| Creating a container image                                                   | 13       |
| Prerequisites                                                                | 14       |
| Create a Docker image                                                        | 15       |
| Push your image to Amazon Elastic Container Registry                         | 18       |
| Clean up                                                                     | 19       |
| Next steps                                                                   | 19       |
| Learn how to create a task for Amazon ECS Managed Instances                  | 20       |
| Prerequisites                                                                | 20       |
| Step 1: Create a cluster                                                     | 21       |
| Step 2: Create a task definition                                             | 21       |
| Step 3: Create a service                                                     | 23       |
| Step 4: View your service                                                    | 23       |
| Step 5: Clean up                                                             | 23       |
| Learn how to create a task for Amazon ECS Managed Instances with the AWS CLI | 24       |
| Prerequisites                                                                | 25       |
| Step 1: Create a cluster                                                     | 26       |
| Step 2: Create a Amazon ECS Managed Instances capacity provider              | 27       |
| Step 3: Configure the cluster's default capacity provider strategy           | 28       |
| Step 4: Register a Linux task definition                                     | 28       |

|                                                                               |    |
|-------------------------------------------------------------------------------|----|
| Step 5: List task definitions .....                                           | 30 |
| Step 6: Create a service .....                                                | 30 |
| Step 7: List services .....                                                   | 31 |
| Step 8: Describe the running service .....                                    | 31 |
| Step 9: Test .....                                                            | 32 |
| Step 10: Clean up .....                                                       | 35 |
| Learn how to create a Linux task for Fargate .....                            | 35 |
| Prerequisites .....                                                           | 36 |
| Step 1: Create the cluster .....                                              | 37 |
| Step 2: Create a task definition .....                                        | 37 |
| Step 3: Create the service .....                                              | 38 |
| Step 4: View your service .....                                               | 39 |
| Step 5: Clean up .....                                                        | 39 |
| Learn how to create a Windows task for Fargate .....                          | 40 |
| Prerequisites .....                                                           | 40 |
| Step 1: Create a cluster .....                                                | 41 |
| Step 2: Register a Windows task definition .....                              | 42 |
| Step 3: Create a service with your task definition .....                      | 43 |
| Step 4: View your service .....                                               | 43 |
| Step 5: Clean Up .....                                                        | 44 |
| Learn how to create a Windows task for EC2 .....                              | 45 |
| Prerequisites .....                                                           | 45 |
| Step 1: Create a cluster .....                                                | 46 |
| Step 2: Register a task definition .....                                      | 47 |
| Step 3: Create a Service .....                                                | 48 |
| Step 4: View your Service .....                                               | 49 |
| Step 5: Clean Up .....                                                        | 50 |
| Using the AWS CDK .....                                                       | 50 |
| Step 1: Set up your AWS CDK project .....                                     | 52 |
| Step 2: Use the AWS CDK to define a containerized web server on Fargate ..... | 54 |
| Step 3: Test the web server .....                                             | 62 |
| Step 4: Clean up .....                                                        | 62 |
| Next steps .....                                                              | 62 |
| Creating resources using the AWS Copilot CLI .....                            | 63 |
| Installing the AWS Copilot CLI .....                                          | 64 |
| Deploying a sample Amazon ECS application using the AWS Copilot CLI .....     | 73 |

|                                                                               |            |
|-------------------------------------------------------------------------------|------------|
| <b>Amazon ECS with CloudFormation .....</b>                                   | <b>76</b>  |
| Creating Amazon ECS resources using the CloudFormation console .....          | 77         |
| Prerequisites .....                                                           | 77         |
| Step 1: Create a stack template .....                                         | 77         |
| Step 2: Create a stack for Amazon ECS resources .....                         | 89         |
| Step 3: Verify .....                                                          | 90         |
| Step 4: Clean up resources .....                                              | 91         |
| Creating Amazon ECS resources using AWS CLI commands for CloudFormation ..... | 91         |
| Prerequisites .....                                                           | 91         |
| Step 1: Create a stack .....                                                  | 92         |
| Step 2: Verify Amazon ECS resource creation .....                             | 104        |
| Step 3: Clean up .....                                                        | 106        |
| Example CloudFormation templates .....                                        | 106        |

| <b>Tutorials .....</b>                                                        | <b>2431</b> |
| Creating a Linux task for Fargate with the AWS CLI .....                      | 2433        |
| Prerequisites .....                                                           | 2434        |
| Step 1: Create a Cluster .....                                                | 2435        |
| Step 2: Register a Linux Task Definition .....                                | 2436        |
| Step 3: List Task Definitions .....                                           | 2437        |
| Step 4: Create a Service .....                                                | 2437        |
| Step 5: List Services .....                                                   | 2438        |
| Step 6: Describe the Running Service .....                                    | 2439        |

|                                                                                 |      |
|---------------------------------------------------------------------------------|------|
| Step 7: Test .....                                                              | 2441 |
| Step 8: Clean Up .....                                                          | 2445 |
| Creating a Windows task for the Fargate with the AWS CLI .....                  | 2445 |
| Prerequisites .....                                                             | 2446 |
| Step 1: Create a Cluster .....                                                  | 2446 |
| Step 2: Register a Windows Task Definition .....                                | 2447 |
| Step 3: List task definitions .....                                             | 2449 |
| Step 4: Create a service .....                                                  | 2449 |
| Step 5: List services .....                                                     | 2450 |
| Step 6: Describe the Running Service .....                                      | 2450 |
| Step 7: Clean Up .....                                                          | 2452 |
| Creating a task for EC2 with the AWS CLI .....                                  | 2453 |
| Prerequisites .....                                                             | 2454 |
| Create a cluster .....                                                          | 2454 |
| Launch a container instance with the Amazon ECS AMI .....                       | 2455 |
| List container instances .....                                                  | 2457 |
| Describe your container instance .....                                          | 2458 |
| Register a task definition .....                                                | 2461 |
| List task definitions .....                                                     | 2463 |
| Create a service .....                                                          | 2463 |
| List services .....                                                             | 2464 |
| Describe the service .....                                                      | 2464 |
| Describe the running task .....                                                 | 2465 |
| Test the web server .....                                                       | 2466 |
| Clean up resources .....                                                        | 2467 |
| Configuring Amazon ECS to listen for CloudWatch Events events .....             | 2469 |
| Prerequisite: Set up a test cluster .....                                       | 2469 |
| Step 1: Create the Lambda function .....                                        | 2469 |
| Step 2: Register an event rule .....                                            | 2470 |
| Step 3: Create a task definition .....                                          | 2471 |
| Step 4: Test your rule .....                                                    | 2472 |
| Sending Amazon Simple Notification Service alerts for task stopped events ..... | 2473 |
| Prerequisite: Set up a test cluster .....                                       | 2473 |
| Prerequisite: Configure permissions for Amazon SNS .....                        | 2473 |
| Step 1: Create and subscribe to an Amazon SNS topic .....                       | 2473 |
| Step 2: Register an event rule .....                                            | 2474 |

|                                                                                                                                                         |      |
|---------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| Step 3: Test your rule .....                                                                                                                            | 2475 |
| Concatenating multiline or stack-trace log messages .....                                                                                               | 2476 |
| Required IAM permissions .....                                                                                                                          | 2477 |
| Determine when to use the multiline log setting .....                                                                                                   | 2477 |
| Parse and concatenate options .....                                                                                                                     | 2479 |
| Deploying Fluent Bit on Windows containers .....                                                                                                        | 2498 |
| Prerequisites .....                                                                                                                                     | 2500 |
| Step 1: Create the IAM access roles .....                                                                                                               | 2501 |
| Step 2: Create an Amazon ECS Windows container instance .....                                                                                           | 2502 |
| Step 3: Configure Fluent Bit .....                                                                                                                      | 2503 |
| Step 4: Register a Windows Fluent Bit task definition which routes the logs to<br>CloudWatch .....                                                      | 2505 |
| Step 5: Run the <code>ecs-windows-fluent-bit</code> task definition as an Amazon ECS service<br>using the <code>daemon</code> scheduling strategy ..... | 2507 |
| Step 6: Register a Windows task definition which generates the logs .....                                                                               | 2508 |
| Step 7: Run the <code>windows-app-task</code> task definition .....                                                                                     | 2510 |
| Step 8: Verify the logs on CloudWatch .....                                                                                                             | 2510 |
| Step 9: Clean up .....                                                                                                                                  | 2511 |
| Using gMSA for EC2 Linux containers .....                                                                                                               | 2512 |
| Considerations .....                                                                                                                                    | 2513 |
| Prerequisites .....                                                                                                                                     | 2514 |
| Setup .....                                                                                                                                             | 2515 |
| CredSpec file .....                                                                                                                                     | 2522 |
| Using gMSA for Linux containers on Fargate .....                                                                                                        | 2523 |
| Considerations .....                                                                                                                                    | 2523 |
| Prerequisites .....                                                                                                                                     | 2524 |
| Setup .....                                                                                                                                             | 2524 |
| CredSpec file .....                                                                                                                                     | 2527 |
| Using Windows containers with domainless gMSA using the AWS CLI .....                                                                                   | 2528 |
| Prerequisites .....                                                                                                                                     | 2529 |
| Step 1: Create and configure the gMSA account on Active Directory Domain Services (AD<br>DS) .....                                                      | 2531 |
| Step 2: Upload Credentials to Secrets Manager .....                                                                                                     | 2533 |
| Step 3: Modify your CredSpec JSON to include domainless gMSA information .....                                                                          | 2534 |
| Step 4: Upload CredSpec to Amazon S3 .....                                                                                                              | 2535 |
| Step 5: (Optional) Create an Amazon ECS cluster .....                                                                                                   | 2536 |

|                                                                         |             |
|-------------------------------------------------------------------------|-------------|
| Step 6: Create an IAM role for container instances .....                | 2536        |
| Step 7: Create a custom task execution role .....                       | 2536        |
| Step 8: Create a task role for Amazon ECS Exec .....                    | 2538        |
| Step 9: Register a task definition .....                                | 2540        |
| Step 10: Register a Windows container instance .....                    | 2541        |
| Step 11: Verify the container instance .....                            | 2542        |
| Step 12: Run a Windows task .....                                       | 2543        |
| Step 13: Verify the container has gMSA credentials .....                | 2544        |
| Step 14: Clean up .....                                                 | 2544        |

# What is Amazon Elastic Container Service?

## Tip

Join the upcoming hands-on workshops to learn best practices for Amazon ECS and AWS Fargate. [Register for a workshop.](#)

Amazon Elastic Container Service (Amazon ECS) is a fully managed container orchestration service that helps you easily deploy, manage, and scale containerized applications. As a fully managed service, Amazon ECS comes with AWS configuration and operational best practices built-in. It's integrated with both AWS tools, such as Amazon Elastic Container Registry, and third-party tools, such as Docker. This integration makes it easier for teams to focus on building the applications, not the environment. You can run and scale your container workloads across AWS Regions in the cloud, and on-premises, without the complexity of managing a control plane.

## Terminology and components

There are three layers in Amazon ECS:

- Capacity - The infrastructure where your containers run
- Controller - Deploy and manage your applications that run on the containers
- Provisioning - The tools that you can use to interface with the scheduler to deploy and manage your applications and containers

The following diagram shows the Amazon ECS layers.

## Amazon Elastic Container Service Layers

### Provisioning

### Controller

### Capacity options

The capacity is the infrastructure where your containers run. The following is an overview of the capacity options:

- Amazon ECS Managed Instances is a compute option for Amazon ECS that enables you to run containerized workloads on a range of Amazon EC2 instance types while offloading infrastructure management to AWS. With Amazon ECS Managed Instances, you can access specific compute capabilities such as GPU acceleration, specific CPU architectures, high network performance, and specialized instances types, while AWS handles provisioning, patching, scaling, and maintenance of the underlying infrastructure.
- Amazon EC2 instances in the AWS cloud

You choose the instance type, the number of instances, and manage the capacity.

- Serverless in the AWS cloud

Fargate is a serverless, pay-as-you-go compute engine. With Fargate you don't need to manage servers, handle capacity planning, or isolate container workloads for security.

- On-premises virtual machines (VM) or servers

Amazon ECS Anywhere provides support for registering an external instance such as an on-premises server or virtual machine (VM), to your Amazon ECS cluster.

The Amazon ECS scheduler is the software that manages your applications.

## Features

Amazon ECS provides the following high-level features:

### Task definition

The blueprint for the application.

### Cluster

The infrastructure your application runs on.

### Task

An application such as a batch job that performs work, and then stops.

### Service

A long running stateless application.

### Account Setting

Allows access to features.

### Cluster Auto Scaling

Amazon ECS manages the scaling of Amazon EC2 instances that are registered to your cluster.

### Service Auto Scaling

Amazon ECS increases or decreases the desired number of tasks in your service automatically.

## Provisioning

There are multiple options for provisioning Amazon ECS:

- **AWS Management Console** — Provides a web interface that you can use to access your Amazon ECS resources.

- **AWS Command Line Interface (AWS CLI)** — Provides commands for a broad set of AWS services, including Amazon ECS. It's supported on Windows, Mac, and Linux. For more information, see [AWS Command Line Interface](#).
- **AWS SDKs** — Provides language-specific APIs and takes care of many of the connection details. These include calculating signatures, handling request retries, and error handling. For more information, see [AWS SDKs](#).
- **AWS CDK** — Provides an open-source software development framework that you can use to model and provision your cloud application resources using familiar programming languages. The AWS CDK provisions your resources in a safe, repeatable manner through AWS CloudFormation.

## Pricing

Amazon ECS pricing depends on the capacity option you choose for your containers.

- [Amazon ECS pricing](#) – Pricing information for Amazon ECS.
- [AWS Fargate pricing](#) – Pricing information for Fargate.

## Related services

### Services to use with Amazon ECS

You can use other AWS services to help you deploy your tasks and services on Amazon ECS.

#### [Amazon EC2 Auto Scaling](#)

Helps ensure you have the correct number of Amazon EC2 instances available to handle the load for your application.

#### [Amazon CloudWatch](#)

Monitor your services and tasks.

#### [Amazon Elastic Container Registry](#)

Store and manage container images.

#### [Elastic Load Balancing](#)

Automatically distribute incoming service traffic.

## [Amazon GuardDuty](#)

Detect potentially unauthorized or malicious use of your container instances and workloads.

# Learn how to create and use Amazon ECS resources

The following guides provide an introduction to the tools available to access Amazon ECS and introductory procedures to run containers. Docker basics takes you through the basic steps to create a Docker container image and upload it to an Amazon ECR private repository. The getting started guides walk you through using the AWS Copilot command line interface and the AWS Management Console to complete the common tasks to run your containers on Amazon ECS and AWS Fargate.

## Contents

- [Creating Amazon ECS resources using the AWS Copilot command line interface](#)

## Set up to use Amazon ECS

If you've already signed up for Amazon Web Services (AWS) and have been using Amazon Elastic Compute Cloud (Amazon EC2), you are close to being able to use Amazon ECS. The set-up process for the two services is similar. The following guide prepares you for launching your first Amazon ECS cluster.

Complete the following tasks to get set up for Amazon ECS.

## AWS Management Console

The AWS Management Console is a browser-based interface for managing Amazon ECS resources. The console provides a visual overview of the service, making it easy to explore Amazon ECS features and functions without needing to use additional tools. Many related tutorials and walkthroughs are available that can guide you through use of the console.

For a tutorial that guides you through the console, see [Learn how to create and use Amazon ECS resources](#).

When starting out, many customers prefer using the console because it provides instant visual feedback on whether the actions they take succeed. AWS customers that are familiar with the AWS Management Console, can easily manage related resources such as load balancers and Amazon EC2 instances.

Start with the AWS Management Console.

## Sign up for an AWS account

To get started with AWS, you need an AWS account. There are two ways to sign up for AWS. If you want complete control over account configuration and where your content is stored, or if you have regulated workloads such as HIPAA or FedRAMP, use [Sign up for AWS \(advanced\)](#). If you are a new user and want to use a login you already own to sign in to AWS and create an AWS environment with preconfigured defaults in select [AWS Regions](#), use [Sign up for AWS](#).

## Create a virtual private cloud

You can use Amazon Virtual Private Cloud (Amazon VPC) to launch AWS resources into a virtual network that you've defined. We strongly suggest that you launch your container instances in a VPC.

If you have a default VPC, you can skip this section and move to the next task, [Create a security group](#). To determine whether you have a default VPC, see [Work with your default VPC and default subnets](#) in the *Amazon VPC User Guide*. Otherwise, you can create a nondefault VPC in your account using the following steps.

For information about how to create a VPC, see [Create a VPC](#) in the *Amazon VPC User Guide*, and use the following table to determine what options to select.

| Option              | Value                                   |  |
|---------------------|-----------------------------------------|--|
| Resources to create | VPC only                                |  |
| Name                | Optionally provide a name for your VPC. |  |
| IPv4 CIDR block     | IPv4 CIDR manual input                  |  |

| Option          | Value                                                     |  |
|-----------------|-----------------------------------------------------------|--|
|                 | The CIDR block size must have a size between /16 and /28. |  |
| IPv6 CIDR block | No IPv6 CIDR block                                        |  |
| Tenancy         | Default                                                   |  |

For more information about Amazon VPC, see [What is Amazon VPC?](#) in the *Amazon VPC User Guide*.

## Create a security group

Security groups act as a firewall for associated container instances, controlling both inbound and outbound traffic at the container instance level. You can add rules to a security group that enable you to connect to your container instance from your IP address using SSH. You can also add rules that allow inbound and outbound HTTP and HTTPS access from anywhere. Add any rules to open ports that are required by your tasks. Container instances require external network access to communicate with the Amazon ECS service endpoint.

If you plan to launch container instances in multiple Regions, you need to create a security group in each Region. For more information, see [Regions and Availability Zones](#) in the *Amazon EC2 User Guide*.

### Tip

You need the public IP address of your local computer, which you can get using a service. For example, we provide the following service: <http://checkip.amazonaws.com/> or <https://checkip.amazonaws.com/>. To locate another service that provides your IP address, use the search phrase "what is my IP address." If you are connecting through an internet service provider (ISP) or from behind a firewall without a static IP address, you must find out the range of IP addresses used by client computers.

For information about how to create a security group, see [Create a security group for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide* and use the following table to determine what options to select.

| Option                                                                                                                                                                                                          | Value                                                                                   |  |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|--|
| Region                                                                                                                                                                                                          | The same Region in which you created your key pair.                                     |  |
| Name                                                                                                                                                                                                            | A name that is easy for you to remember, such as <i>ecs-instances-default-cluster</i> . |  |
| VPC                                                                                                                                                                                                             | The default VPC (marked with "(default)").                                              |  |
| <div> <b>Note</b><br/>If your account supports Amazon EC2 Classic, select the VPC that you created in the previous task.</div> |                                                                                         |  |

For information about the outbound rules to add for your use cases, see [Security group rules for different use cases](#) in the *Amazon EC2 User Guide*.

Amazon ECS container instances do not require any inbound ports to be open. However, you might want to add an SSH rule so you can log into the container instance and examine the tasks with Docker commands. You can also add rules for HTTP and HTTPS if you want your container instance to host a task that runs a web server. Container instances do require external network access to communicate with the Amazon ECS service endpoint. Complete the following steps to add these optional security group rules.

Add the following three inbound rules to your security group. For information about how to create a security group, see [Configure security group rules](#) in the *Amazon EC2 User Guide*.

| Option    | Value      |  |
|-----------|------------|--|
| HTTP rule | Type: HTTP |  |

| Option     | Value                                                                                                                                                                                                                                                                                                                                 |  |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|            | <p>Source: Anywhere<br/>(0.0.0.0/0 )</p> <p>This option automatically adds the 0.0.0.0/0 IPv4 CIDR block as the source. This is acceptable for a short time in a test environment, but it's unsafe in production environments. In production, authorize only a specific IP address or range of addresses to access your instance.</p> |  |
| HTTPS rule | <p>Type: HTTPS</p> <p>Source: Anywhere<br/>(0.0.0.0/0 )</p> <p>This is acceptable for a short time in a test environment, but it's unsafe in production environments. In production, authorize only a specific IP address or range of addresses to access your instance.</p>                                                          |  |

| Option   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| SSH rule | <p>Type: SSH</p> <p>Source: Custom, specify the public IP address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing prefix /32. For example, if your IP address is 203.0.113.25 , specify 203.0.113.25/32 . If your company allocates addresses from a range, specify the entire range, such as 203.0.113.0/24 .</p> <div><p> <b>Important</b></p><p>For security reasons, we don't recommend that you allow SSH access from all IP addresses (0.0.0.0/0 ) to your instance, except for testing purposes and only for a short time.</p></div> |  |

## Create the credentials to connect to your EC2 instance

For Amazon ECS, a key pair is only needed if you intend on using EC2.

AWS uses public-key cryptography to secure the login information for your instance. A Linux instance, such as an Amazon ECS container instance, has no password to use for SSH access. You use a key pair to log in to your instance securely. You specify the name of the key pair when you launch your container instance, then provide the private key when you log in using SSH.

If you haven't created a key pair already, you can create one using the Amazon EC2 console. If you plan to launch instances in multiple regions, you'll need to create a key pair in each region. For more information about regions, see [Regions and Availability Zones](#) in the *Amazon EC2 User Guide*.

### To create a key pair

- Use the Amazon EC2 console to create a key pair. For more information about creating a key pair, see [Create a key pair](#) in the *Amazon EC2 User Guide*.

For information about how to connect to your instance, see [Connect to your Linux instance](#) in the *Amazon EC2 User Guide*.

## Install the AWS CLI

The AWS Management Console can be used to manage all operations manually with Amazon ECS. However, you can install the AWS CLI on your local desktop or a developer box so that you can build scripts that can automate common management tasks in Amazon ECS.

To use the AWS CLI with Amazon ECS, install the latest AWS CLI version. For information about installing the AWS CLI or upgrading it to the latest version, see [Installing or updating to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The AWS Command Line Interface (AWS CLI) is a unified tool that you can use to manage your AWS services. With this one tool alone, you can both control multiple AWS services and automate these services through scripts. The Amazon ECS commands in the AWS CLI are a reflection of the Amazon ECS API.

The AWS CLI is suitable for customers who prefer and are used to scripting and interfacing with a command line tool and know exactly which actions they want to perform on their Amazon ECS resources. The AWS CLI is also helpful to customers who want to familiarize themselves with the Amazon ECS APIs. Customers can use the AWS CLI to perform a number of operations on Amazon ECS resources, including Create, Read, Update, and Delete operations, directly from the command line interface.

Use the AWS CLI if you are or want to become familiar with the Amazon ECS APIs and corresponding CLI commands and want to write automated scripts and perform specific actions on Amazon ECS resources.

AWS also provides the command line tools [AWS Tools for Windows PowerShell](#). For more information, see the [AWS Tools for Windows PowerShell User Guide](#).

## Next steps for using Amazon ECS

After installing the AWS CLI, there are many different tools you can use as you continue to use Amazon ECS. The following links explain what some of those tools are and give examples of how to use them with Amazon ECS.

- [Create your first container image](#) with Docker and push it to Amazon ECR for use in your Amazon ECS task definitions.
- [Learn how to create an Amazon ECS Linux task for Fargate](#).
- [Learn how to create an Amazon ECS Windows task for Fargate](#).
- [Learn how to create an Amazon ECS Windows task for EC2](#).
- Using your preferred programming language, define infrastructure or architecture as code with the [Creating Amazon ECS resources using the AWS CDK](#).
- Define and manage all AWS resources in your environment with automated deployment using [Using Amazon ECS with AWS CloudFormation](#).
- Use the complete [Creating Amazon ECS resources using the AWS Copilot command line interface](#) end-to-end developer workflow to create, release, and operate container applications that comply with AWS best practices for infrastructure.

## Creating a container image for use on Amazon ECS

Amazon ECS uses Docker images in task definitions to launch containers. Docker is a technology that provides the tools for you to build, run, test, and deploy distributed applications in containers.

Amazon ECS schedules containerized applications on to container instances or on to AWS Fargate. Containerized applications are packaged as container images. This example creates a container image for a web server.

You can create your first Docker image, and then push that image to Amazon ECR, which is a container registry, for use in your Amazon ECS task definitions. This walkthrough assumes that you

possess a basic understanding of what Docker is and how it works. For more information about Docker, see [What is Docker?](#) and the [Docker documentation](#).

## Prerequisites

Before you begin, ensure the following prerequisites are met.

- Ensure you have completed the Amazon ECR setup steps. For more information, see [Moving an image through its lifecycle in Amazon ECR](#) in the *Amazon Elastic Container Registry User Guide*.
- Your user has the required IAM permissions to access and use the Amazon ECR service. For more information, see [Amazon ECR managed policies](#).
- You have Docker installed. For Docker installation steps for Amazon Linux 2023, see [Installing Docker on AL2023](#). For all other operating systems, see the Docker documentation at [Docker Desktop overview](#).
- You have the AWS CLI installed and configured. For more information, see [Installing or updating to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

If you don't have or need a local development environment and you prefer to use an Amazon EC2 instance to use Docker, we provide the following steps to launch an Amazon EC2 instance using Amazon Linux 2023 and install Docker Engine and the Docker CLI.

### Installing Docker on AL2023

Docker is available on many different operating systems, including most modern Linux distributions, like Ubuntu, and even macOS and Windows. For more information about how to install Docker on your particular operating system, go to the [Docker installation guide](#).

You do not need a local development system to use Docker. If you are using Amazon EC2 already, you can launch an Amazon Linux 2023 instance and install Docker to get started.

If you already have Docker installed, skip to [Create a Docker image](#).

### To install Docker on an Amazon EC2 instance using an Amazon Linux 2023 AMI

1. Launch an instance with the latest Amazon Linux 2023 AMI. For more information, see [Launch an EC2 instance using the launch instance wizard in the console](#) in the *Amazon EC2 User Guide*.
2. Connect to your instance. For more information, see [Connect to your EC2 instance](#) in the *Amazon EC2 User Guide*.
3. Update the installed packages and package cache on your instance.

```
sudo yum update -y
```

4. Install the most recent Docker Community Edition package.

```
sudo yum install docker
```

5. Start the Docker service.

```
sudo service docker start
```

6. Add the `ec2-user` to the `docker` group so you can execute Docker commands without using `sudo`.

```
sudo usermod -a -G docker ec2-user
```

7. Log out and log back in again to pick up the new `docker` group permissions. You can accomplish this by closing your current SSH terminal window and reconnecting to your instance in a new one. Your new SSH session will have the appropriate `docker` group permissions.
8. Verify that the `ec2-user` can run Docker commands without `sudo`.

```
docker info
```

#### Note

In some cases, you may need to reboot your instance to provide permissions for the `ec2-user` to access the Docker daemon. Try rebooting your instance if you see the following error:

```
Cannot connect to the Docker daemon. Is the docker daemon running on this host?
```

## Create a Docker image

Amazon ECS task definitions use container images to launch containers on the container instances in your clusters. In this section, you create a Docker image of a simple web application, and test

it on your local system or Amazon EC2 instance, and then push the image to the Amazon ECR container registry so you can use it in an Amazon ECS task definition.

## To create a Docker image of a simple web application

1. Create a file called `Dockerfile`. A Dockerfile is a manifest that describes the base image to use for your Docker image and what you want installed and running on it. For more information about Dockerfiles, go to the [Dockerfile Reference](#).

**touch Dockerfile**

2. Edit the Dockerfile you just created and add the following content.

```
FROM public.ecr.aws/amazonlinux/amazonlinux:latest

# Update installed packages and install Apache
RUN yum update -y && \
    yum install -y httpd

# Write hello world message
RUN echo 'Hello World!' > /var/www/html/index.html

# Configure Apache
RUN echo 'mkdir -p /var/run/httpd' >> /root/run_apache.sh && \
    echo 'mkdir -p /var/lock/httpd' >> /root/run_apache.sh && \
    echo '/usr/sbin/httpd -D FOREGROUND' >> /root/run_apache.sh && \
    chmod 755 /root/run_apache.sh

EXPOSE 80

CMD /root/run_apache.sh
```

This Dockerfile uses the public Amazon Linux 2023 image hosted on Amazon ECR Public. The RUN instructions update the package caches, installs some software packages for the web server, and then write the "Hello World!" content to the web servers document root. The EXPOSE instruction means that port 80 on the container is the one that is listening, and the CMD instruction starts the web server.

3. Build the Docker image from your Dockerfile.

**Note**

Some versions of Docker may require the full path to your Dockerfile in the following command, instead of the relative path shown in the following example.

If you run the command on an ARM based system, such as [Apple Silicon](#), use the `--platform` option `"--platform linux/amd64"`.

```
docker build -t hello-world .
```

4. List your container image.

```
docker images --filter reference=hello-world
```

Output:

| REPOSITORY<br>SIZE   | TAG    | IMAGE ID     | CREATED       |
|----------------------|--------|--------------|---------------|
| hello-world<br>194MB | latest | e9ffedc8c286 | 4 minutes ago |

5. Run the newly built image. The `-p 80:80` option maps the exposed port 80 on the container to port 80 on the host system.

```
docker run -t -i -p 80:80 hello-world
```

**Note**

Output from the Apache web server is displayed in the terminal window. You can ignore the "Could not reliably determine the fully qualified domain name" message.

6. Open a browser and point to the server that is running Docker and hosting your container.
  - If you are using an EC2 instance, this is the **Public DNS** value for the server, which is the same address you use to connect to the instance with SSH. Make sure that the security group for your instance allows inbound traffic on port 80.

- If you are running Docker locally, point your browser to <http://localhost/>.

You should see a web page with your "Hello World!" statement.

7. Stop the Docker container by typing **Ctrl + c**.

## Push your image to Amazon Elastic Container Registry

Amazon ECR is a managed AWS managed image registry service. You can use the Docker CLI to push, pull, and manage images in your Amazon ECR repositories. For Amazon ECR product details, featured customer case studies, and FAQs, see the [Amazon Elastic Container Registry product detail pages](#).

### To tag your image and push it to Amazon ECR

1. Create an Amazon ECR repository to store your hello-world image. Note the `repositoryUri` in the output.

Substitute `region`, with your AWS Region, for example, `us-east-1`.

```
aws ecr create-repository --repository-name hello-repository --region region
```

Output:

```
{
  "repository": {
    "registryId": "aws_account_id",
    "repositoryName": "hello-repository",
    "repositoryArn": "arn:aws:ecr:region:aws_account_id:repository/hello-  
repository",
    "createdAt": 1505337806.0,
    "repositoryUri": "aws_account_id.dkr.ecr.region.amazonaws.com/hello-  
repository"
  }
}
```

2. Tag the hello-world image with the `repositoryUri` value from the previous step.

```
docker tag hello-world aws_account_id.dkr.ecr.region.amazonaws.com/hello-repository
```

3. Run the `aws ecr get-login-password` command. Specify the registry URI you want to authenticate to. For more information, see [Registry Authentication](#) in the *Amazon Elastic Container Registry User Guide*.

```
aws ecr get-login-password --region region | docker login --username AWS --password-stdin aws_account_id.dkr.ecr.region.amazonaws.com
```

Output:

```
Login Succeeded
```

### Important

If you receive an error, install or upgrade to the latest version of the AWS CLI. For more information, see [Installing or updating to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

4. Push the image to Amazon ECR with the `repositoryUri` value from the earlier step.

```
docker push aws_account_id.dkr.ecr.region.amazonaws.com/hello-repository
```

## Clean up

To continue on with creating an Amazon ECS task definition and launching a task with your container image, skip to the [Next steps](#). When you are done experimenting with your Amazon ECR image, you can delete the repository so you are not charged for image storage.

```
aws ecr delete-repository --repository-name hello-repository --region region --force
```

## Next steps

Your task definitions require a task execution role. For more information, see [Amazon ECS task execution IAM role](#).

After you have created and pushed your container image to Amazon ECR, you can use that image in a task definition. For more information, see one of the following:

- [the section called “Learn how to create a Linux task for Fargate”](#)

- [the section called “Learn how to create a Windows task for Fargate”](#)
- [Creating an Amazon ECS Linux task for the Fargate with the AWS CLI](#)

## Learn how to create a task for Amazon ECS Managed Instances

Learn how to use Amazon ECS with Amazon ECS Managed Instances to run a containerized application.

### Prerequisites

Complete the following before you start the tutorial:

- You've completed the steps in [Set up to use Amazon ECS](#).
- The steps in [the section called “Set up”](#) have been completed.
- You have the required IAM roles for Amazon ECS Managed Instances. This includes:
  - Infrastructure role - Allows Amazon ECS to make calls to AWS services on your behalf to manage Amazon ECS Managed Instances infrastructure.

For more information, see [Amazon ECS infrastructure IAM role](#).

- Instance profile - Provides permissions for the Amazon ECS container agent and Docker daemon running on managed instances.

The instance role name must include `ecsInstanceRole` as a prefix to match the `iam:PassRole` action in the infrastructure role.

For more information, see [Amazon ECS Managed Instances instance profile](#).

- You have a VPC and security group created to use. This tutorial uses a container image hosted on Amazon ECR Public so your instances must have internet access. To give your instances a route to the internet, use one of the following options:
  - Use a private subnet with a NAT gateway that has an elastic IP address.
  - Use a public subnet and assign a public IP address to the instances.

For more information, see [the section called “Create a virtual private cloud”](#).

For information about security groups and rules, see [Default security groups for your VPCs](#) and [Example rules](#) in the *Amazon Virtual Private Cloud User Guide*.

- (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see [What is AWS CloudShell?](#) in the *AWS CloudShell User Guide*.

## Step 1: Create a cluster

1. Open the Amazon ECS console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, for **Cluster name**, enter a unique name for your cluster.
6. Under **Infrastructure**, choose **Fargate and Managed EC2**.
7. Configure the Managed Instances settings:
  - a. For **Infrastructure role**, select the IAM role you created for Managed Instances infrastructure management.
  - b. For **Instance profile**, select the `ecsInstanceRole` you created.
  - c. For **Instance attributes**, choose **Use ECS defaults**.
8. Under **Networking**, configure the VPC and subnets for your Managed Instances:
  - a. For **VPC**, select the VPC that hosts the Managed Instances.
  - b. For **Subnets**, select one or more subnets where your Managed Instances will be launched.
  - c. For **Security groups**, select one or more security groups.
9. (Optional) To add tags to your cluster, expand **Tags**, and then configure your tags.
10. Choose **Create**.

## Step 2: Create a task definition

A task definition is a blueprint for your application. Each time you launch a task in Amazon ECS, you specify a task definition. The service then knows which Docker image to use for containers, how many containers to use in the task, and the resource allocation for each container. Follow these steps to create a task definition:

1. In the navigation pane, choose **Task Definitions**.

2. Choose **Create new task definition, Create new task definition with JSON**.
3. Copy and paste the following JSON into the editor, replacing the pre-populated JSON:

Replace **account-id** with your AWS account ID and **region** with the Region you're using.

```
{
  "family": "managed-instance-tutorial",
  "networkMode": "awsvpc",
  "executionRoleArn": "arn:aws:iam::account-id:role/ecsTaskExecutionRole",
  "containerDefinitions": [
    {
      "name": "sample-app",
      "image": "public.ecr.aws/docker/library/httpd:latest",
      "essential": true,
      "portMappings": [
        {
          "containerPort": 80,
          "hostPort": 80,
          "protocol": "tcp"
        }
      ],
      "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
          "awslogs-group": "/ecs/managed-instance-tutorial",
          "awslogs-region": "region",
          "awslogs-stream-prefix": "ecs"
        }
      }
    }
  ],
  "requiresCompatibilities": [
    "MANAGED_INSTANCES"
  ],
  "cpu": "1024",
  "memory": "2048"
}
```

4. Choose **Create**.

## Step 3: Create a service

An Amazon ECS service allows you to run and maintain a specified number of instances of a task definition simultaneously in an Amazon ECS cluster. Follow these steps to create a service:

1. In the navigation pane, choose **Clusters**, and then select the **managed-instance-tutorial** cluster.
2. From the **Services** tab, choose **Create**.
3. For **Task definition family**, choose **managed-instance-tutorial**.
4. For **Service name**, enter **managed-instance-tutorial-service**.
5. Under **Environment**, Choose **Capacity provider strategy**.
6. Under **Networking**, configure the following:
  - a. Choose an existing VPC or create a new one.
  - b. For **Subnets**, choose the subnets to use.
  - c. For **Security groups**, either choose an existing security group or create a new one that allows inbound traffic on port 80.
7. Choose **Create**.

## Step 4: View your service

After your service has launched, you can view it to learn more about it and test it.

1. Choose the **managed-instance-tutorial-service** service.
2. From the **Tasks** tab, choose the task ID of the running task.
3. Under **Network**, in **Public IP**, choose **Open address**.
4. You should see the Apache HTTP Server test page, which confirms that the web server is running properly.

## Step 5: Clean up

When you're finished with this tutorial, you should clean up the associated resources to avoid incurring charges for resources that you're not using.

1. In the navigation pane, choose **Clusters**.

2. On the **Clusters** page, select the **managed-instance-tutorial** cluster.
3. Choose the **Services** tab.
4. Select the **managed-instance-tutorial-service** service, and then choose **Delete**.
5. At the confirmation prompt, enter **delete** and then choose **Delete**.
6. After the service is deleted, choose **Clusters** in the navigation pane.
7. On the **Clusters** page, select the **managed-instance-tutorial** cluster, and then choose **Delete cluster**.
8. At the confirmation prompt, enter **delete managed-instance-tutorial** and then choose **Delete**.

