimension1Name, Dimension1Value, Dimension2Name, Dimension2Value...
            {Options Object}]
```

Namespace

The AWS namespace containing the metric. To use the same namespace as the previous metric in the array, you may specify `"."` for each entry after the first.

Type: String

Required: Yes

MetricName

The name of the CloudWatch metric. To use the same name as the previous metric in the array, you may specify `"."` for each entry after the first.

Type: String

Required: Yes

DimensionName

The name of a dimension to further refine what data is shown. To use the same dimension name as the previous metric in the array, you may specify `"."` for each entry after the first. You may specify zero dimensions for a metric, or up to as many dimensions as the metric supports.

Type: String

Required: No

DimensionValue

The value to use for that dimension for the metric. Required if there is a corresponding dimension name.

Type: String

Required: No, unless there is a corresponding dimension name.

Options Object

Specifies either custom rendering properties to be used for the specified CloudWatch metric, or a math expression to display on the graph. For more information about the format, see Options Object Format.

Type: Options Object

Required: No

Examples

```
// The simplest example, a metric with no dimensions
        [ "AWS/EC2", "CPUUtilization" ]

 // A metric with a single dimension
        [ "AWS/EC2", "CPUUtilization", "InstanceId", "i-01234567890123456" ]

 // A metric with a single dimension and rendering properties
        [ "AWS/EC2", "DiskReadBytes", "InstanceId", "i-01234567890123456", { yAxis:
 "right"} ]

 // The following example graphs the DiskReadBytes metric for three instances.
        [ "AWS/EC2", "DiskReadBytes", "InstanceId", "i-01234567890123456" ],
        [ ".", ".", ".", "i-abc" ],
        [ ".", ".", ".", "i-123" ]
```

Options Object Format

Specifies either custom rendering properties to be used for the specified CloudWatch metric, or a math expression to display on the graph.

If this object is specified as part of a CloudWatch metric in the `metrics` array, it sets custom rendering properties for this metric and overrides the defaults used for the whole graph.

You can also specify this object to add a math expression to the graph. In this case, the other settings in this object specify the display options for the result of the math expression.

This section describes the format of these options objects.

color

The six-digit HTML hex color code to be used for this metric or expression.

Type: String

Required: No

expression

A math expression to display. For more information about supported math expression functions and format, see Metric Math Syntax and Functions in the Amazon CloudWatch User Guide.

Type: String that is a valid CloudWatch metric math expression.

Required: Yes if this is an expression.

label

The label to display for this metric or expression in the graph legend. If this is not specified, the metric is given an auto-generated label that distinguishes it from the other metrics in the widget.

Type: String

Required: No

id

An identifier for this metric or expression, which must be unique within this widget. The id can be used as a variable to represent this metric or expression within math expressions. Valid characters are letters, numbers, and underscore. The first character must be a lowercase letter.

Type: String

Required: No

period

The period for this metric, in seconds. If specified, this overrides the default period used for other metrics in this graph. This parameter is not applicable for math expressions.

Valid Values: 1, 5, 10, 30, 60, and any multiple of 60. 1, 5, 10, and 30 are only for high-resolution metrics.

Type: Integer

Required: No

stat

The statistic to be displayed for this metric, if it is to be different than the statistic used for the other metrics in the graph. This parameter is not applicable for math expressions.

Valid Values: `SampleCount` | `Average` | `Sum` | `Minimum` | `Maximum` | p*??*

Type: String that is a valid CloudWatch statistic.

Required: No

visible

Specifies whether this metric or expression is shown on the graph. The default is `true`.

Setting `visible` to `false` is useful if you want to hide the raw metrics that are used in math expressions, and show only the expression results on the graph.

Type: Boolean

Required: No

yAxis

Where on the graph to display the y-axis for this metric or expression. The default is `left`.

Valid Values: `left` | `right`

Type: String

Required: No

Example

In the following example, CloudWatch retrieves a custom `apiLatency` metric. At the top, the p50 statistic is specified to show the median value. Next, for the same metric on the same instance (this

is specified by the four fields that are just periods), the Average value is graphed. Next is an options object with a math expression, showing the halfway value of the two metrics. Finally, another expression shows the rate of change.

To show only the results of the two expressions on the graph and hide the raw metrics, you could change the first two instances of `visible` to `false`.

```
{
        "metrics": [
            [
                "MyNamespace",
                "apiLatency",
                "InstanceId",
                "i-0987654321abcdef0",
                {
                    "id": "m1",
                    "stat": "p50",
                    "label": "Median value",
                    "visible": true,
                    "color": "#dddddd",
                    "yAxis": "left",
                    "period": 300
                }
            ],
            [
                ".",
                ".",
                ".",
                ".",
                {
                    "id": "m2",
                    "stat": "Average",
                    "label": "Average value",
                    "visible": true,
                    "color": "#cccccc",
                    "yAxis": "left",
                    "period": 300
                }
            ],
            [
                {
                    "expression": "(m1+m2)/2",
                    "id": "e1",
```

```
                    "label": "Half way between average and median",
                    "visible": true,
                    "color": "#000000",
                    "yAxis": "left"
                }
            ],
            [
                {
                    "expression": "RATE(e1)",
                    "yAxis": "right",
                    "label": "rate of change of the half way point"
                }
            ]
        ]
    }
```

Annotation Properties Format

A single graph can have multiple horizontal and vertical annotations. All horizontal annotations are specified in one `horizontal` field, and all vertical annotations are specified in one `vertical` field.

horizontal

An array of horizontal annotations. Horizontal annotations have several options for fill shading, including shading above the annotation line, shading below the annotation line, and "band" shading that appears between two linked annotation lines as part of a single annotation. Each horizontal annotation in the array that does not have band shading has the following format:

```
{value, label, color, fill, yAxis, visible}
```

Each horizontal annotation that does have band shading has the following format:

```
[{value, label, color, yAxis, visible}, {value, label}]
```

vertical

An array of vertical annotations. Vertical annotations have several options for fill shading, including shading before the annotation line, shading after the annotation line, and "band" shading that appears between two linked annotation lines as part of a single band annotation. Each vertical annotation in the array that does not have band shading has the following format:

```
{value, label, color, fill, visible}
```

Each vertical annotation that does have band shading has the following format:

```
[{value, label, color, visible}, {value, label}]
```

The `horizontal` array can include the following fields.

value

The metric value in the graph where the horizontal annotation line is to appear. On a band shading annotation, the two values for `Value` define the upper and lower edges of the band.

On a graph with horizontal annotations, the graph is scaled so that all visible horizontal annotations appear on the graph.

Type: Float

Required: Yes, if horizontal annotations are used.

label

A string that appears on the graph next to the annotation.

Type: String

Required: No

color

The six-digit HTML hex color code to be used for the annotation. This color is used for both the annotation line and the fill shading.

Type: String

Required: No

fill

How to use fill shading with the annotation. Valid values are `above` for shading above the annotation, `below` for shading below the annotation, and `none` for no shading. If `fill` is omitted, there is no shading.

The exception is an annotation with band shading. These annotations always have shading between the two values, and any value for `fill` is ignored.

Type: String

Required: No

visible

Set this to `true` to have the annotation appear in the graph, or `false` to have it be hidden. The default is `true`.

Type: Boolean

Required: No

yAxis

If the graph includes multiple metrics, specifies whether the numbers in `Value` refer to the metric associated with the left Y-axis or the right Y-axis. Valid values are `right` and `left`.

Type: String

Required: No

The `vertical` array can include the following fields.

value

The time stamp where the vertical annotation line is to appear. This must be specified as an absolute time stamp, such as `2018-08-28T15:25:26Z`. On a band shading annotation, the two values for `Value` define the beginning and ending edges of the band.

Type: String

Required: Yes, if vertical annotations are used.

label

A descriptive string that appears on the graph next to the annotation.

Type: String

Required: No

color

The six-digit HTML hex color code to be used for the annotation. This color is used for both the annotation line and the fill shading.

Type: String

Required: No

fill

How to use fill shading with the annotation. Valid values are `before` for shading before the annotation, `after` for shading after the annotation, and `none` for no shading. If `fill` is omitted, there is no shading.

The exception is an annotation with band shading. These annotations always have shading between the two values, and any value for `fill` is ignored.

Type: String

Required: No

visible

Set this to `true` to have the annotation appear in the graph, or `false` to have it be hidden. The default is `true`.

Type: Boolean

Required: No

Examples

```
// A single horizontal annotation with fill shading above the annotation line, based on
 the metric associated with the right Y-axis

"annotations": {
     "horizontal": [
         {
              "visible":true,
              "color":"#9467bd",
              "label":"Critical range",
              "value":20,
              "fill":"above",
```

```
             "yAxis":"right"
         }
    ]
}

// A horizontal band annotation. Each value has a label, but other parameters for the
 band need to be specified only with the first number

"annotations": {
    "horizontal": [
        [
             {
                 "label":"Band top",
                 "value":200,
                 "color":"#9467bd",
                 "visible":true,
                 "yAxis":"right"
             },
             {
                 "value":95.5,
                 "label":"Band bottom"
             }
         ]
     ]
}

// A single vertical annotation with fill shading after the annotation line

"annotations": {
    "vertical": [
        {
            "visible": true,
            "color": "#9467bd",
            "label": "Bug fix deployed",
            "value": "2018-08-28T15:25:26Z",
            "fill": "after"
        }
    ]
}

// A vertical band annotation. Each annotation line has a label, but other parameters
 for the band are specified only with the first value
```

```
"annotations": {
    "vertical": [
        [
            {
                "label": "Band start",
                "value": "2018-08-27T15:25:26Z",
                "color": "#9467bd",
                "visible": true
            },
            {
                "value": "2018-08-28T15:25:26Z",
                "label": "Band end"
            }
        ]
    ]
}
```

yAxis Properties Format

Defines the minimum and maximum values for the Y-axis of the graph. Set this within the `MetricWidget` object to affect all metrics in the widget. To override the widget settings for a particular metric, set it in the options object for that metric in the `metrics` array.

left

Optional `min`, `max`, `label`, and `showUnits` settings for the left Y-axis.

Type: YAxis object

Required: No

right

Optional `min`, `max`, `label`, and `showUnits` settings for the right Y-axis.

Type: YAxis object

Required: No

Each of the `left` and `right` objects can include the following parameters:

min

The minimum value for this Y-axis.

Type: Float

Required: No

max

The maximum value for this Y-axis.

Type: Float

Required: No

label

The label for this Y-axis.

Type: String

Required: No

showUnits

Specifies whether to display the unit of the metrics on this Y-axis. The default is `true`.

Type: Boolean

Required: No

Example

```
{
  left: {
    min: 0,
    max: 100,
    label: "Duration (ms)",
    showUnits: false
  },
```