## Learn how to create a task for Amazon ECS Managed Instances with the AWS CLI

The following steps help you set up a cluster, create a capacity provider, register a task definition, run a Linux task, and perform other common scenarios in Amazon ECS with Amazon ECS Managed Instances using the AWS CLI. Use the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing or updating to the latest version of the AWS CLI](#).

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [the section called "Using dual-stack endpoints"](#).

### Topics

- [the section called "Prerequisites"](#)
- [the section called "Step 1: Create a cluster"](#)
- [the section called "Step 2: Create a Amazon ECS Managed Instances capacity provider"](#)
- [the section called "Step 3: Configure the cluster's default capacity provider strategy"](#)
- [the section called "Step 4: Register a Linux task definition"](#)
- [the section called "Step 5: List task definitions"](#)
- [the section called "Step 6: Create a service"](#)

- [the section called “Step 7: List services”](#)
- [the section called “Step 8: Describe the running service”](#)
- [the section called “Step 9: Test”](#)
- [the section called “Step 10: Clean up”](#)

## Prerequisites

Complete the following before you start the tutorial:

- You've completed the steps in [Set up to use Amazon ECS](#).
- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading the AWS CLI, see [Installing or updating to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
- The steps in [the section called “Set up”](#) have been completed.
- You have the required IAM roles for Amazon ECS Managed Instances. This includes:
  - Infrastructure role - Allows Amazon ECS to make calls to AWS services on your behalf to manage Amazon ECS Managed Instances infrastructure.

For more information, see [Amazon ECS infrastructure IAM role](#).

- Instance profile - Provides permissions for the Amazon ECS container agent and Docker daemon running on managed instances.

The instance role name must include `ecsInstanceRole` as a prefix to match the `iam:PassRole` action in the infrastructure role.

For more information, see [Amazon ECS Managed Instances instance profile](#).

- You have a VPC and security group created to use. This tutorial uses a container image hosted on Amazon ECR Public so your instances must have internet access. To give your instances a route to the internet, use one of the following options:
  - Use a private subnet with a NAT gateway that has an elastic IP address.
  - Use a public subnet and assign a public IP address to the instances.

For more information, see [the section called “Create a virtual private cloud”](#).

For information about security groups and rules, see [Default security groups for your VPCs](#) and [Example rules](#) in the *Amazon Virtual Private Cloud User Guide*.

- (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see [What is AWS CloudShell?](#) in the *AWS CloudShell User Guide*.

## Step 1: Create a cluster

By default, your account receives a default cluster.

### Note

The benefit of using the default cluster that is provided for you is that you don't have to specify the `--cluster` *cluster\_name* option in the subsequent commands. If you do create your own, non-default, cluster, you must specify `--cluster` *cluster\_name* for each command that you intend to use with that cluster.

Create your own cluster with a unique name with the following command:

```
aws ecs create-cluster --cluster-name managed-instances-cluster
```

Output:

```
{
  "cluster": {
    "status": "ACTIVE",
    "defaultCapacityProviderStrategy": [],
    "statistics": [],
    "capacityProviders": [],
    "tags": [],
    "clusterName": "managed-instances-cluster",
    "settings": [
      {
        "name": "containerInsights",
        "value": "disabled"
      }
    ],
    "registeredContainerInstancesCount": 0,
    "pendingTasksCount": 0,
    "runningTasksCount": 0,
    "activeServicesCount": 0,
  }
}
```

```

        "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/managed-instances-
cluster"
    }
}

```

## Step 2: Create a Amazon ECS Managed Instances capacity provider

Before you can run tasks using Amazon ECS Managed Instances, you must create a capacity provider that defines the infrastructure configuration. The capacity provider specifies the IAM roles, network configuration, and other settings for your managed instances.

Create a JSON file with your capacity provider configuration. Replace the placeholder values with your actual resource identifiers:

```

{
    "name": "managed-instances-cp",
    "cluster": "managed-instances-cluster",
    "managedInstancesProvider": {
        "infrastructureRoleArn":
"arn:aws:iam::aws_account_id:role/ecsInfrastructureRole",
        "instanceLaunchTemplate": {
            "ec2InstanceProfileArn": "arn:aws:iam::aws_account_id:instance-
profile/ecsInstanceRole",
            "networkConfiguration": {
                "subnets": [
                    "subnet-abcdef01234567890",
                    "subnet-1234567890abcdef0"
                ],
                "securityGroups": [
                    "sg-0123456789abcdef0"
                ]
            },
            "storageConfiguration": {
                "storageSizeGiB": 100
            },
            "monitoring": "basic"
        }
    }
}

```

Save this configuration as `managed-instances-cp.json` and create the capacity provider:

```
aws ecs create-capacity-provider --cli-input-json file://managed-instances-cp.json
```

The command returns a description of the capacity provider after it completes its creation.

### Step 3: Configure the cluster's default capacity provider strategy

Update the cluster to use the Amazon ECS Managed Instances capacity provider as the default capacity provider strategy. This allows tasks and services to automatically use Amazon ECS Managed Instances without explicitly specifying the capacity provider.

Create a JSON file with the cluster capacity provider configuration:

```
{
  "cluster": "managed-instances-cluster",
  "capacityProviders": [
    "managed-instances-cp"
  ],
  "defaultCapacityProviderStrategy": [
    {
      "capacityProvider": "managed-instances-cp",
      "weight": 1
    }
  ]
}
```

Save this configuration as `cluster-cp-strategy.json` and update the cluster:

```
aws ecs put-cluster-capacity-providers --cli-input-json file://cluster-cp-strategy.json
```

### Step 4: Register a Linux task definition

Before you can run a task on your cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that creates a PHP web app using the `httpd` container image hosted on Docker Hub. For more information about the available task definition parameters, see [the section called "Task definition parameters for Fargate"](#).

```
{
  "family": "sample-managed-instances",
  "networkMode": "awsvpc",
```

```

"containerDefinitions": [
  {
    "name": "managed-instances-app",
    "image": "public.ecr.aws/docker/library/httpd:latest",
    "portMappings": [
      {
        "containerPort": 80,
        "hostPort": 80,
        "protocol": "tcp"
      }
    ],
    "essential": true,
    "entryPoint": [
      "sh",
      "-c"
    ],
    "command": [
      "/bin/sh -c \"echo '<html><head><title>Amazon ECS Sample App</title><style>body {margin-top: 40px; background-color: #333;} </style></head><body><div style=color:white;text-align:center><h1>Amazon ECS Sample App</h1><h2>Congratulations!</h2><p>Your application is now running on a container in Amazon ECS using Amazon ECS Managed Instances.</p></div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-foreground\""
    ]
  }
],
"requiresCompatibilities": [
  "MANAGED_INSTANCES"
],
"cpu": "256",
"memory": "512"
}

```

Save the task definition JSON as a file and pass it with the `--cli-input-json` option: `file://path_to_file.json`.

To use a JSON file for container definitions:

```
aws ecs register-task-definition --cli-input-json file://$HOME/tasks/managed-instances-task.json
```

The **register-task-definition** command returns a description of the task definition after it completes its registration.

## Step 5: List task definitions

You can list the task definitions for your account at any time with the **list-task-definitions** command. The output of this command shows the family and revision values that you can use together when calling **run-task** or **start-task**.

```
aws ecs list-task-definitions
```

Output:

```
{
  "taskDefinitionArns": [
    "arn:aws:ecs:region:aws_account_id:task-definition/sample-managed-instances:1"
  ]
}
```

## Step 6: Create a service

After you have registered a task for your account, you can create a service for the registered task in your cluster. For this example, you create a service with one instance of the `sample-managed-instances:1` task definition running in your cluster. The task requires a route to the internet, so there are two ways you can achieve this. One way is to use a private subnet configured with a NAT gateway with an elastic IP address in a public subnet. Another way is to use a public subnet and assign a public IP address to your task. We provide both examples below.

Example using a private subnet:

```
aws ecs create-service --cluster managed-instances-cluster --service-name managed-instances-service --task-definition sample-managed-instances:1 --desired-count 1 --network-configuration "awsvpcConfiguration={subnets=[subnet-abcd1234],securityGroups=[sg-abcd1234]}"
```

Example using a public subnet:

```
aws ecs create-service --cluster managed-instances-cluster --service-name managed-instances-service --task-definition sample-managed-instances:1 --desired-count 1 --network-configuration "awsvpcConfiguration={subnets=[subnet-abcd1234],securityGroups=[sg-abcd1234],assignPublicIp=ENABLED}"
```

The **create-service** command returns a description of the service after it completes its creation.

## Step 7: List services

List the services for your cluster. You should see the service that you created in the previous section. You can take the service name or the full ARN that is returned from this command and use it to describe the service later.

```
aws ecs list-services --cluster managed-instances-cluster
```

Output:

```
{
  "serviceArns": [
    "arn:aws:ecs:region:aws_account_id:service/managed-instances-cluster/managed-
instances-service"
  ]
}
```

## Step 8: Describe the running service

Describe the service using the service name retrieved earlier to get more information about the task.

```
aws ecs describe-services --cluster managed-instances-cluster --services managed-
instances-service
```

If successful, this will return a description of the service failures and services. For example, in the `services` section, you will find information on deployments, such as the status of the tasks as running or pending. You may also find information on the task definition, the network configuration and time-stamped events. In the `failures` section, you will find information on failures, if any, associated with the call.

The output will show that the service is using the Amazon ECS Managed Instances capacity provider:

```
{
  "services": [
    {
      "capacityProviderStrategy": [
```

```

        {
            "capacityProvider": "managed-instances-cp",
            "weight": 1,
            "base": 0
        }
    ],
    "networkConfiguration": {
        "awsVpcConfiguration": {
            "subnets": [
                "subnet-abcd1234"
            ],
            "securityGroups": [
                "sg-abcd1234"
            ],
            "assignPublicIp": "ENABLED"
        }
    },
    "enableECSManagedTags": false,
    "loadBalancers": [],
    "deploymentController": {
        "type": "ECS"
    },
    "desiredCount": 1,
    "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/managed-instances-cluster",
    "serviceArn": "arn:aws:ecs:region:aws_account_id:service/managed-instances-cluster/managed-instances-service",
    "serviceName": "managed-instances-service",
    "taskDefinition": "arn:aws:ecs:region:aws_account_id:task-definition/sample-managed-instances:1"
    }
    ],
    "failures": []
}

```

## Step 9: Test

To test your deployment, you need to find the public IP address of the managed instance running your task.

### Testing task deployed using public subnet

First, get the task ARN from your service:

```
aws ecs list-tasks --cluster managed-instances-cluster --service managed-instances-  
service
```

The output contains the task ARN:

```
{  
  "taskArns": [  
    "arn:aws:ecs:region:aws_account_id:task/managed-instances-cluster/EXAMPLE"  
  ]  
}
```

Describe the task to get the container instance ARN. Use the task ARN for the tasks parameter:

```
aws ecs describe-tasks --cluster managed-instances-cluster --tasks  
arn:aws:ecs:region:aws_account_id:task/managed-instances-cluster/EXAMPLE
```

The output shows the task is running on Amazon ECS Managed Instances and includes the container instance ARN:

```
{  
  "tasks": [  
    {  
      "launchType": "MANAGED_INSTANCES",  
      "capacityProviderName": "managed-instances-cp",  
      "containerInstanceArn": "arn:aws:ecs:region:aws_account_id:container-  
instance/managed-instances-cluster/CONTAINER_INSTANCE_ID",  
      "taskArn": "arn:aws:ecs:region:aws_account_id:task/managed-instances-  
cluster/EXAMPLE",  
      "taskDefinitionArn": "arn:aws:ecs:region:aws_account_id:task-definition/  
sample-managed-instances:1"  
    }  
  ]  
}
```

Describe the container instance to get the EC2 instance ID:

```
aws ecs describe-container-instances --cluster managed-instances-cluster --container-  
instances CONTAINER_INSTANCE_ID
```

The output includes the EC2 instance ID:

```
{
  "containerInstances": [
    {
      "ec2InstanceId": "i-1234567890abcdef0",
      "capacityProviderName": "managed-instances-cp",
      "containerInstanceArn": "arn:aws:ecs:region:aws_account_id:container-
instance/managed-instances-cluster/CONTAINER_INSTANCE_ID"
    }
  ]
}
```

Describe the EC2 instance to get the public IP address:

```
aws ec2 describe-instances --instance-ids i-1234567890abcdef0
```

The public IP address is in the output:

```
{
  "Reservations": [
    {
      "Instances": [
        {
          "PublicIpAddress": "198.51.100.2",
          "InstanceId": "i-1234567890abcdef0"
        }
      ]
    }
  ]
}
```

Enter the public IP address in your web browser and you should see a webpage that displays the **Amazon ECS** sample application running on Amazon ECS Managed Instances.

## Testing task deployed using private subnet

For tasks deployed in private subnets, you can use Amazon ECS Exec to connect to the container and test the deployment from within the instance. Follow the same preceding steps to get the task ARN, then use ECS Exec:

```
aws ecs execute-command --cluster managed-instances-cluster \
  --task arn:aws:ecs:region:aws_account_id:task/managed-instances-cluster/EXAMPLE \
```

```
--container managed-instances-app \  
--interactive \  
--command "/bin/sh"
```

After the interactive shell is running, you can test the web server:

```
curl localhost
```

You should see the HTML equivalent of the **Amazon ECS** sample application webpage.

## Step 10: Clean up

When you are finished with this tutorial, you should clean up the associated resources to avoid incurring charges for unused resources.

Delete the service:

```
aws ecs delete-service --cluster managed-instances-cluster --service managed-instances-  
service --force
```

Wait for the service to be deleted and all tasks to stop, then delete the capacity provider:

```
aws ecs delete-capacity-provider --capacity-provider managed-instances-cp
```

Delete the cluster:

```
aws ecs delete-cluster --cluster managed-instances-cluster
```

### Note

The managed instances are automatically terminated when the capacity provider is deleted. You don't need to manually terminate the EC2 instances.

## Learn how to create an Amazon ECS Linux task for Fargate

Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage your containers. You can host your containers

on a serverless infrastructure that is managed by Amazon ECS by launching your services or tasks on AWS Fargate. For more information on Fargate, see [Architect for AWS Fargate for Amazon ECS](#).

Get started with Amazon ECS on AWS Fargate by using Fargate for your tasks in the Regions where Amazon ECS supports AWS Fargate.

Complete the following steps to get started with Amazon ECS on AWS Fargate.

## Prerequisites

Before you begin, complete the steps in [Set up to use Amazon ECS](#) and that your IAM user has the permissions specified in the AdministratorAccess IAM policy example.

The console attempts to automatically create the task execution IAM role, which is required for Fargate tasks. To ensure that the console is able to create this IAM role, one of the following must be true:

- Your user has administrator access. For more information, see [Set up to use Amazon ECS](#).
- Your user has the IAM permissions to create a service role. For more information, see [Creating a Role to Delegate Permissions to an AWS Service](#).
- A user with administrator access has manually created the task execution role so that it is available on the account to be used. For more information, see [Amazon ECS task execution IAM role](#).

### Important

The security group you select when creating a service with your task definition must have port 80 open for inbound traffic. Add the following inbound rule to your security group. For information about how to create a security group, see [Create a security group for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide*.

- Type: HTTP
- Protocol: TCP
- Port range: 80
- Source: Anywhere (0.0.0.0/0)

## Step 1: Create the cluster

Create a cluster that uses the default VPC.

Before you begin, assign the appropriate IAM permission. For more information, see [the section called “Amazon ECS cluster examples”](#).

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, for **Cluster name**, enter a unique name.

The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.

6. (Optional) To turn on Container Insights, expand **Monitoring**, and then turn on **Use Container Insights**.
7. (Optional) To help identify your cluster, expand **Tags**, and then configure your tags.

[Add a tag] Choose **Add tag** and do the following:

- For **Key**, enter the key name.
- For **Value**, enter the key value.

[Remove a tag] Choose **Remove** to the right of the tag's Key and Value.

8. Choose **Create**.

## Step 2: Create a task definition

A task definition is like a blueprint for your application. Each time you launch a task in Amazon ECS, you specify a task definition. The service then knows which Docker image to use for containers, how many containers to use in the task, and the resource allocation for each container.

1. In the navigation pane, choose **Task Definitions**.
2. Choose **Create new Task Definition, Create new revision with JSON**.
3. Copy and paste the following example task definition into the box and then choose **Save**.

```
{
  "family": "sample-fargate",
  "networkMode": "awsvpc",
  "containerDefinitions": [
    {
      "name": "fargate-app",
      "image": "public.ecr.aws/docker/library/httpd:latest",
      "portMappings": [
        {
          "containerPort": 80,
          "hostPort": 80,
          "protocol": "tcp"
        }
      ],
      "essential": true,
      "entryPoint": [
        "sh",
        "-c"
      ],
      "command": [
        "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-foreground\""
      ]
    }
  ],
  "requiresCompatibilities": [
    "FARGATE"
  ],
  "cpu": "256",
  "memory": "512"
}
```

#### 4. Choose **Create**.

## Step 3: Create the service

Create a service using the task definition.

1. In the navigation pane, choose **Clusters**, and then select the cluster you created in [Step 1: Create the cluster](#).
2. From the **Services** tab, choose **Create**.
3. Under **Service details**, specify how your application is deployed.
  - a. For **Task definition family**, choose the task definition you created in [Step 2: Create a task definition](#).
  - b. For **Service name**, enter a name for your service.
4. Under **Environment**, choose **Launch type** and then choose FARGATE.
5. Under **Deployment configuration**, for **Desired tasks**, enter **1**.
6. Under **Networking**, you can create a new security group or choose an existing security group for your task. Ensure that the security group you use has the inbound rule listed under [Prerequisites](#).
7. Choose **Create**.

## Step 4: View your service

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. Choose the cluster where you ran the service.
4. In the **Services** tab, under **Service name**, choose the service you created in [Step 3: Create the service](#).
5. Choose the **Tasks** tab, and then choose the task in your service.
6. On the task page, in the **Configuration** section, under **Public IP**, choose **Open address**.

## Step 5: Clean up

When you are finished using an Amazon ECS cluster, you should clean up the resources associated with it to avoid incurring charges for resources that you are not using.

Some Amazon ECS resources, such as tasks, services, clusters, and container instances, are cleaned up using the Amazon ECS console. Other resources, such as Amazon EC2 instances, Elastic Load Balancing load balancers, and Auto Scaling groups, must be cleaned up manually in the Amazon EC2 console or by deleting the CloudFormation stack that created them.

1. In the navigation pane, choose **Clusters**.
2. On the **Clusters** page, select the cluster you created for this tutorial.
3. Choose the **Services** tab.
4. Select the service, and then choose **Delete**.
5. At the confirmation prompt, enter **delete** and then choose **Delete**. Alternatively, you can use the **Force delete** option to have Amazon ECS scale the service down on your behalf before deleting it.

Wait until the service is deleted.

6. Choose **Delete Cluster**. At the confirmation prompt, enter **delete *cluster-name***, and then choose **Delete**. Deleting the cluster cleans up the associated resources that were created with the cluster, including Auto Scaling groups, VPCs, or load balancers.

## Learn how to create an Amazon ECS Windows task for Fargate

Get started with Amazon ECS on AWS Fargate by using Fargate for your tasks in the Regions where Amazon ECS supports AWS Fargate.

Complete the following steps to get started with Amazon ECS on AWS Fargate.

### Prerequisites

Before you begin, complete the steps in [Set up to use Amazon ECS](#) and that your IAM user has the permissions specified in the AdministratorAccess IAM policy example.

The console attempts to automatically create the task execution IAM role, which is required for Fargate tasks. To ensure that the console is able to create this IAM role, one of the following must be true:

- Your user has administrator access. For more information, see [Set up to use Amazon ECS](#).
- Your user has the IAM permissions to create a service role. For more information, see [Creating a Role to Delegate Permissions to an AWS Service](#).
- A user with administrator access has manually created the task execution role so that it is available on the account to be used. For more information, see [Amazon ECS task execution IAM role](#).

### Important

The security group you select when creating a service with your task definition must have port 80 open for inbound traffic. Add the following inbound rule to your security group. For information about how to create a security group, see [Create a security group for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide*.

- Type: HTTP
- Protocol: TCP
- Port range: 80
- Source: Anywhere (0.0.0.0/0)

## Step 1: Create a cluster

You can create a new cluster called **windows** that uses the default VPC.

### To create a cluster with the AWS Management Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, for **Cluster name**, enter **windows**.
6. (Optional) To turn on Container Insights, expand **Monitoring**, and then turn on **Use Container Insights**.
7. (Optional) To help identify your cluster, expand **Tags**, and then configure your tags.

[Add a tag] Choose **Add tag** and do the following:

- For **Key**, enter the key name.
- For **Value**, enter the key value.

[Remove a tag] Choose **Remove** to the right of the tag's Key and Value.

8. Choose **Create**.

## Step 2: Register a Windows task definition

Before you can run Windows containers in your Amazon ECS cluster, you must register a task definition. The following task definition example displays a simple webpage on port 8080 of a container instance with the `mcr.microsoft.com/windows/servercore/iis` container image.

### To register the sample task definition with the AWS Management Console

1. In the navigation pane, choose **Task definitions**.
2. Choose **Create new task definition**, **Create new task definition with JSON**.
3. Copy and paste the following example task definition into the box and then choose **Save**.

```
{
  "containerDefinitions": [
    {
      "command": ["New-Item -Path C:\\\\inetpub\\\\wwwroot\\\\index.html
-Type file -Value '<html> <head> <title>Amazon ECS Sample App</title>
<style>body {margin-top: 40px; background-color: #333;} </style> </head><body>
<div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1>
<h2>Congratulations!</h2> <p>Your application is now running on a container in
Amazon ECS.</p>'; C:\\\\ServiceMonitor.exe w3svc"],
      "entryPoint": [
        "powershell",
        "-Command"
      ],
      "essential": true,
      "cpu": 2048,
      "memory": 4096,
      "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-
ltsc2019",
      "name": "sample_windows_app",
      "portMappings": [
        {
          "hostPort": 80,
          "containerPort": 80,
          "protocol": "tcp"
        }
      ]
    }
  ],
  "memory": "4096",
  "cpu": "2048",
```

```
"networkMode": "awsvpc",
"family": "windows-simple-iis-2019-core",
"executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
"runtimePlatform": {"operatingSystemFamily": "WINDOWS_SERVER_2019_CORE"},
"requiresCompatibilities": ["FARGATE"]
}
```

4. Verify your information and choose **Create**.

## Step 3: Create a service with your task definition

After you have registered your task definition, you can place tasks in your cluster with it. The following procedure creates a service with your task definition and places one task in your cluster.

### To create a service from your task definition with the console

1. In the navigation pane, choose **Clusters**, and then select the cluster you created in [Step 1: Create a cluster](#).
2. From the **Services** tab, choose **Create**.
3. Under **Deployment configuration**, specify how your application is deployed.
  - a. For **Task definition**, choose the task definition you created in [Step 2: Register a Windows task definition](#).
  - b. For **Service name**, enter a name for your service.
  - c. For **Desired tasks**, enter **1**.
4. Under **Networking**, you can create a security group or choose an existing group. Ensure that the security group you use has the inbound rule listed under [Prerequisites](#).
5. Choose **Create**.

## Step 4: View your service

After your service has launched a task into your cluster, you can view the service and open the IIS test page in a browser to verify that the container is running.

**Note**

It can take up to 15 minutes for your container instance to download and extract the Windows container base layers.

**To view your service**

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. Choose the cluster where you ran the service.
4. In the **Services** tab, under **Service name**, choose the service you created in [Step 3: Create a service with your task definition](#).
5. Choose the **Tasks** tab, and then choose the task in your service.
6. On the task page, in the **Configuration** section, under **Public IP**, choose **Open address**.

**Step 5: Clean Up**

When you are finished using an Amazon ECS cluster, you should clean up the resources associated with it to avoid incurring charges for resources that you are not using.

Some Amazon ECS resources, such as tasks, services, clusters, and container instances, are cleaned up using the Amazon ECS console. Other resources, such as Amazon EC2 instances, Elastic Load Balancing load balancers, and Auto Scaling groups, must be cleaned up manually in the Amazon EC2 console or by deleting the CloudFormation stack that created them.

1. In the navigation pane, choose **Clusters**.
2. On the **Clusters** page, select the cluster you created for this tutorial.
3. Choose the **Services** tab.
4. Select the service, and then choose **Delete**.
5. At the confirmation prompt, enter **delete** and then choose **Delete**.

Wait until the service is deleted.

6. Choose **Delete Cluster**. At the confirmation prompt, enter **delete *cluster-name***, and then choose **Delete**. Deleting the cluster cleans up the associated resources that were created with the cluster, including Auto Scaling groups, VPCs, or load balancers.

# Learn how to create an Amazon ECS Windows task for EC2

Get started with Amazon ECS using EC2 by registering a task definition, creating a cluster, and creating a service in the console.

Complete the following steps to get started with Amazon ECS using the EC2 launch type.

## Prerequisites

Before you begin, complete the steps in [Set up to use Amazon ECS](#) and that your IAM user has the permissions specified in the AdministratorAccess IAM policy example.

The console attempts to automatically create the task execution IAM role, which is required for Fargate tasks. To ensure that the console is able to create this IAM role, one of the following must be true:

- Your user has administrator access. For more information, see [Set up to use Amazon ECS](#).
- Your user has the IAM permissions to create a service role. For more information, see [Creating a Role to Delegate Permissions to an AWS Service](#).
- A user with administrator access has manually created the task execution role so that it is available on the account to be used. For more information, see [Amazon ECS task execution IAM role](#).

### Important

The security group you select when creating a service with your task definition must have port 80 open for inbound traffic. Add the following inbound rule to your security group. For information about how to create a security group, see [Create a security group for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide*.

- Type: HTTP
- Protocol: TCP
- Port range: 80
- Source: Anywhere (0.0.0.0/0)

## Step 1: Create a cluster

An Amazon ECS cluster is a logical grouping of tasks, services, and container instances.

The following steps walk you through creating a cluster with one Amazon EC2 instance registered to it which will enable us to run a task on it. If a specific field is not mentioned, leave the default console values.

### To create a new cluster (Amazon ECS console)

Before you begin, assign the appropriate IAM permission. For more information, see [the section called "Amazon ECS cluster examples"](#).

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, for **Cluster name**, enter a unique name.

The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.

6. (Optional) To change the VPC and subnets where your tasks and services launch, under **Networking**, perform any of the following operations:
  - To remove a subnet, under **Subnets**, choose **X** for each subnet that you want to remove.
  - To change to a VPC other than the **default** VPC, under **VPC**, choose an existing **VPC**, and then under **Subnets**, select each subnet.
7. To add Amazon EC2 instances to your cluster, expand **Infrastructure**, and then select **Amazon EC2 instances**. Next, configure the Auto Scaling group which acts as the capacity provider:
  - a. To using an existing Auto Scaling group, from **Auto Scaling group (ASG)**, select the group.
  - b. To create a Auto Scaling group, from **Auto Scaling group (ASG)**, select **Create new group**, and then provide the following details about the group:
    - For **Operating system/Architecture**, choose the Amazon ECS-optimized AMI for the Auto Scaling group instances.
    - For **EC2 instance type**, choose the instance type for your workloads. For more information about the different instance types, see [Amazon EC2 Instances](#).

Managed scaling works best if your Auto Scaling group uses the same or similar instance types.

- For **SSH key pair**, choose the pair that proves your identity when you connect to the instance.
- For **Capacity**, enter the minimum number and the maximum number of instances to launch in the Auto Scaling group. Amazon EC2 instances incur costs while they exist in your AWS resources. For more information, see [Amazon EC2 Pricing](#).

8. (Optional) To turn on Container Insights, expand **Monitoring**, and then turn on **Use Container Insights**.
9. (Optional) To manage the cluster tags, expand **Tags**, and then perform one of the following operations:

[Add a tag] Choose **Add tag** and do the following:

- For **Key**, enter the key name.
- For **Value**, enter the key value.

[Remove a tag] Choose **Remove** to the right of the tag's Key and Value.

10. Choose **Create**.

## Step 2: Register a task definition

To register the sample task definition with the AWS Management Console

1. In the navigation pane, choose **Task Definitions**.
2. Choose **Create new task definition**, **Create new task definition with JSON**.
3. Copy and paste the following example task definition into the box, and then choose **Save**.

```
{
  "containerDefinitions": [
    {
      "command": ["New-Item -Path C:\\\\inetpub\\wwwroot\\index.html
-Type file -Value '<html> <head> <title>Amazon ECS Sample App</title>
<style>body {margin-top: 40px; background-color: #333;} </style> </head><body>
<div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1>
```

```

<h2>Congratulations!</h2> <p>Your application is now running on a container in
Amazon ECS.</p>'; C:\\ServiceMonitor.exe w3svc"],
    "entryPoint": [
        "powershell",
        "-Command"
    ],
    "essential": true,
    "cpu": 2048,
    "memory": 4096,
    "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-
ltsc2019",
    "name": "sample_windows_app",
    "portMappings": [
        {
            "hostPort": 443,
            "containerPort": 80,
            "protocol": "tcp"
        }
    ]
}
],
"memory": "4096",
"cpu": "2048",
"family": "windows-simple-iis-2019-core",
"executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
"runtimePlatform": {"operatingSystemFamily": "WINDOWS_SERVER_2019_CORE"},
"requiresCompatibilities": ["EC2"]
}

```

4. Verify your information and choose **Create**.

## Step 3: Create a Service

An Amazon ECS service helps you to run and maintain a specified number of instances of a task definition simultaneously in an Amazon ECS cluster. If any of your tasks should fail or stop for any reason, the Amazon ECS service scheduler launches another instance of your task definition to replace it in order to maintain the desired number of tasks in the service. For more information on services, see [Amazon ECS services](#).

### To create a service

1. In the navigation pane, choose **Clusters**.

2. Select the cluster you created in [Step 1: Create a cluster](#).
3. On the **Services** tab, choose **Create**.
4. In the **Environment** section, do the following:
  - a. For **Compute options**, choose Launch type.
  - b. For **Launch type**, select **EC2**
5. In the **Deployment configuration** section, do the following:
  - a. For **Family**, choose the task definition you created in [Step 2: Register a task definition](#).
  - b. For **Service name**, enter a name for your service.
  - c. For **Desired tasks**, enter 1.
6. Review the options and choose **Create**.
7. Choose **View service** to review your service.

## Step 4: View your Service

The service is a web-based application so you can view its containers with a web browser.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. Choose the cluster where you ran the service.
4. In the **Services** tab, under **Service name**, choose the service you created in [Step 3: Create a Service](#).
5. Choose the **Tasks** tab, and then choose the task in your service.
6. On the task page, in the **Configuration** section, under **Public IP**, choose **Open address**. The screen shot below is the expected output.

# Amazon ECS Sample App

## Congratulations!

Your application is now running on a container in Amazon ECS.

## Step 5: Clean Up

When you are finished using an Amazon ECS cluster, you should clean up the resources associated with it to avoid incurring charges for resources that you are not using.

Some Amazon ECS resources, such as tasks, services, clusters, and container instances, are cleaned up using the Amazon ECS console. Other resources, such as Amazon EC2 instances, Elastic Load Balancing load balancers, and Auto Scaling groups, must be cleaned up manually in the Amazon EC2 console or by deleting the CloudFormation stack that created them.

1. In the navigation pane, choose **Clusters**.
2. On the **Clusters** page, select the cluster you created for this tutorial.
3. Choose the **Services** tab.
4. Select the service, and then choose **Delete**.
5. At the confirmation prompt, enter **delete** and then choose **Delete**.

Wait until the service is deleted.

6. Choose **Delete Cluster**. At the confirmation prompt, enter **delete *cluster-name***, and then choose **Delete**. Deleting the cluster cleans up the associated resources that were created with the cluster, including Auto Scaling groups, VPCs, or load balancers.

## Creating Amazon ECS resources using the AWS CDK

The AWS Cloud Development Kit (AWS CDK) is an Infrastructure-as-Code (IAC) framework that you can use to define AWS cloud infrastructure by using a programming language of your choosing.

To define your own cloud infrastructure, you first write an app (in one of the CDK's supported languages) that contains one or more stacks. Then, you synthesize it to an CloudFormation template and deploy your resources to your AWS account. Follow the steps in this topic to deploy a containerized web server with Amazon Elastic Container Service (Amazon ECS) and the AWS CDK on Fargate.

The AWS Construct Library, included with the CDK, provides modules that you can use to model the resources that AWS services provide. For popular services, the library provides curated constructs with smart defaults and best practices. One of these modules, specifically [aws-ecs-patterns](#), provides high-level abstractions that you can use to define your containerized service and all the necessary supporting resources in a few lines of code.

This topic uses the [ApplicationLoadBalancedFargateService](#) construct. This construct deploys an Amazon ECS service on Fargate behind an application load balancer. The `aws-ecs-patterns` module also includes constructs that use a network load balancer and run on Amazon EC2.

Before starting this task, set up your AWS CDK development environment, and install the AWS CDK by running the following command. For instructions on how to set up your AWS CDK development environment, see [Getting Started With the AWS CDK - Prerequisites](#).

```
npm install -g aws-cdk
```

### Note

These instructions assume you are using AWS CDK v2.

## Topics

- [Step 1: Set up your AWS CDK project](#)
- [Step 2: Use the AWS CDK to define a containerized web server on Fargate](#)
- [Step 3: Test the web server](#)
- [Step 4: Clean up](#)
- [Next steps](#)

## Step 1: Set up your AWS CDK project

Create a directory for your new AWS CDK app and initialize the project.

### TypeScript

```
mkdir hello-ecs
cd hello-ecs
cdk init --language typescript
```

### JavaScript

```
mkdir hello-ecs
cd hello-ecs
cdk init --language javascript
```

### Python

```
mkdir hello-ecs
cd hello-ecs
cdk init --language python
```

After the project is started, activate the project's virtual environment and install the AWS CDK's baseline dependencies.

```
source .venv/bin/activate
python -m pip install -r requirements.txt
```

### Java

```
mkdir hello-ecs
cd hello-ecs
cdk init --language java
```

Import this Maven project to your Java IDE. For example, in Eclipse, use **File > Import > Maven > Existing Maven Projects**.

### C#

```
mkdir hello-ecs
cd hello-ecs
```

```
cdk init --language csharp
```

Go

```
mkdir hello-ecs  
cd hello-ecs  
cdk init --language go
```

### Note

The AWS CDK application template uses the name of the project directory to generate names for source files and classes. In this example, the directory is named `hello-ecs`. If you use a different project directory name, your app won't match these instructions.

AWS CDK v2 includes stable constructs for all AWS services in a single package that's called `aws-cdk-lib`. This package is installed as a dependency when you initialize the project. When working with certain programming languages, the package is installed when you build the project for the first time. This topic covers how to use an Amazon ECS Patterns construct, which provides high-level abstractions for working with Amazon ECS. This module relies on Amazon ECS constructs and other constructs to provision the resources that your Amazon ECS application needs.

The names that you use to import these libraries into your CDK application might differ slightly depending on which programming language you use. For reference, the following are the names that are used in each supported CDK programming language.

### TypeScript

```
aws-cdk-lib/aws-ecs  
aws-cdk-lib/aws-ecs-patterns
```

### JavaScript

```
aws-cdk-lib/aws-ecs  
aws-cdk-lib/aws-ecs-patterns
```

### Python

```
aws_cdk.aws_ecs
```

```
aws_cdk.aws_ecs_patterns
```

## Java

```
software.amazon.awscdk.services.ecs  
software.amazon.awscdk.services.ecs.patterns
```

## C#

```
Amazon.CDK.AWS.ECS  
Amazon.CDK.AWS.ECS.Patterns
```

## Go

```
github.com/aws/aws-cdk-go/awscdk/v2/awsecs  
github.com/aws/aws-cdk-go/awscdk/v2/awsecspatterns
```

## Step 2: Use the AWS CDK to define a containerized web server on Fargate

Use the container image [amazon-ecs-sample](#). This image contains a PHP web app that runs on nginx.

In the AWS CDK project that you created, edit the file that contains the stack definition to resemble one of the following examples.

### Note

A stack is a unit of deployment. All resources must be in a stack, and all the resources that are in a stack are deployed at the same time. If a resource fails to deploy, any other resources that were already deployed are rolled back. An AWS CDK app can contain multiple stacks, and resources in one stack can refer to resources in another stack.

## TypeScript

Update `lib/hello-ecs-stack.ts` so that it resembles the following.

```
import * as cdk from 'aws-cdk-lib';
import { Construct } from 'constructs';
import * as ecs from 'aws-cdk-lib/aws-ecs';
import * as ecsp from 'aws-cdk-lib/aws-ecs-patterns';

export class HelloEcsStack extends cdk.Stack {
  constructor(scope: Construct, id: string, props?: cdk.StackProps) {
    super(scope, id, props);

    new ecsp.ApplicationLoadBalancedFargateService(this, 'MyWebServer', {
      taskImageOptions: {
        image: ecs.ContainerImage.fromRegistry('public.ecr.aws/ecs-sample-image/
amazon-ecs-sample:latest'),
      },
      publicLoadBalancer: true
    });
  }
}
```

## JavaScript

Update `lib/hello-ecs-stack.js` so that it resembles the following.

```
const cdk = require('aws-cdk-lib');
const { Construct } = require('constructs');
const ecs = require('aws-cdk-lib/aws-ecs');
const ecsp = require('aws-cdk-lib/aws-ecs-patterns');

class HelloEcsStack extends cdk.Stack {
  constructor(scope = Construct, id = string, props = cdk.StackProps) {
    super(scope, id, props);

    new ecsp.ApplicationLoadBalancedFargateService(this, 'MyWebServer', {
      taskImageOptions: {
        image: ecs.ContainerImage.fromRegistry('amazon/amazon-ecs-sample'),
      },
      publicLoadBalancer: true
    });
  }
}

module.exports = { HelloEcsStack }
```

## Python

Update `hello-ecs/hello_ecs_stack.py` so that it resembles the following.

```
import aws_cdk as cdk
from constructs import Construct

import aws_cdk.aws_ecs as ecs
import aws_cdk.aws_ecs_patterns as ecsp

class HelloEcsStack(cdk.Stack):

    def __init__(self, scope: Construct, construct_id: str, **kwargs) -> None:
        super().__init__(scope, construct_id, **kwargs)

        ecsp.ApplicationLoadBalancedFargateService(self, "MyWebServer",
            task_image_options=ecsp.ApplicationLoadBalancedTaskImageOptions(
                image=ecs.ContainerImage.from_registry("amazon/amazon-ecs-sample")),
            public_load_balancer=True
        )
```

## Java

Update `src/main/java/com.myorg/HelloEcsStack.java` so that it resembles the following.

```
package com.myorg;

import software.constructs.Construct;
import software.amazon.awscdk.Stack;
import software.amazon.awscdk.StackProps;

import software.amazon.awscdk.services.ecs.ContainerImage;
import
    software.amazon.awscdk.services.ecs.patterns.ApplicationLoadBalancedFargateService;
import
    software.amazon.awscdk.services.ecs.patterns.ApplicationLoadBalancedTaskImageOptions;

public class HelloEcsStack extends Stack {
    public HelloEcsStack(final Construct scope, final String id) {
        this(scope, id, null);
    }
}
```

```

    public HelloEcsStack(final Construct scope, final String id, final StackProps
props) {
        super(scope, id, props);

        ApplicationLoadBalancedFargateService.Builder.create(this, "MyWebServer")
            .taskImageOptions(ApplicationLoadBalancedTaskImageOptions.builder()
                .image(ContainerImage.fromRegistry("amazon/amazon-ecs-sample"))
                .build())
            .publicLoadBalancer(true)
            .build();
    }
}

```

## C#

Update `src/HelloEcs/HelloEcsStack.cs` so that it resembles the following.

```

using Amazon.CDK;
using Constructs;
using Amazon.CDK.AWS.ECS;
using Amazon.CDK.AWS.ECS.Patterns;
namespace HelloEcs
{
    public class HelloEcsStack : Stack
    {
        internal HelloEcsStack(Construct scope, string id, IStackProps props =
null) : base(scope, id, props)
        {
            new ApplicationLoadBalancedFargateService(this, "MyWebServer",
                new ApplicationLoadBalancedFargateServiceProps
                {
                    TaskImageOptions = new ApplicationLoadBalancedTaskImageOptions
                    {
                        Image = ContainerImage.FromRegistry("amazon/amazon-ecs-
sample")
                    },
                    PublicLoadBalancer = true
                });
        }
    }
}

```

## Go

Update `hello-ecs.go` so that it resembles the following.

```
package main

import (
    "github.com/aws/aws-cdk-go/awscdk/v2"
    // "github.com/aws/aws-cdk-go/awscdk/v2/awssqs"
    "github.com/aws/aws-cdk-go/awscdk/v2/awsecs"
    "github.com/aws/aws-cdk-go/awscdk/v2/awsecspatterns"
    "github.com/aws/constructs-go/constructs/v10"
    "github.com/aws/jsii-runtime-go"
)

type HelloEcsStackProps struct {
    awscdk.StackProps
}

func NewHelloEcsStack(scope constructs.Construct, id string, props
    *HelloEcsStackProps) awscdk.Stack {
    var sprops awscdk.StackProps
    if props != nil {
        sprops = props.StackProps
    }
    stack := awscdk.NewStack(scope, &id, &sprops)

    // The code that defines your stack goes here

    // example resource
    // queue := awssqs.NewQueue(stack, jsii.String("HelloEcsQueue"),
    // &awssqs.QueueProps{
    //     VisibilityTimeout: awscdk.Duration_Seconds(jsii.Number(300)),
    // })
    res := awsecspatterns.NewApplicationLoadBalancedFargateService(stack,
    jsii.String("MyWebServer"),
    &awsecspatterns.ApplicationLoadBalancedFargateServiceProps{
        TaskImageOptions: &awsecspatterns.ApplicationLoadBalancedTaskImageOptions{
            Image: awsecs.ContainerImage_FromRegistry(jsii.String("amazon/amazon-ecs-
sample")), &awsecs.RepositoryImageProps{}),
        },
    },
    )
}
```

```

    awscdk.NewCfnOutput(stack, jsii.String("LoadBalancerDNS"),
    &awscdk.CfnOutputProps{Value: res.LoadBalancer().LoadBalancerDnsName()})

    return stack
}

func main() {
    defer jsii.Close()

    app := awscdk.NewApp(nil)

    NewHelloEcsStack(app, "HelloEcsStack", &HelloEcsStackProps{
        awscdk.StackProps{
            Env: env(),
        },
    })

    app.Synth(nil)
}

// env determines the AWS environment (account+region) in which our stack is to
// be deployed. For more information see: https://docs.aws.amazon.com/cdk/latest/
// guide/environments.html
func env() *awscdk.Environment {
    // If unspecified, this stack will be "environment-agnostic".
    // Account/Region-dependent features and context lookups will not work, but a
    // single synthesized template can be deployed anywhere.
    //-----
    return nil

    // Uncomment if you know exactly what account and region you want to deploy
    // the stack to. This is the recommendation for production stacks.
    //-----
    // return &awscdk.Environment{
    //     Account: jsii.String("123456789012"),
    //     Region:  jsii.String("us-east-1"),
    // }

    // Uncomment to specialize this stack for the AWS Account and Region that are
    // implied by the current CLI configuration. This is recommended for dev
    // stacks.
    //-----
    // return &awscdk.Environment{
    //     Account: jsii.String(os.Getenv("CDK_DEFAULT_ACCOUNT")),

```

```
// Region: jsii.String(os.Getenv("CDK_DEFAULT_REGION")),  
// }  
}
```

The preceding short snippet includes the following:

- The service's logical name: `MyWebServer`.
- The container image that was obtained from the Amazon ECR Public Gallery: `amazon/amazon-ecs-sample`.
- Other relevant information, such as the fact that the load balancer has a public address and is accessible from the Internet.

The AWS CDK will create all the resources that are required to deploy the web server including the following resources. These resources were omitted in this example.

- Amazon ECS cluster
- Amazon VPC and Amazon EC2 instances
- Auto Scaling group
- Application Load Balancer
- IAM roles and policies

Some automatically provisioned resources are shared by all Amazon ECS services defined in the stack.

Save the source file, then run the `cdk synth` command in your application's main directory. The AWS CDK runs the app and synthesizes a CloudFormation template from it, and then displays the template. The template is an approximately 600-line YAML file. The beginning of the file is shown here. Your template might differ from this example.

```
Resources:  
  MyWebServerLB3B5FD3AB:  
    Type: AWS::ElasticLoadBalancingV2::LoadBalancer  
    Properties:  
      LoadBalancerAttributes:  
        - Key: deletion_protection.enabled  
          Value: "false"
```

```

Scheme: internet-facing
SecurityGroups:
  - Fn::GetAtt:
      - MyWebServerLBSecurityGroup01B285AA
      - GroupId
Subnets:
  - Ref: EcsDefaultClusterMnL3mNNYNVpcPublicSubnet1Subnet3C273B99
  - Ref: EcsDefaultClusterMnL3mNNYNVpcPublicSubnet2Subnet95FF715A
Type: application
DependsOn:
  - EcsDefaultClusterMnL3mNNYNVpcPublicSubnet1DefaultRouteFF4E2178
  - EcsDefaultClusterMnL3mNNYNVpcPublicSubnet2DefaultRouteB1375520
Metadata:
  aws:cdk:path: HelloEcsStack/MyWebServer/LB/Resource
MyWebServerLBSecurityGroup01B285AA:
  Type: AWS::EC2::SecurityGroup
  Properties:
    GroupDescription: Automatically created Security Group for ELB

    Ref: EcsDefaultClusterMnL3mNNYNVpc7788A521
Metadata:
  aws:cdk:path: HelloEcsStack/MyWebServer/LB/SecurityGroup/Resource
# and so on for another few hundred lines

```

To deploy the service in your AWS account, run the `cdk deploy` command in your application's main directory. You're asked to approve the IAM policies that the AWS CDK generated.

The deployment takes several minutes during which the AWS CDK creates several resources. The last few lines of the output from the deployment include the load balancer's public hostname and your new web server's URL. They are as follows.

```

Outputs:
HelloEcsStack.MyWebServerLoadBalancerDNSXXXXXXX = Hello-MyWeb-ZZZZZZZZZZZZZZ-
ZZZZZZZZZZ.us-west-2.elb.amazonaws.com

```

```
HelloEcsStack.MyWebServerServiceURLYYYYYYY = http://Hello-MyWeb-ZZZZZZZZZZZZZZ-  
ZZZZZZZZZZ.us-west-2.elb.amazonaws.com
```

## Step 3: Test the web server

Copy the URL from the deployment output and paste it into your web browser. The following welcome message from the web server is displayed.

## Step 4: Clean up

After you're finished with the web server, end the service using the CDK by running the `cdk destroy` command in your application's main directory. Doing this prevents you from incurring any unintended charges in the future.

## Next steps

To learn more about how to develop AWS infrastructure using the AWS CDK, see the [AWS CDK Developer Guide](#).

For information about writing AWS CDK apps in your language of choice, see the following:

TypeScript

## Creating Amazon ECS resources using the AWS Copilot command line interface

### AWS Copilot CLI End-of-Support Notice

AWS Copilot CLI will reach end-of-support on **June 12, 2026**. After this date, the tool will no longer receive updates, security patches, or technical support.

- No new features or enhancements after June 12, 2026
- No security updates or bug fixes
- No technical support
- Existing deployments will continue to function, but without ongoing maintenance

**Need Help?** Contact AWS Support or visit our [blogpost](#) for detailed migration guidance.

The AWS Copilot command line interface (CLI) commands simplify building, releasing, and operating production-ready containerized applications on Amazon ECS from a local development environment. The AWS Copilot CLI aligns with developer workflows that support modern application best practices: from using infrastructure as code to creating a CI/CD pipeline provisioned on behalf of a user. Use the AWS Copilot CLI as part of your everyday development and testing cycle as an alternative to the AWS Management Console.

AWS Copilot currently supports Linux, macOS, and Windows systems. For more information about the latest version of the AWS Copilot CLI, see [Releases](#).

### Note

The source code for the AWS Copilot CLI is available on [GitHub](#). We recommend that you submit issues and pull requests for changes that you would like to have included. However, Amazon Web Services doesn't currently support running modified copies of AWS Copilot code. Report issues with AWS Copilot by connecting with us on [Gitter](#) or [GitHub](#) where you can open issues, provide feedback, and report bugs.

For information about Copilot development, see [What's the future of Copilot?](#).

## Topics

- [Installing the AWS Copilot CLI](#)
- [Deploying a sample Amazon ECS application using the AWS Copilot CLI](#)

Additional documentation for the AWS Copilot CLI is available on the [AWS Copilot website](#)

## Installing the AWS Copilot CLI

### AWS Copilot CLI End-of-Support Notice

AWS Copilot CLI will reach end-of-support on **June 12, 2026**. After this date, the tool will no longer receive updates, security patches, or technical support.

- No new features or enhancements after June 12, 2026
- No security updates or bug fixes
- No technical support
- Existing deployments will continue to function, but without ongoing maintenance

**Need Help?** Contact AWS Support or visit our [blogpost](#) for detailed migration guidance.

You can install the AWS Copilot CLI by using Homebrew or by manually downloading the binary with the following steps.

## Use Homebrew

The following command is used to install the AWS Copilot CLI on your macOS or Linux system using Homebrew. Before installation, you should have Homebrew installed. For more information, see [Homebrew](#).

```
brew install aws/tap/copilot-cli
```

## Download binary

As an alternative to Homebrew, you can manually install the AWS Copilot CLI on your macOS, Windows, or Linux system. Use the following command for your operating system to download the binary. The macOS and Linux examples also include commands that apply execute permissions to the binary, and list the help menu to verify that the installation works.

### macOS

For macOS:

```
sudo curl -Lo /usr/local/bin/copilot https://github.com/aws/copilot-cli/releases/
latest/download/copilot-darwin \
  && sudo chmod +x /usr/local/bin/copilot \
  && copilot --help
```

For macOS ARM systems:

```
sudo curl -Lo /usr/local/bin/copilot https://github.com/aws/copilot-cli/releases/
latest/download/copilot-darwin-arm64 \
  && sudo chmod +x /usr/local/bin/copilot \
  && copilot --help
```

## Linux

For Linux x86 (64-bit) systems:

```
sudo curl -Lo /usr/local/bin/copilot https://github.com/aws/copilot-cli/releases/
latest/download/copilot-linux \
  && sudo chmod +x /usr/local/bin/copilot \
  && copilot --help
```

For Linux ARM systems:

```
sudo curl -Lo /usr/local/bin/copilot https://github.com/aws/copilot-cli/releases/
latest/download/copilot-linux-arm64 \
  && sudo chmod +x /usr/local/bin/copilot \
  && copilot --help
```

## Windows

Using Powershell, run the following command:

```
New-Item -Path 'C:\copilot' -ItemType directory; `
  Invoke-WebRequest -OutFile 'C:\copilot\copilot.exe' https://github.com/aws/
copilot-cli/releases/latest/download/copilot-windows.exe
```

### (Optional) Verify the manually installed AWS Copilot CLI using PGP signatures

The AWS Copilot CLI executables are cryptographically signed using PGP signatures. The PGP signatures can be used to verify the validity of the AWS Copilot CLI executable. Use the following steps to verify the signatures using the GnuPG tool.

1. Download and install GnuPG. For more information, see the [GnuPG website](#).

## macOS

We recommend using Homebrew. Install Homebrew using the instructions from their website. For more information, see [Homebrew](#). After Homebrew is installed, use the following command from your macOS terminal.

```
brew install gnupg
```

## Linux

Install gpg using the package manager on your flavor of Linux.

## Windows

Download the Windows simple installer from the GnuPG website and install as an Administrator. After you install GnuPG, close and reopen the Administrator PowerShell.

For more information, see [GnuPG Download](#).

2. Verify the GnuPG path is added to your environment path.

## macOS

```
echo $PATH
```

If you do not see the GnuPG path in the output, run the following command to add it to the path.

```
PATH=$PATH:<path to GnuPG executable files>
```

## Linux

```
echo $PATH
```

If you do not see the GnuPG path in the output, run the following command to add it to the path.

```
export PATH=$PATH:<path to GnuPG executable files>
```

## Windows

```
Write-Output $Env:PATH
```

If you do not see the GnuPG path in the output, run the following command to add it to the path.

```
$Env:PATH += "<path to GnuPG executable files>"
```

### 3. Create a local plain text file.

#### macOS

On the terminal, enter:

```
touch <public_key_filename.txt>
```

Open the file with TextEdit.

#### Linux

Create a text file in a text editor such as gedit. Save as `public_key_filename.txt`

#### Windows

Create a text file in a text editor such as Notepad. Save as `public_key_filename.txt`

### 4. Add the following contents of the Amazon ECS PGP public key and save the file.

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
```

```
Version: GnuPG v2
```

```

-----END PGP PUBLIC KEY BLOCK-----
```

The details of the Amazon ECS PGP public key for reference:

```
Key ID: BCE9D9A42D51784F
Type: RSA
Size: 4096/4096
Expires: Never
User ID: Amazon ECS
Key fingerprint: F34C 3DDA E729 26B0 79BE AEC6 BCE9 D9A4 2D51 784F
```

5. Import the file with the Amazon ECS PGP public key with the following command in the terminal.

```
gpg --import <public_key_filename.txt>
```

6. Download the AWS Copilot CLI signatures. The signatures are ASCII detached PGP signatures stored in files with the extension `.asc`. The signatures file has the same name as its corresponding executable, with `.asc` appended.

macOS

For macOS systems, run the following command.

```
sudo curl -Lo copilot.asc https://github.com/aws/copilot-cli/releases/latest/download/copilot-darwin.asc
```

## Linux

For Linux x86 (64-bit) systems, run the following command.

```
sudo curl -Lo copilot.asc https://github.com/aws/copilot-cli/releases/latest/download/copilot-linux.asc
```

For Linux ARM systems, run the following command.

```
sudo curl -Lo copilot.asc https://github.com/aws/copilot-cli/releases/latest/download/copilot-linux-arm64.asc
```

## Windows

Using Powershell, run the following command.

```
Invoke-WebRequest -OutFile 'C:\copilot\copilot.asc' https://github.com/aws/copilot-cli/releases/latest/download/copilot-windows.exe.asc
```

7. Verify the signature with the following command.

- For macOS and Linux systems:

```
gpg --verify copilot.asc /usr/local/bin/copilot
```

- For Windows systems:

```
gpg --verify 'C:\copilot\copilot.asc' 'C:\copilot\copilot.exe'
```

## Expected output:

```
gpg: Signature made Tue Apr  3 13:29:30 2018 PDT
gpg:                using RSA key DE3CBD61ADAF8B8E
gpg: Good signature from "Amazon ECS <ecs-security@amazon.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:                There is no indication that the signature belongs to the owner.
```

```
Primary key fingerprint: F34C 3DDA E729 26B0 79BE  AEC6 BCE9 D9A4 2D51 784F
Subkey fingerprint: EB3D F841 E2C9 212A 2BD4  2232 DE3C BD61 ADAF 8B8E
```

### Important

The warning in the output is expected and is not problematic. It occurs because there is not a chain of trust between your personal PGP key (if you have one) and the Amazon ECS PGP key. For more information, see [Web of trust](#).

8. For Windows installations, run the following command on Powershell to add AWS Copilot directory to the path.

```
$Env:PATH += ";<path to Copilot executable files>"
```

## Deploying a sample Amazon ECS application using the AWS Copilot CLI

### AWS Copilot CLI End-of-Support Notice

AWS Copilot CLI will reach end-of-support on **June 12, 2026**. After this date, the tool will no longer receive updates, security patches, or technical support.

- No new features or enhancements after June 12, 2026
- No security updates or bug fixes
- No technical support
- Existing deployments will continue to function, but without ongoing maintenance

**Need Help?** Contact AWS Support or visit our [blogpost](#) for detailed migration guidance.

After installing the AWS Copilot CLI, you can follow these steps to deploy a sample app, verify the deployment, and clean up resources.

## Prerequisites

Before you begin, make sure that you meet the following prerequisites:

- Install and configure the AWS CLI. For more information, see [AWS Command Line Interface](#).

- Run `aws configure` to set up a default profile that the AWS Copilot CLI will use to manage your application and services.
- Install and run Docker. For more information, see [Get started with Docker](#).

## Deploy a sample Amazon ECS application using a single command

1. Deploy a sample web application that is cloned from a GitHub repository using the following command. For more information about AWS Copilot `init` and its flags, see the [AWS Copilot documentation](#).

```
git clone https://github.com/aws-samples/aws-copilot-sample-service.git demo-app && \
cd demo-app && \
copilot init --app demo \
  --name api \
  --type 'Load Balanced Web Service' \
  --dockerfile './Dockerfile' \
  --port 80 \
  --tag latest \
  --deploy
```

2. After the deployment is complete, the AWS Copilot CLI will return a URL that you can use to verify the deployment. You can also use the following commands to verify the app's status.
- List all of your AWS Copilot applications.

```
copilot app ls
```

- Show information about the environments and services in your application.

```
copilot app show
```

- Show information about your environments.

```
copilot env ls
```

- Show information about the service, including endpoints, capacity and related resources.

```
copilot svc show
```

- List of all the services in an application.

```
copilot svc ls
```

- Show logs of a deployed service.

```
copilot svc logs
```

- Show service status.

```
copilot svc status
```

3. When you're finished with this demo, run the following command to clean up associated resources and avoid incurring charges for unused resources.

```
copilot app delete
```

# Using Amazon ECS with AWS CloudFormation

Amazon ECS is integrated with AWS CloudFormation, a service that you can use to model and set up AWS resources with templates that you define. CloudFormation uses **templates** that are either a YAML or JSON formatted text file. Templates are like blueprints for the AWS resource you want to create. When you create and submit a template, CloudFormation creates a **stack**. You manage the resources you defined in your template through the stack. When you want to create, update, or delete a resource, you create, update, or delete the stack that was created from that resource. When it comes to updating your stacks, you need to create a **change set** first. Change sets show you what is impacted by the change before you make it. This keeps you from deleting databases accidentally by changing your database name, for example. For more information on templates, stacks, and change sets, see [How CloudFormation works](#) in the *AWS CloudFormation User Guide*.

By using CloudFormation, you can spend less time creating and managing your resources and infrastructure. You can create a template that describes all the AWS resources that you want, such as Amazon ECS clusters, task definitions, services. Then, CloudFormation takes care of provisioning and configuring those resources for you.

CloudFormation also allows you to reuse your template to set up your Amazon ECS resources in a consistent and repeatable manner. You describe your resources one time and then provision the same resources again across multiple AWS accounts and AWS Regions.

CloudFormation templates can be used with both the AWS Management Console or the AWS Command Line Interface to create resources.

To learn more about CloudFormation, see the following resources:

- [AWS CloudFormation](#)
- [AWS CloudFormation User Guide](#)
- [AWS CloudFormation Command Line Interface User Guide](#)

## Topics

- [Creating Amazon ECS resources using the CloudFormation console](#)

# Creating Amazon ECS resources using the CloudFormation console

One way to use Amazon ECS with CloudFormation is through the AWS Management Console. Here you can create your CloudFormation stacks for Amazon ECS components like task definitions, clusters, and services and deploy them directly from the console. The following tutorial shows how you can use the CloudFormation console to create Amazon ECS resources using a template.

## Prerequisites

This tutorial assumes that the following prerequisites have been completed.

- The steps in [Set up to use Amazon ECS](#) have been completed.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.

## Step 1: Create a stack template

Use the following steps to create an CloudFormation stack template for an Amazon ECS service and other related resources.

1. Using a text editor of your choice, create a file called `ecs-tutorial-template.yaml`.
2. In the `ecs-tutorial-template.yaml` file, paste the following template and save the changes.

```
AWSTemplateFormatVersion: '2010-09-09'
Description: '[AWS Docs] ECS: load-balanced-web-application'

Parameters:
  VpcCidr:
    Type: String
    Default: '10.0.0.0/16'
    Description: CIDR block for the VPC
  ContainerImage:
    Type: String
    Default: 'public.ecr.aws/ecs-sample-image/amazon-ecs-sample:latest'
    Description: Container image to use in task definition

  PublicSubnet1Cidr:
```

Type: String  
Default: '10.0.1.0/24'  
Description: CIDR block for public subnet 1

PublicSubnet2Cidr:

Type: String  
Default: '10.0.2.0/24'  
Description: CIDR block for public subnet 2

PrivateSubnet1Cidr:

Type: String  
Default: '10.0.3.0/24'  
Description: CIDR block for private subnet 1

PrivateSubnet2Cidr:

Type: String  
Default: '10.0.4.0/24'  
Description: CIDR block for private subnet 2

ServiceName:

Type: String  
Default: 'tutorial-app'  
Description: Name of the ECS service

ContainerPort:

Type: Number  
Default: 80  
Description: Port on which the container listens

DesiredCount:

Type: Number  
Default: 2  
Description: Desired number of tasks

MinCapacity:

Type: Number  
Default: 1  
Description: Minimum number of tasks for auto scaling

MaxCapacity:

Type: Number  
Default: 10  
Description: Maximum number of tasks for auto scaling

```

    Name: !Sub '${AWS::StackName}-Private-Subnet-2'
```

The template used in this tutorial creates an Amazon ECS service with two tasks that run on Fargate. The tasks each run a sample Amazon ECS application. The template also creates an Application Load Balancer that distributes application traffic and an Application Auto Scaling policy that scales the application based on CPU utilization. The template also creates the networking resources necessary to deploy the application, the logging resources for container logs, and an Amazon ECS task execution IAM role. For more information about the task execution role, see [Amazon ECS task execution IAM role](#). For more information about auto scaling, see [Automatically scale your Amazon ECS service](#).

## Step 2: Create a stack for Amazon ECS resources

After creating a file for the template, you can follow these steps to create a stack with the template by using the CloudFormation console.

For information about how to create a stack using the CloudFormation console, see [Creating a stack on the CloudFormation console](#) in the *AWS CloudFormation User Guide* and use the following table to determine what options to specify.

| Option                          | Value                                                                                                                         |  |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------|--|
| Prerequisite - Prepare template | Choose an existing template                                                                                                   |  |
| Specify template                | Upload a template file                                                                                                        |  |
| Choose file                     | ecs-tutorial-template.yaml                                                                                                    |  |
| Stack name                      | ecs-tutorial-stack                                                                                                            |  |
| Parameters                      | Leave all parameter values as defaults.                                                                                       |  |
| Capabilities                    | Choose <b>I acknowledge that this template may create IAM resources</b> to acknowledge CloudFormation creating IAM resources. |  |

## Step 3: Verify

Use the following steps to verify the creation of Amazon ECS resources using the provided template.

For information about how to view stack information and resources, see [Viewing stack information from the CloudFormation console](#) in the *AWS CloudFormation User Guide* and use the following table to determine what to verify.

| Stack details field | What to look for                                                                                      |  |
|---------------------|-------------------------------------------------------------------------------------------------------|--|
| Stack info          | A status of CREATE_COMPLETE .                                                                         |  |
| Resources           | A list of the created resources with links to service console. Choose links to ECSCluster , ECSServic |  |

| Stack details field | What to look for                                                                                                          |  |
|---------------------|---------------------------------------------------------------------------------------------------------------------------|--|
|                     | e ,TaskDefinition to view more details about the created service, cluster, and task definition in the Amazon ECS console. |  |
| Outputs             | <b>LoadBalancerURL.</b> Paste the URL into a web browser to view a webpage that displays a sample Amazon ECS application. |  |

## Step 4: Clean up resources

To clean up resources and avoid incurring further costs, follow the steps in [Delete a stack from the CloudFormation console](#) in the *CloudFormation user guide*.

## Creating Amazon ECS resources using AWS CLI commands for CloudFormation

Another way to use Amazon ECS with CloudFormation is through the AWS CLI. You can use commands to create your CloudFormation stacks for Amazon ECS components like task definitions, clusters, and services and deploy them. The following tutorial shows how you can use the AWS CLI to create Amazon ECS resources using an CloudFormation template.

### Prerequisites

- The steps in [Set up to use Amazon ECS](#) have been completed.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.

## Step 1: Create a stack

To create a stack using the AWS CLI saved in a file called `ecs-tutorial-template.yaml`, run the following command.

```
cat << 'EOF' > ecs-tutorial-template.yaml
AWSTemplateFormatVersion: '2010-09-09'
Description: '[AWS Docs] ECS: load-balanced-web-application'
Parameters:
  VpcCidr:
    Type: String
    Default: '10.0.0.0/16'
    Description: CIDR block for the VPC
  ContainerImage:
    Type: String
    Default: 'public.ecr.aws/ecs-sample-image/amazon-ecs-sample:latest'
    Description: Container image to use in task definition

  PublicSubnet1Cidr:
    Type: String
    Default: '10.0.1.0/24'
    Description: CIDR block for public subnet 1

  PublicSubnet2Cidr:
    Type: String
    Default: '10.0.2.0/24'
    Description: CIDR block for public subnet 2

  PrivateSubnet1Cidr:
    Type: String
    Default: '10.0.3.0/24'
    Description: CIDR block for private subnet 1

  PrivateSubnet2Cidr:
    Type: String
    Default: '10.0.4.0/24'
    Description: CIDR block for private subnet 2

  ServiceName:
    Type: String
    Default: 'tutorial-app'
    Description: Name of the ECS service
```

```
ContainerPort:
  Type: Number
  Default: 80
  Description: Port on which the container listens

DesiredCount:
  Type: Number
  Default: 2
  Description: Desired number of tasks

MinCapacity:
  Type: Number
  Default: 1
  Description: Minimum number of tasks for auto scaling

MaxCapacity:
  Type: Number
  Default: 10
  Description: Maximum number of tasks for auto scaling

    Description: Private Subnet 1 ID
    Value: !Ref PrivateSubnet1
    Export:
      Name: !Sub '${AWS::StackName}-Private-Subnet-1'

  PrivateSubnet2:
    Description: Private Subnet 2 ID
    Value: !Ref PrivateSubnet2
    Export:
      Name: !Sub '${AWS::StackName}-Private-Subnet-2'

EOF
```

The template used in this tutorial creates an Amazon ECS service with two tasks that run on Fargate. The tasks each run a sample Amazon ECS application. The template also creates an Application Load Balancer that distributes application traffic and an Application Auto Scaling policy that scales the application based on CPU utilization. The template also creates the networking

resources necessary to deploy the application, the logging resources for container logs, and an Amazon ECS task execution IAM role. For more information about the task execution role, see [Amazon ECS task execution IAM role](#). For more information about auto scaling, see [Automatically scale your Amazon ECS service](#).

After creating a template file, use the following command to create a stack. The `--capabilities` flag is required to create an Amazon ECS task execution role as specified in the template. You can also specify the `--parameters` flag to customize the template parameters.

```
aws cloudformation create-stack \  
  --stack-name ecs-tutorial-stack \  
  --template-body file://ecs-tutorial-template.yaml \  
  --region aws-region \  
  --capabilities CAPABILITY_NAMED_IAM
```

After running the `create-stack` command, you can use `describe-stacks` to check the status of stack creation.

```
aws cloudformation describe-stacks \  
  --stack-name ecs-tutorial-stack \  
  --region aws-region
```

## Step 2: Verify Amazon ECS resource creation

To ensure that Amazon ECS resources are created correctly, follow these steps.

1. Run the following command to list all task definitions in an AWS Region.

```
aws ecs list-task-definitions
```

The command returns a list of task definition Amazon Resource Name (ARN)s. The ARN of the task definition that you created using the template will be displayed in the following format.

```
{  
  "taskDefinitionArns": [  
    ....  
    "arn:aws:ecs:aws-region:111122223333:task-definition/ecs-tutorial-stack-  
task:1",  
    ....  
  ]  
}
```

```
}
```

2. Run the following command to list all clusters in an AWS Region.

```
aws ecs list-clusters
```

The command returns a list of cluster ARNs. The ARN of the cluster that you created using the template will be displayed in the following format.

```
{
  "clusterArns": [
    .....
    "arn:aws:ecs:aws-region:111122223333:cluster/ecs-tutorial-stack-cluster",
    .....
  ]
}
```

3. Run the following command to list all services in the cluster `ecs-tutorial-stack-cluster`.

```
aws ecs list-services \
  --cluster ecs-tutorial-stack-cluster
```

The command returns a list of service ARNs. The ARN of the service that you created using the template will be displayed in the following format.

```
{
  "serviceArns": [
    "arn:aws:ecs:aws-region:111122223333:service/ecs-tutorial-stack-cluster/
    ecs-tutorial-stack-service"
  ]
}
```

You can also obtain the DNS name of the Application Load Balancer that was created and use it to verify the creation of resources. To obtain the DNS name, run the following command:

Run the following command to retrieve outputs of the created stack.

```
aws cloudformation describe-stacks \
  --stack-name ecs-tutorial-stack \
```

```
--region aws-region \  
--query 'Stacks[0].Outputs[?OutputKey==`LoadBalancerURL`].OutputValue' \  
--output text
```

Output:

```
http://ecs-tutorial-stack-alb-0123456789.aws-region.elb.amazonaws.com
```

Paste the DNS name into a browser to view a webpage that displays a sample Amazon ECS application.

## Step 3: Clean up

To clean up the resources you created, run the following command.

```
aws cloudformation delete-stack \  
--stack-name ecs-stack
```

The `delete-stack` command initiates deletion of the CloudFormation stack that was created in this tutorial, deleting all the resources in the stack. To verify deletion, you can repeat the procedure in [Step 2: Verify Amazon ECS resource creation](#). The list of ARNs in the outputs will no longer include a task definition called `ecs-tutorial-stack-task` or a cluster called `ecs-tutorial-stack-cluster`. The `list-services` call will fail.

## CloudFormation example templates for Amazon ECS

You can create Amazon ECS clusters, task definitions, and services using CloudFormation. The following topics include templates that demonstrate how to create resources with different configurations. You can create these resources with these templates by using the CloudFormation console or the AWS CLI.

CloudFormation templates are text files in the JSON or YAML format that describe the resources that you want to provision in your CloudFormation stacks. If you're unfamiliar with either the JSON or YAML format, or both, you can use AWS Infrastructure Composer to get started using CloudFormation templates. For more information, see [Create templates visually with Infrastructure Composer](#) in the *AWS CloudFormation User Guide*.

The following topics list example templates for Amazon ECS task definitions, clusters, and services.

### Topics

- [Task definitions](#)
- [Capacity providers](#)
- [Clusters](#)
- [Services](#)
- [IAM roles for Amazon ECS](#)

## Task definitions

A task definition is a blueprint for your application that describes the parameters and one or more containers that form your application. The following are example CloudFormation templates for Amazon ECS task definitions. For more information about Amazon ECS task definitions, see [Amazon ECS task definitions](#).

### Fargate Linux task definition

You can use the following template to create a sample Fargate Linux task.

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Description": "ECS Task Definition with parameterized values",
  "Parameters": {
    "ContainerImage": {
      "Type": "String",
      "Default": "public.ecr.aws/docker/library/httpd:2.4",
      "Description": "The container image to use for the task"
    },

## YAML

```

AWSTemplateFormatVersion: 2010-09-09
Description: Create a task definition for a web server with parameterized values.
Parameters:
  ExecutionRoleArn:
    Type: String
    Default: arn:aws:iam::123456789012:role/ecsTaskExecutionRole
    Description: The ARN of the task execution role
  NetworkMode:
    Type: String
    Default: awsvpc
    Description: The Docker networking mode to use
    AllowedValues: [awsvpc, bridge, host, none]
  TaskFamily:
    Type: String
    Default: my-ecs-task
    Description: The name of the task definition family
  ContainerCpu:

```

```
Type: String
Default: "256"
Description: The number of CPU units to reserve for the container
AllowedValues: ["256", "512", "1024", "2048", "4096"]
ContainerMemory:
  Type: String
  Default: "512"
  Description: The amount of memory (in MiB) to reserve for the container
  AllowedValues: ["512", "1024", "2048", "3072", "4096", "5120", "6144", "7168",
"8192"]
ContainerName:
  Type: String
  Default: nginx
  Description: The name of the container
ContainerImage:
  Type: String
  Default: public.ecr.aws/nginx/nginx:latest
  Description: The container image to use for the task
ContainerPort:
  Type: Number
  Default: 80
  Description: The port number on the container
InitProcessEnabled:
  Type: String
  Default: "true"
  Description: Whether to enable the init process inside the container
  AllowedValues: ["true", "false"]
EfsVolumeName:
  Type: String
  Default: efs-volume
  Description: The name of the EFS volume
EfsContainerPath:
  Type: String
  Default: /usr/share/nginx/html
  Description: The path in the container where the EFS volume will be mounted
LogGroup:
  Type: String
  Default: LogGroup
  Description: The CloudWatch log group for container logs
LogStreamPrefix:
  Type: String
  Default: efs-task
  Description: The prefix for the log stream
EfsFileSystemId:
```

```
Type: String
Default: fs-1234567890abcdef0
Description: The ID of the EFS filesystem
EfsRootDirectory:
  Type: String
  Default: /
  Description: The root directory in the EFS filesystem
EfsTransitEncryption:
  Type: String
  Default: ENABLED
  Description: Whether to enable transit encryption for EFS
  AllowedValues: [ENABLED, DISABLED]

## Capacity providers

Capacity providers are associated with an Amazon ECS cluster and are used to manage compute capacity for your workloads.

### Create a capacity provider for Amazon ECS Managed Instances

By default, Amazon ECS provides a capacity provider that automatically selects the most cost-optimized general-purpose instance types. However, you can create custom capacity providers to specify instance requirements such as instance types, CPU manufacturers, accelerator types, and other requirements. You can use the following template to create a capacity provider for Amazon ECS Managed Instances that satisfies the specified memory and CPU requirements.