```
  right: {
    min: 0,
    label: "Invocations"
  }
}
```

Explore related telemetry

Computer systems can generate a large amount of telemetry, including both metrics and logs, and complex systems even more so. When looking at a specific set of telemetry, it can be a challenge to find other telemetry related to your initial set. It can take advanced training to gain the skills needed to find issues and troubleshoot them. Because systems are complex, understanding what is going on can involve viewing metrics and logs from many different services and resources, requiring context switching and navigating between systems.

The Amazon CloudWatch **Explore related** feature offers access to AWS resource relationships, related metrics, and logs across service consoles, enhancing observability and efficiency for operators of all skill levels. When viewing alarms or anomalies in CloudWatch dashboards, or metrics in AWS, users can quickly find and view metrics and logs for related resources in your system.

CloudWatch provides visibility into metrics and logs tied to specific resources. The **Explore related** pane extends that by allowing you to correlate your infrastructure resources to your workloads with all of their associated telemetry. This gives you quick access to the information you need to troubleshoot infrastructure-related issues. You view the relationship between resources, and their related telemetry in the **Explore related** pane. The **Explore related** pane is accessed from CloudWatch or from other AWS consoles showing resources or telemetry.

> **Note**
>
> **Explore related** is currently limited in accounts set up as monitoring accounts in CloudWatch cross-account observability. You should access **Explore related** from the source accounts where the resources are originally created and managed. In source accounts, you can navigate between connected resources, and view related logs and metrics.

The following topics discuss the details of exploring related telemetry.

Topics

- What is related telemetry?
- How to access the Explore related pane
- Navigating related telemetry
- Using the topology map
- Finding a specific resource
- Permissions and prerequisites needed to view and explore related telemetry
- How does CloudWatch find related telemetry?
- AWS services that support related telemetry
- How to add related information to custom telemetry sent to CloudWatch

What is related telemetry?

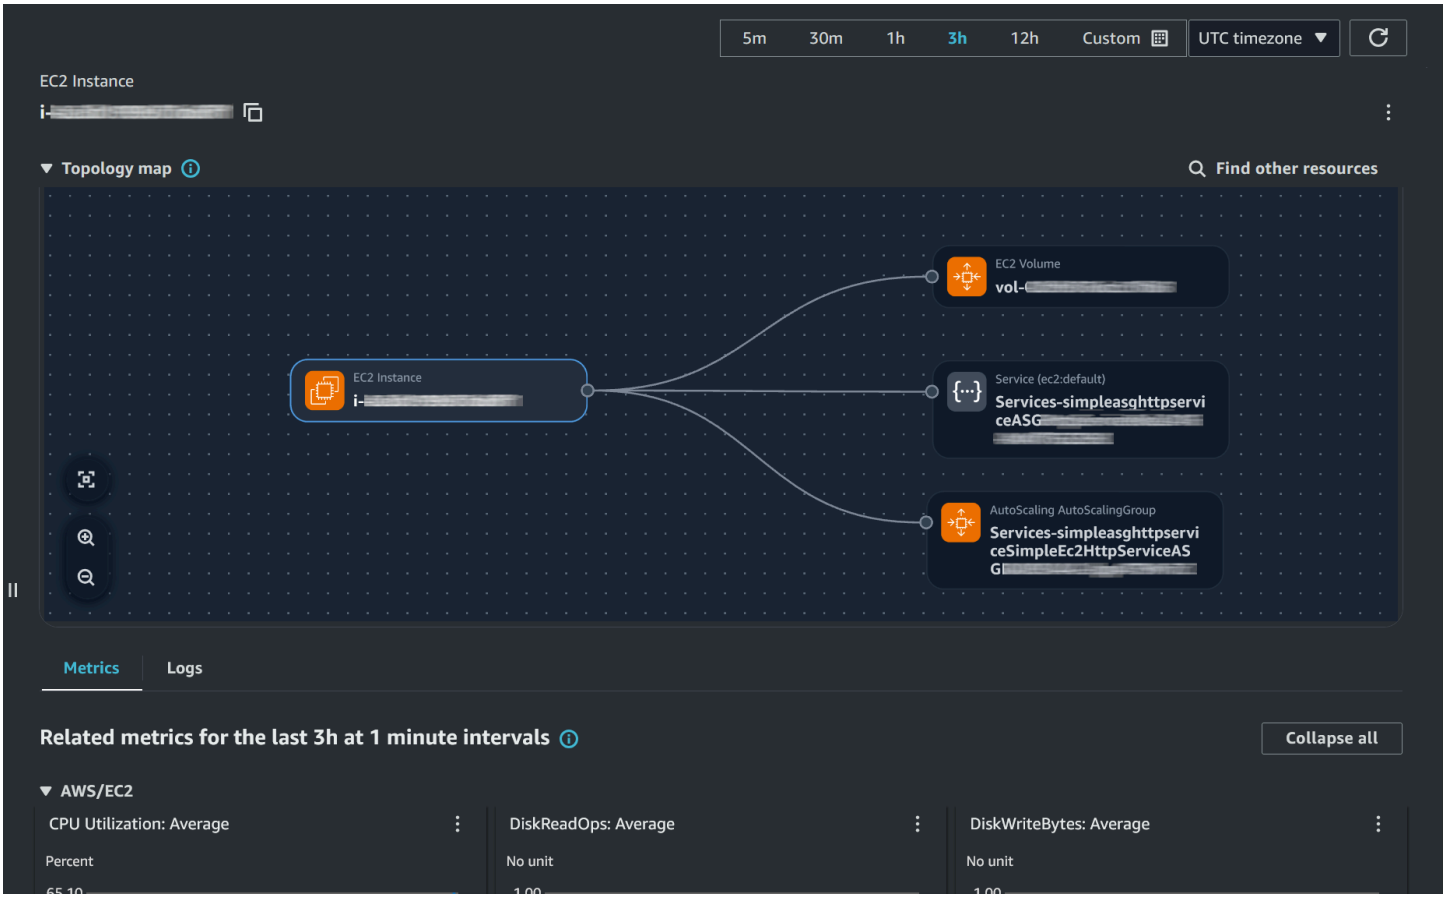
Related telemetry is metrics and log data from resources that are related to the current resource or service. Traditionally, you might look at the metrics and logs that are related to a single load balancer, or all telemetry related to Amazon EC2. The **Explore related** feature in Amazon CloudWatch adds an interactive *topology map*. The map is a resource-centric view where you can find metrics and logs for a specific resource, but you can also see how that resource is connected to other resources.

For example, if you are looking at the telemetry for a load balancer in the **Explore related** pane, besides the metrics and logs associated with that load balancer, the maps shows you the target groups for that load balancer. Selecting one of the target groups will then show you the Amazon EC2 instances associated with that target group. At each step in this process, the telemetry, including metrics and logs, for the selected resources are shown, making it easy to quickly find the telemetry you are looking for, or to explore the telemetry, looking for the cause of a specific issue.

How to access the Explore related pane

Within the CloudWatch console, there are multiple ways to access telemetry related to your current view. For example, if you are looking at a graph on a dashboard, and you want to view telemetry related to that graph or an aspect of the graph, you can choose to explore related data directly from that graph. From many places in the console, you can choose an **Explore related** menu item, or select a compass icon () to show the **Explore related** pane.

You can access the exploring experience from entry points throughout the CloudWatch console (and other AWS consoles), including:



- **Metrics navigation** – When you choose **Metrics** then **Classic metrics** from the CloudWatch console left hand menu, the tile for any supported service or metric source will show the compass icon that brings up related telemetry in the bottom right corner.
- **Metric legend** – When viewing any metric graph (in CloudWatch or other AWS consoles), hovering over the legend of the graph shows information about the data, as well as an **Explore related** button that brings up the related telemetry.
- **Metric datapoints** – When viewing any metric graph, hovering over a datapoint in the graph shows information about the metric, as well as a compass icon, to bring up the related telemetry.
- **Metric search** – When searching for metrics in CloudWatch, if you choose a found metric name, you can select **Explore related** from the menu that pops up, which will bring up the related telemetry.
- **Console toolbar** – In many AWS console pages, the console toolbar (usually in the upper right of the console) includes a CloudWatch service icon, which will bring up CloudWatch tools, including the **Explore related** pane.

Depending on where you access the pane from, the default context of the pane will show an appropriate filter, if possible.

Navigating related telemetry

When you select any of the entry points to the **Explore related** pane, it appears on the right side of the CloudWatch console. This pane gives you access to view and find telemetry related to *entities*, in your system. An entity is a resource, such as an Amazon EC2 instance, or a service, such as an application that you have built. You can work within this pane without interrupting your current workflow, because it opens to the side of your initial page.

The following image shows the **Explore related** pane focused on a single Amazon EC2 instance, and the associated entities.

The top of the **Explore related** pane is a visual *topology map* (map) of the current entity and other related entities. The currently selected entity sets the focus for the pane. There are two ways to select an entity.

- Topology map – The *map* is a visual display of the current entity with focus. It also displays any related entities, allowing you to navigate around the set of resources and services that are related to each other.
- Find other resources – You can use the **Find other resources** button to filter and search for entities to use as the focus.

The bottom part of the pane shows you an automated search of metrics and logs for the current focal entity.

By default, the focus is set to an entity matching the location from which you accessed the **Explore related** pane. For example, if you accessed it by clicking the compass icon associated with a metric from a specific Amazon EC2 instance, then the focus will be set to that Amazon EC2 instance.

When you select an AWS resource for the focus in the **Explore related** pane, you can navigate to the resource-specific console for the selected resource. For example, if you have selected an Amazon EC2 instance, you can select the **View in EC2 console** link to open the Amazon EC2 console with that instance selected.

When you set a focus, the metrics and logs are automatically filtered to show the telemetry related to your focus.

- **Metrics** – Each metric is shown as a graph for the time period that you have chosen.

  Much like any dashboard graph in CloudWatch, you can hover over or select a graph to get more information about the metric graph, and to see options including viewing in CloudWatch metrics. Choosing to view in CloudWatch will open the metrics view with the same viewing context as the **Explore related** pane, including resource and time range.

- **Log patterns** – CloudWatch analyzes the log groups associated with the focal resource and shows common patterns in those logs. For more information about log patterns, see Pattern analysis in the *Amazon CloudWatch Logs User Guide*.

  You can select **Compare timerange** to choose another time range and compare logs across the two time ranges.

  You can select **View in Logs Insights** to analyze the logs in CloudWatch Logs Insights with the same options as your current view, including resource, log group, and time range. For more information, see Analyzing log data with CloudWatch Logs Insights in the *Amazon CloudWatch Logs User Guide*.

- **Log groups** – The log groups that contain the logs are shown.

  You can select the log groups and then perform one of the following actions:

  - Choose **Start tailing in Live Tail** to view a streaming list of new log events as they are ingested for the selected log groups. The Live Tail session is started in the CloudWatch console. For more information on Live Tail, see Troubleshoot with CloudWatch Logs LiveTail in the *Amazon CloudWatch Logs User Guide*.
  - Choose **Query in Logs Insights** to open Logs Insights with a query scoped to just those log groups, applying your current context, including resources and time range.

Using the topology map

The *topology map* (map) is a visual display of the current focal entity and its related resources or services. You can use this interactive visualization to see the connections between different resources and services, and explore the relationships between components in your system. For example, if you are viewing *load balancer* resource, the map will show connected *target group* resources. Selecting a target group will display the associated instances. The visualization of connectivity helps operators understand and explore the relationships between different resources and services in your system.

You can drag the map, and zoom in and out, to see more of the associated entities, or to focus on fewer entities.

When you select an associated entity, like a target group, the pane's focus shifts to show telemetry for that entity. The map updates to center on the selected target group, displaying its connections to other entities, such as the load balancer and and any Amazon EC2 instances that are specified in that target group. As you navigate through different entities in the map, the metrics and logs at the bottom of the pane dynamically update, providing you with relevant telemetry for the newly selected resources.

Finding a specific resource

If a resource doesn't appear on the topology map, you can use the **Find other resources** feature to locate it. You can filter resources by tag or type, then select the ones you are looking for. After you have found resources to focus on, you are returned to the topology map, with those resources selected, to browse associated entities and telemetry.

> **Note**
>
> There are many reasons why you might not see your resources on the topology map. For example:
>
> - It's not related to the current focal entity.
> - You don't have permissions to access associated entities or telemetry.
> - The resource or service may not support telemetry or associated entities.

By using **Find other resources**, you can discover and visualize resources that may not be directly connected or visible in the current map. This ensures that you can access and analyze all relevant components of your infrastructure.

Select a resource with Find resources.

1. Open the **Explore related** pane from any of the entry points in the CloudWatch console.
2. Choose **Find resources**.
3. Choose the time frame for which you want to view logs or metrics.
4. Choose **Resource types**, then select the type of the resource you want to focus on from the drop down list, for example, **EC2 instances**.
5. Optionally, filter the set of resources by providing a tag to filter on. You can do this by selecting the **Filter resources by tags** filter, or by choosing the label that says **5 tags found** (the number will depend on the tags in your system). This gives you a list of tags to choose from.

   After you have selected the tags, the list of resources is automatically filtered to only those that are associated with those tags.
6. Optionally, choose one or more specific resources from the ones found that match your filters.
7. Choose **Show on map** to return to the **Topology map** with your resources selected.

Your list of **Metrics** and **Logs** is now filtered to just logs and metrics that are associated with that resource type. You can choose the **Metrics** or **Logs** tab to view the kind of telemetry that you want to view.

Permissions and prerequisites needed to view and explore related telemetry

To explore related telemetry, you must be getting entity information with the telemetry from your workloads, and you must have the proper permissions to view that data.

Many services send entity information automatically. For workloads that use the CloudWatch agent, you must have at least version `1.300049.1` of the agent, and you must configure it correctly. For information about configuring the agent, see How to add related information to custom telemetry sent to CloudWatch. For workloads running on Amazon EKS, you must have at least version `v2.3.1-eksbuild.1` of the Amazon CloudWatch Observability EKS add-on. For more information about this add-on, see Quick start: OTel Container Insights on Amazon EKS.

To explore related telemetry you must be signed in with certain permissions. Exploring related telemetry is a read-only activity, and requires at least read-only access to CloudWatch.

The permissions needed for viewing associations between telemetry and entities are: `logs:ListLogGroupsForEntity`, `logs:ListEntitiesForLogGroup`, `cloudwatch:ListEntitiesForMetric`, and `application-signals:ListObservedEntities`.

Each of the following AWS managed policies will provide the CloudWatch permissions needed to access related telemetry in the CloudWatch console:

- CloudWatchFullAccessV2 – Provides full access to CloudWatch.
- CloudWatchReadOnlyAccess – Provides read-only access to CloudWatch.
- ReadOnlyAccess – Provides read-only access to AWS services and resources.

Additionally, you must have at least read-only access (`Describe*` and `Get*`) to any resources in the topology map, in order for CloudWatch to discover and display relationships.

For more details about using policies to control access, see Identity-based policy examples for Amazon CloudWatch.

How does CloudWatch find related telemetry?

The CloudWatch **Explore related** pane shows you metrics and logs that are related to each other, but how does that work?

Metrics and logs that are sent to CloudWatch can include an optional *entity* to which they are related. Typically, the entity will be a representation of what the telemetry is about. For example, a metric about CPU usage is about an Amazon EC2 instance, and will use that instance as its entity. When you view that metric in the **Explore related** pane, it shows you other telemetry for that same instance.

The *topology map* (map) in the **Explore related** pane displays the currently selected resource, along with *related resources*. For AWS resources, CloudWatch automatically displays other resources that it knows are related. For example, if you are viewing an Amazon EC2 instance, the map will also display any Amazon EBS volumes that are attached to the instance. Selecting a volume shows telemetry for the volume, and the map is updated to display resources related to the volume. It also displays resources that are part of the same *service*.

The entity information associated with your telemetry defines the resource that the telemetry is associated with, such as the Amazon EC2 instance. However, it can also include contextual data about the resource. For example, if you have a website application that includes resources such as an Amazon EC2 instance and a database, the entity information can include the website application as a service. In this case, the topology map shows the service as a related entity, and when you select it, it displays the instances and database. This can make finding all the telemetry for a service simpler.

> **Note**
>
> CloudWatch must have received telemetry with entity information within the last three hours in order to find related resources and telemetry.

Where does the entity data come from?

There are different ways that CloudWatch gets entities for telemetry:

- Most telemetry sent to CloudWatch from AWS services are associated with resources automatically. For a complete list of supported resources, see AWS services that support related telemetry.
- The CloudWatch agent automatically adds entity information to the telemetry that it sends to CloudWatch.

  > **Note**
  >
  > You may need to update your CloudWatch agent to the latest version to include entity data. For more information, see Collect metrics, logs, and traces using the CloudWatch agent, and Configure CloudWatch agent service and environment names for related entities.