#### JSON

```

{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
    "MyCapacityProvider": {
      "Type": "AWS::ECS::CapacityProvider",
      "Properties": {
        "ManagedInstancesProvider": {
          "InfrastructureRoleArn": "arn:aws:iam::123456789012:role/
ECSInfrastructureRole",
          "InstanceLaunchTemplate": {
            "Ec2InstanceProfileArn":
"arn:aws:iam::123456789012:instance-profile/ecsInstanceProfile",
            "NetworkConfiguration": null,
            "Subnets": [
              "subnet-12345678"
            ]
          }
        }
      }
    }
  }
}

```

```
StorageSizeGiB: 30
InstanceRequirements:
  VCpuCount:
    Min: 1
    Max: 4
  MemoryMiB:
    Min: 2048
    Max: 8192
```

## Clusters

An Amazon ECS cluster is a logical grouping of tasks or services. You can use the following templates to create clusters with different configurations. For more information about Amazon ECS clusters, see [Amazon ECS clusters](#).

### Create an empty cluster with default settings

You can use the following template to create an empty cluster with default settings.

#### JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
    "ECSCluster": {
      "Type": "AWS::ECS::Cluster",
      "Properties": {
        "ClusterName": "MyEmptyCluster"
      }
    }
  }
}
```

#### YAML

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  ECSCluster:
    Type: 'AWS::ECS::Cluster'
    Properties:
      ClusterName: MyEmptyCluster
```

## Create an empty cluster with managed storage encryption and enhanced Container Insights

You can use the following template to create a cluster with cluster-level managed storage and enhanced Container Insights enabled. Cluster-level encryption applies to Amazon ECS managed data volumes such as Amazon EBS volumes. For more information about Amazon EBS encryption, see [Encrypt data stored in Amazon EBS volumes attached to Amazon ECS tasks](#). For more information about using Container Insights with enhanced observability, see [Monitor Amazon ECS containers using Container Insights with enhanced observability](#).

### JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
    "Cluster": {
      "Type": "AWS::ECS::Cluster",
      "Properties": {
        "ClusterName": "EncryptedEnhancedCluster",
        "ClusterSettings": [
          {
            "Name": "containerInsights",
            "Value": "enhanced"
          }
        ],
        "Configuration": {
          "ManagedStorageConfiguration": {
            "KmsKeyId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
          }
        }
      }
    }
  }
}
```

### YAML

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  Cluster:
    Type: AWS::ECS::Cluster
    Properties:
```

```
ClusterName: EncryptedEnhancedCluster
ClusterSettings:
  - Name: containerInsights
    Value: enhanced
Configuration:
  ManagedStorageConfiguration:
    KmsKeyId: a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

## Create a cluster with the AL2023 Amazon ECS-Optimized-AMI

You can use the following template to create a cluster that uses a capacity provider that launches AL2023 instances on Amazon EC2.

### Important

For the latest AMI IDs, see [Amazon ECS-optimized AMI](#) in the *Amazon Elastic Container Service Developer Guide*.

## JSON

## YAML

```

AWSTemplateFormatVersion: '2010-09-09'
Description: EC2 ECS cluster that starts out empty, with no EC2 instances yet. An
  ECS capacity provider automatically launches more EC2 instances as required on the
  fly when you request ECS to launch services or standalone tasks.
Parameters:
  InstanceType:
    Type: String
    Description: EC2 instance type
    Default: t2.medium
    AllowedValues:
      - t1.micro
      - t2.2xlarge
      - t2.large
      - t2.medium
      - t2.micro
      - t2.nano
      - t2.small
      - t2.xlarge
      - t3.2xlarge
      - t3.large
      - t3.medium
      - t3.micro
      - t3.nano
      - t3.small
      - t3.xlarge
  DesiredCapacity:
    Type: Number
    Default: '0'
    Description: Number of EC2 instances to launch in your ECS cluster.
  MaxSize:
    Type: Number
    Default: '100'
    Description: Maximum number of EC2 instances that can be launched in your ECS
  cluster.
  ECSAMI:
    Description: The Amazon Machine Image ID used for the cluster
    Type: AWS::SSM::Parameter::Value<AWS::EC2::Image::Id>
    Default: /aws/service/ecs/optimized-ami/amazon-linux-2023/recommended/image_id
  VpcId:
    Type: AWS::EC2::VPC::Id
    Description: VPC ID where the ECS cluster is launched
    Default: vpc-1234567890abcdef0

```

**SubnetIds:**

        Value: CapacityProvider

```

## Services

You can use an Amazon ECS service to run and maintain a specified number of instances of a task definition simultaneously in an Amazon ECS cluster. If one of your tasks fails or stops, the Amazon ECS service scheduler launches another instance of your task definition to replace it. This helps maintain your desired number of tasks in the service. The following templates can be used to deploy services. For more information about Amazon ECS services, see [Amazon ECS services](#).

### Deploy a load balanced web application

The following template creates an Amazon ECS service with two tasks that run on Fargate. The tasks each have an NGINX container. The template also creates an Application Load Balancer that distributes application traffic and an Application Auto Scaling policy that scales the application based on CPU utilization. The template also creates the networking resources necessary to deploy the application, the logging resources for container logs, and an Amazon ECS task execution IAM role. For more information about the task execution role, see [Amazon ECS task execution IAM role](#). For more information about auto scaling, see [Automatically scale your Amazon ECS service](#).

## YAML

```

AWSTemplateFormatVersion: '2010-09-09'
Description: '[AWSDocs] ECS: load-balanced-web-application'

Parameters:
  VpcCidr:
    Type: String

```

```
Default: '10.0.0.0/16'
Description: CIDR block for the VPC
ContainerImage:
  Type: String
  Default: 'public.ecr.aws/ecs-sample-image/amazon-ecs-sample:latest'
  Description: Container image to use in task definition

PublicSubnet1Cidr:
  Type: String
  Default: '10.0.1.0/24'
  Description: CIDR block for public subnet 1

PublicSubnet2Cidr:
  Type: String
  Default: '10.0.2.0/24'
  Description: CIDR block for public subnet 2

PrivateSubnet1Cidr:
  Type: String
  Default: '10.0.3.0/24'
  Description: CIDR block for private subnet 1

PrivateSubnet2Cidr:
  Type: String
  Default: '10.0.4.0/24'
  Description: CIDR block for private subnet 2

ServiceName:
  Type: String
  Default: 'tutorial-app'
  Description: Name of the ECS service

ContainerPort:
  Type: Number
  Default: 80
  Description: Port on which the container listens

DesiredCount:
  Type: Number
  Default: 2
  Description: Desired number of tasks

MinCapacity:
  Type: Number
```

Default: 1  
 Description: Minimum number of tasks for auto scaling

MaxCapacity:

Type: Number  
 Default: 10  
 Description: Maximum number of tasks for auto scaling

## Deploy a service with ECS Exec enabled

You can use the following template to deploy a service with ECS Exec enabled. The service runs in a cluster with a KMS key for encrypting ECS Exec sessions and a log configuration for redirecting execute command session logs to an Amazon S3 bucket. For more information, see [Monitor Amazon ECS containers with ECS Exec](#).

## YAML

```

AWSTemplateFormatVersion: '2010-09-09'
Description: ECS Cluster with Fargate Service and Task Definition and ECS Exec
  enabled.
Parameters:
  ClusterName:
    Type: String
    Default: CFNCluster
    Description: Name of the ECS Cluster
  S3BucketName:

```

Type: String  
Default: amzn-s3-demo-bucket  
Description: S3 bucket for ECS execute command logs

KmsKeyId:  
Type: String  
Default: a1b2c3d4-5678-90ab-cdef-EXAMPLE11111  
Description: KMS Key ID for ECS execute command encryption

ContainerImage:  
Type: String  
Default: public.ecr.aws/docker/library/httpd:2.4  
Description: Container image to use for the task

ContainerCpu:  
Type: Number  
Default: 256  
AllowedValues: [256, 512, 1024, 2048, 4096]  
Description: CPU units for the container (256 = 0.25 vCPU)

ContainerMemory:  
Type: Number  
Default: 512  
AllowedValues: [512, 1024, 2048, 3072, 4096, 5120, 6144, 7168, 8192]  
Description: Memory for the container (in MiB)

DesiredCount:  
Type: Number  
Default: 1  
Description: Desired count of tasks in the service

SecurityGroups:  
Type: List<AWS::EC2::SecurityGroup::Id>  
Description: Security Group IDs for the ECS Service

Subnets:  
Type: List<AWS::EC2::Subnet::Id>  
Description: Subnet IDs for the ECS Service

ServiceName:  
Type: String  
Default: cfn-service  
Description: Name of the ECS service

TaskFamily:  
Type: String  
Default: task-definition-cfn  
Description: Family name for the task definition

TaskExecutionRoleArn:  
Type: String  
Description: ARN of an existing IAM role for ECS task execution  
Default: 'arn:aws:iam::111122223333:role/ecsTaskExecutionRole'

TaskRoleArn:

Type: String  
 Description: ARN of an existing IAM role for ECS tasks  
 Default: 'arn:aws:iam::**111122223333**:role/execTaskRole'

```

## Deploy service that uses Amazon VPC Lattice

You can use the following template to get started with creating an Amazon ECS service with VPC Lattice. You may need to complete the following additional steps to set up VPC Lattice:

- Update your security group's inbound rules for VPC Lattice to allow the inbound rule `vpc-lattice` prefix and to allow traffic on port 80.
- Associate VPC for the service to a VPC Lattice service network.
- Configure a private or public hosted zone with Amazon Route 53.
- Configure listeners and listener rules in a VPC Lattice service.
- Verify health check configurations of the target group.

For more information about using VPC Lattice with Amazon ECS, see [Use Amazon VPC Lattice to connect, observe, and secure your Amazon ECS services](#).

## YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Description: The template used to create an ECS Service with VPC Lattice.

Parameters:
  ECSClusterName:
    Type: String
    Default: vpc-lattice-cluster
  ECSServiceName:
    Type: String
    Default: vpc-lattice-service
  SecurityGroupIDs:
    Type: List<AWS::EC2::SecurityGroup::Id>
    Description: Security Group IDs for the ECS Service
  SubnetIDs:
    Type: List<AWS::EC2::Subnet::Id>
    Description: Subnet IDs for the ECS Service
  VpcID:
    Type: AWS::EC2::VPC::Id
    Description: VPC ID for the resources
  ContainerImage:
    Type: String
    Default: public.ecr.aws/docker/library/httpd:2.4
    Description: Container image to use for the task
  TaskCpu:
    Type: Number
    Default: 256
    AllowedValues: [256, 512, 1024, 2048, 4096]
    Description: CPU units for the task
  TaskMemory:
    Type: Number
    Default: 512
    AllowedValues: [512, 1024, 2048, 4096, 8192, 16384]
    Description: Memory (in MiB) for the task
  LogGroupName:
    Type: String
    Default: /ecs/vpc-lattice-task
    Description: CloudWatch Log Group name
  EnableContainerInsights:
    Type: String
    Default: 'enhanced'
    AllowedValues: ['enabled', 'disabled', 'enhanced']
    Description: Enable or disable CloudWatch Container Insights for the cluster
```

## Deploy service with a volume configuration

The following template includes a volume configuration in the service definition. Amazon ECS supports configuring the following data volumes by using a volume configuration at launch: Amazon EBS volumes. For more information about Amazon EBS volumes, see [Use Amazon EBS volumes with Amazon ECS](#).

### JSON

## YAML

AWSTemplateFormatVersion: 2010-09-09

Description: The template used to create an ECS Service that includes a volume configuration. The configuration is used to create Amazon EBS volumes for attachment to the tasks. One volume is attached per task.

Parameters:

**ECSClusterName:**  
Type: String  
Default: volume-config-cluster  
Description: Name of the ECS cluster

**SecurityGroupIDs:**  
Type: List<AWS::EC2::SecurityGroup::Id>  
Description: Security Group IDs for the ECS Service

**SubnetIDs:**  
Type: List<AWS::EC2::Subnet::Id>  
Description: Subnet IDs for the ECS Service

**InfrastructureRoleArn:**  
Type: String  
Description: ARN of the IAM role that ECS will use to manage EBS volumes

**ContainerImage:**  
Type: String  
Default: public.ecr.aws/nginx/nginx:latest  
Description: Container image to use for the task

**TaskCpu:**  
Type: String  
Default: "2048"  
Description: CPU units for the task

**TaskMemory:**  
Type: String  
Default: "4096"  
Description: Memory (in MiB) for the task

**VolumeSize:**  
Type: String  
Default: "10"  
Description: Size of the EBS volume in GiB

**VolumeType:**  
Type: String  
Default: gp3  
AllowedValues: [gp2, gp3, io1, io2, st1, sc1, standard]  
Description: EBS volume type

**VolumeIops:**

Type: String  
 Default: "3000"  
 Description: IOPS for the EBS volume (required for io1, io2, and gp3)

VolumeThroughput:

Type: String  
 Default: "125"  
 Description: Throughput for the EBS volume (only for gp3)

FilesystemType:

Type: String  
 Default: xfs  
 AllowedValues: [xfs, ext4]  
 Description: Filesystem type for the EBS volume

EnableContainerInsights:

Type: String  
 Default: 'enhanced'  
 AllowedValues: ['enabled', 'disabled', 'enhanced']  
 Description: Enable or disable CloudWatch Container Insights for the cluster

Resources:

## Deploy service with capacity providers

The following template defines a service that uses the capacity provider to request AL2023 capacity to run on. Containers will be launched onto the AL2023 instances as they come online.

## YAML

```

AWSTemplateFormatVersion: '2010-09-09'
Description: >-
  An example service that deploys in AWS VPC networking mode on EC2 capacity.
  Service uses a capacity provider to request EC2 instances to run on. Service
  runs with networking in private subnets, but still accessible to the internet
  via a load balancer hosted in public subnets.
Parameters:
  VpcId:
    Type: String
    Description: The VPC that the service is running inside of
  PublicSubnetIds:
    Type: 'List<AWS::EC2::Subnet::Id>'
    Description: List of public subnet ID's to put the load balancer in
  PrivateSubnetIds:
    Type: 'List<AWS::EC2::Subnet::Id>'
    Description: List of private subnet ID's that the AWS VPC tasks are in
  ClusterName:
    Type: String
    Description: The name of the ECS cluster into which to launch capacity.
  ECSTaskExecutionRole:
    Type: String
    Description: The role used to start up an ECS task
  CapacityProvider:
    Type: String
    Description: >-
      The cluster capacity provider that the service should use to request
      capacity when it wants to start up a task
  ServiceName:
    Type: String
    Default: web
    Description: A name for the service
  ImageUrl:
    Type: String

```

```
Default: 'public.ecr.aws/docker/library/nginx:latest'
Description: >-
  The url of a docker image that contains the application process that will
  handle the traffic for this service
ContainerCpu:
  Type: Number
  Default: 256
  Description: How much CPU to give the container. 1024 is 1 CPU
ContainerMemory:
  Type: Number
  Default: 512
  Description: How much memory in megabytes to give the container
ContainerPort:
  Type: Number
  Default: 80
  Description: What port that the application expects traffic on
DesiredCount:
  Type: Number
  Default: 2
  Description: How many copies of the service task to run

## IAM roles for Amazon ECS

You can use CloudFormation templates to create IAM roles for use with Amazon ECS. For more information about IAM roles for Amazon ECS, see [IAM roles for Amazon ECS](#).

### Amazon ECS task execution role

The task execution role grants the Amazon ECS container and Fargate agents permission to make AWS API calls on your behalf. The role is required depending on the requirements of your task. For more information, see [Amazon ECS task execution IAM role](#).

The following template can be used to create a simple task execution role that uses the AmazonECSTaskExecutionRolePolicy managed policy.

# Architect your solution for Amazon ECS

You must architect your applications so that they can run on *containers*. A container is a standardized unit of software development that holds everything that your software application requires to run. This includes relevant code, runtime, system tools, and system libraries. Containers are created from a read-only template that's called an *image*. A container image, is a static artifact containing your application and its dependencies. Images are typically built from a Dockerfile. A Dockerfile is a plaintext file that contains the instructions for building a container. After they're built, these images are stored in a *registry* such as Amazon ECR where they can be downloaded from.

After you create and store your image, you create an Amazon ECS task definition. A *task definition* is a blueprint for your application. It is a text file in JSON format that describes the parameters and one or more containers that form your application. For example, you can use it to specify the image and parameters for the operating system, which containers to use, which ports to open for your application, and what data volumes to use with the containers in the task. The specific parameters available for your task definition depend on the needs of your specific application.

After you define your task definition, you deploy it as either a service or a task on your cluster. A *cluster* is a logical grouping of tasks or services that runs on the capacity infrastructure that is registered to a cluster.

A *task* is the instantiation of a task definition within a cluster. You can run a standalone task, or you can run a task as part of a service. You can use an Amazon ECS *service* to run and maintain your desired number of tasks simultaneously in an Amazon ECS cluster. How it works is that, if any of your tasks fail or stop for any reason, the Amazon ECS service scheduler launches another instance based on your task definition. It does this to replace it and thereby maintain your desired number of tasks in the service.

The *container agent* runs on each container instance within an Amazon ECS cluster. The agent sends information about the current running tasks and resource utilization of your containers to Amazon ECS. It starts and stops tasks whenever it receives a request from Amazon ECS.

After you deploy the task or service, you can use any of the following tools to monitor your deployment and application:

- CloudWatch
- Runtime Monitoring

# Capacity

The capacity is the infrastructure where your containers run. Amazon ECS offers three infrastructure types for your clusters:

- Amazon ECS Managed Instances - AWS fully manages the underlying Amazon EC2 instances running in your account, including provisioning, patching, and scaling. This option provides the optimal balance of performance, cost-effectiveness, and operational simplicity.
- Serverless (Fargate) - Pay only for the resources your tasks use without managing any infrastructure. Ideal for variable workloads and getting started quickly.
- Amazon EC2 instances - You manage the underlying Amazon EC2 instances directly, including instance selection, configuration, and maintenance.

Use Amazon ECS Managed Instances when:

- You want the simplicity of Fargate with more control over the underlying infrastructure.
- You need predictable performance and cost optimization.
- You want AWS to handle infrastructure management while maintaining flexibility.

Use Fargate when:

- You want to focus on your application without managing infrastructure.
- You have variable or unpredictable workloads.
- You're getting started with containers and want the simplest deployment option.

Use Amazon EC2 instances when:

- You need specialized hardware requirements (GPU acceleration, high-performance computing).
- You require capacity reservations or specific instance types.
- You need privileged capabilities or custom AMIs.

You specify the infrastructure when you create a cluster. You also specify the infrastructure type when you register a task definition. The task definition refers to the infrastructure as the "launch type". You can also use capacity providers.

## Service endpoints

The service endpoint is the URL of the entry point for Amazon ECS that you use to connect to the service programmatically using either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6). By default, requests that you make to connect to Amazon ECS programmatically use service endpoints that support only IPv4 requests. To connect programmatically with Amazon ECS using either IPv4 or IPv6 requests, you can use a dual-stack endpoint. For information about using a dual-stack endpoint, see [Using Amazon ECS dual-stack endpoints](#).

## Networking

AWS resources are created in subnets. When you use EC2 instances, Amazon ECS launches the instances in the subnet that you specify when you create a cluster. Your tasks run in the instance subnet. For Fargate or on-premises virtual machines, you specify the subnet when you run a task or create a service.

Depending on your application, the subnet can be a private or public subnet and the subnet can be in any of the following AWS resources:

- Availability Zones
- Local Zones
- Wavelength Zones
- AWS Regions
- AWS Outposts

For more information, see [Amazon ECS applications in shared subnets, Local Zones, and Wavelength Zones](#) or [Amazon Elastic Container Service on AWS Outposts](#).

You can have your application connect to the internet by using one of the following methods:

- A public subnet with an internet gateway

Use public subnets when you have public applications that require large amounts of bandwidth or minimal latency. Applicable scenarios include video streaming and gaming services.

- A private subnet with a NAT gateway

Use private subnets when you want to protect your containers from direct external access. Applicable scenarios include payment processing systems or containers storing user data and passwords.

- AWS PrivateLink

Use AWS PrivateLink to have private connectivity between VPCs, AWS services, and your on-premises networks without exposing your traffic to the public internet.

## Feature access

You can use your Amazon ECS account settings to access the following features:

- Container Insights

CloudWatch Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. The metrics include utilization for resources such as CPU, memory, disk, and network.

- awsvpc trunking

For certain EC2 instances types, you can have additional network interfaces (ENIs) available on newly launched container instances.

- Tagging authorization

Users must have permissions for actions that create a resource, such as `ecsCreateCluster`. If tags are specified in the resource-creating action, AWS performs additional authorization on the `ecs:TagResource` action to verify if users or roles have permissions to create tags.

- Fargate FIPS-140 compliance

Fargate supports the Federal Information Processing Standard (FIPS-140) which specifies the security requirements for cryptographic modules that protect sensitive information. It is the current United States and Canadian government standard, and is applicable to systems that are required to be compliant with Federal Information Security Management Act (FISMA) or Federal Risk and Authorization Management Program (FedRAMP).

- Fargate task retirement time changes

You can configure the wait period before Fargate tasks are retired for patching.

- Dual stack VPC

Allow tasks to communicate over IPv4, IPv6, or both.

- Amazon Resource Name (ARN) format

Certain features, such as tagging authorization, require a new Amazon Resource Name (ARN) format.

For more information, see [Access Amazon ECS features with account settings](#).

## IAM roles

An IAM role is an IAM identity that you can create in your account that has specific permissions. In Amazon ECS, you can create roles to grant permissions to Amazon ECS resource such as containers or services.

Some Amazon ECS features require roles. For more information, see [IAM roles for Amazon ECS](#).

## Logging

Logging and monitoring are important aspects of maintaining the reliability, availability, and performance of Amazon ECS workloads. The following options are available:

- Amazon CloudWatch logs - route logs to Amazon CloudWatch
- FireLens for Amazon ECS - route logs to an AWS service or AWS Partner Network destination for log storage and analysis. The AWS Partner Network is a global community of partners that leverages programs, expertise, and resources to build, market, and sell customer offerings.

## Container image best practices

The following are key principles for Amazon ECS container images:

- Include all dependencies in the image
- Run one process per container
- Handle SIGTERM for graceful shutdowns
- Write logs to `stdout` and `stderr`

- Use unique tags, avoid latest in production

## Amazon Amazon ECS launch types and capacity providers

Amazon ECS provides two methods for configuring capacity for workloads. You can use launch types or capacity providers. Launch types include EC2, Fargate, and External. Capacity providers offer enhanced flexibility and advanced features for capacity management. You can run workloads on serverless compute with Fargate and Fargate Spot capacity providers, on self-managed EC2 instances through Auto Scaling group capacity providers, or on fully-managed compute using Amazon ECS Managed Instances capacity providers that combine the simplicity of Fargate with the flexibility of EC2 compute. Capacity providers offer better control over resource allocation and can help optimize both performance and costs. Capacity providers are the recommended way to configure capacity for workloads compared to traditional launch types. Use the following to understand the differences between capacity providers and launch types.

### Best practices

The following are the best practices:

#### Use launch types to define infrastructure compatibility

Launch types define the infrastructure on which tasks and services run. When you define tasks, specify `RequiresCompatibilities` to include one or more launch types that are compatible with tasks. You can use following launch types: EC2, Fargate, External, and Amazon ECS Managed Instances. While you can also use launch type to run your tasks or services, we recommend using the launch type only for defining compatibilities in your task definitions, and use capacity providers for launching tasks or services. Note that you can choose one or more launch types to define compatibilities for tasks.

#### Use capacity providers to configure compute capacity

When you launch tasks or services, configure a capacity provider strategy. Amazon ECS supports following capacity providers: Fargate and FARGATE\_SPOT, Auto Scaling groups for self-managed EC2 instances, and Amazon ECS Managed Instances. Note that Spot Fleet is only available as a capacity provider and not as a launch type. You can create one or more Amazon ECS Managed Instances or Auto Scaling groups capacity providers in a cluster. Fargate and Fargate Spot capacity providers are created and managed by Amazon ECS on every cluster and you do not need to create them. A cluster can have a mix of all capacity provider types, however, a capacity provider strategy can't have a mix of different capacity provider types.

## Update the capacity for services

You can simply update a capacity provider strategy for a service to move it from one compute type to the other.

## Service mutability

Amazon ECS supports updating services between different capacity providers. This allows for:

- Seamless update from launch types to capacity providers
- Transitions between different capacity provider types
- Testing different compute options without service recreation

The following is a high-level overview of the process:

1. Update the task definition – Ensure `requiresCompatibilities` includes the target capacity provider, for example `MANAGED_INSTANCES`.

### Note

Task definitions must pass compatibility validation for the target capacity provider. If the `requiresCompatibilities` check fails for the task definition version, the `UpdateService` call fails.

2. Create a capacity provider – If you use custom Amazon EC2 Auto Scaling groups, create the capacity provider.
3. Update the service – Modify the service to use a capacity provider strategy instead of the launch type.
4. Validate the deployment – Confirm that tasks deploy successfully.
5. Monitor and optimize – Adjust capacity provider settings as needed.

## Capacity provider to capacity provider

All capacity provider to capacity provider updates are supported:

- Amazon EC2 Auto Scaling group capacity provider to Amazon ECS Managed Instances

- Fargate capacity provider to Amazon ECS Managed Instances
- Amazon EC2 Auto Scaling group capacity provider to Fargate capacity provider
- Amazon ECS Managed Instances to Fargate capacity provider
- Fargate capacity provider to Amazon EC2 Auto Scaling group capacity provider
- Amazon ECS Managed Instances to Amazon EC2 Auto Scaling group capacity provider

## Launch type to capacity provider

All launch type to capacity provider updates are supported:

- EC2 launch type to Amazon ECS Managed Instances
- Fargate launch type to Amazon ECS Managed Instances
- EC2 launch type to Fargate capacity provider
- EC2 launch type to EC2 Auto Scaling group capacity provider
- Fargate launch type to Amazon EC2 Auto Scaling group capacity provider
- Fargate launch type to Fargate capacity provider
- External launch type to Amazon ECS Managed Instances
- External launch type to Fargate capacity provider
- External launch type to Amazon EC2 Auto Scaling group capacity provider

## Launch type to launch type

Launch type to launch type updates are not supported:

- EC2 launch type to Fargate launch type (use Fargate capacity provider instead)
- Fargate launch type to EC2 launch type (use Amazon EC2 Auto Scaling group capacity provider instead)

Instead of migrating between launch types, migrate to the equivalent capacity provider for enhanced functionality and future compatibility.

## Capacity provider to launch type

Capacity provider to launch type updates are not supported. If you originally created a service with a launch type and then updated the service to use capacity providers, you can revert the service to

its original launch type. To revert, pass an empty list as the `capacityProviderStrategy` when you call `UpdateService`.

 **Note**

This only reverts the service to the launch type specified when the service was originally created. You cannot use this method to switch a service to a different launch type.

## Using Amazon ECS dual-stack endpoints

Amazon ECS dual-stack endpoints support requests to Amazon ECS over Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6). For a list of all Amazon ECS endpoints, see [Amazon ECS endpoints and quotas](#) in the AWS General Reference.

When using the REST API, you directly access an Amazon ECS endpoint by using the endpoint name (URI). Amazon ECS supports only regional dual-stack endpoint names, which means that you must specify the region as part of the name.

Use the following naming convention for the dual-stack endpoint names: `ecs.region.api.aws`.

When using the AWS Command Line Interface (AWS CLI) and AWS SDKs, you can use a parameter or a flag to change to a dual-stack endpoint. You can also specify the dual-stack endpoint directly as an override of the Amazon ECS endpoint in the config file.

The following sections describe how to use dual-stack endpoints from the AWS CLI, the AWS SDKs, and the REST API.

### Topics

- [Using dual-stack endpoints from the AWS CLI](#)
- [Using dual-stack endpoints from the AWS SDKs](#)
- [Using dual-stack endpoints from the REST API](#)

## Using dual-stack endpoints from the AWS CLI

This section provides examples of AWS CLI commands used to make requests to a dual-stack endpoint. For more information about installing the AWS CLI or updating to the latest version, see

[Installing or updating to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide for Version 2*.

To use a dual-stack endpoint, you can set the configuration value `use_dualstack_endpoint` to `true` in the config file for the AWS CLI to direct all Amazon ECS requests made by the `ecs` AWS CLI command to the dual-stack endpoint for the specified region. You can specify the region in the config file or in a command by using the `--region` option. For more information about configuration files for the AWS CLI, see [Configuration and credential file settings in the AWS CLI](#) in the *AWS Command Line Interface User Guide for Version 2*.

If you want to use a dual-stack endpoint for specific AWS CLI commands, you can use either of the following methods:

- You can use the dual-stack endpoint per command by setting the `--endpoint-url` parameter to `https://ecs.aws-region.api.aws` or `http://ecs.aws-region.api.aws` for any `ecs` command.

The following example command lists all available clusters and uses the dual-stack endpoint for the request.

```
$ aws ecs list-clusters --endpoint-url https://ecs.aws-region.api.aws
```

- You can set up separate profiles in your AWS Config file. For example, create one profile that sets `use_dualstack_endpoint` to `true` and a profile that does not set `use_dualstack_endpoint`. When you run a command, specify which profile you want to use, depending upon whether or not you want to use the dual-stack endpoint.

## Using dual-stack endpoints from the AWS SDKs

This section provides examples of how to access a dual-stack endpoint by using the AWS SDKs.

### AWS SDK for Java 2.x

The following example shows how to specify a dual-stack endpoint for the `us-east-1` Region using the AWS SDK for Java 2.x.

```
Region region = Region.US_EAST_1
EcsClient client =
    EcsClient.builder().region(region).dualstackEnabled(true).build();
```

## AWS SDK for Go

The following example shows how to specify a dual-stack endpoint for the us-east-1 Region using the AWS SDK for Go.

```
sess := session.Must(session.NewSession())
svc := ecs.New(sess, &aws.Config{
    Region: aws.String(endpoints.UsEast1RegionID),
    Endpoint: aws.String("https://ecs.us-east-1.api.aws")
})
```

For more information, see [Dual-stack and FIPS endpoints](#) in the *AWS SDKs and Tools Reference Guide*.

## Using dual-stack endpoints from the REST API

When using the REST API, you can directly access a dual-stack endpoint by specifying it in your request. The following example uses the dual-stack endpoint to list all Amazon ECS clusters in the us-east-1 Region.

```
POST / HTTP/1.1
Host: ecs.us-east-1.api.aws
Accept-Encoding: identity
Content-Length: 2
X-Amz-Target: AmazonEC2ContainerServiceV20141113.ListClusters
X-Amz-Date: 20150429T170621Z
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{}
```

## Amazon ECS applications in shared subnets, Local Zones, and Wavelength Zones

Amazon ECS supports workloads that use Local Zones, Wavelength Zones, and AWS Outposts for when low latency or local data processing is a requirement.

- You can use Local Zones as an extension of an AWS Region to place resources in multiple locations closer to your end users.

- You can use Wavelength Zones to build applications that deliver ultra-low latencies to 5G devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks.
- AWS Outposts brings native AWS services, infrastructure, and operating models to virtually any data center, co-location space, or on-premises facility.

### Important

Amazon ECS on AWS Fargate workloads aren't supported in Local Zones, Wavelength Zones, or on AWS Outposts at this time.

For information about the differences between Local Zones, Wavelength Zones, and AWS Outposts, see [How should I think about when to use AWS Wavelength, AWS Local Zones, or AWS Outposts for applications requiring low latency or local data processing](#) in the AWS Wavelength FAQs.

## Shared subnets

You can use *VPC sharing* to share subnets with other AWS accounts within the same AWS Organizations.

You can use shared VPCs for EC2 with the following considerations:

- The owner of the VPC subnet must share a subnet with a participant account before that account can use it for Amazon ECS resources.
- You can't use the VPC default security group for your container instances because it belongs to the owner. Additionally, participants can't launch instances using security groups that are owned by other participants or the owner.
- In a shared subnet, the participant and the owner separately controls the security groups within each respective account. The subnet owner can see security groups that are created by the participants but cannot perform any actions on them. If the subnet owner wants to remove or modify these security groups, the participant that created the security group must take the action.
- The shared VPC owner cannot view, update or delete a cluster that a participant creates in the shared subnet. This is in addition to the VPC resources that each account has different access to.

For more information, see [Responsibilities and permissions for owners and participants](#) in the *Amazon VPC User Guide*.

You can use shared VPCs for Fargate with the following considerations::

- The owner of the VPC subnet must share a subnet with a participant account before that account can use it for Amazon ECS resources.
- You can't create a service or run a task using the default security group for the VPC because it belongs to the owner. Additionally, participants can't create a service or run a task using security groups that are owned by other participants or the owner.
- In a shared subnet, the participant and the owner separately controls the security groups within each respective account. The subnet owner can see security groups that are created by the participants but cannot perform any actions on them. If the subnet owner wants to remove or modify these security groups, the participant that created the security group must take the action.
- The shared VPC owner cannot view, update or delete a cluster that a participant creates in the shared subnet. This is in addition to the VPC resources that each account has different access to. For more information, see [Responsibilities and permissions for owners and participants](#) in the *Amazon VPC User Guide*.

For more information about VPC subnet sharing, see [Share your VPC with other accounts](#) in the *Amazon VPC User Guide*.

## Local Zones

A *Local Zone* is an extension of an AWS Region in close geographic proximity to your users. Local Zones have their own connections to the internet and support Direct Connect. Resources that are created in a Local Zone can serve local users with low-latency communications. For more information, see [AWS Local Zones](#).

A Local Zone is represented by a Region code followed by an identifier that indicates the location (for example, us-west-2-lax-1a).

To use a Local Zone, you must opt in to the zone. After you opt in, you must create an Amazon VPC and subnet in the Local Zone.

You can launch Amazon EC2 instances, Amazon FSx file servers, and Application Load Balancers to use for your Amazon ECS clusters and tasks.

For more information, see [What is AWS Local Zones?](#) in the *AWS Local Zones User Guide*.

## Wavelength Zones

You can use *AWS Wavelength* to build applications that deliver ultra-low latency to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. You can extend an Amazon Virtual Private Cloud to one or more Wavelength Zones. Then, you can use AWS resources such as Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region.

A Wavelength Zone is an isolated Zone in the carrier location where the Wavelength infrastructure is deployed. Wavelength Zones are tied to an AWS Region. A Wavelength Zone is a logical extension of a Region, and is managed by the control plane in the Region.

A Wavelength Zone is represented by a Region code followed by an identifier that indicates the Wavelength Zone (for example, `us-east-1-wl1-bos-wlz-1`).

To use a Wavelength Zone, you must opt in to the Zone. After you opt in, you must create an Amazon VPC and subnet in the Wavelength Zone. Then, you can launch your Amazon EC2 instances in the Zone to use for your Amazon ECS clusters and tasks.

For more information, see [Get started with AWS Wavelength](#) in the *AWS Wavelength Developer Guide*.

Wavelength Zones aren't available in all AWS Regions. For information about the Regions that support Wavelength Zones, see [Available Wavelength Zones](#) in the *AWS Wavelength Developer Guide*.

## Amazon Elastic Container Service on AWS Outposts

AWS Outposts enables native AWS services, infrastructure, and operating models in on-premises facilities. In AWS Outposts environments, you can use the same AWS APIs, tools, and infrastructure that you use in the AWS Cloud.

Amazon ECS on AWS Outposts is ideal for low-latency workloads that need to be run in close proximity to on-premises data and applications.

For more information about AWS Outposts, see the [AWS Outposts User Guide](#).

## Considerations

The following are considerations of using Amazon ECS on AWS Outposts:

- Amazon Elastic Container Registry, AWS Identity and Access Management, and Network Load Balancer run in the AWS Region, not on AWS Outposts. This will increase latencies between these services and the containers.
- AWS Fargate is not available on AWS Outposts.

The following are network connectivity considerations for AWS Outposts:

- If network connectivity between your AWS Outposts and its AWS Region is lost, your clusters will continue to run. However, you cannot create new clusters or take new actions on existing clusters until connectivity is restored. In case of instance failures, the instance will not be automatically replaced. The CloudWatch Logs agent will be unable to update logs and event data.
- We recommend that you provide reliable, highly available, and low latency connectivity between your AWS Outposts and its AWS Region.

## Prerequisites

The following are prerequisites for using Amazon ECS on AWS Outposts:

- You must have installed and configured an Outpost in your on-premises data center.
- You must have a reliable network connection between your Outpost and its AWS Region.

## Overview of cluster creation on AWS Outposts

The following is an overview of the configuration:

1. Create a role and policy with rights on AWS Outposts.
2. Create an IAM instance profile with rights on AWS Outposts.
3. Create a VPC, or use an existing one that is in the same Region as your AWS Outposts.
4. Create a subnet or use an existing one that is associated with the AWS Outposts.

This is the subnet where the container instances run.

5. Create a security group for the container instances in your cluster.

6. Create an Amazon ECS cluster.
7. Define the Amazon ECS container agent environment variables to launch the instance into the cluster.
8. Run a container.

For detailed information about how to integrate Amazon ECS with AWS Outposts, see [Extend Amazon ECS across two AWS Outposts racks](#).

The following example creates an Amazon ECS cluster on an AWS Outposts.

1. Create a role and policy with rights on AWS Outposts.

The `role-policy.json` file is the policy document that contains the effect and actions for resources. For information about the file format, see [PutRolePolicy](#) in the *IAM API Reference*

```
aws iam create-role --role-name ecsRole \  
    --assume-role-policy-document file://ecs-policy.json  
aws iam put-role-policy --role-name ecsRole --policy-name ecsRolePolicy \  
    --policy-document file://role-policy.json
```

2. Create an IAM instance profile with rights on AWS Outposts.

```
aws iam create-instance-profile --instance-profile-name outpost  
aws iam add-role-to-instance-profile --instance-profile-name outpost \  
    --role-name ecsRole
```

3. Create a VPC.

```
aws ec2 create-vpc --cidr-block 10.0.0.0/16
```

4. Create a subnet associated with your AWS Outposts.

```
aws ec2 create-subnet \  
    --cidr-block 10.0.3.0/24 \  
    --vpc-id vpc-xxxxxxxx \  
    --outpost-arn arn:aws:outposts:us-west-2:123456789012:outpost/op-  
xxxxxxxxxxxxxxxxxxxx \  
    --availability-zone-id usw2-az1
```

5. Create a security group for the container instances, specifying the proper CIDR range for the AWS Outposts. (This step is different for AWS Outposts.)

```
aws ec2 create-security-group --group-name MyOutpostSG
aws ec2 authorize-security-group-ingress --group-name MyOutpostSG --protocol tcp \
    --port 22 --cidr 10.0.3.0/24
aws ec2 authorize-security-group-ingress --group-name MyOutpostSG --protocol tcp \
    --port 80 --cidr 10.0.3.0/24
```

6. Create the Cluster.
7. Define the Amazon ECS container agent environment variables to launch the instance into the cluster created in the previous step and define any tags you want to add to help identify the cluster (for example, Outpost to indicate that the cluster is for an Outpost).

```
#!/bin/bash
cat << 'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_IMAGE_PULL_BEHAVIOR=prefer-cached
ECS_CONTAINER_INSTANCE_TAGS={"environment": "Outpost"}
EOF
```

#### Note

In order to avoid delays caused by pulling container images from Amazon ECR in the Region, use image caches. To do this, each time a task is run, configure the Amazon ECS agent to default to using the cached image on the instance itself by setting `ECS_IMAGE_PULL_BEHAVIOR` to `prefer-cached`.

8. Create the container instance, specifying the VPC and subnet for the AWS Outposts where this instance should run and an instance type that is available on the AWS Outposts. (This step is different for AWS Outposts.)

The `userdata.txt` file contains the user data the instance can use to perform common automated configuration tasks and even run scripts after the instance starts. For information about the file for API calls, see [Run commands on your Linux instance at launch](#) in the *Amazon EC2 User Guide*.

```
aws ec2 run-instances --count 1 --image-id ami-xxxxxxx --instance-type c5.large \
    --key-name aws-outpost-key --subnet-id subnet-xxxxxxxxxxxxxxxx \
```

```
--iam-instance-profile Name outpost --security-group-id sg-xxxxxx \  
--associate-public-ip-address --user-data file://userdata.txt
```

**Note**

This command is also used when adding additional instances to the cluster. Any containers deployed in the cluster will be placed on that specific AWS Outposts.

## Best practices for Amazon ECS container images

A container image is a set of instructions on how to build the container. A container image holds your application code and all the dependencies that your application code requires to run. Application dependencies include the source code packages that your application code relies on, a language runtime for interpreted languages, and binary packages that your dynamically linked code relies on.

Use the following guidelines when you design and build your container images:

- Make your container images complete by storing all application dependencies as static files inside the container image.

If you change something in the container image, build a new container image with the changes.

- Run a single application process within a container.

The container lifetime is as long as the application process runs. Amazon ECS replaces crashed processes and determines where to launch the replacement process. A complete image makes the overall deployment more resilient.

- Make your application handle SIGTERM.

When Amazon ECS stops a task, it first sends a SIGTERM signal to the task to notify the application that it needs to finish and shut down. Amazon ECS then sends a SIGKILL message. When applications ignore the SIGTERM, the Amazon ECS service must wait to send the SIGKILL signal to terminate the process.

You need to identify how long it takes your application to complete its work, and ensure that your applications handles the SIGTERM signal. The application's signal handling needs to

stop the application from taking new work and complete the work that is in-progress, or save unfinished work to storage outside of the task when the work takes too long to complete.

- Configure containerized applications to write logs to `stdout` and `stderr`.

Decoupling log handling from your application code gives you flexibility to adjust log handling at the infrastructure level. One example of this is to change your logging system. Instead of modifying your services, and building and deploying a new container image, you can adjust the settings.

- Use tags to version your container images.

Container images are stored in a container registry. Each image in a registry is identified by a tag. There's a tag called `latest`. This tag functions as a pointer to the latest version of the application container image, similar to the `HEAD` in a git repository. We recommend that you use the `latest` tag only for testing purposes. As a best practice, tag container images with a unique tag for each build. We recommend that you tag your images using the git SHA for the git commit that was used to build the image.

You don't need to build a container image for every commit. However, we recommend that you build a new container image each time you release a particular code commit to the production environment. We also recommend that you tag the image with a tag that corresponds to the git commit of the code that's inside the image. If you tagged the image with the git commit, you can more quickly find which version of the code the image is running.

We also recommend that you turn on immutable image tags in Amazon Elastic Container Registry. With this setting, you can't change the container image that a tag points at. Instead Amazon ECR enforces that a new image must be uploaded to a new tag. For more information, see [Image tag mutability](#) in the *Amazon ECR User Guide*.

When you architect your application to run on AWS Fargate, you must decide between deploying multiple containers into the same task definition and deploying containers separately in multiple task definitions. If the following conditions are required, we recommend deploying multiple containers into the same task definition:

- Your containers share a common lifecycle (that is, they're launched and terminated together).
- Your containers must run on the same underlying host (that is, one container references the other on a localhost port).
- Your containers share resources.

- Your containers share data volumes.

If these conditions aren't required, we recommend deploying containers separately in multiple task definitions. This allows you to scale, provision, and deprovision the containers separately.

## Amazon ECS networking best practices

Modern applications are typically built out of multiple distributed components that communicate with each other. For example, a mobile or web application might communicate with an API endpoint, and the API might be powered by multiple microservices that communicate over the internet.

For information about the best practices for connection applications to the internet, see [Connect Amazon ECS applications to the internet](#).

For information about the best practices for receiving inbound connections to Amazon ECS from the internet, see [Best practices for receiving inbound connections to Amazon ECS from the internet](#).

For information about the best practices for connecting Amazon ECS to other AWS services, see [Best practices for connecting Amazon ECS to AWS services from inside your VPC](#).

For information about the best practices for connecting services within a VPC, see [Best practices for connecting Amazon ECS services in a VPC](#).

For information about the best practices for networking services across AWS accounts and VPCs, see [Best practices for networking Amazon ECS services across AWS accounts and VPCs](#).

For information about the best practices for services to troubleshoot networking issues, see [AWS services for Amazon ECS networking troubleshooting](#).

## Connect Amazon ECS applications to the internet

Most containerized applications have at least some components that need outbound access to the internet. For example, the backend for a mobile app requires outbound access to push notifications.

Amazon Virtual Private Cloud has two main methods for facilitating communication between your VPC and the internet.

## Public subnet and internet gateway

When you use a public subnet that has a route to an internet gateway, your containerized application can run on a host inside a VPC on a public subnet. The host that runs your container is assigned a public IP address. This public IP address is routable from the internet. For more information, see [Internet gateways](#) in the *Amazon VPC User Guide*.

This network architecture facilitates direct communication between the host that runs your application and other hosts on the internet. The communication is bi-directional. This means that not only can you establish an outbound connection to any other host on the internet, but other hosts on the internet might also attempt to connect to your host. Therefore, you should pay close

attention to your security group and firewall rules. This ensures that other hosts on the internet can't open any connections that you don't want to be opened.

For example, if your application runs on Amazon EC2, make sure that port 22 for SSH access is not open. Otherwise, your instance could receive constant SSH connection attempts from malicious bots on the internet. These bots trawl through public IP addresses. After they find an open SSH port, they attempt to brute-force passwords to try to access your instance. Because of this, many organizations limit the usage of public subnets and prefer to have most, if not all, of their resources inside of private subnets.

Using public subnets for networking is suitable for public applications that require large amounts of bandwidth or minimal latency. Applicable use cases include video streaming and gaming services.

This networking approach is supported both when you use Amazon ECS on Amazon EC2 and when you use it on AWS Fargate.

- **Amazon EC2** — You can launch EC2 instances on a public subnet. Amazon ECS uses these EC2 instances as cluster capacity, and any containers that are running on the instances can use the underlying public IP address of the host for outbound networking. This applies to both the host and bridge network modes. However, the `awsvpc` network mode doesn't provide task ENIs with public IP addresses. Therefore, they can't make direct use of an internet gateway.
- **Fargate** — When you create your Amazon ECS service, specify public subnets for the networking configuration of your service, and use the **Assign public IP address** option. Each Fargate task is networked in the public subnet, and has its own public IP address for direct communication with the internet.

## Private subnet and NAT gateway

When you use a private subnet and a NAT gateway, you can run your containerized application on a host that's in a private subnet. As such, this host has a private IP address that's routable inside your VPC, but isn't routable from the internet. This means that other hosts inside the VPC can connect to the host using its private IP address, but other hosts on the internet can't make any inbound communications to the host.

With a private subnet, you can use a Network Address Translation (NAT) gateway to allow a host inside a private subnet to connect to the internet. Hosts on the internet receive an inbound connection that appears to be coming from the public IP address of the NAT gateway that's inside a public subnet. The NAT gateway is responsible for serving as a bridge between the internet and the private subnet. This configuration is often preferred for security reasons because it means that your VPC is protected from direct access by attackers on the internet. For more information, see [NAT gateways](#) in the *Amazon VPC User Guide*.

This private networking approach is suitable for scenarios where you want to protect your containers from direct external access. Applicable scenarios include payment processing systems or

containers storing user data and passwords. You're charged for creating and using a NAT gateway in your account. NAT gateway hourly usage and data processing rates also apply. For redundancy purposes, you should have a NAT gateway in each Availability Zone. This way, the loss in availability of a single Availability Zone doesn't compromise your outbound connectivity. Because of this, if you have a small workload, it might be more cost effective to use private subnets and NAT gateways.

This networking approach is supported both when using Amazon ECS on Amazon EC2 and when using it on AWS Fargate.

- **Amazon EC2** — You can launch EC2 instances on a private subnet. The containers that run on these EC2 hosts use the underlying hosts networking, and outbound requests go through the NAT gateway.
- **Fargate** — When you create your Amazon ECS service, specify private subnets for the networking configuration of your service, and don't use the **Assign public IP address** option. Each Fargate task is hosted in a private subnet. Its outbound traffic is routed through any NAT gateway that you have associated with that private subnet.

## Best practices for receiving inbound connections to Amazon ECS from the internet

If you run a public service, you must accept inbound traffic from the internet. For example, your public website must accept inbound HTTP requests from browsers. In such case, other hosts on the internet must also initiate an inbound connection to the host of your application.

One approach to this problem is to launch your containers on hosts that are in a public subnet with a public IP address. However, we don't recommend this for large-scale applications. For these, a better approach is to have a scalable input layer that sits between the internet and your application. For this approach, you can use any of the AWS services listed in this section as an input.

### Application Load Balancer

An Application Load Balancer functions at the application layer. It's the seventh layer of the Open Systems Interconnection (OSI) model. This makes an Application Load Balancer suitable for public HTTP services. If you have a website or an HTTP REST API, then an Application Load Balancer is a suitable load balancer for this workload. For more information, see [What is an Application Load Balancer?](#) in the *User Guide for Application Load Balancers*.

With this architecture, you create an Application Load Balancer in a public subnet so that it has a public IP address and can receive inbound connections from the internet. When the Application Load Balancer receives an inbound connection, or more specifically an HTTP request, it opens a connection to the application using its private IP address. Then, it forwards the request over the internal connection.

An Application Load Balancer has the following advantages.

- **SSL/TLS termination** — An Application Load Balancer can sustain secure HTTPS communication and certificates for communications with clients. It can optionally terminate the SSL connection at the load balancer level so that you don't have to handle certificates in your own application.
- **Advanced routing** — An Application Load Balancer can have multiple DNS hostnames. It also has advanced routing capabilities to send incoming HTTP requests to different destinations based on metrics such as the hostname or the path of the request. This means that you can use a single Application Load Balancer as the input for many different internal services, or even microservices on different paths of a REST API.
- **gRPC support and websockets** — An Application Load Balancer can handle more than just HTTP. It can also load balance gRPC and websocket based services, with HTTP/2 support.
- **Security** — An Application Load Balancer helps protect your application from malicious traffic. It includes features such as HTTP de sync mitigations, and is integrated with AWS Web Application Firewall (AWS WAF). AWS WAF can further filter out malicious traffic that might contain attack patterns, such as SQL injection or cross-site scripting.

## Network Load Balancer

A Network Load Balancer functions at the fourth layer of the Open Systems Interconnection (OSI) model. It's suitable for non-HTTP protocols or scenarios where end-to-end encryption is necessary, but doesn't have the same HTTP-specific features of an Application Load Balancer. Therefore, a Network Load Balancer is best suited for applications that don't use HTTP. For more information, see [What is a Network Load Balancer?](#) in the *User Guide for Network Load Balancers*.

When a Network Load Balancer is used as an input, it functions similarly to an Application Load Balancer. This is because it's created in a public subnet and has a public IP address that can be accessed on the internet. The Network Load Balancer then opens a connection to the private IP address of the host running your container, and sends the packets from the public side to the private side.

### Network Load Balancer features

Because the Network Load Balancer operates at a lower level of the networking stack, it doesn't have the same set of features that Application Load Balancer does. However, it does have the following important features.

- End-to-end encryption — Because a Network Load Balancer operates at the fourth layer of the OSI model, it doesn't read the contents of packets. This makes it suitable for load balancing communications that need end-to-end encryption.
- TLS encryption — In addition to end-to-end encryption, Network Load Balancer can also terminate TLS connections. This way, your backend applications don't have to implement their own TLS.
- UDP support — Because a Network Load Balancer operates at the fourth layer of the OSI model, it's suitable for non HTTP workloads and protocols other than TCP.

## Closing connections

Because the Network Load Balancer does not observe the application protocol at the higher layers of the OSI model, it cannot send closure messages to the clients in those protocols. Unlike the Application Load Balancer, those connections need to be closed by the application or you can configure the Network Load Balancer to close the fourth layer connections when a task is stopped or replaced. See the connection termination setting for Network Load Balancer target groups in the [Network Load Balancer documentation](#).

Letting the Network Load Balancer close connections at the fourth layer can cause clients to display undesired error messages, if the client does not handle them. See the Builders Library for more information on recommended client configuration [here](#).

The methods to close connections will vary by application, however one way is to ensure that the Network Load Balancer target deregistration delay is longer than client connection timeout. The client would timeout first and reconnect gracefully through the Network Load Balancer to the next task while the old task slowly drains all of its clients. For more information about the Network Load Balancer target deregistration delay, see the [Network Load Balancer documentation](#).

## Amazon API Gateway HTTP API

Amazon API Gateway is suitable for HTTP applications with sudden bursts in request volumes or low request volumes. For more information, see [What is Amazon API Gateway?](#) in the *API Gateway Developer Guide*.

The pricing model for both Application Load Balancer and Network Load Balancer include an hourly price to keep the load balancers available for accepting incoming connections at all times. In contrast, API Gateway charges for each request separately. This has the effect that, if no requests come in, there are no charges. Under high traffic loads, an Application Load Balancer or Network Load Balancer can handle a greater volume of requests at a cheaper per-request price than API Gateway. However, if you have a low number of requests overall or have periods of low traffic, then the cumulative price for using the API Gateway should be more cost effective than paying a hourly charge to maintain a load balancer that's being underutilized. The API Gateway can also cache API responses, which might result in lower backend request rates.

API Gateway functions which use a VPC link that allows the AWS managed service to connect to hosts inside the private subnet of your VPC, using its private IP address. It can detect these private IP addresses by looking at AWS Cloud Map service discovery records that are managed by Amazon ECS Service Discovery.

API Gateway supports the following features.

- The API Gateway operation is similar to a load balancer, but has additional capabilities unique to API management
- The API Gateway provides additional capabilities around client authorization, usage tiers, and request/response modification. For more information, see [Amazon API Gateway features](#).
- The API Gateway can support edge, regional, and private API gateway endpoints. Edge endpoints are available through a managed CloudFront distribution. Regional and private endpoints are both local to a Region.

- SSL/TLS termination
- Routing different HTTP paths to different backend microservices

Besides the preceding features, API Gateway also supports using custom Lambda authorizers that you can use to protect your API from unauthorized usage. For more information, see [Field Notes: Serverless Container-based APIs with Amazon ECS and Amazon API Gateway](#).

## Best practices for connecting Amazon ECS to AWS services from inside your VPC

For Amazon ECS to function properly, the Amazon ECS container agent that runs on each host must communicate with the Amazon ECS control plane. If you're storing your container images in Amazon ECR, the Amazon EC2 hosts must communicate to the Amazon ECR service endpoint, and to Amazon S3, where the image layers are stored. If you use other AWS services for your containerized application, such as persisting data stored in DynamoDB, double-check that these services also have the necessary networking support.

### NAT gateway

Using a NAT gateway is the easiest way to ensure that your Amazon ECS tasks can access other AWS services. For more information about this approach, see [Private subnet and NAT gateway](#).

The following are the disadvantages to using this approach:

- You can't limit what destinations the NAT gateway can communicate with. You also can't limit which destinations your backend tier can communicate to without disrupting all outbound communications from your VPC.
- NAT gateways charge for every GB of data that passes through. If you use the NAT gateway for any of the following operations, you're charged for every GB of bandwidth:
  - Downloading large files from Amazon S3
  - Doing a high volume of database queries to DynamoDB
  - Pulling images from Amazon ECR

Additionally, NAT gateways support 5 Gbps of bandwidth and automatically scale up to 45 Gbps. If you route through a single NAT gateway, applications that require very high bandwidth connections might encounter networking constraints. As a workaround, you can divide your workload across multiple subnets and give each subnet its own NAT gateway.

## AWS PrivateLink

AWS PrivateLink provides private connectivity between VPCs, AWS services, and your on-premises networks without exposing your traffic to the public internet.

A VPC endpoint allows private connections between your VPC and supported AWS services and VPC endpoint services. Traffic between your VPC and the other service doesn't leave the Amazon network. A VPC endpoint doesn't require an internet gateway, virtual private gateway, NAT device, VPN connection, or Direct Connect connection. Amazon EC2 instances in your VPC don't require public IP addresses to communicate with resources in the service.

The following diagram shows how communication to AWS services works when you are using VPC endpoints instead of an internet gateway. AWS PrivateLink provisions elastic network interfaces (ENIs) inside of the subnet, and VPC routing rules are used to send any communication to the service hostname through the ENI, directly to the destination AWS service. This traffic no longer needs to use the NAT gateway or internet gateway.

The following are some of the common VPC endpoints that are used with the Amazon ECS service.

- [Gateway endpoints for Amazon S3](#)
- [DynamoDB VPC endpoint](#)
- [Amazon ECS VPC endpoint](#)
- [Amazon ECR VPC endpoint](#)

Many other AWS services support VPC endpoints. If you make heavy usage of any AWS service, you should look up the specific documentation for that service and how to create a VPC endpoint for that traffic.

## Best practices for connecting Amazon ECS services in a VPC

Using Amazon ECS tasks in a VPC, you can split monolithic applications into separate parts that can be deployed and scaled independently in a secure environment. This architecture is called service-oriented architecture (SOA) or microservices. However, it can be challenging to make sure that all of these parts, both in and outside of a VPC, can communicate with each other. There are several approaches for facilitating communication, all with different advantages and disadvantages.

### Using Service Connect

We recommend Service Connect, which provides Amazon ECS configuration for service discovery, connectivity, and traffic monitoring. With Service Connect, your applications can use short names and standard ports to connect to services in the same cluster, other clusters, including across VPCs in the same Region. For more information, see [Amazon ECS Service Connect](#).

When you use Service Connect, Amazon ECS manages all of the parts of service discovery: creating the names that can be discovered, dynamically managing entries for each task as the tasks start and stop, running an agent in each task that is configured to discover the names. Your application can look up the names by using the standard functionality for DNS names and making connections. If your application does this already, you don't need to modify your application to use Service Connect.

## Changes only happen during deployments

You provide the complete configuration inside each service and task definition. Amazon ECS manages changes to this configuration in each service deployment, to ensure that all tasks in a deployment behave in the same way. For example, a common problem with DNS as service discovery is controlling a migration. If you change a DNS name to point to the new replacement IP addresses, it might take the maximum TTL time before all the clients begin using the new service. With Service Connect, the client deployment updates the configuration by replacing the client tasks. You can configure the deployment circuit breaker and other deployment configuration to affect Service Connect changes in the same way as any other deployment.

## Using service discovery

Another approach for service-to-service communication is direct communication using service discovery. In this approach, you can use the AWS Cloud Map service discovery integration with Amazon ECS. Using service discovery, Amazon ECS syncs the list of launched tasks to AWS Cloud Map, which maintains a DNS hostname that resolves to the internal IP addresses of one or more

tasks from that particular service. Other services in the Amazon VPC can use this DNS hostname to send traffic directly to another container using its internal IP address. For more information, see [Service discovery](#).

In the preceding diagram, there are three services. `service-a-local` has one container and communicates with `service-b-local`, which has two containers. `service-b-local` must also communicate with `service-c-local`, which has one container. Each container in all three of these services can use the internal DNS names from AWS Cloud Map to find the internal IP addresses of a container from the downstream service that it needs to communicate to.

This approach to service-to-service communication provides low latency. At first glance, it's also simple as there are no extra components between the containers. Traffic travels directly from one container to the other container.

This approach is suitable when using the `awsvpc` network mode, where each task has its own unique IP address. Most software only supports the use of DNS A records, which resolve directly to IP addresses. When using the `awsvpc` network mode, the IP address for each task are an A record. However, if you're using `bridge` network mode, multiple containers could be sharing the same IP address. Additionally, dynamic port mappings cause the containers to be randomly assigned port numbers on that single IP address. At this point, an A record is no longer enough

for service discovery. You must also use an SRV record. This type of record can keep track of both IP addresses and port numbers but requires that you configure applications appropriately. Some prebuilt applications that you use might not support SRV records.

Another advantage of the `awsvpc` network mode is that you have a unique security group for each service. You can configure this security group to allow incoming connections from only the specific upstream services that need to talk to that service.

The main disadvantage of direct service-to-service communication using service discovery is that you must implement extra logic to have retries and deal with connection failures. DNS records have a time-to-live (TTL) period that controls how long they are cached for. It takes some time for the DNS record to be updated and for the cache to expire so that your applications can pick up the latest version of the DNS record. So, your application might end up resolving the DNS record to point at another container that's no longer there. Your application needs to handle retries and have logic to ignore bad backends.

## Using an internal load balancer

Another approach to service-to-service communication is to use an internal load balancer. An internal load balancer exists entirely inside of your VPC and is only accessible to services inside of your VPC.

The load balancer maintains high availability by deploying redundant resources into each subnet. When a container from `serviceA` needs to communicate with a container from `serviceB`, it opens a connection to the load balancer. The load balancer then opens a connection to a container from `service B`. The load balancer serves as a centralized place for managing all connections between each service.

If a container from `serviceB` stops, then the load balancer can remove that container from the pool. The load balancer also does health checks against each downstream target in its pool and can automatically remove bad targets from the pool until they become healthy again. The applications no longer need to be aware of how many downstream containers there are. They just open their connections to the load balancer.

This approach is advantageous to all network modes. The load balancer can keep track of task IP addresses when using the `awsvpc` network mode, as well as more advanced combinations of IP addresses and ports when using the `bridge` network mode. It evenly distributes traffic across all

the IP address and port combinations, even if several containers are actually hosted on the same Amazon EC2 instance, just on different ports.

The one disadvantage of this approach is cost. To be highly available, the load balancer needs to have resources in each Availability Zone. This adds extra cost because of the overhead of paying for the load balancer and for the amount of traffic that goes through the load balancer.

However, you can reduce overhead costs by having multiple services share a load balancer. This is particularly suitable for REST services that use an Application Load Balancer. You can create path-based routing rules that route traffic to different services. For example, `/api/user/*` might route to a container that's part of the user service, whereas `/api/order/*` might route to the associated order service. With this approach, you only pay for one Application Load Balancer, and have one consistent URL for your API. However, you can split the traffic off to various microservices on the backend.

## Best practices for networking Amazon ECS services across AWS accounts and VPCs

If you're part of an organization with multiple teams and divisions, you probably deploy services independently into separate VPCs inside a shared AWS account or into VPCs that are associated with multiple individual AWS accounts. No matter which way you deploy your services, we recommend that you supplement your networking components to help route traffic between VPCs. For this, several AWS services can be used to supplement your existing networking components.

- **AWS Transit Gateway** — You should consider this networking service first. This service serves as a central hub for routing your connections between Amazon VPCs, AWS accounts, and on-premises networks. For more information, see [What is a transit gateway?](#) in the *Amazon VPC Transit Gateways Guide*.
- **Amazon VPC and VPN support** — You can use this service to create site-to-site VPN connections for connecting on-premises networks to your VPC. For more information, see [What is AWS Site-to-Site VPN?](#) in the *AWS Site-to-Site VPN User Guide*.
- **Amazon VPC** — You can use Amazon VPC peering to help you to connect multiple VPCs, either in the same account, or across accounts. For more information, see [What is VPC peering?](#) in the *Amazon VPC Peering Guide*.
- **Shared VPCs** — You can use a VPC and VPC subnets across multiple AWS accounts. For more information, see [Working with shared VPCs](#) in the *Amazon VPC User Guide*.

## AWS services for Amazon ECS networking troubleshooting

The following services and features can help you to gain insights about your network and service configurations. You can use this information to troubleshoot networking issues and better optimize your services.

### CloudWatch Container Insights

CloudWatch Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. Metrics include the utilization of resources such as CPU, memory, disk, and network. They're available in CloudWatch automatic dashboards. For more information, see [Setting up Container Insights on Amazon ECS](#) in the *Amazon CloudWatch User Guide*.

### AWS X-Ray

AWS X-Ray is a tracing service that you can use to collect information about the network requests that your application makes. You can use the SDK to instrument your application and capture timings and response codes of traffic between your services, and between your services and AWS service endpoints. For more information, see [What is AWS X-Ray](#) in the *AWS X-Ray Developer Guide*.

You can also explore AWS X-Ray graphs of how your services network with each other. Or, use them to explore aggregate statistics about how each service-to-service link is performing. Last, you can dive deeper into any specific transaction to see how segments representing network calls are associated with that particular transaction.

You can use these features to identify if there's a networking bottleneck or if a specific service within your network isn't performing as expected.

### VPC Flow Logs

You can use Amazon VPC flow logs to analyze network performance and debug connectivity issues. With VPC flow logs enabled, you can capture a log of all the connections in your VPC. These include connections to networking interfaces that are associated with Elastic Load Balancing, Amazon RDS, NAT gateways, and other key AWS services that you might be using. For more information, see [VPC Flow Logs](#) in the *Amazon VPC User Guide*.

### Network tuning tips

There are a few settings that you can fine tune in order to improve your networking.

## **nofile ulimit**

If you expect your application to have high traffic and handle many concurrent connections, you should take into account the system quota for the number of files allowed. When there are a lot of network sockets open, each one must be represented by a file descriptor. If your file descriptor quota is too low, it will limit your network sockets. This results in failed connections or errors. You can update the container specific quota for the number of files in the Amazon ECS task definition. If you're running on Amazon EC2 (instead of AWS Fargate), then you might also need to adjust these quotas on your underlying Amazon EC2 instance.

## **sysctl net**

Another category of tunable setting is the `sysctl` net settings. You should refer to the specific settings for your Linux distribution of choice. Many of these settings adjust the size of read and write buffers. This can help in some situations when running large-scale Amazon EC2 instances that have a lot of containers on them.

# **Optimize Amazon ECS task launch time**

In order to speed up your task launches, consider the following recommendations.

- **Cache container images and binpack instances**

If you use EC2, you can configure the Amazon ECS container agent pull behavior to `ECS_IMAGE_PULL_BEHAVIOR: prefer-cached`. The image is pulled remotely if there is no cached image. Otherwise, the cached image on the instance is used. Automated image cleanup is turned off for the container to ensure that the cached image isn't removed. This reduces image pull-time for subsequent launches. The effect of caching is even greater when you have a high task density in your container instances, which you can configure using the binpack placement strategy. Caching container images is especially beneficial for windows-based workloads which usually have large (tens of GBs) container image sizes. When using the binpack placement strategy, you can also consider using Elastic Network Interface (ENI) trunking to place more tasks with the `awsvpc` network mode on each container instance. ENI trunking increases the number of tasks you can run on `awsvpc` mode. For example, a `c5.large` instance that may support running only 2 tasks concurrently, can run up to 10 tasks with ENI trunking.

- **Choose an optimal network mode**

Although there are many instances where `awsvpc` network mode is ideal, this network mode can inherently increase task launch latency, because for each task in `awsvpc` mode, Amazon

ECS workflows need to provision and attach an ENI by invoking Amazon EC2 APIs which adds an overhead of several seconds to your task launches. By contrast, a key advantage of using `awsvpc` network mode is that each task has a security group to allow or deny traffic. This means you have greater flexibility to control communications between tasks and services at a more granular level. If the deployment speed is your priority, you can consider using `bridge` mode to speed up task launches. For more information, see [the section called “AWSVPC network mode”](#).

- **Track your task launch lifecycle to find optimization opportunities**

It is often difficult to know the amount of time it takes for your application to start-up. Launching your container image, running start-up scripts, and other configurations during application start-up can take a surprising amount of time. You can use the Task metadata endpoint to post metrics to track application start-up time from `StartedAt` in the container metadata response to the `StartedAt` time for your task or service. With this data, you can understand how your application is contributing to the total launch time, and find areas where you can reduce unnecessary application-specific overhead and optimize your container images. For more information, see [Amazon ECS Auto scaling and capacity management best practices](#).

- **Choose an optimal instance type (for EC2)**

Choosing the correct instance type is based on the resource reservation (for example, CPU, memory) that you configure on your task. Therefore, when sizing the instance, you can calculate how many tasks can be placed on a single instance. A simple example of a well-placed task, is hosting 4 tasks requiring 0.5 vCPU and 2GB of memory reservations in an `m5.large` instance (supporting 2 vCPU and 8 GB memory). The reservations of this task definition take full advantage of the instance’s resources.

## Operating Amazon ECS at scale

As you begin operating Amazon ECS at scale, consider how service quotas and API throttles for Amazon ECS and the AWS services that integrate with Amazon ECS might affect you.

### Topics

- [Amazon ECS service quotas and API throttling limits](#)
- [Handle Amazon ECS throttling issues](#)

## Amazon ECS service quotas and API throttling limits

Amazon ECS integrates with several AWS services, including Elastic Load Balancing, AWS Cloud Map, and Amazon EC2. With this tight integration, Amazon ECS includes several features such as service load balancing, service discovery, task networking, and cluster auto scaling. Amazon ECS and the other AWS services that it integrates with all maintain service quotas and API rate limits to ensure consistent performance and utilization. These service quotas also prevent the accidental provisioning of more resources than needed and protect against malicious actions that might increase your bill.

By familiarizing yourself with your service quotas and the AWS API rate limits, you can plan for scaling your workloads without worrying about unexpected performance degradation. For more information, see [Amazon ECS service quotas](#) and [Request throttling for the Amazon ECS API](#).

When scaling your workloads on Amazon ECS, consider the following service quota. For instructions on how to request a service quota increase, see [Managing your Amazon ECS and AWS Fargate service quotas in the AWS Management Console](#).

- AWS Fargate has quotas that limit the number of concurrent running tasks in each AWS Region. There are quotas for both On-Demand and Fargate Spot tasks on Amazon ECS. Each service quota also includes any Amazon EKS pods that you run on Fargate. For more information about the Fargate quotas, see [AWS Fargate service quotas](#) in the *Amazon Elastic Container Service User Guide for AWS Fargate*.
- For tasks that run on Amazon EC2 instances, the maximum number of Amazon EC2 instances that you can register for each cluster is 5,000. If you use Amazon ECS cluster auto scaling with an Auto Scaling group capacity provider, or if you manage Amazon EC2 instances for your cluster on your own, this quota might become a deployment bottleneck. If you require more capacity, you can create more clusters or request a service quota increase.
- If you use Amazon ECS cluster auto scaling with an Auto Scaling group capacity provider, when scaling your services consider the Tasks in the PROVISIONING state per cluster quota. This quota is the maximum number of tasks in the PROVISIONING state for each cluster for which capacity providers can increase capacity. When you launch a large number of tasks all at the same time, you can easily meet this quota. One example is if you simultaneously deploy tens of services, each with hundreds of tasks. When this happens, the capacity provider needs to launch new container instances to place the tasks when the cluster has insufficient capacity. While the capacity provider is launching additional Amazon EC2 instances, the Amazon ECS service scheduler likely will continue to launch tasks in parallel. However, this activity might be

throttled because of insufficient cluster capacity. The Amazon ECS service scheduler implements a back-off and exponential throttling strategy for retrying task placement as new container instances are launched. As a result, you might experience slower deployment or scale-out times. To avoid this situation, you can plan your service deployments in one of the following ways. Either deploy a large number of tasks that don't require increasing cluster capacity, or keep spare cluster capacity for new task launches.

In addition to considering Amazon ECS service quota when scaling your workloads, consider also the service quota for the other AWS services that are integrated with Amazon ECS. The following section covers the key rate limits for each service in detail, and provides recommendations to deal with potential throttling issues.

## Elastic Load Balancing

You can configure your Amazon ECS services to use Elastic Load Balancing to distribute traffic evenly across the tasks. For more information about how to choose a load balancer, see [Use load balancing to distribute Amazon ECS service traffic](#).

### Elastic Load Balancing service quotas

When you scale your workloads, consider the following Elastic Load Balancing service quotas. Most Elastic Load Balancing service quotas are adjustable, and you can request an increase in the Service Quotas console.

### Application Load Balancer

When you use an Application Load Balancer, depending on your use case, you might need to request a quota increase for:

- The `Targets per Application Load Balancer` quota which is the number of targets behind your Application Load Balancer.
- The `Targets per Target Group per Region` quota which is the number of targets behind your Target Groups.

For more information, see [Quotas for your Application Load Balancers](#).

### Network Load Balancer

There are stricter limitations on the number of targets you can register with a Network Load Balancer. When using a Network Load Balancer, you often will want to enable cross-zone support, which comes with additional scaling limitations on Targets per Availability Zone Per Network Load Balancer the maximum number of targets per Availability Zone for each Network Load Balancer. For more information, see [Quotas for your Network Load Balancers](#).

## Elastic Load Balancing API throttling

When you configure an Amazon ECS service to use a load balancer, the target group health checks must pass before the service is considered healthy. For performing these health checks, Amazon ECS invokes Elastic Load Balancing API operations on your behalf. If you have a large number of services configured with load balancers in your account, you might experience slower service deployments because of potential throttling specifically for the RegisterTarget, DeregisterTarget, and DescribeTargetHealth Elastic Load Balancing API operations. When throttling occurs, throttling errors occur in your Amazon ECS service event messages.

If you experience AWS Cloud Map API throttling, you can contact Support for guidance on how to increase your AWS Cloud Map API throttling limits. For more information about monitoring and troubleshooting such throttling errors, see [Handling throttling issues](#).

## Elastic network interfaces

When your tasks use the awsvpc network mode, Amazon ECS provisions a unique elastic network interface (ENI) for each task. When your Amazon ECS services use an Elastic Load Balancing load balancer, these network interfaces are also registered as targets to the appropriate target group defined in the service.

## Elastic network interface service quotas

When you run tasks that use the awsvpc network mode, a unique elastic network interface is attached to each task. If those tasks must be reached over the internet, assign a public IP address to the elastic network interface for those tasks. When you scale your Amazon ECS workloads, consider these two important quotas:

- The Network interfaces per Region quota which is the maximum number of network interfaces in an AWS Region for your account.
- The Elastic IP addresses per Region quota which is the maximum number of elastic IP addresses in an AWS Region.

Both of these service quotas are adjustable and you can request an increase from your Service Quotas console for these. For more information, see [Amazon VPC service quotas](#).

For Amazon ECS workloads that are hosted on Amazon EC2 instances, when running tasks that use the `awsvpc` network mode consider the `Maximum network interfaces` service quota, the maximum number of network instances for each Amazon EC2 instance. This quota limits the number of tasks that you can place on an instance. You cannot adjust the quota and it's not available in the Service Quotas console. For more information, see [IP addresses per network interface per instance type](#) in the *Amazon EC2 User Guide*.

Although you can't change the number of network interfaces that can be attached to an Amazon EC2 instance, you can use the elastic network interface trunking feature to increase the number of available network interfaces. For example, by default a `c5.large` instance can have up to three network interfaces. The primary network interface for the instance counts as one. So, you can attach an additional two network interfaces to the instance. Because each task that uses the `awsvpc` network mode requires a network interface, you can typically only run two such tasks on this instance type. This can lead to under-utilization of your cluster capacity. If you enable elastic network interface trunking, you can increase the network interface density to place a larger number of tasks on each instance. With trunking turned on, a `c5.large` instance can have up to 12 network interfaces. The instance has the primary network interface and Amazon ECS creates and attaches a "trunk" network interface to the instance. As a result, with this configuration you can run 10 tasks on the instance instead of the default two tasks. For more information, see [Elastic network interface trunking](#).

### Elastic network interface API throttling

When you run tasks that use the `awsvpc` network mode, Amazon ECS relies on the following Amazon EC2 APIs. Each of these APIs have different API throttles. For more information, see [Request throttling for the Amazon EC2 API](#).

- `CreateNetworkInterface`
- `AttachNetworkInterface`
- `DetachNetworkInterface`
- `DeleteNetworkInterface`
- `DescribeNetworkInterfaces`
- `DescribeVpcs`
- `DescribeSubnets`

- DescribeSecurityGroups
- DescribeInstances

If the Amazon EC2 API calls are throttled during the elastic network interface provisioning workflows, the Amazon ECS service scheduler automatically retries with exponential back-offs. These automatic retries might sometimes lead to a delay in launching tasks, which results in slower deployment speeds. When API throttling occurs, you will see the message `Operations are being throttled. Will try again later.` on your service event messages. If you consistently meet Amazon EC2 API throttles, you can contact Support for guidance on how to increase your API throttling limits. For more information about monitoring and troubleshooting throttling errors, see [Handling throttling issues](#).

## AWS Cloud Map

Amazon ECS service discovery uses AWS Cloud Map APIs to manage namespaces for your Amazon ECS services. If your services have a large number of tasks, consider the following recommendations. For more information, see [Amazon ECS service discovery considerations](#).

### AWS Cloud Map service quotas

When Amazon ECS services are configured to use service discovery, the `Tasks per service` quota which is the maximum number of tasks for the service, is affected by the `AWS Cloud Map Instances per service` service quota which is the maximum number of instances for that service. In particular, the AWS Cloud Map service quota decreases the amount of tasks that you can run to at most 1,000 tasks per service. You cannot change the AWS Cloud Map quota. For more information, see [AWS Cloud Map service quotas](#).

### AWS Cloud Map API throttling

Amazon ECS calls the `ListInstances`, `GetInstancesHealthStatus`, `RegisterInstance`, and `DeregisterInstance` AWS Cloud Map APIs on your behalf. They help with service discovery and perform health checks when you launch a task. When multiple services that use service discovery with a large number of tasks are deployed at the same time, this can result in exceeding the AWS Cloud Map API throttling limits. When this happens, you likely will see the following message: `Operations are being throttled. Will try again later` in your Amazon ECS service event messages and slower deployment and task launch speed. AWS Cloud Map doesn't document throttling limits for these APIs. If you experience throttling from these, you can contact Support for

guidance on increasing your API throttling limits. For more recommendations on monitoring and troubleshooting such throttling errors, see [Handling throttling issues](#).

## Handle Amazon ECS throttling issues

Throttling errors fall into two major categories: synchronous throttling and asynchronous throttling.

### Synchronous throttling

When synchronous throttling occurs, you immediately receive an error response from Amazon ECS. This category typically occurs when you call Amazon ECS APIs while running tasks or creating services. For more information about the throttling involved and the relevant throttle limits, see [Request throttling for the Amazon ECS API](#).

When your application initiates API requests, for example, by using the AWS CLI or an AWS SDK, you can remediate API throttling. You can do this by either architecting your application to handle the errors or by implementing an exponential backoff and jitter strategy with retry logic for the API calls. For more information, see [Timeouts, retries, and backoff with jitter](#).

If you use an AWS SDK, the automatic retry logic is built-in and configurable.

### Asynchronous throttling

Asynchronous throttling occurs because of asynchronous workflows where Amazon ECS or CloudFormation might be calling APIs on your behalf to provision resources. It's important to know which AWS APIs that Amazon ECS invokes on your behalf. For example, the `CreateNetworkInterface` API is invoked for tasks that use the `awsvpc` network mode, and the `DescribeTargetHealth` API is invoked when performing health checks for tasks registered to a load balancer.

When your workloads reach a considerable scale, these API operations might be throttled. That is, they might be throttled enough to breach the limits enforced by Amazon ECS or the AWS service that is being called. For example, if you deploy hundreds of services, each having hundreds of tasks concurrently that use the `awsvpc` network mode, Amazon ECS invokes Amazon EC2 API operations such as `CreateNetworkInterface` and Elastic Load Balancing API operations such as `RegisterTarget` or `DescribeTargetHealth` to register the elastic network interface and load balancer, respectively. These API calls can exceed the API limits, resulting in throttling errors. The following is an example of an Elastic Load Balancing throttling error that's included in the service event message.