- When you are submitting your own telemetry, you can add entity information to the data. For more information, see How to add related information to custom telemetry sent to CloudWatch.
- CloudWatch makes a best effort to recognize the entity information associated with other telemetry (for example, custom telemetry that you send to CloudWatch without any entity information).

Where does service data come from?

Besides recognizing the natural connections between resources, such as an instance resource and an attached volume resource, CloudWatch can also group resources by *service*. For example, a service might be a website application. An Amazon EC2 instance with a web server, and another with a database might both be part of the same service, and are connected on the topology map based on that service.

There are different ways that CloudWatch gets a service name for telemetry, including:

- Application signals or otel instrumented telemetry use the `OTEL_SERVICE_NAME` environment variable used by supported OpenTelemetry instrumentation libraries to set the service name.
- The CloudWatch agent configuration allows configuring a service name. For more information, see Configure CloudWatch agent service and environment names for related entities.
- Kubernetes workloads use a corresponding name from the cluster, such as the Deployment, ReplicaSet, Pod, or Container, for the service name.
- For Amazon EC2 workloads, the service can come from tags (the `service`, `application`, or `app` tags).

> **Note**
>
> To use tags to generate service names, you must first set up instance metadata for the Amazon EC2 instance.

- When you are submitting your own telemetry, you can add service information to the data. For more information, see How to add related information to custom telemetry sent to CloudWatch.
- When it cannot use the above, CloudWatch uses the name of the IAM role that sends the metrics as the service name. This, for example, can provide a service name for Amazon ECS telemetry.

AWS services that support related telemetry

The following table lists the AWS services that support related entity information in their CloudWatch telemetry. Services or resources that are not listed in the table do not have related entity information exposed in CloudWatch.

Note

For services that use the CloudWatch agent, you may need to update the agent to the latest version to get related telemetry. For information about sending related entity information with your own custom metrics, see How to add related information to custom telemetry sent to CloudWatch.

AWS Service	Resource	Metrics	Logs
Amazon API Gateway	`AWS::ApiGateway::Method`	Yes	No
Amazon API Gateway	`AWS::ApiGateway::Resource`	Yes	No
Amazon API Gateway	`AWS::ApiGateway::RestApi`	Yes	No

How to add related information to custom telemetry sent to CloudWatch

When you publish your own metrics and logs to CloudWatch, the entity information needed for related telemetry is not there by default. When you send metrics to CloudWatch or logs to CloudWatch Logs (with the PutMetricData or PutLogEvents operations), you can add entity information to those logs or metrics. The entity information is associated with the telemetry, and used in the **Explore related** feature to find related telemetry that is associated with the same entity.

The entity sent with telemetry represents a resource or service that the telemetry is associated with. For example, a metric about a service, or that comes from an AWS resource. To identify the entity associated in your code, you create a set of `KeyAttributes` and optional `Attributes` of the entity.

> **Note**
>
> CloudWatch can only find related resources for entities that have had telemetry sent within the previous three hours. If your resource only emits sparse telemetry (less than once every 3 hours), you may want to send additional *heartbeat* telemetry, to keep the entity active within CloudWatch.

For information on how to add entity information, see Entity information in EMF format.

The following sections describe how to create the `KeyAttributes` and `Attributes` so that CloudWatch can identify the resources and services associated with the telemetry.

Identifying the entity with the KeyAttributes object

The `KeyAttributes` property of the Entity objects (in CloudWatch or in CloudWatch logs) uniquely identifies the entity for CloudWatch. It is a list of key-value pairs. Entities with the same `KeyAttributes` are considered to be the same entity. Telemetry associated with the same entity are considered related, and can be easily found in the **Explore related** pane.

> **Note**
>
> In the CloudWatch API, the property is called `KeyAttributes`. In the CloudWatch Logs API, the property is called `keyAttributes`. Here they are treated as the same property.

There are five possible types of object that an `Entity` can represent.

- **AWS::Resource** – The entity represents an AWS resource, such as a DynamoDB table or Amazon EC2 instance.
- **AWS::Service** – The entity represent an AWS service, such as Amazon S3. This might be used, for example, when calling the `ListBuckets` operation, which is not associated with a specific Amazon S3 resource.
- **Service** – The entity represents a workload running in your account. For example, an application or service that you manage.
- **Resource** – The entity represents a resource that is not managed by AWS, for example, operating system resources, such as processes or file volumes.
- **RemoteService** – The entity represents an external service in a remote call. For example, a remote call to a database, external cache, or an external endpoint.

Depending on which of the above types you are trying to represent, you must provide the correct key-value pairs for the `KeyAttributes`. The following describes each type.

AWS::Resource

To specify an AWS Resource, you must include the following three key value pairs:

- `"Type": "AWS::Resource"` – This key-value pair identifies the entity as an AWS resource.
- `"ResourceType": "<resource-type>"` – The string value of the `ResourceType` is the CloudFormation resource type string. For example, `AWS::DynamoDB::Table`.

- `"Identifier": "<resource-id>"` – The primary identifier for the resource. For more information, see primaryIdentifier in the *Extension Development for CloudFormation User Guide*.

AWS::Service

To specify an AWS Service, you must include the following two key value pairs:

- `"Type": "AWS::Service"` – This key-value pair identifies the entity as an AWS service.
- `"Name": "<service-name>"` – The value of the `Name` is the CloudFormation service name string. For example, `AWS::DynamoDB`.

Service

To specify a service that is not operated by AWS, you must include the following three key value pairs:

- `"Type": "Service"` – This key-value pair identifies the entity as a service.
- `"Name": "<service-name>"` – This represents the name of the service that is sending the metrics. For example, `my-service-frontend` or `api.myservice.com`.
- `"Environment": "<environment-name>"` – This attribute specifies where the service is hosted, or the environment to which it belongs. For example `us-west-2`, or `myservice.production`.

Resource

To specify a resource that is not provided by AWS, you must include the following three key value pairs:

- `"Type": "Resource"` – This key-value pair identifies the entity as a resource.
- `"ResourceType": "<resource-type>"` – A string specifying the type of resource. For example, `K8s::Pod` for a Kubernetes Pod.
- `"Identifier": "<resource-id>"` – A string identifier for the resource. Can contain multiple names, separated by pipes. For example, a Kubernetes Pod might be represented by it's cluster name, namespace, and pod name, such as `MyCluster|MyNamespace|MyPod`.

RemoteService

To specify a remote service, you must include the following two key value pairs:

- `"Type": "RemoteService"` – This key-value pair identifies the entity as a remote service.
- `"Name": "<remote-service-name>"` – Specifies how the application refers to the external service in a remote call. For example, `api.test.myservice.com`.

Providing additional details about the entity with the Attributes object

You can provide additional details about the `Entity` that you provide with your telemetry. This can include details about the platform, resource, application, or telemetry provider. The following tables describes the key words that you can use for each of these types of data.

> **Note**
>
> In the CloudWatch API, the property is called `Attributes`. In the CloudWatch Logs API, the property is called `attributes`. Here they are treated as the same property.

Platform details

Keyword	Usage	Domain of values	Examples
`PlatformType`	Defines the hosted-in platform.	AWS::EKS, AWS::ECS, AWS::EC2, AWS::Lambda, K8s, Generic	`AWS::EC2`
`EKS.Cluster`	Name of the Amazon EKS cluster.	Alphanumeric string with basic delimiters.	`FlyingSquad`
`K8s.Cluster`	Name of the self-hosted Kubernetes cluster.	Alphanumeric string with basic delimiters.	`minicube`
`K8s.Namespace`	Name of Kubernete s namespace in	Alphanumeric string with basic delimiters.	`default`, `pet-clinic`

Keyword	Usage	Domain of values	Examples
	Amazon EKS or K8s clusters.		
K8s.Workload	Name of Kubernetes workload in Amazon EKS and K8s clusters.	Alphanumeric string with basic delimiters.	frontend
K8s.Node	Identity of Kubernetes node in Amazon EKS and K8s clusters.	K8s node name (for example, Amazon EC2 instance DNS name).	ip-11-22-33-44.ec2.internal
K8s.Pod	Identity of Kubernetes pod in Amazon EKS and K8s clusters.	K8s pod identifier.	frontend-1234abcd56-ef7890
EC2.AutoScalingGroup	Name of the Amazon EC2 AutoScaling Group.	Alphanumeric string with basic delimiters.	my-asg-name-1
EC2.InstanceId	Identity of the Amazon EC2 instance.	Amazon EC2 instance identifier.	i-1234abcd5678ef90
ECS.Cluster	Identity of the Amazon ECS cluster.	Amazon ECS cluster name.	MyCluster
ECS.Service	Identity of the Amazon ECS service.	Amazon ECS service name.	MyService
ECS.Task	Identity of the Amazon ECS task.	Amazon ECS task ID.	task-123abc
Lambda.Function	Identity of the Lambda function.	Lambda function name.	MyFunction

Keyword	Usage	Domain of values	Examples
`Host`	Name of the host for all platform types.	Sub-domain format.	`ip-111-22-33-44.example.com`

Resource details

Keyword	Usage	Domain of values	Examples
`AWS.Resource.ARN`	ARN for the AWS resource.	Alphanumeric string with basic delimiters.	`arn:aws:dynamodb:us-east-1:123456789012:table/myDynamoDBTable`

Application details

Keyword	Usage	Domain of values	Examples
`AWS.Application`	Name of the application in AppRegistry.	Alphanumeric string with basic delimiters.	`PetClinicApp`
`AWS.Application.ARN`	ARN of the application in AppRegistry.	Alphanumeric string with basic delimiters.	`arn:aws:servicecatalog:us-east-1:1234567890:/applications/...`

Telemetry provider details

Keyword	Usage	Domain of values	Examples
`Telemetry.SDK`	The fingerprint of OTEL SDK version for instrumented services.	Alphanumeric string with basic delimiters.	`opentelemetry,1.32.0-aws-SNAPSHOT,java,Auto`
`Telemetry.Agent`	The fingerprint of the Agent used to collect and send telemetry data.	Alphanumeric string with basic delimiters.	`CWAgent/1.300026.3, ADOTCollector/1.x`
`Telemetry.Source`	Specifies the point of application where the telemetry was collected or what was used for the source of telemetry data.	ServerSpan, ClientSpan, ProducerSpan, ConsumerSpan, LocalRoot Span, JMX, OS.	`ClientSpan, JMX`

Metrics in Amazon CloudWatch

Metrics are data about the performance of your systems. Amazon CloudWatch collects metrics through two paths: AWS vended metrics from services such as Amazon EC2, Amazon EBS, and Amazon RDS, and custom metrics that you publish using the OpenTelemetry Protocol (OTLP) or the CloudWatch API.

Overview

OpenTelemetry: open-source native metrics in CloudWatch

CloudWatch supports OpenTelemetry as the recommended path for metric ingestion and querying. You can use vendor-agnostic, open-source instrumentation to send metrics to CloudWatch – the same OTel SDKs and collectors that work with Prometheus, Grafana, and other backends work with CloudWatch out of the box.

Two metric models

CloudWatch supports two metric models. Both are fully supported – choose based on your needs:

	OpenTelemetry Metrics (Recommended)	CloudWatch Metrics (Classic)
Identity	Metric name, up to 150 labels	Namespace, metric name, up to 30 dimensions
Metric types	Gauge, sum, histogram, exponential histogram	Single values, statistic sets
Ingestion	OTLP endpoint (OTel SDKs, collectors)	PutMetricData API, EMF
Query APIs	PromQL query API	GetMetricData, GetMetricStatistics, ListMetrics, CloudWatch Metrics Insights (SQL)
Alarms	PromQL-based CloudWatch alarms	Standard CloudWatch alarms

	OpenTelemetry Metrics (Recommended)	CloudWatch Metrics (Classic)
Console	CloudWatch Query Studio	CloudWatch Metrics console
Pricing model	Per GB ingested	Per metric per month
Storage	Up to 15 months	Up to 15 months (with automatic rollup)
Metric names	Open-source native	Proprietary (CloudWatch-format)
Best for	New workloads, containers, high-cardinality	Existing integrations, low-cardinality AWS service metrics

GetMetricData, GetMetricStatistics, ListMetrics, and CloudWatch Metrics Insights operate only on CloudWatch Metrics (Classic). Use the PromQL query API for OpenTelemetry Metrics.

Getting started

- **New to CloudWatch metrics?** Start with OpenTelemetry Metrics (Recommended).
- **Already using PutMetricData or EMF?** See CloudWatch Metrics (Classic).
- **Want AWS service metrics in PromQL?** Enable AWS vended metrics in OpenTelemetry format.

OpenTelemetry Metrics (Recommended)

OpenTelemetry is an open-source observability framework that provides vendor-agnostic instrumentation for collecting metrics, logs, and traces from your applications. Amazon CloudWatch supports OpenTelemetry natively, enabling you to use community-standard SDKs and collectors to send metrics directly to CloudWatch without vendor lock-in.

With OpenTelemetry metrics in CloudWatch, you get:

- **No vendor lock-in** – Instrument once with OTel SDKs, send to CloudWatch or any OTel-compatible backend. Switch destinations with a config change, not a code change.

- **Open-source native metric names** – Use community-standard metric names (for example, `container_cpu_usage_seconds_total` from cAdvisor) instead of proprietary names. Existing PromQL dashboards and runbooks work as-is.
- **PromQL querying** – Query with the industry-standard Prometheus Query Language. No proprietary query syntax needed.
- **High cardinality at low cost** – Up to 150 labels per data point with per-GB pricing. No penalty for adding pod names, request IDs, or custom tags.
- **Unified telemetry pipeline** – The same OTel Collector that collects your metrics can also collect logs and traces, simplifying your observability stack.

Topics

- CloudWatch OpenTelemetry Metrics
- Publish custom metrics with OpenTelemetry
- How CloudWatch stores histogram metrics
- Query metrics with PromQL
- Anomaly detection using PromQL
- CloudWatch detailed monitoring for OpenTelemetry metrics
- OTel metrics pricing and storage
- Migrate from Classic to OTel metrics
- AWS vended metrics in OpenTelemetry format

CloudWatch OpenTelemetry Metrics

OpenTelemetry metrics in CloudWatch use the OpenTelemetry Protocol (OTLP) for ingestion and PromQL for querying. This model supports open-source metric names, up to 150 labels per data point, and includes 15 months of storage with no per-metric charges.

Use OpenTelemetry metrics when:

- You are starting new workloads and want the recommended path
- You need high-cardinality labels (pod names, custom tags, OTel semantic conventions)
- You want to query with PromQL (industry-standard, compatible with existing Grafana dashboards)

- You use Container Insights OTel, Application Signals, or AWS vended OTel metrics

In this section

Page	Description
Publish custom metrics with OpenTelemetry	Publish custom metrics through the OTLP endpoint using OTel SDKs or collectors
AWS vended metrics in OpenTelemetry format	Enable AWS services to publish metrics as OTel data points with resource tags. Uses OTel Vended Metric Enrichmen t to convert existing AWS service metrics (Amazon EC2, Amazon RDS, ELB, and so on) into the OTel path with full label enrichment — no agent or code changes required.
Query metrics with PromQL	Query, aggregate, and filter OTel metrics using the Prometheus Query Language
OTel metrics pricing and storage	Per-GB ingestion pricing, included 15-month retention, no per-metric or API charges
Migrate from Classic to OTel metrics	Incremental migration from PutMetricData/EMF to OTLP

Publish custom metrics with OpenTelemetry

You can publish custom metrics to CloudWatch using the OpenTelemetry Protocol (OTLP). You can use OTel SDKs (Java, Python, Go, .NET, Node.js), the OTel Collector, or any OTLP-compatible client.

CloudWatch OTLP endpoint

Send metrics to the CloudWatch OTLP endpoint in your Region:

```
https://monitoring.region.amazonaws.com/v1/metrics
```

Authentication uses standard AWS SigV4 signing. The service name is `monitoring`. For more information about the endpoint, authentication options, and limits, see OTLP Endpoints.

Quick start: publish your first metric

Option 1: OTel Collector (recommended for production)

Configure an OTel Collector with the OTLP HTTP exporter and SigV4 authentication:

```
receivers:
  otlp:
    protocols:
      grpc:
        endpoint: 0.0.0.0:4317
      http:
        endpoint: 0.0.0.0:4318

processors:
  batch:
    send_batch_size: 200
    timeout: 10s

exporters:
  otlphttp:
    tls:
      insecure: false
    metrics_endpoint: "https://monitoring.us-east-1.amazonaws.com/v1/metrics"
    auth:
      authenticator: sigv4auth

extensions:
  sigv4auth:
    service: "monitoring"
    region: "us-east-1"

service:
  extensions: [sigv4auth]
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [batch]
      exporters: [otlphttp]
```

For detailed setup instructions, see Getting started.

Option 2: OTel SDK (Python example)

```
from opentelemetry import metrics
from opentelemetry.sdk.metrics import MeterProvider
from opentelemetry.sdk.metrics.export import PeriodicExportingMetricReader
from opentelemetry.exporter.otlp.proto.http.metric_exporter import OTLPMetricExporter

# Point at the CloudWatch OTLP endpoint
exporter = OTLPMetricExporter(
    endpoint="https://monitoring.us-east-1.amazonaws.com:443/v1/metrics"
)
reader = PeriodicExportingMetricReader(exporter, export_interval_millis=60000)
provider = MeterProvider(metric_readers=[reader])
metrics.set_meter_provider(provider)

# Create and record a metric
meter = metrics.get_meter("my-app")
counter = meter.create_counter("http_requests_total", description="Total HTTP
 requests")
counter.add(1, {"method": "GET", "path": "/api/users", "status": "200"})
```

Option 3: OTel SDK (Java example)

```
import io.opentelemetry.api.metrics.Meter;
import io.opentelemetry.api.metrics.LongCounter;

Meter meter = GlobalOpenTelemetry.getMeter("my-app");
LongCounter counter = meter.counterBuilder("http_requests_total")
    .setDescription("Total HTTP requests")
    .build();

counter.add(1, Attributes.of(
    AttributeKey.stringKey("method"), "GET",
    AttributeKey.stringKey("path"), "/api/users",
    AttributeKey.stringKey("status"), "200"
));
```

IAM permissions required

The identity sending metrics needs the `cloudwatch:PutMetricData` permission. For SigV4 authentication, attach the following policy:

```
{
  "Effect": "Allow",
  "Action": [
    "cloudwatch:PutMetricData"
  ],
  "Resource": "*"
}
```

For bearer token authentication, see Setting up bearer token authentication for Metrics.

Verify metrics are arriving

Open the CloudWatch console, navigate to **Query Studio**, and run:

```
http_requests_total
```

Metrics typically appear within 1–2 minutes of the first data point being sent.

Supported metric types

The following table describes the OTel metric types that CloudWatch supports and how to query them with PromQL.

OTel metric type	PromQL behavior
Counter	Use `rate()` or `increase()` to query
Gauge	Query directly (current value)
Histogram	Use `histogram_quantile()` for percentiles

Best practices

Follow these recommendations when sending metrics through OTLP:

- **Use meaningful metric names** — Follow OTel naming conventions (for example, `http.server.request.duration` or `http_request_duration_seconds`).
- **Keep label cardinality reasonable** — Avoid request IDs or UUIDs as label values.

- **Set an appropriate export interval** — 60 seconds is standard. Shorter intervals increase cost.
- **Use resource attributes** — Use resource attributes for static metadata (service name, version, environment) rather than per-data-point labels.

How CloudWatch stores histogram metrics

Histogram metrics describe the distribution of many measurements, such as request latency or payload size, instead of a single value. OpenTelemetry defines two histogram types, and Amazon CloudWatch (CloudWatch) stores both as exponential histograms:

- **Explicit-bucket histograms** – also called fixed-boundary histograms. You choose the bucket boundaries in advance, and every measurement is counted into the bucket that contains it. This is the default aggregation for the `Histogram` instrument in most OpenTelemetry SDKs, and it is the format that Prometheus classic histograms use.
- **Exponential histograms** – the bucket boundaries follow an exponential scale rather than a fixed list, so bucket width grows with the magnitude of the value. This gives consistent relative resolution across a wide range of values without you having to choose boundaries.

CloudWatch stores exponential histograms directly. It might reduce the scale of a histogram, which merges adjacent buckets and lowers resolution while preserving the total count and sum. The OpenTelemetry specification allows this, and any consumer of exponential histograms can do it. For more information, see ExponentialHistogram in the OpenTelemetry metrics data model.

When you send an explicit-bucket histogram, CloudWatch converts it to an exponential histogram at ingestion. This is a different operation from a scale reduction: the two formats describe the same distribution with different buckets, so the conversion has to place the counts from each source bucket into the exponential buckets that cover the same range of values.

What the conversion preserves

The following values are carried through the conversion exactly, and queries against them return the same result they would for the source histogram:

- **Count** – the total number of recorded measurements.
- **Sum** – the sum of the recorded values. Because count and sum are both exact, the average is also exact.

- **Minimum and maximum** – when the source histogram carries them. Both fields are optional in OpenTelemetry, and not every SDK and exporter records them, so they aren't always available. When they are missing, CloudWatch doesn't estimate them.

Percentiles are the exception. A percentile read from a histogram of any kind is an estimate, because the histogram records how many measurements fell in each bucket but not the individual values. That is true of the source explicit-bucket histogram before any conversion takes place.

How counts are redistributed

To place a source bucket's count into exponential buckets, CloudWatch subdivides the range that the source bucket covers. It then distributes the count across those subdivisions, weighting them by how the density of measurements compares with neighboring buckets instead of spreading them evenly.

> **Note**
>
> Estimating a percentile directly from an explicit-bucket histogram – for example, with `histogram_quantile()` in Prometheus – interpolates linearly within the bucket that contains the percentile. This approach assumes that measurements are spread evenly across that bucket. Long-tailed distributions such as latency usually violate that assumption, so this is a known source of error in percentile estimates from explicit-bucket histograms. For more information, see `histogram_quantile()` in the Prometheus documentation.

What limits percentile accuracy

How closely an estimated percentile matches the true value depends mostly on the source histogram, not on the conversion. Once measurements are counted into a bucket, their individual values are gone, and no conversion can recover them. Accuracy is therefore best when your bucket boundaries are narrow across the range where your measurements actually fall.

Estimates are least accurate in these cases:

- **Wide buckets** – a percentile that falls inside a wide bucket can only be located somewhere within that bucket's range.

- **The unbounded top bucket** – the last bucket of an explicit-bucket histogram has no upper boundary. High percentiles that fall into this bucket are therefore the least constrained. This matters most for tail latency, where the values you care about are the ones above your highest boundary. If your SDK can record a minimum and maximum, enable it: the bucket counts alone don't capture the true extremes, and CloudWatch preserves those two values when they're present.
- **Boundaries that don't match your data** – if most measurements land in one or two buckets, the histogram carries little information about the distribution regardless of how many buckets you defined.

If you rely on percentiles, configure your OpenTelemetry SDK to use exponential bucket aggregation for your `Histogram` instruments instead of the default explicit buckets. This avoids the redistribution described earlier, and you don't have to predict the range of your measurements in advance. For more information, see Base2 Exponential Bucket Histogram Aggregation in the OpenTelemetry documentation.

Querying histogram metrics

You query histograms in CloudWatch with the same PromQL histogram functions regardless of which format you sent. To estimate a percentile, use `histogram_quantile()`; to get the exact average, use `histogram_avg()`. For example, the following query returns the estimated 95th percentile of request duration:

```
histogram_quantile(0.95, http_request_duration_seconds)
```

For more information about querying metrics with PromQL, see PromQL querying.

Query metrics with PromQL

Topics

- What is Prometheus Query Language (PromQL)?
- PromQL limits and restrictions
- Supported AWS Regions
- IAM permissions for PromQL
- PromQL querying
- Grafana integration

- Running PromQL queries in Query Studio
- Using PromQL in alarms
- Prometheus-compatible APIs

What is Prometheus Query Language (PromQL)?

Prometheus Query Language (PromQL) is a functional query language that lets you select, aggregate, and transform time series data in real time. PromQL was originally designed for Prometheus and has become a popular query language for metrics.

Amazon CloudWatch supports PromQL for querying metrics including metrics ingested through OpenTelemetry Protocol (OTLP) and AWS enriched vended metrics. When you ingest OTLP metrics, CloudWatch preserves the full semantic structure of your telemetry, including resource attributes, instrumentation scope, datapoint attributes, and AWS-specific metadata, and exposes them as queryable PromQL labels.

With PromQL you can do the following:

- Select time series by metric name and label matchers.
- Apply mathematical functions and operators across time series.
- Aggregate metrics across dimensions such as service, region, or account.
- Compute rates, histograms, quantiles, and moving averages.

You can use PromQL queries interactively in Running PromQL queries in Query Studio and also to create CloudWatch Alarms. For more information, see PromQL querying and Using PromQL in alarms.

> **Note**
>
> CloudWatch uses PromQL based on the Prometheus 3.0 specification. This includes support for UTF-8 metric names and label names.
> Some query patterns from Prometheus documentation assume cumulative histograms and don't apply to OpenTelemetry delta histograms. For more information, see Querying histogram metrics.

The following concepts are fundamental to working with PromQL in CloudWatch.

Concept	Description
Time series	A stream of timestamped values identified by a metric name and a set of key-value pairs called *labels*. Each unique combination of metric name and labels forms a distinct time series.
Instant vector	A set of time series containing a single sample for each series, all sharing the same timestamp. Returned by queries like `{"http.server.active_requests", "@resource.service.name"="myservice"}` .
Range vector	A set of time series containing a range of data points over time for each series. Created by appending a time duration selector in brackets, for example, `avg_over_time({"http.server.active_requests", "@resource.service.name"="myservice"}[5m])`.
Label	A key-value pair attached to a time series. In OTLP-ingested metrics, labels are derived from resource attributes, instrumentation scope, datapoint attributes, and AWS-specific metadata.
Label matcher	An expression in curly braces that filters time series by label value. Supports exact match (=), not equal (!=), regex match (=~), and negative regex match (!~).
Aggregation operator	A function that combines multiple time series into fewer series. Common operators include `sum`, `avg`, `min`, `max`, `count`, and `topk`.

PromQL limits and restrictions

The following table lists the limits and restrictions for PromQL:

Limit	Value	Additional information	Error code
Max TPS for query requests per account	300	Maximum number of query requests (/query, /query_ra	422

Limit	Value	Additional information	Error code
		nge) per second allowed per account.	
Max TPS for discovery requests per account	10	Maximum number of discovery requests (/series, /label, /label_values) per second allowed per account.	422
Max concurrent query requests per account	30	Maximum number of queries (/query, /query_range) an account can have actively executing at the same time.	429
Max concurrent discovery requests per account	30	Maximum number of discovery requests (/series, /labels, /label_values) an account can have actively executing at the same time.	429
Max series returned per query request	500	Maximum number of unique time series a query request (/query, /query_range) can return.	200 - truncated response
Max labels returned per discovery request	10,000	Maximum number of unique labels a discovery request (/series, /labels, /label_values) can return.	200 - truncated response
Max range per request	7 days	Maximum time range a query can span, including range parameters and lookback periods.	422

Limit	Value	Additional information	Error code
Max series scanned per 24h window	100,000	Maximum number of unique time series that can be scanned per 24-hour window of query execution.	422
Max samples scanned per 24h window	300,000,000	Maximum number of samples that can be scanned per 24-hour window of query execution.	422
Max samples processed per 24h window	3,000,000,000	Maximum number of samples that can be processed per 24-hour window of query execution.	422
Execution timeout	20 seconds	Maximum time the engine can spend evaluating a query, excluding time spent in queue and fetching data from storage.	422

Supported AWS Regions

The following table lists the AWS Regions where OTLP metrics ingestion, PromQL querying, and Query Studio are available.

Region name	Region code	OTLP metrics ingest	PromQL query	Query Studio
US East (N. Virginia)	us-east-1	✓	✓	✓
US West (Oregon)	us-west-2	✓	✓	✓
Europe (Ireland)	eu-west-1	✓	✓	✓

Region name	Region code	OTLP metrics ingest	PromQL query	Query Studio
Asia Pacific (Singapore)	ap-southeast-1	✓	✓	✓
Asia Pacific (Sydney)	ap-southeast-2	✓	✓	✓
US West (N. California)	us-west-1	✓	✓	✓
US East (Ohio)	us-east-2	✓	✓	✓
Europe (London)	eu-west-2	✓	✓	✓
Europe (Paris)	eu-west-3	✓	✓	✓
Europe (Frankfurt)	eu-central-1	✓	✓	✓
Europe (Stockholm)	eu-north-1	✓	✓	✓
Europe (Milan)	eu-south-1	✓	✓	✓
Europe (Spain)	eu-south-2	✓	✓	✓
Europe (Zurich)	eu-central-2	✓	✓	✓
Asia Pacific (Tokyo)	ap-northeast-1	✓	✓	✓
Asia Pacific (Seoul)	ap-northeast-2	✓	✓	✓
Asia Pacific (Osaka)	ap-northeast-3	✓	✓	✓
Asia Pacific (Mumbai)	ap-south-1	✓	✓	✓
Asia Pacific (Hyderabad)	ap-south-2	✓	✓	✓

Region name	Region code	OTLP metrics ingest	PromQL query	Query Studio

IAM permissions for PromQL

To execute PromQL queries, you need both `cloudwatch:GetMetricData` and `cloudwatch:ListMetrics` permissions. The following table lists the Prometheus-compatible API endpoint paths and their required IAM actions:

API endpoint path	HTTP methods	Required actions
`/api/v1/query`	GET, POST	`cloudwatch:GetMetricData` , `cloudwatch:ListMetrics`
`/api/v1/query_range`	GET, POST	`cloudwatch:GetMetricData` , `cloudwatch:ListMetrics`
`/api/v1/series`	GET, POST	`cloudwatch:ListMetrics`
`/api/v1/labels`	GET, POST	`cloudwatch:ListMetrics`
`/api/v1/label/` *`label_name`* `/values`	GET	`cloudwatch:ListMetrics`

PromQL querying

When you ingest OpenTelemetry metrics into CloudWatch through the Metrics endpoint, the hierarchical OTLP data model is flattened into PromQL-compatible labels. This section describes the label structure, the PromQL syntax for querying these labels, and the UTF-8 support in PromQL.

> **Note**
>
> PromQL in Prometheus 3 supports full UTF-8 characters in metric names and label names. This is particularly important for OTLP metrics, because OpenTelemetry semantic conventions use dots in attribute names such as `service.name`. Previously, these dots were replaced with underscores during translation, causing discrepancies between what was defined in OTel conventions and what was queryable in Prometheus.
> A metric name that contains dots must be quoted, either inside the curly braces, as in `{"http.server.active_requests"}`, or as the value of the `__name__` label, as in `{__name__="http.server.active_requests"}`. A bare, unquoted name such as `http.server.active_requests` isn't valid PromQL.

When using PromQL in CloudWatch, the @ prefix convention distinguishes OTLP-scoped labels from standard Prometheus labels. Fields within each scope use a double-@ prefix (for example, `@resource.@schema_url`), while attributes use a single-@ scope prefix, for example, `@resource.service.name`. Datapoint attributes also support bare (un-prefixed) access for backward compatibility with standard PromQL queries, for example, `{"http.server.active_requests"}` and `{"@datapoint.@name"="http.server.active_requests"}` are equivalent.

A PromQL expression is enclosed in curly braces, specifying the metric name and an optional set of label matchers. The following example selects all time series for the `http.server.active_requests` metric:

```
{"http.server.active_requests"}
```

The following example selects all time series for the metric `http.server.active_requests` where the OpenTelemetry resource attribute `service.name` equals `myservice`:

```
{"http.server.active_requests", "@resource.service.name"="myservice"}
```

You can combine multiple label matchers in a single query. The following example selects all time series for the `http.server.active_requests` metric where the OpenTelemetry resource attribute `service.name` equals `myservice` across all US regions:

```
{"http.server.active_requests",
 "@resource.service.name"="myservice",
 "@aws.region"=~"us-.*"}
```

The following example shows a range query. It calculates the average value of all datapoints within a specified time range for each time series:

```
avg_over_time(
  {"http.server.active_requests",
   "@resource.service.name"="myservice"}[5m]
)
```

The following table summarizes the prefix conventions for each OTLP scope:

OTLP scope	Fields prefix	Attributes prefix	Example
Resource	`@resource.@`	`@resource.`	`@resource.service.name="myservice"`
Instrumentation Scope	`@instrumentation.@`	`@instrumentation.`	`@instrumentation.@name="otel-go/metrics"`
Datapoint	`@datapoint.@`	`@datapoint.` or bare	`cpu="cpu0"` or `@datapoint.cpu="cpu0"`
AWS-reserved	N/A	`@aws.`	`@aws.account_id="123456789"`

Querying vended AWS metrics with PromQL

To be able to query vended AWS metrics in PromQL, you first need to enable OTel enrichment of vended metrics. See: AWS vended metrics in OpenTelemetry format.

After you enable OTel enrichment, vended AWS metrics become queryable through PromQL with additional labels. The metric name is the same as the original CloudWatch metric name, and the original CloudWatch dimensions are available as datapoint attributes. The following labels are available (the example below is for an EC2 instance):

PromQL Label	Description	Example
`InstanceId`	Original CloudWatch dimension, as a datapoint attribute	`i-0123456789abcdef0`
`"@resource.cloud.resource_id"`	Full ARN of the resource	`arn:aws:ec2:us-east-1:123456789012:instance/i-0123456789abcdef0`
`"@resource.cloud.provider"`	Cloud provider	`aws`

PromQL Label	Description	Example
"@resource.cloud.region"	AWS Region where this metric originated	us-east-1
"@resource.cloud.account.id"	AWS account ID where this metric originated	123456789012
"@instrumentation.@name"	Instrumentation scope name identifying the source service	cloudwatch.aws/ec2
"@instrumentation.cloudwatch.source"	Source service identifier	aws.ec2
"@instrumentation.cloudwatch.solution"	Enrichment solution identifier	CloudWatchOTelEnrichment
"@aws.tag.Environment"	AWS resource tag	production
"@aws.account"	AWS account where this metric was ingested (system label)	123456789012
"@aws.region"	AWS Region where this metric was ingested (system label)	us-east-1

The following example selects `Invocations` for a specific Lambda function:

```
{Invocations, FunctionName="my-api-handler"}
```

The following example selects Lambda `Errors` for all functions tagged with a specific team:

```
{Errors, "@instrumentation.@name"="cloudwatch.aws/lambda", "@aws.tag.Team"="backend"}
```

The following example computes the total Lambda `Invocations` grouped by team:

```
sum by ("@aws.tag.Team")(
    {Invocations, "@instrumentation.@name"="cloudwatch.aws/lambda"}
)
```

The following example selects all time series for the EC2 `CPUUtilization` metric. The usage of `"@instrumentation.@name"="cloudwatch.aws/ec2"` is to exclusively match CPUUtilization from EC2 and not from other AWS services such as Amazon Relational Database Service:

```
histogram_avg({CPUUtilization, "@instrumentation.@name"="cloudwatch.aws/ec2"})
```

Querying histogram metrics

OpenTelemetry histogram metrics, such as request durations and latencies, are stored as histogram samples rather than float samples. Some AWS vended metrics are also stored as histograms. That's why the previous example uses `histogram_avg`. Histogram samples behave differently from float samples in PromQL, so a query pattern that works for one type can return an empty or incorrect result for the other.

To check whether a metric is a histogram, select its raw time series and inspect the `__type__` label on the results:

```
{"http.server.request.duration"}
```

Delta and cumulative histograms

OpenTelemetry histograms use one of two aggregation temporalities:

Cumulative

Each datapoint is a running total since the start of the series.

Delta

Each datapoint is a complete total for its own export period.

The temporality determines which query pattern returns a correct result. CloudWatch reports a histogram's temporality in the `__temporality__` label, whose value is either `cumulative` or `delta`. To check the temporality of a metric, select its raw time series and inspect the `__temporality__` label on the results:

```
{"http.server.request.duration"}
```

The `rate`, `increase`, `irate`, and `resets` functions assume cumulative data. They measure growth between datapoints. CloudWatch applies this assumption to every histogram, including delta histograms. On a delta histogram, these functions return an incorrect result without a warning. For example, the common Prometheus pattern `histogram_count(rate(`*`histogram`*`[5m]))` returns the correct observation rate for a cumulative histogram. It doesn't return a correct rate for a delta histogram.

For a cumulative histogram, use `rate`. The following example returns the observation rate, in observations per second:

```
sum(histogram_count(rate({"http.server.request.duration"}[5m])))
```

For a delta histogram, add up the per-period totals with `sum_over_time` and divide by the length of the range. This example also returns the observation rate:

```
sum(histogram_count(sum_over_time({"http.server.request.duration"}[5m]))) / 5m
```

You can adapt the delta pattern as follows:

- To return the total number of observations in the range instead of a rate, remove `/ 5m`.
- To return the mean observed value in the range, use `histogram_avg` instead of `histogram_count`.

> **Note**
>
> Don't use a subquery such as `rate(histogram_count(`*`histogram`*`)[5m:1m])` to calculate a rate from a delta histogram. It returns the correct result only when the export interval equals the subquery step. If the export interval changes, it returns an incorrect result without a warning.

Getting statistics from a histogram

The `min` and `max` aggregation operators operate only on float samples. They skip histogram samples, so applying them to a histogram metric returns an empty result rather than an error. The response includes an informational annotation that contains the text `ignored histogram`.

To read a statistic from a histogram metric, use a histogram function:

`histogram_quantile(`*`q`*`, `*`histogram`*`)`

Returns the value at the *q* quantile — the value below which a fraction *q* of observations fall. *q* is a value between 0 and 1. For example, use `0.99` for p99, not 99.

`histogram_avg(`*`histogram`*`)`

Returns the mean of the observed values.

`histogram_count(`*`histogram`*`)` and `histogram_sum(`*`histogram`*`)`

Return the number of observations and the sum of the observed values.

PromQL doesn't provide an exact maximum for a histogram. The closest equivalent is a high quantile such as `histogram_quantile(1, `*`histogram`*`)`. Because a quantile is estimated from bucket boundaries, the result can be slightly higher than the largest observed value.

For a delta histogram, apply the function directly to the metric. The following example returns the p99 duration for each export period:

```
histogram_quantile(0.99, {"http.server.request.duration"})
```

The preceding form returns the p99 for a single export period. To calculate the p99 over a longer window, first combine the per-period histograms with `sum_over_time`. You don't divide by the range, because a quantile is unaffected by scaling the bucket counts. The following example returns the p99 duration over the last five minutes:

```
histogram_quantile(0.99, sum_over_time({"http.server.request.duration"}[5m]))
```

For a cumulative histogram, applying the function directly returns a statistic over the whole life of the series. To get a statistic for a recent window, apply the function to `rate`. The following example returns the p99 duration over the last five minutes:

```
histogram_quantile(0.99, rate({"http.server.request.duration"}[5m]))
```

Keeping labels in the result

An aggregation operator such as `avg` or `sum` combines all matching time series into one. It removes every label that you don't group by. To keep one result per label value, add a `by` clause. The following example returns the observation rate of a delta histogram for each service:

```
sum by ("@resource.service.name")(
    histogram_count(sum_over_time({"http.server.request.duration"}[5m]))
) / 5m
```

Histogram functions such as `histogram_quantile` and `histogram_avg` are functions rather than aggregations, so they keep all labels and return one result for each time series.

Querying with MCP tools

The CloudWatch MCP Server provides Model Context Protocol (MCP) tools that let AI assistants and development tools query CloudWatch PromQL data on your behalf. The MCP tools handle authentication and request formatting automatically, so you can focus on writing PromQL queries rather than managing HTTP requests and SigV4 signing.

The following PromQL tools are available in the CloudWatch MCP Server:

Tool	Description
`execute_promql_query`	Runs an instant PromQL query, returning metric values at a single point in time.
`execute_promql_range_query`	Runs a PromQL range query over a time window, returning time series data for trend analysis and graphing.
`get_promql_label_values`	Retrieves values for a specific PromQL label, such as `__name__` for metric names or `@resource.service.name` for services.
`get_promql_series`	Finds time series matching PromQL label selectors and returns the full label set of each matching series.

Tool	Description
`get_promql_labels`	Lists all available PromQL label names to help discover the label structure of your metrics.

For full details on parameters, configuration, and setup instructions, see Tools for CloudWatch PromQL in the CloudWatch MCP Server documentation.

Querying with the HTTP API

You can also query CloudWatch PromQL data programmatically by calling the Prometheus-compatible HTTP endpoints directly. Requests must be signed with AWS Signature Version 4 using `monitoring` as the service name.

The PromQL endpoint follows the pattern `https://monitoring.`*`AWS Region`*`.amazonaws.com/api/v1/`*`operation`*. For example, for the US East (N. Virginia) (us-east-1) Region, the endpoint for an instant query is `https://monitoring.us-east-1.amazonaws.com/api/v1/query`.

For the full API reference, including supported operations, request parameters, and response formats, see Prometheus-compatible APIs. For the list of AWS Regions where PromQL querying is available, see Supported AWS Regions. For the IAM actions required for each operation, see IAM permissions for PromQL.

Grafana integration

After you ingest OpenTelemetry metrics into CloudWatch and make them queryable with PromQL, you can visualize and explore that data in Grafana and Amazon Managed Grafana. We recommend that you use the **PromQL** query type in the **Amazon CloudWatch** data source plugin. It uses the same authentication and Region settings as your other CloudWatch queries, so you don't need to configure a separate data source. For more information, see Querying with the CloudWatch data source.

Alternatively, you can connect to the CloudWatch monitoring endpoint through the **Amazon Managed Service for Prometheus** data source plugin, which signs requests with Signature Version 4 (SigV4). Use this option if your Grafana version or Amazon Managed Grafana workspace doesn't support the PromQL query type in the CloudWatch data source. For more information, see Querying from Grafana with the Amazon Managed Service for Prometheus data source and

Querying from Amazon Managed Grafana with the Amazon Managed Service for Prometheus data source.

Querying with the CloudWatch data source

The **Amazon CloudWatch** data source plugin includes a **PromQL** query type, alongside the **Metric Search** and **Metric Insights** query types. The plugin sends SigV4-signed requests to the CloudWatch PromQL endpoint for the selected Region. You don't need to change the data source configuration or set a signing service.

The PromQL query type is available in the following environments:

- **Amazon Managed Grafana** — workspaces that use Grafana version 13 or later. For more information, see Grafana version 13 in the *Amazon Managed Grafana User Guide*.
- **Grafana** — version 12.10.0 or later of the CloudWatch data source plugin, which includes both the Builder and Code editing modes. The plugin requires Grafana `>=11.6.11 <12 || >=12.0.10 <12.1 || >=12.1.7 <12.2 || >=12.2.5`. To update the plugin, use the Grafana plugins catalog.

IAM prerequisites — the IAM principal that the CloudWatch data source uses, such as the Amazon Managed Grafana workspace IAM role, must have both `cloudwatch:GetMetricData` (required for instant and range queries) and `cloudwatch:ListMetrics` (required for metric, label key, and label value autocomplete). For details, see IAM permissions for PromQL.

> **Note**
>
> If the IAM principal has only these permissions, choosing **Save & test** on the CloudWatch data source reports an error for the CloudWatch Logs check because it can't call `logs:DescribeLogGroups`. The metrics check still succeeds, and PromQL queries aren't affected. To clear the error, also grant the permissions that the CloudWatch data source needs for logs queries.

To query CloudWatch metrics with PromQL, complete the following steps.

1. Add an **Amazon CloudWatch** data source, or use an existing one. In Amazon Managed Grafana, you can use the AWS data source configuration option to add the data source and manage its credentials. For more information, see Connect to an Amazon CloudWatch data source in the *Amazon Managed Grafana User Guide*.

2. In a dashboard panel or in **Explore**, select the CloudWatch data source.
3. In the query editor, choose **PromQL** as the query type.
4. For **Region**, keep the data source default or choose the AWS Region that contains your OpenTelemetry metrics.
5. Build the query in one of the following editing modes. Use the **Builder/Code** toggle to switch between them.
   - **Builder** — select a metric, add label filters, and optionally add operations such as aggregations and functions.
   - **Code** — enter a PromQL expression directly. The editor suggests metric names, label keys, and label values. To build a selector visually, choose **Metrics browser**.
6. (Optional) Under the query options, set **Legend**, **Min step**, **Format** (`Time series` or `Table`), and **Type** (`Range` or `Instant`).

Querying from Grafana with the Amazon Managed Service for Prometheus data source

You can also query CloudWatch PromQL data from Grafana by adding the **Amazon Managed Service for Prometheus** data source plugin and pointing it at the CloudWatch monitoring endpoint. SigV4 signing is built in to the plugin and is always enabled, so there is no toggle to turn on. The plugin is published at grafana.com/grafana/plugins/grafana-amazonprometheus-datasource/; install it from the Grafana plugins catalog before adding the data source. AMP plugin v3.0.0 requires Grafana `>=11.6.11 <12 || >=12.0.10 <12.1 || >=12.1.7 <12.2 || >=12.2.5`.

IAM prerequisites — the IAM principal whose credentials Grafana uses must have both `cloudwatch:GetMetricData` (required for instant and range queries) and `cloudwatch:ListMetrics` (required for series and label discovery). For details, see IAM permissions for PromQL.

To configure Grafana, complete the following steps.

1. Install the **Amazon Managed Service for Prometheus** data source plugin from the Grafana plugins catalog.
2. In Grafana, go to **Connections**, **Data sources**, choose **Add data source**, and select **Amazon Managed Service for Prometheus**.
3. Set the data source **URL** to `https://monitoring.`*`AWS Region`*`.amazonaws.com`.

4. Set the **Region** to your AWS Region. Choose an **Authentication provider** appropriate for your environment (default credential chain, access keys, or workspace IAM role).
5. Set the **Service** field to `monitoring`. The plugin defaults this field to `aps` for Amazon Managed Service for Prometheus, but the CloudWatch PromQL endpoint requires `monitoring`.
6. Choose **Save & test**.

> ⚠ **Service must be set to monitoring**
>
> If you leave **Service** at the default value `aps`, every query fails with HTTP 403. The response includes the message `Credential should be scoped to correct service: 'monitoring'`. When you provision the data source as YAML or Terraform, set the equivalent key `sigv4Service` to `monitoring`.

Querying from Amazon Managed Grafana with the Amazon Managed Service for Prometheus data source

If your Amazon Managed Grafana workspace uses Grafana version 12, you can query CloudWatch PromQL data by adding an **Amazon Managed Service for Prometheus** data source that points at the CloudWatch monitoring endpoint. For workspaces that use Grafana version 13 or later, we recommend the CloudWatch data source instead. For more information, see Querying with the CloudWatch data source.

This data source plugin signs requests with SigV4 using the workspace IAM role automatically; SigV4 is always enabled, with no toggle to configure. The plugin is available in Amazon Managed Grafana version 12 and later. For more information, see Connect to an Amazon Managed Service for Prometheus data source in the *Amazon Managed Grafana User Guide*.

IAM prerequisites — the Amazon Managed Grafana workspace IAM role must have both `cloudwatch:GetMetricData` (required for instant and range queries) and `cloudwatch:ListMetrics` (required for series and label discovery). For details, see IAM permissions for PromQL.

To configure the data source, complete the following steps.

1. In your Amazon Managed Grafana workspace, add an **Amazon Managed Service for Prometheus** data source.
2. Set the data source **URL** to `https://monitoring.`*`AWS Region`*`.amazonaws.com`.

3. Set the **Region** to your AWS Region. Amazon Managed Grafana injects credentials from the workspace IAM role automatically; you do not need to configure static keys.
4. Set the **Service** field to `monitoring`. The plugin defaults this field to `aps`, but the CloudWatch PromQL endpoint requires `monitoring`.
5. Choose **Save & test**.

Running PromQL queries in Query Studio

Query Studio is an interactive query environment in the CloudWatch console where you can write, run, and visualize PromQL queries against your CloudWatch metrics. You can use Query Studio to explore metrics ingested through OTLP and AWS vended metrics, create visualizations, set up alarms, and add widgets to your CloudWatch dashboards.

You can run PromQL queries programmatically using the CloudWatch API, or interactively in Query Studio.

Running a PromQL query in Query Studio

To run a PromQL query in Query Studio

1. Open the CloudWatch console.
2. In the navigation pane, choose **Query Studio**.
3. In the query editor tool, select **PromQL** from the drop-down menu.
4. To build the query in **Builder** mode, do the following:

    a. Select a metric name.

    b. (Optional) Select one or more labels and values to filter the time series that the query returns.

    c. (Optional) To aggregate the selected time series, choose the **More options** icon (three dots), and then choose **Add aggregation function**. Then choose a function such as `sum`, `avg`, `min`, or `max`.

> **Note**
>
> An aggregation function applies to all of the time series that match your metric and label selection, and combines them into a single time series. Labels that you don't

group by are removed from the result. To return one result per label value, such as one per host, group by that label.
The `min` and `max` functions operate only on float samples. They skip histogram samples, which are common for durations and latencies, so the query returns an empty result. To get a statistic from a histogram metric, use a histogram function such as `histogram_quantile` or `histogram_avg`. For more information, see Querying histogram metrics.

5. Or enter your PromQL query through the **Editor** mode, for example `{"http.server.active_requests"}`.
6. (Optional) Adjust the time range using the time interval selector at the top of the page.
7. Choose **Run** to execute the query and view the results.

Query Studio will display the results as a time series graph. You can switch between graph and table views to analyze your data.

Creating alarms from Query Studio

After running a PromQL query that returns a single time series, you can create a CloudWatch Alarm directly from Query Studio. Choose **Create alarm** from the actions menu to configure alarm thresholds, evaluation periods, and notification actions based on your query results. For more information, see Using PromQL in alarms.

Adding visualizations to dashboards

You can add any Query Studio visualization to a CloudWatch dashboard. After running a query and viewing the results, choose **Add to dashboard** to save the visualization as a dashboard widget. The widget continues to run the PromQL query at the dashboard's refresh interval, keeping your dashboard up to date.

Using PromQL in alarms

You can create CloudWatch alarms that use PromQL queries to monitor your metrics. PromQL alarms evaluate a PromQL expression and trigger alarm state changes based on the query results.

For information about alarm concepts, see Concepts.

For information about alarm data queries, see Alarm data queries.

For information about alarm actions, see Alarm actions.

For information about alarm limits, see Limits.

Creating a PromQL alarm

You can create a PromQL alarm from the CloudWatch console, the AWS CLI, or the CloudWatch API.

To create a PromQL alarm from the console

1. Open the CloudWatch console.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**, then choose the **PromQL** tab.
5. Enter your PromQL query. The query must return a single time series for the alarm to evaluate.
6. Configure the alarm conditions, including the threshold, evaluation period, and datapoints to alarm.
7. Configure the alarm actions, such as Amazon SNS notifications.
8. Enter a name and description for the alarm, then choose **Create alarm**.

You can also create a PromQL alarm directly from Running PromQL queries in Query Studio after running a query that returns a single time series.

Creating a CloudWatch alarm using PromQL for anomaly detection

You can create a PromQL alarm that triggers when a metric breaches an expected range defined by statistical bounds. The alarm query combines upper and lower bounds into a single expression that returns only the anomalous data points. Any time series returned by the query is considered breaching.

The following example expression detects when an ad request metric exceeds 3 standard deviations from the median over a 60-minute window:

```
1 * {"app.ads.ad_requests"} > quantile_over_time(0.5, {"app.ads.ad_requests"}[60m]
 offset 1m)
    + 3 * stddev_over_time({"app.ads.ad_requests"}[60m] offset 1m)
or
1 * {"app.ads.ad_requests"} < clamp_min(
    quantile_over_time(0.5, {"app.ads.ad_requests"}[60m] offset 1m)
    - 3 * stddev_over_time({"app.ads.ad_requests"}[60m] offset 1m),
```

```
0)
```

This expression works across multiple label values, so the alarm can track anomalies across your entire fleet. Each breaching time series is tracked as a separate contributor. For more information about how PromQL alarms evaluate contributors, see PromQL alarms.

You can adjust the multiplier and time window to match your metric's behavior. A higher multiplier produces wider bounds with fewer false positives. A longer time window smooths out short-term spikes. The `clamp_min` function prevents the lower bound from going negative for metrics that can't have negative values.

For more information about building anomaly detection bands with PromQL, see Anomaly detection using PromQL.

Prometheus-compatible APIs

Topics

- QueryMetrics
- GetSeries
- GetLabels

Amazon CloudWatch supports the following Prometheus-compatible APIs for querying PromQL data. For information about endpoint URLs, signing requests with Signature Version 4, and required IAM permissions, see PromQL querying.

For the limits and restrictions that apply to all PromQL API requests, including per-account TPS, concurrency, and 24-hour scan windows, see PromQL limits and restrictions.

QueryMetrics

The `QueryMetrics` operation evaluates a PromQL instant query at a single point in time, or evaluates a query over a range of time.

Valid HTTP verbs

`GET, POST`

Valid URIs

`/api/v1/query` — evaluates an instant query at a single point in time.

`/api/v1/query_range` — evaluates a query over a range of time.

The full request URL combines the CloudWatch monitoring host for the AWS Region with the operation path, for example `https://monitoring.AWS Region.amazonaws.com/api/v1/query`. For information about endpoints, signing, and required IAM permissions, see PromQL querying.

URL query parameters

The following parameters are passed in the URL query string for GET requests, or as form-encoded body fields for POST requests.

Parameter	Applies to	Description
`query`	Both	Required. The PromQL expression string to evaluate. The expression must select a metric by name — for example, `{"http.server.active_requests"}` or `{__name__="http.server.active_requests"}` . Selecting series only by labels, without a metric name, is not supported.
`time`	`/api/v1/query`	Optional. Evaluation timestamp as an RFC 3339 timestamp or a Unix timestamp. Defaults to the current server time.
`start`	`/api/v1/query_range`	Required. Start of the time range, as an RFC 3339 timestamp or a Unix timestamp.
`end`	`/api/v1/query_range`	Required. End of the time range, as an RFC 3339 timestamp or a Unix timestamp.
`step`	`/api/v1/query_range`	Required. Query resolution step width, in `duration` format or as a floating-point number of seconds.
`limit`	Both	Optional. Maximum number of unique time series to return, from 1 to 500. If you do not specify `limit`, CloudWatch returns up to the maximum (500). See Result limit.

Duration

A `duration` in a Prometheus-compatible API is a number, followed immediately by one of the following units:

- `ms` milliseconds
- `s` seconds
- `m` minutes
- `h` hours
- `d` days, assuming a day always has 24h
- `w` weeks, assuming a week always has 7d
- `y` years, assuming a year always has 365d

Required IAM permissions

To call `QueryMetrics`, the calling identity must have both of the following IAM actions:

- `cloudwatch:GetMetricData`
- `cloudwatch:ListMetrics`

For the complete IAM action mapping for all PromQL operations, see IAM permissions for PromQL.

Result limit

A single `/api/v1/query` or `/api/v1/query_range` response can return up to **500 unique time series**. To request fewer results, pass the `limit` parameter with a value from `1` to `500`. If you do not specify `limit`, CloudWatch returns up to the maximum.

When the matching series exceed the cap, the response is truncated and a message is included in the standard Prometheus `warnings` field. The HTTP status code remains `200`.

For the full list of PromQL limits, including TPS, concurrency, and 24-hour scan windows, see PromQL limits and restrictions.

Sample request

The following `POST` request passes the PromQL expression in a form-encoded body. Special characters such as `{`, `}`, and `"` are percent-encoded.