```
{
  "userIdentity":{
    "arn":"arn:aws:sts::111122223333:assumed-role/AWSServiceRoleForECS/ecs-service-scheduler",
    "eventTime":"2022-03-21T08:11:24Z",
    "eventSource":"elasticloadbalancing.amazonaws.com",
    "eventName":" DescribeTargetHealth ",
    "awsRegion":"us-east-1",
    "sourceIPAddress":"ecs.amazonaws.com",
    "userAgent":"ecs.amazonaws.com",
    "errorCode":"ThrottlingException",
    "errorMessage":"Rate exceeded",
    "eventID":"0aeb38fc-229b-4912-8b0d-2e8315193e9c"
  }
}
```

When these API calls share limits with other API traffic in your account, they might be difficult to monitor even though they're emitted as service events.

## Monitor throttling

It's important to identify which API requests are throttled and who issues these requests. You can use AWS CloudTrail which monitors throttling, and integrates with CloudWatch, Amazon Athena, and Amazon EventBridge. You can configure CloudTrail to send specific events to CloudWatch Logs. CloudWatch Logs log insights parses and analyzes the events. This identifies details in throttling events such as the user or IAM role that made the call and the number of API calls that were made. For more information, see [Monitoring CloudTrail log files with CloudWatch Logs](#).

For more information about CloudWatch Logs insights and instructions on how to query log files, see [Analyzing log data with CloudWatch Logs Insights](#).

With Amazon Athena, you can create queries and analyze data using standard SQL. For example, you can create an Athena table to parse CloudTrail events. For more information, see [Using the CloudTrail console to create an Athena table for CloudTrail logs](#).

After creating an Athena table, you can use SQL queries such as the following one to investigate `ThrottlingException` errors.

Replace the *user-input* with your values.

```
select eventname, errorcode,eventsource,awsregion, useragent,COUNT(*) count
```

```
FROM cloudtrail_table-name
where errorcode = 'ThrottlingException'
AND eventtime between '2024-09-24T00:00:08Z' and '2024-09-23T23:15:08Z'
group by errorcode, awsregion, eventsource, useragent, eventname
order by count desc;
```

Amazon ECS also emits event notifications to Amazon EventBridge. There are resource state change events and service action events. They include API throttling events such as `ECS_OPERATION_THROTTLED` and `SERVICE_DISCOVERY_OPERATION_THROTTLED`. For more information, see [Amazon ECS service action events](#).

These events can be consumed by a service such as AWS Lambda to perform actions in response. For more information, see [Handling Amazon ECS events](#).

If you run standalone tasks, some API operations such as `RunTask` are asynchronous, and retry operations aren't automatically performed. In such cases, you can use services such as AWS Step Functions with EventBridge integration to retry throttled or failed operations. For more information, see [Manage a container task \(Amazon ECS, Amazon SNS\)](#).

## Use CloudWatch to monitor throttling

CloudWatch offers API usage monitoring on the Usage namespace under **By AWS Resource**. These metrics are logged with type **API** and metric name **CallCount**. You can create alarms to start whenever these metrics reach a certain threshold. For more information, see [Visualizing your service quotas and setting alarms](#).

CloudWatch also offers anomaly detection. This feature uses machine learning to analyze and establish baselines based on the particular behavior of the metric that you enabled it on. If there's unusual API activity, you can use this feature together with CloudWatch alarms. For more information, see [Using CloudWatch anomaly detection](#).

By proactively monitoring throttling errors, you can contact Support to increase the relevant throttling limits and also receive guidance for your unique application needs.

## Amazon ECS Auto scaling and capacity management best practices

You can run containerized application workloads of all sizes on Amazon ECS. This includes minimal testing environments and large production environments that operate at a global scale.

With Amazon ECS, like all AWS services, you pay only for what you use. When you architect your application appropriately, you can save costs by consuming only the resources that you need when you need them.

The following recommendations show you how to run your Amazon ECS workloads to meet your service-level objectives while operating cost-effectively.

## Topics

- [Determining the task size for Amazon ECS](#)
- [Optimizing Amazon ECS service auto scaling](#)
- [Amazon ECS capacity and availability](#)
- [Amazon ECS cluster capacity](#)
- [Choosing Fargate task sizes for Amazon ECS](#)
- [Speeding up Amazon ECS cluster capacity provisioning with capacity providers on Amazon EC2](#)

## Determining the task size for Amazon ECS

One of the most important choices when you deploy containers on Amazon ECS is your container and task sizes. Your container and task sizes are essential for scaling and capacity planning.

Amazon ECS uses two resource metrics for capacity: CPU and memory. Amazon ECS measures CPU in units of 1/1024 of a full vCPU (where 1024 units equals 1 whole vCPU). Amazon ECS measures memory in megabytes.

In your task definition, you can declare resource reservations and limits.

When you declare a reservation, you declare the minimum amount of resources that a task requires. Your task receives at least the amount of resources you request. Your application might be able to use more CPU or memory than the reservation you declare. However, this is subject to any limits you also declared.

Using more than the reservation amount is known as bursting. Bursting means your application uses more resources than you reserved but stays within your declared limits. Amazon ECS guarantees reservations. For example, if you use Amazon EC2 instances to provide capacity, Amazon ECS doesn't place a task on an instance where it can't fulfill the reservation.

A limit is the maximum amount of CPU units or memory that your container or task can use. If your container tries to use more CPU than this limit, Amazon ECS throttles it. If your container tries to use more memory than this limit, Amazon ECS stops your container.

Choosing these values can be challenging. The values that work best for your application depend greatly on your application's resource requirements.

Load testing your application is the key to successful resource requirement planning. Load testing helps you better understand your application's requirements.

## Stateless applications

For stateless applications that scale horizontally, such as an application behind a load balancer, we recommend that you first determine how much memory your application consumes when it serves requests.

To do this, you can use traditional tools such as `ps` or `top`. You can also use monitoring solutions such as CloudWatch Container Insights.

When you determine a CPU reservation, consider how you want to scale your application to meet your business requirements.

You can use smaller CPU reservations, such as 256 CPU units (or 1/4 vCPU), to scale out in a fine-grained way that minimizes cost. But they might not scale fast enough to meet significant spikes in demand.

You can use larger CPU reservations to scale in and out more quickly. This helps you match demand spikes more quickly. However, larger CPU reservations cost more.

## Other applications

For applications that don't scale horizontally, such as singleton workers or database servers, available capacity and cost are your most important considerations.

Choose the amount of memory and CPU based on what load testing shows you need to serve traffic and meet your service-level objective. Amazon ECS ensures that your application is placed on a host that has adequate capacity.

## Optimizing Amazon ECS service auto scaling

An Amazon ECS service is a managed collection of tasks. Each service has an associated task definition, a desired task count, and an optional placement strategy.

Amazon ECS service auto scaling works through the Application Auto Scaling service. Application Auto Scaling uses CloudWatch metrics as the source for scaling metrics. It also uses CloudWatch alarms to set thresholds on when to scale your service in or out.

You provide the thresholds for scaling. You can set a metric target, which is called *target tracking scaling*. You can also specify thresholds, which is called *step scaling*.

After you configure Application Auto Scaling, it continually calculates the appropriate desired task count for the service. It also notifies Amazon ECS when the desired task count should change, either by scaling it out or scaling it in.

To use service auto scaling effectively, you must choose an appropriate scaling metric. We discuss how to choose a metric in the following sections.

## Characterizing your application

Properly scaling an application requires you to know the conditions where you should scale your application in and when you should scale it out.

In essence, you should scale out your application if demand is forecasted to outstrip capacity. Conversely, you can scale in your application to conserve costs when resources exceed demand.

## Identifying a utilization metric

To scale effectively, you must identify a metric that indicates utilization or saturation. This metric must exhibit the following properties to be useful for scaling.

- The metric must be correlated with demand. When you hold resources steady but demand changes, the metric value must also change. The metric should increase or decrease when demand increases or decreases.
- The metric value must scale in proportion to capacity. When demand holds constant, adding more resources must result in a proportional change in the metric value. So, doubling the number of tasks should cause the metric to decrease by 50%.

The best way to identify a utilization metric is through load testing in a pre-production environment such as a staging environment. Commercial and open-source load testing solutions are widely available. These solutions typically can either generate synthetic load or simulate real user traffic.

To start the process of load testing, you should first build dashboards for your application's utilization metrics. These metrics include CPU utilization, memory utilization, I/O operations, I/O queue depth, and network throughput. You can collect these metrics with a service such as CloudWatch Container Insights. You can also collect them by using Amazon Managed Service for Prometheus together with Amazon Managed Grafana. During this process, make sure that you collect and plot metrics for your application's response times or work completion rates.

When you load test, begin with a small request or job insertion rate. Keep this rate steady for several minutes to allow your application to warm up. Then, slowly increase the rate and hold it steady for a few minutes. Repeat this cycle, increasing the rate each time until your application's response or completion times are too slow to meet your service-level objectives (SLOs).

While you load test, examine each of the utilization metrics. The metrics that increase along with the load are the top candidates to serve as your best utilization metrics.

Next, identify the resource that reaches saturation. At the same time, also examine the utilization metrics to see which one flattens out at a high level first. Or, examine which one reaches peak and then crashes your application first. For example, if CPU utilization increases from 0% to 70-80% as you add load, then stays at that level after you add even more load, then it's safe to say that the CPU is saturated. Depending on the CPU architecture, it might never reach 100%. For example, assume that memory utilization increases as you add load, and then your application suddenly crashes when it reaches the task or Amazon EC2 instance memory limit. In this situation, it's likely the case that memory has been fully consumed. Multiple resources might be consumed by your application. Therefore, choose the metric that represents the resource that depletes first.

Last, try load testing again after you double the number of tasks or Amazon EC2 instances. Assume that the key metric increases, or decreases, at half the rate as before. If this is the case, then the metric is proportional to capacity. This is a good utilization metric for auto scaling.

Now consider this hypothetical scenario. Suppose that you load test an application and find that the CPU utilization eventually reaches 80% at 100 requests per second. When you add more load, it doesn't make CPU utilization increase anymore. However, it does make your application respond more slowly. Then, you run the load test again, doubling the number of tasks but holding the rate at its previous peak value. If you find the average CPU utilization falls to about 40%, then average CPU utilization is a good candidate for a scaling metric. On the other hand, if CPU utilization remains at 80% after increasing the number of tasks, then average CPU utilization isn't a good scaling metric. In that case, you need more research to find a suitable metric.

## Common application models and scaling properties

You can run software of all kinds on AWS. Many workloads are homegrown, whereas others are based on popular open-source software. Regardless of where they originate, we have observed some common design patterns for services. How you scale effectively depends in large part on the pattern.

### The efficient CPU-bound server

The efficient CPU-bound server utilizes almost no resources other than CPU and network throughput. Each request can be handled by the application alone. Requests don't depend on other services such as databases. The application can handle hundreds of thousands of concurrent requests, and can efficiently utilize multiple CPUs to do so. Each request is either serviced by a dedicated thread with low memory overhead, or there's an asynchronous event loop that runs on each CPU that services requests. Each replica of the application is equally capable of handling a request. The only resource that might be depleted before CPU is network bandwidth. In CPU bound-services, memory utilization, even at peak throughput, is a fraction of the resources available.

You can use CPU-based auto scaling for this type of application. The application enjoys maximum flexibility in terms of scaling. You can scale it vertically by providing larger Amazon EC2 instances or Fargate vCPUs to it. And, you can also scale it horizontally by adding more replicas. Adding more replicas, or doubling the instance size, cuts the average CPU utilization relative to capacity by half.

If you're using Amazon EC2 capacity for this application, consider placing it on compute-optimized instances such as the c5 or c6g family.

### The efficient memory-bound server

The efficient memory-bound server allocates a significant amount of memory per request. At maximum concurrency, but not necessarily throughput, memory is depleted before the CPU resources are depleted. Memory associated with a request is freed when the request ends. Additional requests can be accepted as long as there is available memory.

You can use memory-based auto scaling for this type of application. The application enjoys maximum flexibility in terms of scaling. You can scale it both vertically by providing larger Amazon EC2 or Fargate memory resources to it. And, you can also scale it horizontally by adding more replicas. Adding more replicas, or doubling the instance size, can cut the average memory utilization relative to capacity by half.

If you're using Amazon EC2 capacity for this application, consider placing it on memory-optimized instances such as the `r5` or `r6g` family.

Some memory-bound applications don't free the memory that's associated with a request when it ends, so that a reduction in concurrency doesn't result in a reduction in the memory used. For this, we don't recommend that you use memory-based scaling.

## The worker-based server

The worker-based server processes one request for each individual worker thread one after another. The worker threads can be lightweight threads, such as POSIX threads. They can also be heavier-weight threads, such as UNIX processes. No matter which thread they are, there's always a maximum concurrency that the application can support. Usually the concurrency limit is set proportionally to the memory resources that are available. If the concurrency limit is reached, the application places additional requests into a backlog queue. If the backlog queue overflows, the application immediately rejects additional incoming requests. Common applications that fit this pattern include Apache web server and Gunicorn.

Request concurrency is usually the best metric for scaling this application. Because there's a concurrency limit for each replica, it's important to scale out before the average limit is reached.

The best way to obtain request concurrency metrics is to have your application report them to CloudWatch. Each replica of your application can publish the number of concurrent requests as a custom metric at a high frequency. We recommend that the frequency is set to be at least once every minute. After several reports are collected, you can use the average concurrency as a scaling metric. You calculate this metric by taking the total concurrency and dividing it by the number of replicas. For example, if total concurrency is 1000 and the number of replicas is 10, then the average concurrency is 100.

If your application is behind an Application Load Balancer, you can also use the `ActiveConnectionCount` metric for the load balancer as a factor in the scaling metric. You must divide the `ActiveConnectionCount` metric by the number of replicas to obtain an average value. You must use the average value for scaling, as opposed to the raw count value.

For this design to work best, the standard deviation of response latency should be small at low request rates. We recommend that, during periods of low demand, most requests are answered within a short time, and there isn't a lot of requests that take significantly longer than average time to respond. The average response time should be close to the 95th percentile response time. Otherwise, queue overflows might occur as result. This leads to errors. We recommend that you provide additional replicas where necessary to mitigate the risk of overflow.

## The waiting server

The waiting server does some processing for each request, but it is highly dependent on one or more downstream services to function. Container applications often make heavy use of downstream services like databases and other API services. It can take some time for these services to respond, particularly in high capacity or high concurrency scenarios. This is because these applications tend to use few CPU resources and utilize their maximum concurrency in terms of available memory.

The waiting service is suitable either in the memory-bound server pattern or the worker-based server pattern, depending on how the application is designed. If the application's concurrency is limited only by memory, then average memory utilization should be used as a scaling metric. If the application's concurrency is based on a worker limit, then average concurrency should be used as a scaling metric.

## The Java-based server

If your Java-based server is CPU-bound and scales proportionally to CPU resources, then it might be suitable for the efficient CPU-bound server pattern. If that is the case, average CPU utilization might be appropriate as a scaling metric. However, many Java applications aren't CPU-bound, making them challenging to scale.

For the best performance, we recommend that you allocate as much memory as possible to the Java Virtual Machine (JVM) heap. Recent versions of the JVM, including Java 8 update 191 or later, automatically set the heap size as large as possible to fit within the container. This means that, in Java, memory utilization is rarely proportional to application utilization. As the request rate and concurrency increases, memory utilization remains constant. Because of this, we don't recommend scaling Java-based servers based on memory utilization. Instead, we typically recommend scaling on CPU utilization.

In some cases, Java-based servers encounter heap exhaustion before exhausting CPU. If your application is prone to heap exhaustion at high concurrency, then average connections are the best scaling metric. If your application is prone to heap exhaustion at high throughput, then average request rate is the best scaling metric.

## Servers that use other garbage-collected runtimes

Many server applications are based on runtimes that perform garbage collection such as .NET and Ruby. These server applications might fit into one of the patterns described earlier. However,

as with Java, we don't recommend scaling these applications based on memory, because their observed average memory utilization is often uncorrelated with throughput or concurrency.

For these applications, we recommend that you scale on CPU utilization if the application is CPU bound. Otherwise, we recommend that you scale on average throughput or average concurrency, based on your load testing results.

## Job processors

Many workloads involve asynchronous job processing. They include applications that don't receive requests in real time, but instead subscribe to a work queue to receive jobs. For these types of applications, the proper scaling metric is almost always queue depth. Queue growth is an indication that pending work outstrips processing capacity, whereas an empty queue indicates that there's more capacity than work to do.

AWS messaging services, such as Amazon SQS and Amazon Kinesis Data Streams, provide CloudWatch metrics that can be used for scaling. For Amazon SQS, `ApproximateNumberOfMessagesVisible` is the best metric. For Kinesis Data Streams, consider using the `MillisBehindLatest` metric, published by the Kinesis Client Library (KCL). This metric should be averaged across all consumers before using it for scaling.

## Amazon ECS capacity and availability

Application availability is crucial for providing an error-free experience and for minimizing application latency. Availability depends on having resources that are accessible and have enough capacity to meet demand. AWS provides several mechanisms to manage availability. For applications that you host on Amazon ECS, these include autoscaling and Availability Zones (AZs). Autoscaling manages the number of tasks or instances based on metrics you define, while Availability Zones allow you to host your application in isolated but geographically-close locations.

As with task sizes, capacity and availability present certain trade-offs you must consider. Ideally, capacity would be perfectly aligned with demand. There would always be just enough capacity to serve requests and process jobs to meet Service Level Objectives (SLOs) including a low latency and error rate. Capacity would never be too high, leading to excessive cost; nor would it never be too low, leading to high latency and error rates.

Autoscaling is a latent process. First, CloudWatch must receive real-time metrics. Then, CloudWatch needs to aggregate them for analysis, which can take up to several minutes depending on the granularity of the metric. CloudWatch compares the metrics against alarm thresholds to identify a

shortage or excess of resources. To prevent instability, you should configure alarms to require the set threshold be crossed for a few minutes before the alarm goes off. It also takes time to provision new tasks and to terminate tasks that are no longer needed.

Because of these potential delays in the system, you should maintain some headroom by over-provisioning. Over-provisioning can help accommodate short-term bursts in demand. This also helps your application service additional requests without reaching saturation. As a good practice, you can set your scaling target between 60-80% of utilization. This helps your application better handle bursts of extra demand while additional capacity is still in the process of being provisioned.

Another reason we recommend that you over-provision is so that you can quickly respond to Availability Zone failures. AWS recommends that production workloads be served from multiple Availability Zones. This is because, if an Availability Zone failure occurs, your tasks that are running in the remaining Availability Zones can still serve the demand. If your application runs in two Availability Zones, you need to double your normal task count. This is so that you can provide immediate capacity during any potential failure. If your application runs in three Availability Zones, we recommend that you run 1.5 times your normal task count. That is, run three tasks for every two that are needed for ordinary serving.

## Maximizing scaling speed

Autoscaling is a reactive process that takes time to take effect. However, there are some ways to help minimize the time that's needed to scale out.

**Minimize image size.** Larger images take longer to download from an image repository and unpack. Therefore, keeping image sizes smaller reduces the amount of time that's needed for a container to start. To reduce the image size, you can follow these specific recommendations:

- If you can build a static binary or use Golang, build your image FROM scratch and include only your binary application in the resulting image.
- Use minimized base images from upstream distro vendors, such as Amazon Linux or Ubuntu.
- Don't include any build artifacts in your final image. Using multi-stage builds can help with this.
- Compact RUN stages wherever possible. Each RUN stage creates a new image layer, leading to an additional round trip to download the layer. A single RUN stage that has multiple commands joined by && has fewer layers than one with multiple RUN stages.
- If you want to include data, such as ML inference data, in your final image, include only the data that's needed to start up and begin serving traffic. If you fetch data on demand from Amazon S3 or other storage without impacting service, then store your data in those places instead.

**Keep your images close.** The higher the network latency, the longer it takes to download the image. Host your images in a repository in the same AWS Region that your workload is in. Amazon ECR is a high-performance image repository that's available in every Region that Amazon ECS is available in. Avoid traversing the Internet or a VPN link to download container images. Hosting your images in the same Region improves overall reliability. It mitigating the risk of network connectivity issues and availability issues in a different Region. Alternatively, you can also implement Amazon ECR cross-region replication to help with this.

**Reduce load balancer health check thresholds.** Load balancers perform health checks before sending traffic to your application. The default health check configuration for a target group can take 90 seconds or longer. During this, the load balancer checks the health status and receives requests. Lowering the health check interval and threshold count can make your application accept traffic quicker and reduce load on other tasks.

**Consider cold-start performance.** Some application use runtimes such as Java perform Just-In-Time (JIT) compilation. The compilation process at least as it starts can show application performance. A workaround is to rewrite the latency-critical parts of your workload in languages that don't impose a cold-start performance penalty.

**Use step scaling, not target-tracking scaling policies.** You have several Application Auto Scaling options for Amazon ECS tasks. Target tracking is the easiest mode to use. With it, all you need to do is set a target value for a metric, such as CPU average utilization. Then, the auto scaler automatically manages the number of tasks that are needed to attain that value. With step scaling you can more quickly react to changes in demand, because you define the specific thresholds for your scaling metrics, and how many tasks to add or remove when the thresholds are crossed. And, more importantly, you can react very quickly to changes in demand by minimizing the amount of time a threshold alarm is in breach. For more information, see [Service Auto Scaling](#) in the *Amazon Elastic Container Service Developer Guide*.

If you're using Amazon EC2 instances to provide cluster capacity, consider the following recommendations:

**Use larger Amazon EC2 instances and faster Amazon EBS volumes.** You can improve image download and preparation speeds by using a larger Amazon EC2 instance and faster Amazon EBS volume. Within a given Amazon EC2 instance family, the network and Amazon EBS maximum throughput increases as the instance size increases (for example, from `m5.xlarge` to `m5.2xlarge`). Additionally, you can also customize Amazon EBS volumes to increase their throughput and IOPS. For example, if you're using `gp2` volumes, use larger volumes that offer more

baseline throughput. If you're using gp3 volumes, specify throughput and IOPS when you create the volume.

**Use bridge network mode for tasks running on Amazon EC2 instances.** Tasks that use bridge network mode on Amazon EC2 start faster than tasks that use the awsvpc network mode. When awsvpc network mode is used, Amazon ECS attaches an elastic network interface (ENI) to the instance before launching the task. This introduces additional latency. There are several tradeoffs for using bridge networking though. These tasks don't get their own security group, and there are some implications for load balancing. For more information, see [Load balancer target groups](#) in the *Elastic Load Balancing User Guide*.

## Handling demand shocks

Some applications experience sudden large shocks in demand. This happens for a variety of reasons: a news event, big sale, media event, or some other event that goes viral and causes traffic to quickly and significantly increase in a very short span of time. If unplanned, this can cause demand to quickly outstrip available resources.

The best way to handle demand shocks is to anticipate them and plan accordingly. Because autoscaling can take time, we recommend that you scale out your application before the demand shock begins. For the best results, we recommend having a business plan that involves tight collaboration between teams that use a shared calendar. The team that's planning the event should work closely with the team in charge of the application in advance. This gives that team enough time to have a clear scheduling plan. They can schedule capacity to scale out before the event and to scale in after the event. For more information, see [Scheduled scaling](#) in the *Application Auto Scaling User Guide*.

If you have an Enterprise Support plan, be sure also to work with your Technical Account Manager (TAM). Your TAM can verify your service quotas and ensure that any necessary quotas are raised before the event begins. This way, you don't accidentally hit any service quotas. They can also help you by prewarming services such as load balancers to make sure your event goes smoothly.

Handling unscheduled demand shocks is a more difficult problem. Unscheduled shocks, if large enough in amplitude, can quickly cause demand to outstrip capacity. It can also outpace the ability for autoscaling to react. The best way to prepare for unscheduled shocks is to over-provision resources. You must have enough resources to handle maximum anticipated traffic demand at any time.

Maintaining maximum capacity in anticipation of unscheduled demand shocks can be costly. To mitigate the cost impact, find a leading indicator metric or event that predicts a large demand

shock is imminent. If the metric or event reliably provides significant advance notice, begin the scale-out process immediately when the event occurs or when the metric crosses the specific threshold that you set.

If your application is prone to sudden unscheduled demand shocks, consider adding a high-performance mode to your application that sacrifices non-critical functionality but retains crucial functionality for a customer. For example, assume that your application can switch from generating expensive customized responses to serving a static response page. In this scenario, you can increase throughput significantly without scaling the application at all.

Last, you can consider breaking apart monolithic services to better deal with demand shocks. If your application is a monolithic service that's expensive to run and slow to scale, you might be able to extract or rewrite performance-critical pieces and run them as separate services. These new services then can be scaled independently from less-critical components. Having the flexibility to scale out performance-critical functionality separately from other parts of your application can both reduce the time it takes to add capacity and help conserve costs.

## Amazon ECS cluster capacity

You can provide capacity to an Amazon ECS cluster in several ways. For example, you can launch Amazon EC2 instances and register them with the cluster at start-up using the Amazon ECS container agent. However, this method can be challenging because you need to manage scaling on your own. Therefore, we recommend that you use Amazon ECS capacity providers. Capacity providers manage resource scaling for you. There are three kinds of capacity providers: Amazon EC2, Fargate, and Fargate Spot. For more information about Fargate capacity providers, see [Amazon ECS clusters for Fargate workloads](#) and for EC2 workloads, see [Amazon ECS clusters for EC2 workloads](#).

The Fargate and Fargate Spot capacity providers handle the lifecycle of Fargate tasks for you. Fargate provides on-demand capacity, and Fargate Spot provides Spot capacity. When you launch a task, Amazon ECS provisions a Fargate resource for you. This Fargate resource comes with the memory and CPU units that directly correspond to the task-level limits that you declared in your task definition. Each task receives its own Fargate resource, making a 1:1 relationship between the task and compute resources.

Tasks that run on Fargate Spot are subject to interruption. Interruptions come after a two-minute warning. These occur during periods of heavy demand. Fargate Spot works best for interruption-tolerant workloads such as batch jobs, development or staging environments. They're also suitable for any other scenario where high availability and low latency isn't a requirement.

You can run Fargate Spot tasks alongside Fargate on-demand tasks. By using them together, you receive provision “burst” capacity at a lower cost.

Amazon ECS can also manage the Amazon EC2 instance capacity for your tasks. Each Amazon EC2 capacity provider is associated with an Amazon EC2 Auto Scaling group that you specify. When you use the Amazon EC2 capacity provider, cluster auto scaling maintains the size of the Amazon EC2 Auto Scaling group to ensure all scheduled tasks can be placed.

## Choosing Fargate task sizes for Amazon ECS

For AWS Fargate task definitions, you're required to specify CPU and memory at the task level, and do not need to account for any overhead. You can also specify CPU and memory at the container level for Fargate tasks. However, doing so isn't required. The resource limits must be greater than or equal to any reservations that you declared. In most cases, you can set them to the sum of the reservations of each of the container that's declared in your task definition. Then, round the number up to the nearest Fargate size. For more information about the available sizes, see [Task CPU and memory](#).

## Speeding up Amazon ECS cluster capacity provisioning with capacity providers on Amazon EC2

Customers who run Amazon ECS on Amazon EC2 can take advantage of [Amazon ECS Cluster Auto Scaling \(CAS\)](#) to manage the scaling of Amazon EC2 Auto Scaling groups (ASG). With CAS, you can configure Amazon ECS to scale your ASG automatically, and just focus on running your tasks. Amazon ECS will ensure the ASG scales in and out as needed with no further intervention required. Amazon ECS capacity providers are used to manage the infrastructure in your cluster by ensuring there are enough container instances to meet the demands of your application. To learn how Amazon ECS CAS works, see [Deep Dive on Amazon ECS Cluster Auto Scaling](#).

Since CAS relies on a CloudWatch based integration with ASG for adjusting cluster capacity, it has inherent latency associated with publishing the CloudWatch metrics, the time taken for the metric `CapacityProviderReservation` to breach CloudWatch alarms (both high and low), and the time taken by a newly launched Amazon EC2 instance to warm-up. You can take the following actions to make CAS more responsive for faster deployments:

### Capacity provider step scaling sizes

Amazon ECS capacity providers will eventually grow/shrink the container instances to meet the demands of your application. The minimum number of instances that Amazon ECS will launch

is set to 1 by default. This may add additional time to your deployments, if several instances are required for placing your pending tasks. You can increase the [minimumScalingStepSize](#) by using the Amazon ECS API to increase the minimum number of instances that Amazon ECS scales in or out at a time. A [maximumScalingStepSize](#) that is too low can limit how many container instances are scaled in or out at a time, which can slow down your deployments.

**Note**

This configuration is currently only available by using the [CreateCapacityProvider](#) or [UpdateCapacityProvider](#) APIs.

## Instance warm-up period

The instance warm-up period is the period of time after which a newly launched Amazon EC2 instance can contribute to CloudWatch metrics for the Auto Scaling group. After the specified warm-up period expires, the instance is counted toward the aggregated metrics of the ASG, and CAS proceeds with its next iteration of calculations to estimate the number instances required.

The default value for [instanceWarmupPeriod](#) is 300 seconds, which you can configure to a lower value by using the [CreateCapacityProvider](#) or [UpdateCapacityProvider](#) APIs for more responsive scaling.

## Spare capacity

If your capacity provider has no container instances available for placing tasks, then it needs to increase (scale out) cluster capacity by launching Amazon EC2 instances on the fly, and wait for them to boot up before it can launch containers on them. This can significantly lower the task launch rate. You have two options here.

In this case, having spare Amazon EC2 capacity already launched and ready to run tasks will increase the effective task launch rate. You can use the `TargetCapacity` configuration to indicate that you wish to maintain spare capacity in your clusters. For example, by setting `TargetCapacity` at 80%, you indicate that your cluster needs 20% spare capacity at all times. This spare capacity can allow any standalone tasks to be immediately launched, ensuring task launches are not throttled. The trade-off for this approach is potential increased costs of keeping spare cluster capacity.

An alternate approach you can consider is adding headroom to your service, not to the capacity provider. This means that instead of reducing `Target Capacity` configuration to launch spare capacity, you can increase the number of replicas in your service by modifying the target tracking scaling metric or the step scaling thresholds of the service auto scaling. Note that this approach will only be helpful for spiky workloads, but won't have an effect when you're deploying new services and going from 0 to N tasks for the first time. For more information about the related scaling policies, see [Target Tracking Scaling Policies](#) or [Step Scaling Policies](#).

## Access Amazon ECS features with account settings

You can go into Amazon ECS account settings to opt in or out of specific features. For each AWS Region, you can opt in to, or opt out of, each account setting at the account-level or for a specific user or role.

You might want to opt in or out of specific features if any of the following is relevant to you:

- A user or role can opt in or opt out specific account settings for their individual account.
- A user or role can set the default opt-in or opt-out setting for all users on the account.
- The root user or a user with administrator privileges can opt in to, or opt out of, any specific role or user on the account. If the account setting for the root user is changed, it sets the default for all the users and roles that no individual account setting was selected for.

### Note

Federated users assume the account setting of the root user and can't have explicit account settings set for them separately.

The following account settings are available. You must separately opt-in and opt-out to each account setting.

## Amazon Resource Names (ARNs) and IDs

When Amazon ECS resources are created, each resource is assigned a unique Amazon Resource Name (ARN) and resource identifier (ID). If you use a command line tool or the Amazon ECS API to work with Amazon ECS, resource ARNs or IDs are required for certain commands. For example, if you use the [stop-task](#) AWS CLI command to stop a task, you must specify the task ARN or ID in the command.

Amazon ECS introduced a new format for Amazon Resource Names (ARNs) and resource IDs for Amazon ECS services, tasks, and container instances. The opt-in status for each resource type determines the Amazon Resource Name (ARN) format the resource uses. You must opt in to the new ARN format to use features such as resource tagging for that resource type.

You can opt in to and opt out of the new Amazon Resource Name (ARN) and resource ID format on a per-Region basis. Currently, any new account created is opted in by default.

You can opt in or opt out of the new Amazon Resource Name (ARN) and resource ID format at any time. After you opt in, any new resources that you create use the new format.

### Note

A resource ID doesn't change after it's created. Therefore, opting in or out of the new format doesn't affect your existing resource IDs.

The following sections describe how ARN and resource ID formats are changing. For more information about the transition to the new formats, see [Amazon Elastic Container Service FAQ](#).

## Amazon Resource Name (ARN) format

Some resources have a user-friendly name, such as a service named `production`. In other cases, you must specify a resource using the Amazon Resource Name (ARN) format. The new ARN format for Amazon ECS tasks, services, and container instances includes the cluster name. For information about opting in to the new ARN format, see [Modifying Amazon ECS account settings](#).

The following table shows both the current format and the new format for each resource type.

| Resource type      | ARN                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Container instance | <p>Current: <code>arn:aws:ecs: <i>region</i>:<i>aws_account_id</i> :container-instance/ <i>container-instance-id</i></code></p> <p>New: <code>arn:aws:ecs: <i>region</i>:<i>aws_account_id</i> :container-instance/ <i>cluster-name</i> /<i>container-instance-id</i></code></p> |
| Amazon ECS service | <p>Current: <code>arn:aws:ecs: <i>region</i>:<i>aws_account_id</i> :service/<i>service-name</i></code></p> <p>New: <code>arn:aws:ecs: <i>region</i>:<i>aws_account_id</i> :service/ <i>cluster-name</i> /<i>service-name</i></code></p>                                          |
| Amazon ECS task    | <p>Current: <code>arn:aws:ecs: <i>region</i>:<i>aws_account_id</i> :task/<i>task-id</i></code></p> <p>New: <code>arn:aws:ecs: <i>region</i>:<i>aws_account_id</i> :task/<i>cluster-name</i> /<i>task-id</i></code></p>                                                           |

## Resource ID length

A resource ID takes the form of a unique combination of letters and numbers. New resource ID formats include shorter IDs for Amazon ECS tasks and container instances. The current resource ID format is 36 characters long. The new IDs are in a 32-character format that doesn't include any hyphens. For information about opting in to the new resource ID format, see [Modifying Amazon ECS account settings](#).

The default is enabled.

Only resources launched after opting in receive the new ARN and resource ID format. All existing resources aren't affected. For Amazon ECS services and tasks to transition to the new ARN and resource ID formats, you must recreate the service or task. To transition a container instance to the new ARN and resource ID format, the container instance must be drained and a new container instance must be launched and registered to the cluster.

### Note

Tasks launched by an Amazon ECS service can only receive the new ARN and resource ID format if the service was created on or after November 16, 2018, and the user who created the service has opted in to the new format for tasks.

## ARN and resource ID format timeline

The timeline for the opt-in and opt-out periods for the new Amazon Resource Name (ARN) and resource ID format for Amazon ECS resources ended on April 1, 2021. By default, all accounts are opted in to the new format. All new resources created receive the new format, and you can no longer opt out.

## Container Insights

On December 2, 2024, AWS released Container Insights with enhanced observability for Amazon ECS. This version supports enhanced observability for Amazon ECS clusters using Fargate Amazon ECS Managed Instances, and EC2. After you configure Container Insights with enhanced observability on Amazon ECS, Container Insights auto-collects detailed infrastructure telemetry from cluster level down to the container level in your environment and displays your data in dashboards that show you a variety of metrics and dimensions. You can then use these out-of-the-

box dashboards on the Container Insights console to better understand your container health and performance, and to mitigate issues faster by identifying anomalies.

We recommend that you use Container Insights with enhanced observability instead of Container Insights because it provides detailed visibility in your container environment, reducing the mean time to resolution. For more information, see [Amazon ECS Container Insights with enhanced observability metrics](#) in the *Amazon CloudWatch User Guide*.

The default for the `containerInsights` account setting is disabled.

## Container Insights with enhanced observability

Use the following command to turn on Container Insights with enhanced observability.

Set the `containerInsights` account setting to enhanced.

```
aws ecs put-account-setting --name containerInsights --value enhanced
```

### Example output

```
{
  "setting": {
    "name": "containerInsights",
    "value": "enhanced",
    "principalArn": "arn:aws:iam::123456789012:johndoe",
    "type": "user"
  }
}
```

After you set this account setting, all new clusters automatically use Container Insights with enhanced observability. Use the `update-cluster-settings` command to add Container Insights with enhanced observability to an existing cluster, or to upgrade a cluster from Container Insights to Container Insights with enhanced observability.

```
aws ecs update-cluster-settings --cluster cluster-name --settings
name=containerInsights,value=enhanced
```

You can also use the console to configure Container Insights with enhanced observability. For more information, see [Modifying Amazon ECS account settings](#).

## Container Insights

When you set the `containerInsights` account setting to `enabled`, all new clusters have Container Insights enabled by default. You can modify existing clusters by using `update-cluster-settings`.

To use Container Insights, set the `containerInsights` account setting to `enabled`. Use the following command to turn on Container Insights.

```
aws ecs put-account-setting --name containerInsights --value enabled
```

### Example output

```
{
  "setting": {
    "name": "containerInsights",
    "value": "enabled",
    "principalArn": "arn:aws:iam::123456789012:johnndoe",
    "type": user
  }
}
```

When you set the `containerInsights` account setting to `enabled`, all new clusters have Container Insights enabled by default. Use the `update-cluster-settings` command to add Container Insights to an existing cluster.

```
aws ecs update-cluster-settings --cluster cluster-name --settings
name=containerInsights,value=enabled
```

You can also use the console to configure Container Insights. For more information, see [Modifying Amazon ECS account settings](#).

## AWS Fargate Federal Information Processing Standard (FIPS-140) compliance

Fargate supports the Federal Information Processing Standard (FIPS-140) which specifies the security requirements for cryptographic modules that protect sensitive information. It is the current United States and Canadian government standard, and is applicable to systems that are

required to be compliant with Federal Information Security Management Act (FISMA) or Federal Risk and Authorization Management Program (FedRAMP).

The resource name is `fargateFIPSMODE`.

The default is disabled.

You must turn on Federal Information Processing Standard (FIPS-140) compliance on Fargate. For more information, see [the section called "AWS Fargate FIPS-140 compliance"](#).

 **Important**

The `fargateFIPSMODE` account setting can only be changed using either the Amazon ECS API or the AWS CLI. For more information, see [Modifying Amazon ECS account settings](#).

Run `put-account-setting-default` with the `fargateFIPSMODE` option set to enabled. For more information, see, [put-account-setting-default](#) in the *Amazon Elastic Container Service API Reference*.

- You can use the following command to turn on FIPS-140 compliance.

```
aws ecs put-account-setting-default --name fargateFIPSMODE --value enabled
```

Example output

```
{
  "setting": {
    "name": "fargateFIPSMODE",
    "value": "enabled",
    "principalArn": "arn:aws:iam::123456789012:root",
    "type": "user"
  }
}
```

You can run `list-account-settings` to view the current FIPS-140 compliance status. Use the `effective-settings` option to view the account level settings.

```
aws ecs list-account-settings --effective-settings
```

## Tagging authorization

Amazon ECS is introducing tagging authorization for resource creation. Users must have tagging permissions for actions that create the resource, such as `ecsCreateCluster`. When you create a resource and specify tags for that resource, AWS performs additional authorization to verify that there are permissions to create tags. Therefore, you must grant explicit permissions to use the `ecs:TagResource` action. For more information, see [the section called “Tag resources during creation”](#).

In order to opt in to tagging authorization, run `put-account-setting-default` with the `tagResourceAuthorization` option set to on. For more information, see, [put-account-setting-default](#) in the *Amazon Elastic Container Service API Reference*. You can run `list-account-settings` to view the current tagging authorization status.

- You can use the following command to enable tagging authorization.

```
aws ecs put-account-setting-default --name tagResourceAuthorization --value on --  
region region
```

### Example output

```
{  
  "setting": {  
    "name": "tagResourceAuthorization",  
    "value": "on",  
    "principalArn": "arn:aws:iam::123456789012:root",  
    "type": user  
  }  
}
```

After you enable tagging authorization, you must configure the appropriate permissions to allow users to tag resources on creation. For more information, see [the section called “Tag resources during creation”](#).

You can run `list-account-settings` to view the current tagging authorization status. Use the `effective-settings` option to view the account level settings.

```
aws ecs list-account-settings --effective-settings
```

## Tagging authorization timeline

You can confirm whether tagging authorization is active by running `list-account-settings` to view the `tagResourceAuthorization` value. When the value is on, it means that the tagging authorization is in use. For more information, see, [list-account-settings](#) in the *Amazon Elastic Container Service API Reference*.

The following are the important dates related to tagging authorization.

- April 18, 2023 – Tagging authorization is introduced. All new and existing accounts must opt in to use the feature. You can opt in to start using tagging authorization. By opting in, you must grant the appropriate permissions.
- February 9, 2024 - March 6, 2024 – All new accounts and non-impacted existing accounts have tagging authorization on by default. You can enable or disable the `tagResourceAuthorization` account setting to verify your IAM policy.

AWS has notified impacted accounts.

To disable the feature, run `put-account-setting-default` with the `tagResourceAuthorization` option set to off.

- March 7, 2024 – If you have enabled tagging authorization, you can no longer disable the account setting.

We recommend that you complete your IAM policy testing before this date.

- March 29, 2024 – All accounts use tagging authorization. The account-level setting will no longer be available in the Amazon ECS console or AWS CLI.

## AWS Fargate task retirement wait time

AWS sends out notifications when you have Fargate tasks running on a platform version revision marked for retirement. For more information, see [Task retirement and maintenance for AWS Fargate on Amazon ECS](#).

AWS is responsible for patching and maintaining the underlying infrastructure for AWS Fargate. When AWS determines that a security or infrastructure update is needed for an Amazon ECS task hosted on Fargate, the tasks need to be stopped and new tasks launched to replace them. You can configure the wait period before tasks are retired for patching. You have the option to retire the task immediately, to wait 7 calendar days, or to wait 14 calendar days.

This setting is at the account-level.

You can configure the time that Fargate starts the task retirement. The default wait period is 7 days. For workloads that require immediate application of the updates, choose the immediate setting (0). If you need more time, configure the 7, or 14 day option.

We recommend that you choose a shorter waiting period in order to pick up newer platform versions revisions sooner.

Configure the wait period by running `put-account-setting-default` or `put-account-setting` as the root user or an administrative user. Use the `fargateTaskRetirementWaitPeriod` option for the name and the value option set to one of the following values:

- 0 - AWS sends the notification, and immediately starts to retire the affected tasks.
- 7 - AWS sends the notification, and waits 7 calendar days before starting to retire the affected tasks. This is the default.
- 14 - AWS sends the notification, and waits 14 calendar days before starting to retire the affected tasks.

For more information, see, [put-account-setting-default](#) and [put-account-setting](#) in the *Amazon Elastic Container Service API Reference*.

You can run the following command to set the wait period to 14 days.

```
aws ecs put-account-setting-default --name fargateTaskRetirementWaitPeriod --value 14
```

Example output

```
{
  "setting": {
    "name": "fargateTaskRetirementWaitPeriod",
    "value": "14",
    "principalArn": "arn:aws:iam::123456789012:root",
    "type": "user"
  }
}
```

You can run `list-account-settings` to view the current Fargate task retirement wait time. Use the `effective-settings` option.

```
aws ecs list-account-settings --effective-settings
```

## AWS Fargate task retirements using EC2 event windows

AWS is responsible for patching and maintaining the underlying infrastructure for AWS Fargate. When AWS determines that a security or infrastructure update is needed for an Amazon ECS task hosted on Fargate, the tasks need to be stopped and new tasks launched to replace them. By enabling this account setting AWS Fargate will use EC2 event windows to determine the time and day when your tasks will be retired. Note that this is a one time enablement for an account.

To enable usage of EC2 event windows for Fargate task retirements, you can use the following CLI command:

```
aws ecs put-account-setting-default --name fargateEventWindows --value enabled
```

This is an account level setting. You can associate EC2 event windows with Fargate tasks at the account, cluster and service levels using the following instance tags:

- `aws:ecs:serviceArn` : for service tasks
- `aws:ecs:clusterArn` : for tasks belonging to a cluster
- `aws:ecs:fargateTask` : set to true to target all Fargate tasks in the account

To learn more about how [Amazon EC2 event windows](#) work for your Amazon ECS tasks running on Fargate, see [Step 1: Set the task wait time or use Amazon EC2 event windows](#)

## Increase Linux container instance network interfaces

Each Amazon ECS task that uses the `awsvpc` network mode receives its own elastic network interface (ENI), which is attached to the container instance that hosts it. There is a default limit to the number of network interfaces that can be attached to an Amazon EC2 instance, and the primary network interface counts as one. For example, by default a `c5.large` instance may have up to three ENIs attached to it. The primary network interface for the instance counts as one, so you can attach an additional two ENIs to the instance. Because each task using the `awsvpc` network mode requires an ENI, you can typically only run two such tasks on this instance type.

Amazon ECS supports launching container instances with increased ENI density using supported Amazon EC2 instance types. When you use these instance types and turn on the `awsvpcTrunking`

account setting, additional ENIs are available on newly launched container instances. This configuration allows you to place more tasks on each container instance.

For example, a `c5.large` instance with `awsVpcTrunking` has an increased ENI limit of twelve. The container instance will have the primary network interface and Amazon ECS creates and attaches a "trunk" network interface to the container instance. So this configuration allows you to launch ten tasks on the container instance instead of the current two tasks.

## Runtime Monitoring (Amazon GuardDuty integration)

Runtime Monitoring is an intelligent threat detection service that protects workloads running on Fargate and EC2 container instances by continuously monitoring AWS log and networking activity to identify malicious or unauthorized behavior.

The `guardDutyActivate` parameter is read-only in Amazon ECS and indicates whether Runtime Monitoring is turned on or off by your security administrator in your Amazon ECS account. GuardDuty controls this account setting on your behalf. For more information, see [Protecting Amazon ECS workloads with Runtime Monitoring](#).

You can run `list-account-settings` to view the current GuardDuty integration setting.

```
aws ecs list-account-settings
```

### Example output

```
{
  "setting": {
    "name": "guardDutyActivate",
    "value": "on",
    "principalArn": "arn:aws:iam::123456789012:doej",
    "type": "aws-managed"
  }
}
```

## Dual stack IPv6 VPC

Amazon ECS supports providing tasks with an IPv6 address in addition to the primary private IPv4 address.

For tasks to receive an IPv6 address, the task must use the `awsVpc` network mode, must be launched in a VPC configured for dual-stack mode, and the `dualStackIPv6` account setting must

be enabled. For more information about other requirements, see [Using a VPC in dual-stack mode](#) for EC2 capacity, [Using a VPC in dual-stack mode](#) for Amazon ECS Managed Instances capacity, and [Using a VPC in dual-stack mode](#) for Fargate capacity.

### Important

The `dualStackIPv6` account setting can only be changed using either the Amazon ECS API or the AWS CLI. For more information, see [Modifying Amazon ECS account settings](#).

If you had a running task using the `awsvpc` network mode in an IPv6 enabled subnet between the dates of October 1, 2020 and November 2, 2020, the default `dualStackIPv6` account setting in the Region that the task was running in is disabled. If that condition isn't met, the default `dualStackIPv6` setting in the Region is enabled.

The default is disabled.

## Default log driver mode

Amazon ECS supports setting a default delivery mode of log messages from a container to the chosen log driver. The delivery mode affects application stability when the flow of logs from the container to the log driver is interrupted.

The `defaultLogDriverMode` setting supports two values: `blocking` and `non-blocking`. For more information about these delivery modes, see [LogConfiguration](#) in the *Amazon Elastic Container Service API Reference*.

If you don't specify a delivery mode in your container definition's `logConfiguration`, the mode you specify using this account setting will be used as the default.

The default delivery mode is `non-blocking`.

### Note

On June 25, 2025, Amazon ECS changed the default log driver mode from `blocking` to `non-blocking` to prioritize task availability over logging. To continue using the `blocking` mode after this change, do one of the following:

- Set the `mode` option in your container definition's `logConfiguration` as `blocking`.

- Set the defaultLogDriverMode account setting to blocking.

To set a default log driver mode to blocking, you can run the following command.

```
aws ecs put-account-setting-default --name defaultLogDriverMode --value "blocking"
```

## Viewing Amazon ECS account settings using the console

View your account settings in the console to see which features you have access to.

### Important

The dualStackIPv6, fargateFIPSPMode, fargateTaskRetirementWaitPeriod and the fargateEventWindows account settings can only be viewed or changed using the AWS CLI.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose **Account Settings**.

## Modifying Amazon ECS account settings

Modify your account settings to access Amazon ECS features.

The guardDutyActivate parameter is read-only in Amazon ECS and indicates whether Runtime Monitoring is turned on or off by your security administrator in your Amazon ECS account. GuardDuty controls this account setting on your behalf. For more information, see [Protecting Amazon ECS workloads with Runtime Monitoring](#).

### Important

The dualStackIPv6, fargateFIPSPMode, fargateTaskRetirementWaitPeriod and the fargateEventWindows account settings can only be viewed or changed using the AWS CLI.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose **Account Settings**.
4. Choose **Update**.
5. (Optional) To increase or decrease the number of tasks that you can run in the awsvpc network mode for each EC2 instance, under **AWSVPC Trunking**, select **AWSVPC Trunking**.
6. (Optional) To use, or stop using CloudWatch Container Insights by default for clusters, under **CloudWatch Container Insights observability**, choose one of the following options:
  - To use Container Insights with enhanced observability, choose **Container Insights with enhanced observability**.
  - To use Container Insights, choose **Container Insights**.
  - To stop using Container Insights, choose **Turned off**.
7. (Optional) To enable or disable tagging authorization, under **Resource Tagging Authorization**, select or clear **Resource Tagging Authorization**.
8. (Optional) To configure a default log driver mode for when a log delivery mode isn't defined in a container's logConfiguration, under **Default log driver mode**, choose one of the following options:
  - To set the default log driver mode as blocking, choose **Blocking**.
  - To set the default log driver mode as non-blocking, choose **Non-blocking**.
9. Choose **Save changes**.
10. On the confirmation screen, choose **Confirm** to save the selection.

## Next steps

If you turned on Container Insights with enhanced observability or Container Insights, you can optionally update your existing clusters to use the feature. For more information, see [Updating an Amazon ECS cluster](#).

## Reverting to the default Amazon ECS account settings

You can use the AWS Management Console to revert your Amazon ECS account settings to the default.

The **Revert to account default** option is only available when your account settings are no longer the default settings.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose **Account Settings**.
4. Choose **Update**.
5. Choose **Revert to account default**.
6. On the confirmation screen, choose **Confirm** to save the selection.

## Managing Amazon ECS account settings using the AWS CLI

You can manage your account settings using the Amazon ECS API, AWS CLI or SDKs. The `dualStackIPv6`, `fargateFIPSPMode`, `fargateTaskRetirementWaitPeriod` and the `fargateEventWindows` account settings can only be viewed or changed using those tools.

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

For information about the available API actions for task definitions see [Account setting actions](#) in the *Amazon Elastic Container Service API Reference*.

Use one of the following commands to modify the default account setting for all users or roles on your account. These changes apply to the entire AWS account unless a user or role explicitly overrides these settings for themselves.

- [put-account-setting-default](#) (AWS CLI)

```
aws ecs put-account-setting-default --name serviceLongArnFormat --value enabled --  
region us-east-2
```

You can also use this command to modify other account settings. To do this, replace the name parameter with the corresponding account setting.

- [Write-ECSAccountSetting](#) (AWS Tools for Windows PowerShell)

```
Write-ECSAccountSettingDefault -Name serviceLongArnFormat -Value enabled -Region us-east-1 -Force
```

## To modify the account settings for your user account (AWS CLI)

Use one of the following commands to modify the account settings for your user. If you're using these commands as the root user, changes apply to the entire AWS account unless a user or role explicitly overrides these settings for themselves.

- [put-account-setting](#) (AWS CLI)

```
aws ecs put-account-setting --name serviceLongArnFormat --value enabled --region us-east-1
```

You can also use this command to modify other account settings. To do this, replace the name parameter with the corresponding account setting.

- [Write-ECSAccountSetting](#) (AWS Tools for Windows PowerShell)

```
Write-ECSAccountSetting -Name serviceLongArnFormat -Value enabled -Force
```

## To modify the account settings for a specific user or role (AWS CLI)

Use one of the following commands and specify the ARN of a user, role, or root user in the request to modify the account settings for a specific user or role.

- [put-account-setting](#) (AWS CLI)

```
aws ecs put-account-setting --name serviceLongArnFormat --value enabled --principal-arn arn:aws:iam::aws_account_id:user/principalName --region us-east-1
```

You can also use this command to modify other account settings. To do this, replace the name parameter with the corresponding account setting.

- [Write-ECSAccountSetting](#) (AWS Tools for Windows PowerShell)

```
Write-ECSAccountSetting -Name serviceLongArnFormat -Value enabled -PrincipalArn  
arn:aws:iam::aws_account_id:user/principalName -Region us-east-1 -Force
```

## IAM roles for Amazon ECS

An IAM role is an IAM identity that you can create in your account that has specific permissions. In Amazon ECS, you can create roles to grant permissions to Amazon ECS resource such as containers or services.

The roles Amazon ECS requires depend on the task definition launch type and the features that you use. Use the following table to determine which IAM roles you need for Amazon ECS.

| Role                | Definition                                                            | When required                                                                                                                                                                                                                                                                                                                                                                                                       | More information                                   |
|---------------------|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| Task execution role | This role allows Amazon ECS to use other AWS services on your behalf. | <p>Your task is hosted on AWS Fargate or on external instances and:</p> <ul style="list-style-type: none"><li>pulls a container image from an Amazon ECR private repository.</li><li>pulls a container image from an Amazon ECR private repository in a different account from the account that runs the task.</li><li>sends container logs to CloudWatch Logs using the <code>awslogs</code> log driver.</li></ul> | <a href="#">Amazon ECS task execution IAM role</a> |

| Role                     | Definition                                                                              | When required                                                                                                                                                                                                                                                                                                                                         | More information                                       |

# Architect for Amazon ECS Managed Instances

Amazon ECS Managed Instances is a fully managed compute option for Amazon ECS that enables you to run containerized workloads on the full range of Amazon EC2 instance types while offloading infrastructure management to AWS. With Amazon ECS Managed Instances, you can access specific compute capabilities such as GPU acceleration, particular CPU architectures, high network performance, and specialized instance types, while AWS handles provisioning, scaling, patching, and maintenance of the underlying infrastructure.

When you use Amazon ECS Managed Instances, you package your application in containers and specify your compute requirements. AWS automatically selects the most cost-optimized general-purpose Amazon EC2 instance types that meet your workload needs, or you can specify desired instance attributes including instance types, CPU manufacturers, and accelerators. Amazon ECS Managed Instances completely manage all aspects of infrastructure including, scaling, patching, and cost optimization - without trading off access to AWS capabilities and Amazon EC2 integrations.

Amazon ECS Managed Instances support Linux containers with platform-specific optimizations and security configurations. By default, Amazon ECS Managed Instances optimizes infrastructure utilization by placing multiple smaller tasks on larger instances, helping to reduce costs and improve task launch times.

This topic describes the different components of Amazon ECS Managed Instances tasks and services, and calls out special considerations for using Amazon ECS Managed Instances with Amazon ECS.

## Getting started

To get started with Amazon ECS Managed Instances, you create the required IAM roles and enable Amazon ECS Managed Instances in your AWS account. Then you can create a capacity provider and launch tasks or services using the Amazon ECS Managed Instances capacity provider.

For detailed instructions on getting started, see:

- [Learn how to create a task for Amazon ECS Managed Instances](#)
- [Learn how to create a task for Amazon ECS Managed Instances with the AWS CLI](#)

# Capacity providers

Amazon ECS Managed Instances uses capacity providers to manage compute capacity for your workloads. When you create a capacity provider, you can use default instance selection or specify custom instance requirements using `instanceRequirements`.

The following capacity provider options are available:

- **Default capacity provider** - Automatically selects the most cost-optimized general-purpose instance types for your workload requirements.
- **Custom capacity providers** - Allow you to specify instance attributes using attribute-based instance type selection, including vCPU count, memory, CPU manufacturers, accelerator types, and specific instance types.

A capacity provider strategy can only contain one capacity provider type from the following list:

- Amazon ECS Managed Instances
- Auto Scaling group
- Fargate/Fargate\_SPOT

## Instance selection and optimization

Amazon ECS chooses instance types for your Amazon ECS Managed Instances workloads using one of the following methods:

- **Automatic selection** - When using the default capacity provider, Amazon ECS automatically selects the most cost-optimized general-purpose instance types that meet the CPU and memory requirements specified in your task definition.
- **Attribute-based selection** - When using custom capacity providers, you can specify instance attributes such as vCPU count, memory size, CPU manufacturers, accelerator types, and specific instance types. Amazon ECS selects from all instance types that match your specified attributes.

Amazon ECS Managed Instances optimizes infrastructure utilization and cost through several mechanisms:

- **Multi-task placement** - By default, Amazon ECS places multiple smaller tasks on larger instances to maximize utilization and reduce costs.
- **Active workload consolidation** - Amazon ECS identifies when container instances are truly idle while trying to avoid premature termination that could impact application availability or deployment performance. The system respects the minimum and maximum number of tasks set for a service, the start before stop behavior, and the task protection behavior.
- **Right-sizing** - As workload requirements change, Amazon ECS launches replacement instances that are appropriately sized for current needs.

Amazon ECS uses Amazon EC2 event windows to schedule maintenance activities during your preferred time periods. Event windows allow you to define recurring time periods when AWS can perform maintenance on your instances, helping you minimize disruption to your workloads by aligning maintenance with your operational schedule. For more information, see [Scheduled events for your instances](#) in the *Amazon EC2 User Guide*.

If you require strong isolation, you can configure Amazon ECS Managed Instances to run each task on a separate instance with VM-level security isolation boundaries.

## Task definitions

Tasks that use Amazon ECS Managed Instances support most Amazon ECS task definition parameters. Amazon ECS Managed Instances is compatible with existing Fargate task definitions using platform version 1.4.0, making migration straightforward.

To use Amazon ECS Managed Instances, set the `requiresCompatibilities` task definition parameter to include `MANAGED_INSTANCES`. Your task definitions can specify both Fargate and Amazon ECS Managed Instances compatibility for flexibility in deployment options.

## Operating system and CPU architecture

The following operating systems are supported:

- Bottlerocket

There are 2 architectures available for the Amazon ECS task definition, ARM and X86\_64.

When you run Linux containers on Amazon ECS Managed Instances, you can use the X86\_64 CPU architecture, or the ARM64 architecture for your ARM-based applications.

## Key features

The following are key features of Amazon ECS Managed Instances:

- Select specific EC2 instance types to meet your application's requirements, enabling access to specialized hardware capabilities such as GPU-accelerated compute, specific CPU capabilities, and large memory sizes.
- Optimize resource utilization and cost with multiple tasks on a single instance by default, unlike Fargate which runs each task in its own isolated environment.
- Ensure security compliance and regular instance patching. ECS Managed Instances initiates instance draining after 14 days and automatically replaces service-based tasks to new instances.
- Enable advanced networking and system administration functions within containers using privileged Linux capabilities, including CAP\_NET\_ADMIN, CAP\_SYS\_ADMIN, CAP\_BPF, and CAP\_PERFMON.

## IAM roles

Amazon ECS Managed Instances requires two IAM roles:

- *Infrastructure Role*: This role allows AWS to manage the Amazon ECS Managed Instances on your behalf.
- *Instance profile*: An instance profile is a way to pass an IAM role to Amazon ECS Managed Instances. This profile is used to:
  - Define the IAM permissions for the Amazon ECS Managed Instances that run your container workloads.
  - Allow AWS to manage these instances on your behalf.
  - Enable the instances to access AWS services according to the permissions defined in the profile.

## Security and compliance

Amazon ECS Managed Instances implements multiple layers of security to protect your workloads:

- **Secure configuration** - Amazon ECS Managed Instances follow AWS security best practices including no SSH access, immutable root filesystem, and kernel-level mandatory access controls via SELinux.
- **Automatic patching** - AWS regularly updates Amazon ECS Managed Instances with the latest security patches, respecting maintenance windows that you configure.
- **Limited instance lifetime** - ECS automatically initiates instance draining after 14 days, ensuring your applications run on appropriately configured instances with up-to-date security patches.
- **Privileged capabilities** - You can optionally enable privileged Linux capabilities for workloads that require them, such as network monitoring and observability solutions.

Amazon ECS Managed Instances support the same compliance programs as Amazon ECS, including PCI-DSS, HIPAA, and FedRAMP. In supported regions, you can configure FIPS endpoints at the capacity provider level to help achieve FedRAMP compliance.

## Networking

Amazon ECS Managed Instances support the `awsvpc` and `host` network modes. The `awsvpc` network mode provides each task with its own elastic network interface and private IP address within your VPC. This enables fine-grained security group and network ACL controls at the task level. In the `host` network mode, tasks share the host Amazon ECS Managed Instance's network namespace. For more information about task networking on Amazon ECS Managed Instances, see [Amazon ECS task networking for Amazon ECS Managed Instances](#).

## Instance storage

Amazon ECS Managed Instances supports configuring the size of the Amazon EBS data volume that's attached to the instance. This storage is shared between all tasks that run on the instance and can be used for bind mounts. The volume can be shared and mounted among containers that use the `volumes`, `mountPoint`, and `volumesFrom` parameters in the task definition.

The volume is attached during instance creation. You can specify the size of the volume, in GiB, when you create a Amazon ECS Managed Instances capacity provider by using the `storageConfiguration` parameter.

```
{  
  ...  
}
```

```

    "managedInstancesProvider": {
      "infrastructureRoleArn": "arn:aws:iam::123456789012:role/
ecsInfrastructureRole",
      "instanceLaunchTemplate": {
        "ec2InstanceProfileArn": "arn:aws:iam::123456789012:instance-profile/
ecsInstanceProfile",
        "networkConfiguration": {
          "subnets": [
            "subnet-abcdef01234567",
            "subnet-bcdefa98765432"
          ],
          "securityGroups": [
            "sg-0123456789abcdef"
          ]
        },
        "storageConfiguration": {
          "storageSizeinGiB" : 100
        }
      }
    }
  }
  ...
}

```

The minimum size of this volume is 30 GiB and the maximum size is 16,384 GiB. By default, the size of this volume is 80 GiB.

The pulled, compressed, and the uncompressed container image for the task is stored in the volume. To determine the total amount of instance storage your task has to use as bind mount, you must subtract the amount of storage your container image uses from the total amount of instance storage your task is allocated.

The performance of Amazon EBS volumes attached to Amazon ECS Managed Instances matches the performance of corresponding Amazon EC2 instances, as outlined in the [Amazon EBS-optimized instances](#) documentation in the *Amazon EC2 User Guide*.

You can create snapshots of the volume to perform a forensic analysis of security issues or to debug your application. For more information about creating snapshots of Amazon EBS volumes, see [Amazon EBS snapshots](#) in the *Amazon EBS User Guide*. If you have Amazon EBS encryption by default enabled, the volume will be encrypted with the AWS KMS key specified for encryption by

default. For more information about encryption by default, see [Enable Amazon EBS encryption by default](#) in the *Amazon EBS User Guide*.

In addition to using the data volume attached to the instance, you can also configure data volumes for each task that runs on Amazon ECS Managed Instances. For more information about available task-level storage options, see [Storage options for Amazon ECS tasks](#).

## Local Storage

[Amazon EC2 instance store](#) provides temporary block-level storage for your Amazon EC2 instances. The storage provided by Amazon EC2 instance store is accessible through disks that are physically attached to the hosts. You can configure Amazon ECS Managed Instances to use instance store as a data volume for tasks running on the container instance. When you enable local storage and the instance has instance store volumes, Amazon ECS uses the instance store volumes instead of provisioning an Amazon EBS data volume. This can reduce storage costs and improve I/O performance for latency-sensitive workloads. There is no additional charge for using instance store volumes with Amazon ECS Managed Instances.

When an instance has multiple instance store volumes, Amazon ECS automatically combines them into a single RAID 0 volume and presents it as contiguous storage for tasks. When an instance doesn't have instance store volumes, or when local storage is disabled, Amazon ECS provisions an Amazon EBS data volume with the size specified in `storageSizeGiB`. Instance store volumes are ephemeral. Data on instance store volumes is lost when the instance is stopped, terminated, or when hardware fails. Do not use instance store for data that must persist.

To enable local storage, [create a new capacity provider](#) with the `localStorageConfiguration` parameter and set `useLocalStorage` to `true`. You can also use the `instanceRequirements` parameter to ensure that provisioned instances include local storage of a specific size.

### Note

When you create a cluster using the AWS Management Console, the default managed instances capacity provider that Amazon ECS creates doesn't include `localStorageConfiguration`.

The following example shows a capacity provider configuration with local storage enabled and instance requirements that specify SSD-based instance store with a minimum of 50 GiB.

```

{
  ...
  "managedInstancesProvider": {
    "infrastructureRoleArn": "arn:aws:iam::123456789012:role/
ecsInfrastructureRole",
    "instanceLaunchTemplate": {
      "ec2InstanceProfileArn": "arn:aws:iam::123456789012:instance-profile/
ecsInstanceProfile",
      "networkConfiguration": {
        "subnets": [
          "subnet-abcdef01234567",
          "subnet-bcdefa98765432"
        ],
        "securityGroups": [
          "sg-0123456789abcdef"
        ]
      },
      "storageConfiguration": {
        "storageSizeGiB": 50
      },
      "localStorageConfiguration": {
        "useLocalStorage": true
      },
      "instanceRequirements": {
        "vCpuCount": {
          "min": 0
        },
        "memoryMiB": {
          "min": 0
        },
        "localStorage": "REQUIRED",
        "totalLocalStorageGB": {
          "min": 50
        },
        "localStorageTypes": ["ssd"]
      }
    }
  }
}

```

When you omit the `instanceRequirements` configuration, Amazon ECS defaults `localStorage` to `INCLUDED`. In this case, Amazon ECS considers instances both with and without instance store

volumes for provisioning. Instances with instance store volumes use an instance store for data volume, while instances without instance store volumes use an Amazon EBS data volume. When `totalLocalStorageGB` is not specified, Amazon ECS uses all available instance storage, with no minimum size enforced.

The `storageSizeGiB` value in `storageConfiguration` defines only the Amazon EBS data volume size and is used when instance storage is unavailable. The `totalLocalStorageGB` value in `instanceRequirements` controls the minimum instance storage size required on provisioned instances. To guarantee that all instances use local storage, set `localStorage` to `REQUIRED` and specify a minimum size by using `totalLocalStorageGB`.

To verify whether a specific provisioned container instance is using local storage, check for the `ecs.capability.storage.local-storage-enabled` attribute on the container instance.

## Service load balancing

Your Amazon ECS services using Amazon ECS Managed Instances can be configured to use Elastic Load Balancing to distribute traffic evenly across the tasks in your service.

Amazon ECS services on Amazon ECS Managed Instances support Application Load Balancer, Network Load Balancer, and Gateway Load Balancer load balancer types. Application Load Balancers route HTTP/HTTPS (layer 7) traffic, while Network Load Balancers route TCP or UDP (layer 4) traffic.

When you create a target group for these services, you must choose `ip` as the target type, not `instance`. This is because tasks using the `awsvpc` network mode are associated with an elastic network interface, not directly with an Amazon EC2 instance.

## Monitoring and observability

Amazon ECS Managed Instances provides comprehensive monitoring capabilities through CloudWatch metrics and integration with observability tools:

- **CloudWatch metrics** - Monitor CPU, memory, network, and storage utilization at both the task and instance level.
- **Container Insights** - Get detailed performance metrics and logs for your containerized applications.

- **Third-party integrations** - With privileged capabilities enabled, you can run advanced monitoring and observability solutions that require elevated Linux permissions.

## Pricing and cost optimization

With Amazon ECS Managed Instances, you are billed for the entire Amazon EC2 instance that runs your tasks. The pricing depends on the instance types selected for your workloads.

Amazon ECS Managed Instances provides several cost optimization features:

- **Multi-task optimization** - Maximize instance utilization by running multiple tasks on appropriately sized instances.

Your Compute and Instance Savings Plans also apply to Amazon ECS Managed Instances workloads.

## Service quotas

Amazon ECS Managed Instances workloads are subject to your Amazon EC2 On-Demand instance service quotas. Your Amazon ECS services using Amazon ECS Managed Instances are subject to Amazon ECS service quotas.

For more information about service quotas, see:

- [Amazon EC2 endpoints and quotas](#) in the *Amazon Web Services General Reference*
- [Amazon ECS service quotas](#)

## Migration considerations

Migrating to Amazon ECS Managed Instances is straightforward for most workloads:

- **From Fargate** - Requires only a capacity provider configuration change and redeployment. Existing task definitions using platform version 1.4.0 are fully compatible.
- **From EC2** - Similar to migrating to Fargate, but you retain access to Amazon EC2 capabilities such as specific instance types.

Consider the following when planning your migration:

- Applications should tolerate the 14-day instance lifetime and planned maintenance windows.
- Long-running tasks (exceeding 14 days) are not suitable for Amazon ECS Managed Instances.
- Custom AMIs are not supported - Amazon ECS Managed Instances use AWS-managed, security-optimized AMIs.

## Limitations and considerations

The following limitations apply to Amazon ECS Managed Instances:

- Custom AMIs - The AMI is owned and managed by AWS
- Instance lifetime - Maximum runtime of 14 days per instance to ensure security patching and compliance.
- SSH access - Not available for security reasons. Use Amazon ECS Exec for debugging and troubleshooting. Management operations through Amazon ECS APIs only.

## Organization controls

Some organization controls can prevent Amazon ECS Managed Instances from functioning correctly. If so, you must update these controls to allow Amazon ECS to have the permissions required to manage EC2 instances on your behalf.

Amazon ECS uses an infrastructure role for launching the EC2 instances that back Amazon ECS Managed Instances. This infrastructure role is an [IAM role](#) which is created in your account that allows Amazon ECS to manage the Amazon ECS Managed Instances on your behalf. [Service Control Policies](#) (SCPs) always apply to actions performed with infrastructure roles. This allows an SCP to inhibit Amazon ECS Managed Instances operations. The most common occurrence is when an SCP is used to restrict the Amazon Machine Images (AMIs) that can be launched. To allow Amazon ECS Managed Instances to function, modify the SCP to permit launching AMIs from Amazon ECS Managed Instances AMI accounts.

You can also use the [EC2 Allowed AMIs](#) feature to limit the visibility of AMIs in other accounts. If you use this feature, you must expand the image criteria to also include the Amazon ECS Managed Instances AMI accounts in the regions of interest.

## Example SCP to block all AMIs except for Amazon ECS Managed Instances AMIs

The SCP below prevents calling `ec2:RunInstances` unless the AMI belongs to the Amazon ECS Managed Instances AMI account for us-west-2 or us-east-1.

### Note

It's important **not** to use the `ec2:Owner` context key. Amazon owns the Amazon ECS Managed Instances AMI accounts and the value for this key will always be `amazon`. Constructing an SCP that allows launching AMIs if the `ec2:Owner` is `amazon` will allow launching any Amazon owned AMI, not just those for Amazon ECS Managed Instances.

    }
  ]
}
```

## Amazon ECS Managed Instances AMI accounts

AWS accounts that vary by region host Amazon ECS Managed Instances public AMIs.

| AWS Region     | Account      |
|----------------|--------------|
| af-south-1     | 070957084703 |
| ap-east-1      | 587573215167 |
| ap-northeast-1 | 679336465495 |
| ap-northeast-2 | 309903600357 |
| ap-northeast-3 | 384570461223 |
| ap-south-1     | 062344138989 |
| ap-south-2     | 624198668379 |
| ap-southeast-1 | 832199679391 |
| ap-southeast-2 | 552073033681 |
| ap-southeast-3 | 368903466070 |
| ap-southeast-4 | 696793786439 |
| ap-southeast-5 | 003457290689 |
| ap-southeast-6 | 465836752572 |
| ap-southeast-7 | 622515864387 |
| ca-central-1   | 853167153192 |
| ca-west-1      | 899469777611 |
| eu-central-1   | 832570432258 |
| eu-central-2   | 041659148495 |
| eu-north-1     | 851563870067 |
| eu-south-1     | 766433696616 |

| AWS Region   | Account      |
|--------------|--------------|
| eu-south-2   | 003380494496 |
| eu-west-1    | 986619735082 |

| us-west-1    | 187296253231 |
| us-west-2    | 491085424538 |

## Amazon ECS Managed Instances instance types

When you create an Amazon ECS Managed Instances capacity provider, you choose how Amazon ECS selects EC2 instance types for your tasks. You can let Amazon ECS choose automatically, specify exact instance types or families, or define hardware attributes that instances must meet.