```
POST /api/v1/query HTTP/1.1
Host: monitoring.us-east-1.amazonaws.com
Content-Type: application/x-www-form-urlencoded
Authorization: AUTHPARAMS
X-Amz-Date: 20260605T193725Z
User-Agent: awscurl/0.36

query=sum(%7B%22http.server.active_requests%22%7D)
```

The same call with `awscurl`:

```
awscurl --service monitoring --region us-east-1 \
    -X POST 'https://monitoring.us-east-1.amazonaws.com/api/v1/query' \
    -H 'Content-Type: application/x-www-form-urlencoded' \
    -d 'query=sum({"http.server.active_requests"})'
```

Sample response

A successful response uses the standard Prometheus JSON envelope:

```
HTTP/1.1 200 OK
x-amzn-RequestId: 12345678-abcd-4442-b8c5-262b45e9b535
Content-Type: application/json

{
    "status": "success",
    "data": {
        "resultType": "vector",
        "result": [
            {
                "metric": {},
                "value": [
                    1780000000.000,
                    "42"
                ]
            }
        ]
    }
}
```

When the result set exceeds the per-call cap, CloudWatch returns a truncated `result` array and includes a message in the `warnings` field:

```
HTTP/1.1 200 OK
Content-Type: application/json

{
    "status": "success",
    "data": {
        "resultType": "vector",
        "result": [ ... up to 500 series ... ]
    },
    "warnings": [
        "result truncated to the maximum of 500 series; refine the query or use the
 limit parameter"
    ]
}
```

GetSeries

The `GetSeries` operation returns the list of time series whose labels match one or more selectors.

Valid HTTP verbs

`GET, POST`

Valid URI

`/api/v1/series`

The full request URL combines the CloudWatch monitoring host for the AWS Region with the operation path, for example `https://monitoring.`*`AWS Region`*`.amazonaws.com/api/v1/series`. For information about endpoints, signing, and required IAM permissions, see PromQL querying.

URL query parameters

The following parameters are passed in the URL query string for `GET` requests, or as form-encoded body fields for `POST` requests.

Parameter	Description
`match[]`	Required. A series selector that filters the time series to return. Each selector must include an exact match (=) on the metric name — for

Parameter	Description
	example, {"http.server.active_requests"} or {__name__ ="http.server.active_requests"} . Selectors without a metric-name equal matcher are not supported. In addition to exact match, label matchers also support not equal (!=), regex match (=~), and negative regex match (!~). Specify match[] one or more times to combine selectors. For more information about selector syntax, see PromQL querying.
start	Required. Start of the time range to consider, as an RFC 3339 timestamp or a Unix timestamp.
end	Required. End of the time range to consider, as an RFC 3339 timestamp or a Unix timestamp.
limit	Optional. Maximum number of unique time series to return, from 1 to 10000. If you do not specify limit, CloudWatch returns up to the maximum (10,000). See Result limit.

Required IAM permissions

To call GetSeries, the calling identity must have the following IAM action:

- cloudwatch:ListMetrics

For the complete IAM action mapping for all PromQL operations, see IAM permissions for PromQL.

Result limit

A single /api/v1/series response can return up to **10,000 unique time series**. To request fewer results, pass the limit parameter with a value from 1 to 10000. If you do not specify limit, CloudWatch returns up to the maximum.

When the matching series exceed the cap, the response is truncated and a message is included in the standard Prometheus warnings field. The HTTP status code remains 200.

For the full list of PromQL limits, including TPS, concurrency, and 24-hour scan windows, see PromQL limits and restrictions.

Sample requests

The following POST request uses an exact match selector. The selector, `start`, and end are passed as form-encoded fields in the request body. Special characters such as {, }, ", and , are percent-encoded. The decoded `match[]` value is `{"http.server.active_requests","@resource.service.name"="myservice"}`.

```
POST /api/v1/series HTTP/1.1
Host: monitoring.us-east-1.amazonaws.com
Content-Type: application/x-www-form-urlencoded
Authorization: AUTHPARAMS
X-Amz-Date: 20260605T193725Z
User-Agent: awscurl/0.36

match%5B%5D=%7B%22http.server.active_requests%22%2C%22%40resource.service.name%22%3D
%22myservice%22%7D&start=1780662000&end=1780665600
```

The following POST request uses a regex match selector. The decoded `match[]` value is `{"http.server.active_requests","@aws.region"=~"us-.*"}`.

```
POST /api/v1/series HTTP/1.1
Host: monitoring.us-east-1.amazonaws.com
Content-Type: application/x-www-form-urlencoded
Authorization: AUTHPARAMS
X-Amz-Date: 20260605T193725Z
User-Agent: awscurl/0.36

match%5B%5D=%7B%22http.server.active_requests%22%2C%22%40aws.region%22%3D~%22us-.*
%22%7D&start=1780662000&end=1780665600
```

The same call with `awscurl`:

```
awscurl --service monitoring --region us-east-1 \
    -X POST 'https://monitoring.us-east-1.amazonaws.com/api/v1/series' \
    -H 'Content-Type: application/x-www-form-urlencoded' \
    -d
 'match[]={"http.server.active_requests","@aws.region"=~"us-.*"}&start=1780662000&end=178066560
```

Sample response

A successful response uses the standard Prometheus JSON envelope. The `data` field is an array of label maps, one per matched series.

```
HTTP/1.1 200 OK
x-amzn-RequestId: 12345678-abcd-4442-b8c5-262b45e9b535
Content-Type: application/json

{
    "status": "success",
    "data": [
        {
            "__name__": "http.server.active_requests",
            "@resource.service.name": "myservice",
            "@aws.region": "us-east-1"
        },
        {
            "__name__": "http.server.active_requests",
            "@resource.service.name": "myservice",
            "@aws.region": "us-west-2"
        }
    ]
}
```

GetLabels

The `GetLabels` operation returns label names that are present in the metric store, or returns the values for a specific label name.

Valid HTTP verbs

- `GET`, `POST` for `/api/v1/labels`.
- `GET` for `/api/v1/label/`*`label_name`*`/values`.

Valid URIs

- `/api/v1/labels` — returns the list of label names.
- `/api/v1/label/`*`label_name`*`/values` — returns the list of values for the specified label.

The full request URL combines the CloudWatch monitoring host for the AWS Region with the operation path, for example `https://monitoring.AWS Region.amazonaws.com/api/v1/labels`. For information about endpoints, signing, and required IAM permissions, see PromQL querying.

URL query parameters

The following parameters are passed in the URL query string for `GET` requests, or as form-encoded body fields for `POST` requests.

Parameter	Applies to	Description
`match[]`	Both	Optional. A series selector that restricts which series are considered when computing the result. Selectors support exact match (=), not equal (!=), regex match (=~), and negative regex match (!~). Specify `match[]` one or more times to combine selectors. For more information about selector syntax, see PromQL querying.
`start`	Both	Optional. Start of the time range to consider, as an RFC 3339 timestamp or a Unix timestamp.
`end`	Both	Optional. End of the time range to consider, as an RFC 3339 timestamp or a Unix timestamp.
`limit`	Both	Optional. Maximum number of unique labels to return, from 1 to `10000`. If you do not specify `limit`, CloudWatch returns up to the maximum (10,000). See Result limit.

Required IAM permissions

To call `GetLabels` on either path, the calling identity must have the following IAM action:

- `cloudwatch:ListMetrics`

For the complete IAM action mapping for all PromQL operations, see IAM permissions for PromQL.

Result limit

A single `/api/v1/labels` or `/api/v1/label/label_name/values` response can return up to **10,000 labels**. To request fewer results, pass the `limit` parameter with a value from `1` to `10000`. If you do not specify `limit`, CloudWatch returns up to the maximum.

When the matching labels exceed the cap, the response is truncated and a message is included in the standard Prometheus `warnings` field. The HTTP status code remains `200`.

For the full list of PromQL limits, including TPS, concurrency, and 24-hour scan windows, see PromQL limits and restrictions.

Sample requests

List all label names with a POST request and an empty body:

```
POST /api/v1/labels HTTP/1.1
Host: monitoring.us-east-1.amazonaws.com
Content-Type: application/x-www-form-urlencoded
Content-Length: 0
Authorization: AUTHPARAMS
X-Amz-Date: 20260605T193725Z
User-Agent: awscurl/0.36
```

The same call with `awscurl`:

```
awscurl --service monitoring --region us-east-1 \
    -X POST 'https://monitoring.us-east-1.amazonaws.com/api/v1/labels' \
    -H 'Content-Type: application/x-www-form-urlencoded'
```

List label names matching a selector. The selector and time range are passed as form-encoded fields in the request body:

```
awscurl --service monitoring --region us-east-1 \
    -X POST 'https://monitoring.us-east-1.amazonaws.com/api/v1/labels' \
    -H 'Content-Type: application/x-www-form-urlencoded' \
    -d
 'match[]={"http.server.active_requests","@aws.region"=~"us-.*"}&start=1780662000&end=178066560
```

List the values for the `@resource.service.name` label. The label name is part of the URL path and is percent-encoded (`@` → `%40`). This path supports only `GET`:

```
GET /api/v1/label/%40resource.service.name/values HTTP/1.1
Host: monitoring.us-east-1.amazonaws.com
Authorization: AUTHPARAMS
X-Amz-Date: 20260605T193725Z
User-Agent: awscurl/0.36
```

The same call with `awscurl`:

```
awscurl --service monitoring --region us-east-1 \
    'https://monitoring.us-east-1.amazonaws.com/api/v1/label/@resource.service.name/
values'
```

Sample responses

A successful response uses the standard Prometheus JSON envelope. The `data` field is an array of strings.

Response for `/api/v1/labels`:

```
HTTP/1.1 200 OK
Content-Type: application/json

{
    "status": "success",
    "data": [
        "__name__",
        "@aws.account",
        "@aws.region",
        "@resource.service.name",
        "@resource.cloud.region",
        "InstanceId"
    ]
}
```

Response for `/api/v1/label/`*`label_name`*`/values`:

```
HTTP/1.1 200 OK
```

```
Content-Type: application/json

{
    "status": "success",
    "data": [
        "myservice",
        "checkout-api",
        "billing-worker"
    ]
}
```

Anomaly detection using PromQL

You can build anomaly detection bands for any Prometheus-compatible metric by using standard PromQL functions such as `quantile_over_time`, `stddev_over_time`, and `avg_over_time`. This approach computes a baseline and adds or subtracts a scaled standard deviation to define upper and lower bounds that adapt to your metric's natural patterns.

This works for any metric that returns a float value, such as CPU usage, request latency, or error counts. For information about ingesting metrics using OpenTelemetry, see OpenTelemetry.

Defining upper and lower bounds

To define an expected range for a metric, compute a baseline using the median or average over a time window, then add and subtract a multiple of the standard deviation. The multiplier controls sensitivity—higher values produce wider bands with fewer false positives, while lower values catch smaller deviations.

The following example creates an upper bound for an ad request metric using a 60-minute window and a multiplier of 3:

```
quantile_over_time(0.5, {"app.ads.ad_requests"}[60m] offset 1m)
  + 3 * stddev_over_time({"app.ads.ad_requests"}[60m] offset 1m)
```

The following example creates the corresponding lower bound. The `clamp_min` function prevents the lower bound from going negative for metrics that can't have negative values:

```
clamp_min(
    quantile_over_time(0.5, {"app.ads.ad_requests"}[60m] offset 1m)
    - 3 * stddev_over_time({"app.ads.ad_requests"}[60m] offset 1m),
```

```
0)
```

You can graph both bounds together in CloudWatch Query Studio to visualize the expected range for your metric. For more information, see Running PromQL queries in Query Studio.

Detecting breaches

To detect when a metric is outside its expected range, combine both bounds into a single query. The following expression returns only the data points where the metric value exceeds the upper bound or falls below the lower bound:

```
1 * {"app.ads.ad_requests"} > quantile_over_time(0.5, {"app.ads.ad_requests"}[60m]
 offset 1m)
    + 3 * stddev_over_time({"app.ads.ad_requests"}[60m] offset 1m)
or
1 * {"app.ads.ad_requests"} < clamp_min(
    quantile_over_time(0.5, {"app.ads.ad_requests"}[60m] offset 1m)
    - 3 * stddev_over_time({"app.ads.ad_requests"}[60m] offset 1m),
0)
```

This query works across multiple label values, so you can detect anomalies across your entire fleet in a single query. You can use this expression to create a PromQL alarm that triggers when any time series breaches the expected range. For more information, see Creating a CloudWatch alarm using PromQL for anomaly detection.

CloudWatch detailed monitoring for OpenTelemetry metrics

Detailed monitoring gives you higher-resolution OpenTelemetry metrics for supported resources, which helps you diagnose performance issues faster. You can enable detailed monitoring for individual AWS resources through one centralized Amazon CloudWatch API, without building custom per-service infrastructure.

You identify each resource by its Amazon Resource Name (ARN). A resource can have only one configuration at a time.

Key concepts for ResourceMetricsConfiguration

Before you use ResourceMetricsConfiguration, review these terms. The terms explain how a configuration maps to a resource. They also explain which metrics CloudWatch collects by default and what happens when you update a configuration.

One configuration per resource

Each AWS resource identified by its ARN can have at most one ResourceMetricsConfiguration. The resource ARN serves as the unique identifier for the configuration. You do not need a separate configuration ID.

Metric selections

You can optionally specify which detailed metrics to collect by providing a `MetricSelections` list. Each selection contains an `IncludeMetrics` field with metric names. You can include between 1 and 500 metric names for each selection.

Default behavior

When you create a configuration without specifying `MetricSelections`, CloudWatch collects all available detailed metrics for the resource. When you specify `MetricSelections`, CloudWatch collects only the listed metrics.

Full replacement on update

When you update a configuration, the new `MetricSelections` value completely replaces the previous value. To add metrics to an existing selection, include the full list of metrics that you want to collect.

To start collecting detailed metrics for a resource, see Enabling detailed monitoring for a resource.

Enabling detailed monitoring for a resource

To enable detailed monitoring for a supported resource, create a ResourceMetricsConfiguration. You can use the AWS CLI or the `AWS::CloudWatch::ResourceMetricsConfiguration` CloudFormation resource type.

> **Note**
>
> If you attempt to create a ResourceMetricsConfiguration for a resource type that does not support detailed monitoring, the operation returns a `ValidationException`.

To enable detailed monitoring (AWS CLI)

1. Run the following command, replacing the placeholder ARN with the ARN of the resource that you want to monitor.

```
aws cloudwatch create-resource-metrics-configuration \
    --resource-arn arn:aws:service:us-east-1:123456789012:resource-type/resource-id
```

2. To collect only specific metrics instead of all available detailed metrics, include the `--metric-selections` parameter.

```
aws cloudwatch create-resource-metrics-configuration \
    --resource-arn arn:aws:service:us-east-1:123456789012:resource-type/resource-id
 \
    --metric-selections '[{"IncludeMetrics": ["MetricName1", "MetricName2"]}]'
```

To enable detailed monitoring (CloudFormation)

- Add the `AWS::CloudWatch::ResourceMetricsConfiguration` resource type to your CloudFormation template.

```
Resources:
  DetailedMonitoring:
    Type: AWS::CloudWatch::ResourceMetricsConfiguration
    Properties:
      ResourceArn: arn:aws:service:us-east-1:123456789012:resource-type/resource-id
```

Checking if detailed monitoring is enabled

To check whether detailed monitoring is enabled for a specific resource, use the `GetResourceMetricsConfiguration` operation.

To check detailed monitoring status (AWS CLI)

1. Run the following command for the resource that you want to check.

```
aws cloudwatch get-resource-metrics-configuration \
    --resource-arn arn:aws:service:us-east-1:123456789012:resource-type/resource-id
```

2. If detailed monitoring is enabled, the command returns the configuration details, including any metric selections. If no configuration exists, the command returns an error.

Updating the metric selection

You can update an existing ResourceMetricsConfiguration to change which metrics CloudWatch collects. The update fully replaces the `MetricSelections` value.

To update the metric selection (AWS CLI)

1. Run the following command. Include the complete list of metrics you want to collect.