### Instance selection methods

Amazon ECS Managed Instances provides two methods for selecting instance types:

- *Specific instance type or family:* You specify exact instance types (such as `m6i.xlarge`) or instance families using wildcards (such as `c6i.*` or `m6*.*`). Use `allowedInstanceTypes` to include specific types, or `excludedInstanceTypes` to exclude types you don't want.
- *Attribute-based selection:* You define hardware requirements (such as vCPU count, memory, CPU manufacturer, or accelerator type) and Amazon ECS selects instance types that match all of your specified attributes.

If you don't specify instance types or attributes, Amazon ECS automatically selects the most cost-optimized instance types based on your task definition requirements.

## Specific instance type selection

With specific instance type selection, you control exactly which EC2 instance types Amazon ECS Managed Instances can use. You can specify individual instance types, entire instance families, or a combination of both.

Use the `allowedInstanceTypes` field to specify which types to include, or the `excludedInstanceTypes` field to exclude types you don't want. Both fields support wildcards:

- `m6i.xlarge` — a specific instance type
- `c6i.*` — all sizes in the `c6i` family
- `m6*.*` — all `m6` generation families (`m6i`, `m6a`, `m6g`, etc.)

## Attribute-based instance type selection

With attribute-based instance type selection, you define hardware requirements and Amazon ECS selects instance types that meet those requirements. This provides flexibility and helps ensure that your tasks are placed successfully even if specific instance types are not available.

When you specify multiple attributes, Amazon ECS selects instance types that satisfy all of the specified attributes. If you specify multiple values for an attribute, Amazon ECS selects instance types that satisfy any of the specified values.

You can filter by attributes in the following categories:

- *CPU and memory* — vCPU count, memory (MiB), memory per vCPU ratio, CPU manufacturers (Intel, AMD, or AWS Graviton), and instance generation (current or previous).

- *Local storage* — Include, exclude, or require local storage. Filter by storage type (HDD or SSD) and total storage capacity.
- *Network and performance* — Network bandwidth (Gbps), network interface count, baseline EBS bandwidth (Mbps), burstable performance support, and bare metal instances.
- *Accelerators* — Accelerator count, manufacturers, chip names, accelerator types, and total accelerator memory.
- *Price protection* — Maximum Spot price and On-Demand price as a percentage of the lowest priced instance type that matches your requirements.

For the complete list of attributes and valid values, see [InstanceRequirementsRequest](#) in the *Amazon ECS API Reference*.

## Billing and purchase options

You choose a provisioning model when you create a capacity provider. The provisioning model determines how Amazon ECS Managed Instances acquires EC2 instances for your tasks:

### On-Demand

Pay for compute capacity by the hour with no long-term commitments or upfront payments. This is the default.

### Spot

You use spare EC2 capacity at a reduced price. Spot Instances can be interrupted when EC2 needs the capacity back. Set `capacityOptionType` to `Spot` when creating your capacity provider.

### Capacity Reservations

You reserve EC2 capacity in a specific Availability Zone. Set `capacityOptionType` to `Reserved` and provide a [capacity reservation group](#). You can also specify a reservation preference: `reservations-only`, `reservations-first`, or `reservations-excluded`.

Amazon ECS Managed Instances also automatically benefits from AWS Savings Plans and Reserved Instances that you've purchased for the instance types used by your tasks. No additional configuration is required.

## Amazon ECS Managed Instances supported instance types

Amazon ECS Managed Instances supports the following instance types.

- **Compute optimized:** C5 | C5a | C5ad | C5d | C5n | C6a | C6g | C6gd | C6i | C6id | C6in | C7a | C7g | C7gd | C7gn | C7i | C7i-flex | C8a | C8g | C8gb | C8gd | C8gn | C8i | C8ib | C8id | C8i-flex | C8in | C8ine
- **General purpose:** M5 | M5a | M5ad | M5d | M5dn | M5n | M5zn | M6a | M6g | M6gd | M6i | M6id | M6idn | M6in | M7a | M7g | M7gd | M7i | M7i-flex | M8a | M8azn | M8g | M8gb | M8gd | M8gn | M8i | M8ib | M8id | M8idb | M8idn | M8i-flex | M8in | M8ine | M9g | M9gd | T3 | T3a | T4g
- **Memory optimized:** R5 | R5a | R5ad | R5b | R5d | R5dn | R5n | R6a | R6g | R6gd | R6i | R6id | R6idn | R6in | R7a | R7g | R7gd | R7i | R7iz | R8a | R8g | R8gb | R8gd | R8gn | U-3tb1 | U7i-6tb | U7i-8tb | U7i-12tb | U7in-24tb | U7in-32tb | X2gd | X2idn | X2iedn | X2iezn | X8g | Z1d
- **Storage optimized:** D3 | D3en | I3en | I4g | I4i | I7i | I7ie | I8g | I8ge | Im4gn | Is4gen
- **Accelerated computing:** DL1 | G4ad | G4dn | G5 | G5g | G6 | G6e | G6f | G7e | Gr6 | Gr6f | Inf1 | Inf2 | P3dn | P4d | P4de | P5 | P5en | P6-B200 | P6-B300 | Trn1
- **High-performance computing:** Hpc6a | Hpc6id | Hpc7a | Hpc7g

Additionally, Amazon ECS Managed Instances only creates instances that meet the following requirements.

- More than 1 vCPU
- Instance size is not nano or micro

For more information, see [Amazon EC2 instance type naming conventions](#).

## Instance selection best practices for Amazon ECS Managed Instances

Selecting the right instance configuration for your Amazon ECS Managed Instances workloads is crucial for optimizing performance, cost, and resource utilization. Amazon ECS provides flexible instance selection options that allow you to balance your application requirements with cost efficiency. The following best practices help you make informed decisions about instance selection for your containerized workloads.

## 1. Use default instance selection

When you don't specify `instanceRequirements`, Amazon ECS chooses the most cost-effective instances that meet the following task definition and service parameter requirements:

### Task definition

- `operatingSystemFamily`
- `cpuArchitecture`
- `cpu`
- `memory`

### Service definition

- `placementConstraints`
- `placementStrategy`

## 2. Use attribute-based selection for most workloads to provide flexibility and improve placement success rates

Attribute-based instance selection allows Amazon ECS to choose from a broader range of instance types that meet your specified requirements. This approach increases the likelihood of successful task placement and provides better cost optimization by allowing Amazon ECS to select the most cost-effective instances available at launch time.

## 3. Use specific instance types only when applications have specific hardware requirements

Reserve specific instance type selection for workloads that require particular hardware features, such as GPU acceleration, high-frequency processors, or specialized networking capabilities. For general-purpose applications, attribute-based selection typically provides better flexibility and cost optimization.

## 4. Choose balanced resources to avoid over-provisioning and unnecessary costs

Select instance configurations that closely match your application's CPU and memory requirements. Avoid significantly over-provisioning resources, as this leads to higher costs and reduced efficiency. Use monitoring data to understand your actual resource utilization patterns and adjust instance selection accordingly.

## 5. Mix instance types for applications with varying workloads to balance performance and cost

For applications with diverse performance requirements or varying workload patterns, consider using multiple capacity providers with different instance configurations. This approach allows

you to optimize costs by using appropriate instance types for different components of your application while maintaining performance where needed.

6. When using an Amazon ECS Managed Instances capacity provider configured with `capacityOptionType=Reserved`, be aware that ECS services use a default deployment configuration of `minimumHealthyPercent=100%` and `maximumPercent=200%`, meaning ECS deployments attempt to start new tasks before stopping old ones and temporarily require up to 200% of your steady-state capacity. If your service consumes all available capacity in your EC2 Capacity Reservations at steady state, deployments will fail because there is no additional capacity available to launch new tasks during the deployment process. To avoid this, set `minimumHealthyPercent` to less than 100% (e.g., 75%) and consider setting `maximumPercent` to 100% to ensure the service stops tasks before starting new ones, allowing deployments to complete successfully by freeing capacity before launching replacement tasks. Additionally, consider monitoring your capacity utilization regularly to maintain headroom in your reservations to accommodate deployments and handle traffic spikes.

## Amazon ECS Managed Instances container image pull behavior

Container startup time depends on the size of the underlying container image. Larger images, such as full versions of Debian, Ubuntu, or Amazon Linux 2, take longer to start because they include more services than their slim counterparts (Debian-slim, Ubuntu-slim, Amazon-slim) or minimal base images such as Alpine.

When Amazon ECS launches a new Amazon ECS Managed Instances container instance, the local image cache is empty. The first task that runs on that container instance pulls the container image from the container repository to the local image cache. Subsequent tasks that use the same image on that container instance use the cached image instead of pulling it again.

The Amazon ECS agent on Amazon ECS Managed Instances automatically manages disk space on each container instance. When a task stops and no other running task uses the same container image, Amazon ECS starts a 15-minute cleanup timer for that image. If no new task that uses the image starts on that container instance within 15 minutes, the image is removed from the local image cache.

## Container image resolution

Amazon ECS resolves container image tags to image digests to ensure that all tasks in a service run the same image version. This behavior affects Amazon ECS Managed Instances bin packing and

instance selection because Amazon ECS schedules a single task from the service first to retrieve the container image digest before scheduling the remaining tasks. For more information, see [Container image resolution](#).

## Patching in Amazon ECS Managed Instances

In Amazon ECS Managed Instances, patching is a critical maintenance process where AWS automatically manages and updates software on managed container instances to ensure security and compliance while maintaining workload availability through a controlled, configurable process.

### Instance lifecycle

By default, Amazon ECS managed container instances operate on a standardized 14–21 day lifecycle. Amazon ECS initiates graceful workload draining at day 14 from instance launch, with final termination occurring no later than day 21. Amazon ECS accommodates early draining under specific circumstances:

- Detection of security vulnerabilities on the software
- Hardware health degradation
- To honor customer-configured event windows

This approach maintains system compliance while respecting customer-defined maintenance requirements.

### Event windows and maintenance scheduling

AWS manages a managed container instance lifecycle through automated background processes that monitor a node's creation timestamp and maintenance schedules. Upon instance launch, AWS sets a default 14-day draining schedule and evaluates any customer-configured event windows.

You can schedule maintenance activities for Amazon ECS Managed Instances by configuring event windows. You can associate one or more Amazon ECS Managed Instances with an event window by using either instance IDs or instance tags. When an event window is tagged with a specific value, Amazon ECS maps these tags to the corresponding Amazon ECS Managed Instances of the corresponding clusters and schedules instance maintenance during the defined time periods on a best effort basis.

For more information about event windows see [Create custom event windows for scheduled events that affect your Amazon EC2 instances](#) in the *Amazon EC2 User Guide*.

If event windows exist, AWS adjusts the draining schedule to align with these windows, which may result in earlier draining than the default 14-day period to honor the specified event window. Event window modifications only affect newly launched managed container instances, ensuring predictable maintenance scheduling.

Until the scheduled draining time, Amazon ECS continues normal task placement operations on the managed container instances as per the customer's configuration.

## Maintenance sequence

At the designated maintenance time, Amazon ECS begins its maintenance sequence by invoking the `UpdateContainerInstancesState` API to initiate graceful workload draining. During the graceful termination period, Amazon ECS attempts to stop the workload on the instance marked for draining.

Amazon ECS stops tasks and launches replacement tasks according to the service's deployment configuration (`maximumPercent` and `minimumHealthyPercent`). With the default `maximumPercent` of 200%, Amazon ECS first schedules new tasks and waits for them to be running before stopping existing ones, minimizing service disruption. When `maximumPercent` is set to 100%, Amazon ECS stops tasks first, then replaces them. Throughout this process, Amazon ECS services honor all service deployment configurations while continuing draining attempts until day 21 from the instance launch.

If draining has not completed by day 21, Amazon ECS executes the `DeregisterContainerInstance` API to stop the managed container instance and its remaining workloads to maintain compliance and patch the managed instance with the latest software.

## Security considerations for Amazon ECS Managed Instances

Amazon ECS Managed Instances provides a fully managed container compute experience that enables you to run workloads on specific Amazon EC2 instance types while offloading security responsibilities to AWS. This topic describes the security model, features, and considerations when using Amazon ECS Managed Instances.

For information about AWS and customer responsibilities for Amazon ECS Managed Instances security, see [Shared responsibility model for Amazon ECS Managed Instances](#).

## Security model

Amazon ECS Managed Instances implements a comprehensive security model that balances flexibility with protection:

- **AWS-managed infrastructure** - AWS controls the lifecycle of managed instances and handles security patching, eliminating the possibility of human error and tampering.
- **No administrative access** - The security model is locked down and prohibits administrative access to managed instances.
- **Multi-task placement** - By default, Amazon ECS Managed Instances places multiple tasks on a single instance to optimize cost and utilization, which relaxes the workload-isolation constraint compared to Fargate.
- **Data isolation** - Although AWS controls instance lifecycle and task placement, AWS cannot login to managed instances or access customer data.

## Understanding managed instances

Amazon ECS Managed Instances provisions EC2 managed instances in your account. As the designated operator, Amazon ECS manages the full lifecycle of these instances on your behalf, including provisioning, scaling, patching, and termination. You do not have permissions to directly terminate these instances or modify instance settings. For more information, see [Amazon EC2 managed instances](#).

### Identifying managed instances

You can identify Amazon ECS Managed Instances in your account by using the following indicators:

- The `Operator` field in the Amazon EC2 `DescribeInstances` response, with a value of `ecs.amazonaws.com`.
- The `aws:ec2:managed-launch` tag on the instance, with a value of `ecs-managed-instances`.

### Managed resource visibility

Beginning April 22, 2026, Amazon EC2 hides new managed instances from your Amazon EC2 console views and API list operations by default. Visibility settings do not affect billing or resource operation, and managed instances remain fully operational and billable regardless of visibility

configuration. You can adjust this behavior at any time. For more information, see [Managed resource visibility settings](#).

## Security features

Amazon ECS Managed Instances includes several built-in security features designed to protect your workloads and maintain a strong security posture. These features range from automated security patching to support for privileged Linux capabilities when needed.

### Security best practices

Managed instances are configured according to AWS security best practices, including:

- **No SSH access** - Remote shell access is disabled to prevent unauthorized access.
- **Immutable root filesystem** - The root filesystem cannot be modified, ensuring system integrity.
- **Kernel-level mandatory access controls** - SELinux provides additional security enforcement at the kernel level.

### Automatic security patching

Amazon ECS Managed Instances helps improve the security posture of your workloads through automated patching:

- **Regular security updates** - Instances are regularly updated with the latest security patches by AWS, with respect to the maintenance windows that you configure.
- **Limited instance lifetime** - The maximum lifetime of a running instance is limited to 14 days to ensure applications run on appropriately configured instances with up-to-date security patches.
- **Maintenance window control** - You can use Amazon EC2 event windows capability to specify when Amazon ECS should replace your instances with patched ones.

### Privileged Linux capabilities

Amazon ECS Managed Instances supports software that requires elevated Linux privileges, enabling advanced monitoring and security solutions:

- **Supported capabilities** - You can opt-in to all privileged Linux capabilities, including CAP\_NET\_ADMIN, CAP\_SYS\_ADMIN, CAP\_BPF, and CAP\_PERFMON.

- **Popular solutions** - This enables you to run popular network monitoring and observability solutions such as Wireshark and Datadog.
- **Explicit configuration required** - You must explicitly configure your Amazon ECS Managed Instances capacity provider to enable privileged Linux capabilities, as it may pose additional security risks to your applications.

### Important

Enabling privileged Linux capabilities may expose your tasks to additional security risks. Only enable these capabilities when required by your applications and ensure you understand the security implications.

## Compliance and regulatory support

Amazon ECS Managed Instances maintains the same compliance posture as Amazon ECS:

- **Compliance programs** - Amazon ECS Managed Instances is in scope of the same AWS Assurance Programs as Amazon ECS, including PCI-DSS, HIPAA, and FedRAMP.
- **FIPS endpoints** - Amazon ECS Managed Instances supports FIPS endpoint configuration at the capacity provider level. Unlike Fargate, which uses an account-level setting, Amazon ECS Managed Instances uses a per-capacity-provider setting because FIPS is a per-instance configuration. You configure FIPS when creating or updating a capacity provider.
- **Customer Managed Keys** - It supports security features required for achieving compliance, such as Customer Managed Keys for encryption.

## Amazon ECS Managed Instances FIPS-140 Considerations

Consider the following when using FIPS-140 compliance on Amazon ECS Managed Instances:

- FIPS-140-compliant Managed Instances AMIs are available in the AWS GovCloud (US) Regions only.
- Amazon ECS Managed Instances supports FIPS-140-3
- FIPS-140 compliance is enabled by default in the AWS GovCloud (US) Regions. If you need to run workloads without FIPS compliance, turn off FIPS compliance in the Managed Instances Capacity Provider configuration.

- The `cpuArchitecture` for your tasks must be `X86_64` for FIPS-140 compliance.

## Disable FIPS on Amazon ECS Managed Instances

By default, Amazon ECS Managed Instances Capacity Providers in AWS GovCloud (US) Regions launch FIPS-compliant AMIs. You choose to disable FIPS-140 compliance when creating a new Amazon ECS Managed Instances Capacity Provider. Follow these steps to create a new Capacity Provider without FIPS compliance.

1. Disable FIPS-140 compliance on Capacity Provider.

```
aws ecs create-capacity-provider \
  --cluster cluster-name \
  --name capacity-provider-name \
  --managed-instances-provider '{
    "infrastructureRoleArn": "infrastructure-role-arn",
    "instanceLaunchTemplate": {
      "ec2InstanceProfileArn": "instance-profile-arn",
      "fipsEnabled": false,
      "networkConfiguration": {
        "subnets": ["subnet-id"],
        "securityGroups": ["security-group-id"]
      }
    }
  }'
```

2. You can optionally use ECS Exec to run the following command to verify the FIPS-140 compliance status for a capacity provider.

Replace *cluster-name* with the name of your cluster, *task-id* with the ID or ARN of your task, and *container-name* with the name of the container in your task you want to run the command against.

A return value of "1" indicates that you are using FIPS.

```
aws ecs execute-command \
  --cluster cluster-name \
  --task task-id \
  --container container-name \
  --interactive \
```

```
--command "cat /proc/sys/crypto/fips_enabled"
```

## Security considerations

When using Amazon ECS Managed Instances, there are several important security considerations to understand and plan for. These considerations help you make informed decisions about your workload architecture and security requirements.

### Multi-task security model

The default multi-task placement model in Amazon ECS Managed Instances differs from Fargate's single-task isolation:

- **Shared instance resources** - Multiple tasks may run on the same instance, potentially exposing a task to vulnerabilities from other tasks running on the same instance or in the same ECS cluster.
- **Single-task option** - You can configure Amazon ECS Managed Instances to use single-task mode for customers requiring the default Fargate security model with VM-level security isolation boundary.
- **Cost vs. security trade-off** - Multi-task mode provides cost optimization and faster task startup times, while single-task mode provides stronger isolation.

### Handling instance interruptions

It's important to design your applications to tolerate interruptions when using Amazon ECS Managed Instances:

- **Interruption tolerance** - Use Amazon ECS Managed Instances with applications that tolerate interruption to underlying services or tasks.
- **Service-based workloads** - Use Amazon ECS services for automatic task replacement, or run workloads with controlled and limited duration not exceeding 14 days on standalone tasks.
- **Graceful shutdown** - Configure task shutdown grace period to control the impact of interruptions.

### Data access and privacy

Amazon ECS Managed Instances maintains strict data access controls:

- **No customer data access** - Although AWS controls the lifecycle of managed instances and the placement of tasks on the instances, AWS cannot login to managed instances or access customer data.
- **Metrics and logs only** - AWS captures only metrics and related logs required to provide the Amazon ECS Managed Instances capabilities.
- **Locked-down security model** - The security model prohibits administrative access, eliminating the possibility of human error and tampering.

## Security best practices

Follow these best practices when using Amazon ECS Managed Instances:

- **Evaluate security model** - Make a conscious decision about adopting Amazon ECS Managed Instances based on your security requirements, particularly regarding the multi-task placement model.
- **Use single-task mode when needed** - If your workloads require stronger isolation, configure Amazon ECS Managed Instances to use single-task mode.
- **Minimize privileged capabilities** - Only enable privileged Linux capabilities when absolutely necessary and understand the associated security risks.
- **Plan for interruptions** - Design applications to handle instance replacements gracefully, especially considering the 14-day maximum instance lifetime.
- **Configure maintenance windows** - Use EC2 event windows to control when instance replacements occur to minimize impact on your workloads.
- **Monitor and audit** - Regularly review your Amazon ECS Managed Instances configuration and monitor for any security-related events or changes.

## Enabling VPC Encryption control for Amazon ECS Managed Instances

Amazon ECS Managed Instances supports VPC Encryption Controls, a security and compliance feature that provides centralized control to monitor and enforce encryption in transit for all traffic flows within and across your VPCs in a region. When VPC Encryption Controls is enabled on your subnet, you can specify instance types that support encryption in transit in your Amazon ECS

Managed Instances custom capacity provider, guaranteeing that Amazon ECS Managed Instances workloads run with encryption in transit.

## Prerequisites

Before you begin, you need:

- A VPC with encryption in transit enabled on subnets. For more information, see [VPC encryption controls documentation](#).
- An Amazon ECS Managed Instances custom capacity provider. For more information, see [Architect for Amazon ECS Managed Instances](#).

## Identify compatible instance types

Amazon EC2 instance types must meet two requirements:

1. **Support VPC encryption in transit** - Use the following AWS CLI command to list Amazon EC2 instance types that support encryption in transit:

```
aws ec2 describe-instance-types \
  --filters Name=network-info.encryption-in-transit-supported,Values=true \
  --query "InstanceTypes[*].[InstanceType]" \
  --output text | sort
```

2. **Supported by Amazon ECS Managed Instances** - All Amazon EC2 instance types supported by Amazon ECS Managed Instances are documented in [Amazon ECS Managed Instances instance types](#).

If you have additional requirements (such as specific CPU, memory, or architecture needs), filter the compatible instance types further based on your workload requirements.

## Create a cluster with VPC encryption support

To configure Amazon ECS Managed Instances for VPC encryption in transit:

1. Create a new cluster and select **Fargate and Managed Instances** for the infrastructure.
2. Select **Use custom – advanced** to access additional configuration parameters.
3. In **Allowed Instance types**, add only the specific instance types that support VPC encryption in transit.

When configured this way, Amazon ECS Managed Instances will launch only Amazon EC2 instance types that support VPC encryption in transit.

## Considerations

- **Burstable performance instances** - T3, T3a, and T4g instance types do not support VPC encryption in transit and cannot be used in subnets with encryption control enabled in Enforced mode.
- **Mode transitions** - You can transition your VPC subnet from Monitor mode to Enforced mode only if all running instances support VPC encryption in transit.
- **Task launch failures** - In Enforced mode, tasks will fail to launch if you specify instance types that don't support encryption in transit.

## Troubleshooting

### Task launch failures in Enforced mode

If tasks fail to launch, verify that all specified instance types support VPC encryption in transit using the AWS CLI command provided above.

### Cannot transition to Enforced mode

Use the console or `GetVpcResourcesBlockingEncryptionEnforcement` command to identify resources that are not enforcing encryption in transit.

For more information about VPC Encryption Controls, see the [VPC encryption controls documentation](#).

## Amazon ECS Managed Instances infrastructure optimization

Amazon ECS Managed Instances automatically provisions right-sized EC2 instances based on your Capacity Provider configuration and current workload demands, ensuring your containerized applications have the appropriate compute resources from the moment they're deployed. As your application traffic patterns evolve and workload requirements change over time, Amazon ECS Managed Instances continuously monitors and optimizes your infrastructure by intelligently adjusting instance sizes to match current needs, proactively replacing instances that have drifted from optimal configurations, and dynamically balancing cost efficiency, application performance, and system reliability. This resource management system operates without any

manual intervention, reducing infrastructure cost while maintaining high availability for your applications.

Infrastructure optimization has the following benefits:

- **Cost optimization** - Reduces infrastructure costs by maximizing resource utilization and eliminating idle capacity
- **Performance improvement** - Optimizes workload placement based on resource requirements and performance characteristics
- **Operational simplicity** - Automates complex resource management decisions without requiring manual intervention
- **Reliability enhancement** - Maintains high availability through intelligent workload distribution and health monitoring

Amazon ECS Managed Instances performs two types of infrastructure optimizations to maximize efficiency and reduce costs:

## Idle Instance Detection

Identifies and removes EC2 instances that have no running tasks, eliminating unnecessary infrastructure costs from unused capacity. When an idle instance is detected, the optimization process marks the container instance as Deregistering, which initiates the cleanup sequence that safely terminates the underlying EC2 instance.

## Underutilized Instance Detection

Analyzes task distribution across instances to identify opportunities for better resource allocation. When tasks are running sub-optimally across multiple instances, Amazon ECS Managed Instances consolidates workloads onto fewer, more efficiently utilized instances, reducing overall costs while maintaining performance. The optimization process marks underutilized container instances as Draining, which triggers task replacement to move workloads to existing or new, more efficient instances. Once all tasks are safely migrated, the instance transitions to Deregistering state and is cleaned up. This optimization applies to instances running service tasks and ensures safe consolidation by respecting your service's minimum and maximum task limits, honoring start-before-stop deployment behavior, and maintaining any task protection settings throughout the draining process. Instances running standalone tasks are not considered for optimization since ECS Managed instances does not replace standalone tasks.

**Note**

Beginning October 26, 2026, Amazon ECS Managed Instances also consolidates underutilized Spot instances. Before draining a Spot instance, Amazon ECS Managed Instances launches the replacement capacity and waits for the replacement tasks to reach a running state. Only then does it stop the original tasks and reclaim the Spot instance. This start-before-stop approach, together with your service's minimum and maximum task limits and task protection settings, balances cost optimization with application availability.

These optimizations work together to ensure your infrastructure continuously adapts to actual workload demands, automatically eliminating waste and improving resource utilization without impacting application availability. Both mechanisms use event-driven monitoring that responds to task and instance lifecycle events to identify optimization opportunities in real-time. Amazon ECS Managed Instances detects when the last task stops on a container instance, indicating a potential idle condition for cost optimization. For underutilized instances, any task stop or new instance launch triggers analysis to identify opportunities for workload consolidation and improved resource efficiency.

## ScaleInAfter

Both infrastructure optimizations look for opportunities to terminate running instances to improve utilization and reduce costs. You can control the timing of these actions using the `ScaleInAfter` configuration in Amazon ECS Managed Instances capacity provider settings, which applies to both idle and underutilized instances. `ScaleInAfter` allows you to specify the delay, in seconds, between the instance becomes idle or underutilized and the moment Amazon ECS Managed Instances starts optimizing your infrastructure. You can set the delay between 0 and 3600 seconds. You can also specify -1 to disable infrastructure optimization.

### Idle Instances

- ECS waits for the specified duration after the last task stops before deregistering the instance
- If a new task starts during the waiting period, the instance is no longer considered idle and termination is cancelled

### Underutilized Instances

- ECS waits for the specified duration after a task stop event that results in the instance becoming underutilized before draining the instance

- If a new task is launched or an existing task is stopped on a particular instance during the waiting period, the timer resets from either the most recent task stop or new task creation time, and Amazon ECS Managed Instances re-evaluates for inefficiencies and takes actions if necessary after the new waiting period expires

This configuration is optional. When not specified, ECS Managed Instances automatically determines optimal timing based on ECS Managed Instances default configuration.

## GPU auto repair for Amazon ECS managed instances

Amazon ECS monitors NVIDIA GPU health on Amazon ECS Managed Instances that use GPU hardware. When Amazon ECS detects a GPU hardware failure, it can automatically replace the impaired instance. GPU auto repair is enabled by default for Amazon ECS Managed Instances.

### How it works

Amazon ECS uses NVIDIA Data Center GPU Manager (DCGM) to monitor NVIDIA GPU health on managed instances that have GPU hardware. When DCGM reports a critical GPU failure, Amazon ECS marks the instance as impaired.

Amazon ECS also monitors the NVIDIA MPS daemon on instances that use GPU sharing. If the MPS daemon fails, Amazon ECS marks the instance as impaired and replaces it by using the same workflow.

When GPU auto repair is enabled, Amazon ECS replaces the impaired instance by using a start-before-stop workflow:

1. Amazon ECS sets the impaired instance to DRAINING. New tasks are not placed on the instance.
2. Amazon ECS provisions a replacement instance.
3. Amazon ECS allows existing tasks to stop gracefully. Amazon ECS honors the task stop timeout for tasks on the instance.
4. After the drain period ends, Amazon ECS terminates the impaired instance.

Amazon ECS rate-limits repair actions to prevent cascading replacements. No more than 20% of the instances belonging to the capacity provider can be drained at a time. If there are fewer than 9 instances in the capacity provider, at most one instance is drained at a time.

## Monitoring GPU health

You can use the `DescribeContainerInstances` API to check GPU health. For more information, see [Monitor Amazon ECS container instance health](#). You can also monitor GPU health changes through the [Amazon ECS container instance health change events](#).

### Monitored XID error codes

Amazon ECS monitors the following NVIDIA Xid error codes. If Amazon ECS detects any of these errors, it marks the instance as impaired and replaces the instance.

| Xid | Description                                        |
|-----|----------------------------------------------------|
| 46  | GPU stopped processing                             |
| 48  | Double Bit ECC Error                               |
| 54  | Auxiliary power connector not connected            |
| 62  | Internal micro-controller halt                     |
| 64  | GPU memory remapping failure                       |
| 74  | NVLink Error                                       |
| 79  | GPU has fallen off the bus                         |
| 95  | Uncontained memory error                           |
| 109 | Context switch timeout                             |
| 110 | GPU disappeared from the bus                       |
| 136 | GPU memory page retirement limit exceeded          |
| 140 | Unrecoverable ECC Error                            |
| 142 | GPU memory page retired due to uncorrectable error |

| Xid | Description                                                |
|-----|------------------------------------------------------------|
| 143 | GPU memory page retired due to correctable error threshold |
| 151 | GPU to CPU interconnect error                              |
| 155 | GPU NVLink flit CRC error                                  |
| 156 | GPU NVLink lane error                                      |
| 158 | GPU InfoROM corrupted                                      |

For more information on XID errors, see [Xid Errors](#) in the *NVIDIA GPU Deployment and Management Documentation*. For more information on the individual XID messages, see [Understanding Xid Messages](#) in the *NVIDIA GPU Deployment and Management Documentation*.

## Disabling auto repair

GPU auto repair is enabled by default for Amazon ECS Managed Instances. To disable GPU auto repair, set `actionsStatus` to `DISABLED` in `autoRepairConfiguration` when you create or update a capacity provider. You can also disable GPU auto repair in the Amazon ECS console when you create or update a capacity provider.

When GPU auto repair is disabled, Amazon ECS continues to monitor GPU health, but it does not replace impaired instances automatically.

### Note

Disabling GPU auto repair also disables Amazon ECS Managed Daemons auto repair. For more information, see [Amazon ECS Managed Daemons auto repair](#).

## To disable GPU auto repair

```
aws ecs update-capacity-provider \  
  --name my-gpu-capacity-provider \  
  --managed-instances-provider '{  
    "infrastructureRoleArn": "arn:aws:iam::111122223333:role/  
ecsInfrastructureRole",
```

```

    "instanceLaunchTemplate": {
      "ec2InstanceProfileArn": "arn:aws:iam::111122223333:instance-profile/
ecsInstanceRole",
      "networkConfiguration": {
        "subnets": ["subnet-0123456789abcdef0"],
        "securityGroups": ["sg-0123456789abcdef0"]
      }
    },
    "autoRepairConfiguration": {
      "actionsStatus": "DISABLED"
    }
  }
}'

```

## To enable GPU auto repair

```

aws ecs update-capacity-provider \
  --name my-gpu-capacity-provider \
  --managed-instances-provider '{
    "infrastructureRoleArn": "arn:aws:iam::111122223333:role/
ecsInfrastructureRole",
    "instanceLaunchTemplate": {
      "ec2InstanceProfileArn": "arn:aws:iam::111122223333:instance-profile/
ecsInstanceRole",
      "networkConfiguration": {
        "subnets": ["subnet-0123456789abcdef0"],
        "securityGroups": ["sg-0123456789abcdef0"]
      }
    },
    "autoRepairConfiguration": {
      "actionsStatus": "ENABLED"
    }
  }'

```

## To verify the configuration

```

aws ecs describe-capacity-providers \
  --capacity-providers my-gpu-capacity-provider

```

# Migrate from AWS Fargate to Amazon ECS Managed Instances

You can migrate existing workloads from Fargate to Amazon ECS Managed Instances. This migration allows you to access the full range of Amazon EC2 instance types, capacity reservations, and advanced capabilities while maintaining AWS-managed infrastructure.

## Migration considerations

Keep the following considerations in mind when migrating from Fargate to Amazon ECS Managed Instances:

### Task compatibility

Existing task definitions configured for Fargate are mostly compatible with Amazon ECS Managed Instances. For more information about task definition differences, see [Amazon ECS task definition differences for Amazon ECS Managed Instances](#).

### Security model changes

Amazon ECS Managed Instances allows multiple tasks per instance by default. Consider enabling single-task mode if your workloads require stronger isolation.

### Instance lifecycle

Amazon ECS Managed Instances have a maximum lifetime of 14 days. Plan for task replacement and use Amazon ECS services for automatic task management.

### Pricing changes

With Amazon ECS Managed Instances, you pay for the entire instance plus a management fee, rather than per-task resources as with Fargate.

### Maintenance windows

Configure maintenance windows using Amazon EC2 event windows to control when Amazon ECS Managed Instances are replaced for patching.

## Prerequisites

Before migrating to Amazon ECS Managed Instances, ensure you have:

- Existing Fargate tasks running on platform version 1.4.0 or later
- You have the required IAM roles for Amazon ECS Managed Instances. This includes:

- **Infrastructure role** - Allows Amazon ECS to make calls to AWS services on your behalf to manage Amazon ECS Managed Instances infrastructure.

For more information, see [Amazon ECS infrastructure IAM role](#).

- **Instance profile** - Provides permissions for the Amazon ECS container agent and Docker daemon running on managed instances.

For more information, see [Amazon ECS Managed Instances instance profile](#).

- Understanding of the security model differences between Fargate and Amazon ECS Managed