```
aws cloudwatch update-resource-metrics-configuration \
    --resource-arn arn:aws:service:us-east-1:123456789012:resource-type/resource-id
 \
    --metric-selections '[{"IncludeMetrics": ["MetricName1", "MetricName2"]}]'
```

2. Verify the update by calling `GetResourceMetricsConfiguration`.

> **Important**
>
> The `--metric-selections` parameter fully replaces the previous value. To add a metric to an existing selection, include all previously selected metrics in addition to the new metric.

Disabling detailed monitoring

To disable detailed monitoring for a resource, delete its ResourceMetricsConfiguration. After you delete the configuration, CloudWatch stops collecting detailed metrics for that resource.

To disable detailed monitoring (AWS CLI)

1. Run the following command for the resource that you no longer want to monitor.

```
aws cloudwatch delete-resource-metrics-configuration \
    --resource-arn arn:aws:service:us-east-1:123456789012:resource-type/resource-id
```

2. Verify that the configuration was deleted by calling `GetResourceMetricsConfiguration`. The command returns an error if no configuration exists.

Required IAM permissions for ResourceMetricsConfiguration

Ensure your IAM policy includes the actions for the operations you use.

Operation	Required IAM action
Create a configuration	`cloudwatch:CreateResourceMetricsConfiguration`
Get a configuration	`cloudwatch:GetResourceMetricsConfiguration`
Update a configuration	`cloudwatch:UpdateResourceMetricsConfiguration`
Delete a configuration	`cloudwatch:DeleteResourceMetricsConfiguration`

The following example IAM policy grants permissions for all ResourceMetricsConfiguration operations, scoped to a single resource with the `cloudwatch:ResourceArn` condition key.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:CreateResourceMetricsConfiguration",
                "cloudwatch:GetResourceMetricsConfiguration",
                "cloudwatch:UpdateResourceMetricsConfiguration",
                "cloudwatch:DeleteResourceMetricsConfiguration"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "cloudwatch:ResourceArn": "arn:aws:service:us-
east-1:123456789012:resource-type/resource-id"
                }
            }
        }
```

```
    ]
}
```

> **Note**
>
> The ResourceMetricsConfiguration APIs do not support resource-level permissions. You must use `"Resource": "*"` in your IAM policy and scope access with the `cloudwatch:ResourceArn` condition key, as shown in the preceding example.

For more information about `cloudwatch:ResourceArn`, including how to match multiple resources with wildcards, see Condition keys for resource metrics configuration access.

OTel metrics pricing and storage

OpenTelemetry metrics in CloudWatch use a per-GB ingestion model with included storage and query access. There are no per-metric, per-API-call, or separate storage charges. For current pricing details, see Amazon CloudWatch Pricing.

Key pricing characteristics

The OTel metrics pricing model has the following characteristics:

- **Per-GB ingestion** — You pay based on the volume of data ingested, not the number of unique metric series.
- **Storage included** — 15 months retention at no additional charge.
- **Console queries free** — PromQL queries in the CloudWatch console (Query Studio, dashboards) are free.
- **API queries charged per sample** — Programmatic PromQL queries are charged per million samples scanned.
- **No per-metric charge** — Unlike Classic pricing, there is no cost per unique metric name or label combination.

How OTel compares to Classic pricing

The following table compares OTel metrics pricing with Classic metrics pricing.

Feature	OTel Metrics	Classic Metrics
Billing unit	Per GB ingested	Per metric per month
Storage	15 months included	15 months included
Console queries	Free	Free
API queries	Per million samples scanned	Per 1,000 metrics requested (GetMetricData)
High cardinality cost	Linear with data volume (not metric count)	Expensive — each unique dimension combination is a separate billable metric

What counts as ingested data

Each OTLP data point contributes its serialized size to the ingestion volume. The serialized size includes the following components:

- Metric name
- All labels (keys and values)
- Resource attributes
- Timestamp and value

Larger label sets produce more bytes per data point. To see the cost that your OTel metric ingestion generates, filter your cost and usage data by `usage type` in Cost Explorer. For more information about CloudWatch usage types, see To visualize and analyze CloudWatch cost and usage data. For the rates that apply to each usage type, see Amazon CloudWatch Pricing.

Cost optimization tips

Use the following strategies to optimize your OTel metrics costs:

- Use shorter label values where possible. Label values contribute to the byte size of each data point.
- Drop high-cardinality labels that you don't query (for example, request IDs) at the collector level.

- For Container Insights OTel, the default collection generates a predictable volume based on cluster size.

Migrate from Classic to OTel metrics

Customers currently publishing custom metrics through PutMetricData or EMF can migrate incrementally to the OTel path. There is no flag day — migration happens workload by workload at your own pace.

Migration approach

The migration follows four phases:

1. **Dual-write** — Publish metrics through both Classic and OTel paths simultaneously.
2. **Validate** — Confirm OTel metrics appear in Query Studio through PromQL.
3. **Recreate consumers** — Update alarms and dashboards to use PromQL and OTel metric names.
4. **Cut over** — Stop Classic publishing after you validate OTel consumers.

Step 1: Instrument with OTel SDK (dual-write)

Add the OTel SDK alongside your existing PutMetricData calls. Both paths can publish simultaneously — you don't lose data.

```
# Existing Classic publishing (keep running during migration)
cloudwatch.put_metric_data(
    Namespace='MyApp',
    MetricData=[{'MetricName': 'RequestLatency', 'Value': 42.5, 'Unit':
 'Milliseconds'}]
)

# New OTel publishing (add this)
from opentelemetry import metrics
meter = metrics.get_meter("my-app")
histogram = meter.create_histogram("http_request_duration_seconds")
histogram.record(0.0425, {"method": "GET", "path": "/api/users"})
```

Step 2: Verify in Query Studio

To verify that your OTel metrics are arriving, open the CloudWatch console and navigate to Query Studio. Search for your metric:

```
http_request_duration_seconds
```

Confirm that data appears with the labels you expect.

Step 3: Recreate alarms on OTel metrics

Create new alarms that query OTel metrics using PromQL expressions. The following example shows a Classic alarm and its OTel equivalent.

Classic alarm:

```
aws cloudwatch put-metric-alarm \
  --alarm-name "high-latency" \
  --namespace "MyApp" \
  --metric-name "RequestLatency" \
  --statistic Average --threshold 100 ...
```

OTel equivalent (PromQL alarm):

```
aws cloudwatch put-metric-alarm \
  --alarm-name "high-latency-otel" \
  --metrics '[{"Id":"q1","Expression":"avg(http_request_duration_seconds{path=\"/api/
users\"}) * 1000","Period":300,"ReturnData":true}]' \
  --threshold 100 ...
```

Run both alarms in parallel until you are confident the OTel version fires correctly.

Step 4: Stop Classic publishing

After you validate your OTel alarms and dashboards, remove the PutMetricData calls from your application code. Classic metrics stop incurring charges immediately.

Metric name mapping

The following table shows common Classic metric names and their suggested OTel equivalents.

Classic name	Suggested OTel name	Notes
RequestLatency (ms)	http_request_duration_seconds	Convert to seconds (OTel convention)
RequestCount	http_requests_total	Use `_total` suffix for counters
ErrorCount	http_server_errors_total	Use `_total` suffix
QueueDepth	queue_depth	Gauge — no suffix needed

What about AWS vended metrics?

You don't need to migrate AWS vended metrics (Amazon EC2 CPU, Amazon RDS connections, and so on) manually. Enable OTel Vended Metric Enrichment to make them queryable through PromQL automatically. For more information, see AWS vended metrics in OpenTelemetry format.

AWS vended metrics in OpenTelemetry format

> **Tip**
>
> To learn more about OpenTelemetry on CloudWatch, check out the Cloud Operations Enablement workshop and event series on the AWS Experience website.

You can enable OTel enrichment to make vended metrics queryable through PromQL. For the resources and metrics that support this, see Supported AWS resources and metrics for OpenTelemetry enrichment. After you enable OTel enrichment, metrics that contain a resource identifier dimension (for example, EC2 CPUUtilization with an InstanceId dimension) are enriched with resource ARN and resource tag labels and become queryable using PromQL.

The enriched metric preserves the original metric name and CloudWatch dimensions, and adds:

- **Resource attributes** – the resource ARN (`cloud.resource_id`), cloud provider, region, and account ID.
- **Instrumentation scope** – identifies the source service and marks the metric as OTel-enriched.
- **Resource tags** – any AWS resource tags associated with the resource, queryable as PromQL labels.

The original classic CloudWatch metric is not modified and remains available through existing CloudWatch APIs.

Enabling OpenTelemetry enrichment for vended metrics

Before you start OTel enrichment, you must enable resource tags on telemetry for your account.

You can enable OTel enrichment for your account in a specific region using the CloudWatch console, AWS CLI, CloudFormation, Terraform, or AWS SDK.

You will need permissions for the following operation: `cloudwatch:StartOTelEnrichment`

To enable OTel enrichment for AWS metrics (CloudWatch Console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **CloudWatch**, then choose **Settings**.
3. In the **Enable OTel Enrichment for AWS Metrics** pane, toggle the feature On.

AWS CLI

```
aws cloudwatch start-otel-enrichment
```

CloudFormation

> **Note**
>

>
> The `aws_cloudwatch_otel_enrichment` Terraform resource requires the `aws_observabilityadmin_telemetry_enrichment` resource to be configured first.

```
resource "aws_observabilityadmin_telemetry_enrichment" "example" {
}

resource "aws_cloudwatch_otel_enrichment" "example" {
  depends_on = [aws_observabilityadmin_telemetry_enrichment.example]
}
```

For more information, see aws_cloudwatch_otel_enrichment in the Terraform Registry.

To enable across multiple regions, create the same resource in each regional stack or invoke the API in each region of interest.

After enrichment is enabled, you can start querying vended metrics through PromQL. See: Querying vended AWS metrics with PromQL.

Filtering enrichment by namespace and metric

CloudWatch OTel enrichment decorates your account's vended metrics with resource ARN and resource tag labels. You can then group and filter by resource attributes in PromQL and Query Studio. By default, enrichment applies to every namespace that CloudWatch supports for enrichment. You can narrow enrichment to a chosen subset of namespaces and metric names by using two optional parameters, `IncludeFilters` and `ExcludeFilters`. You can also change those filters on a running account with the `UpdateOTelEnrichment` operation. Use filtering to optimize enrichment cost when you need only some of your metrics in OTel.

Before you filter enrichment, you must start enrichment for your account. For more information, see Enabling OpenTelemetry enrichment for vended metrics.

Operations that set enrichment filters

You set enrichment filters with two operations. Each operation applies to your account and is scoped to a single AWS Region.

- `StartOTelEnrichment` — Starts enrichment, and optionally sets the initial filters.
- `UpdateOTelEnrichment` — Replaces the filters of an account that is already running enrichment.

The metric selector

A metric selector is an `OTelEnrichmentMetricSelector` data type that picks the metrics in exactly one namespace. Both `IncludeFilters` and `ExcludeFilters` are lists of these selectors. A selector has the following members.

`Namespace`

Type: String. Length: 1–255 characters. This member is required, and it must not start with a colon. CloudWatch matches the namespace exactly and case-sensitively.

`MetricNames`

Type: list of String. Each name is 1–255 characters, and the list holds 0–100 items. This member is optional. Omit it to match every metric in the namespace.

How filters are evaluated

CloudWatch evaluates `IncludeFilters` and `ExcludeFilters` according to the following rules.

- **Include first, then exclude** – CloudWatch applies `IncludeFilters` first, then subtracts the `ExcludeFilters` match set from the result. Exclude always takes precedence, so a metric matched by both filters is not enriched.
- **Empty and absent are equivalent** – An omitted list, a null list, and an empty list (`[]`) mean the same thing everywhere, including `MetricNames` within a selector.
- **Exact, case-sensitive matching** – CloudWatch matches names exactly and case-sensitively, with no wildcards, prefixes, or normalization. `AWS/EC2` matches only `AWS/EC2`, and `aws/ec2` matches nothing.
- **An inactive direction is permissive** – When you set no `IncludeFilters`, every supported namespace is in scope. When you set no `ExcludeFilters`, nothing is removed.

The following table shows what gets enriched for each combination of filters.

`IncludeFilters`	`ExcludeFilters`	What gets enriched
Absent or empty	Absent or empty	Every namespace that CloudWatch supports for enrichment.
Present	Absent or empty	Only what `IncludeFilters` matches.
Absent or empty	Present	Everything supported, minus what `ExcludeFilters` matches.
Present	Present	The `IncludeFilters` match set, minus the `ExcludeFilters` match set.

Example: Enrich a subset of metrics

Suppose that you want to enrich all of `AWS/EC2` except two network metrics, plus exactly two `AWS/RDS` metrics, and nothing else. The following filter configuration produces that result.

```
{
  "IncludeFilters": [
    { "Namespace": "AWS/EC2" },
    { "Namespace": "AWS/RDS", "MetricNames": ["CPUUtilization",
 "DatabaseConnections"] }
  ],
  "ExcludeFilters": [
    { "Namespace": "AWS/EC2", "MetricNames": ["NetworkPacketsIn",
 "NetworkPacketsOut"] }
  ]
}
```

This configuration produces the following result.

- Every `AWS/EC2` metric except `NetworkPacketsIn` and `NetworkPacketsOut` is enriched.
- `AWS/RDS` `CPUUtilization` and `DatabaseConnections` are enriched.
- Every other `AWS/RDS` metric is not enriched, because `IncludeFilters` did not name it.
- Every other namespace is not enriched, because `IncludeFilters` is active and does not list it.

This configuration consumes 3 of the 100 available selectors: two include selectors and one exclude selector.

Starting enrichment on an account that is already running

Calling `StartOTelEnrichment` on an account that is already running enrichment is a no-op. It does not return an error, and it does not apply the filters in the request. The stored configuration is unchanged.

The response makes this behavior observable. `StartOTelEnrichment` returns the filters that were already stored, not the filters that the request carried. If you send filters and get different filters back, enrichment was already running, and the filters you sent were discarded.

To change filters on a running account, use `UpdateOTelEnrichment`. Do not stop and restart enrichment to change filters, because a restart resets `CreatedAt` and creates an enrichment gap.

Updating filters
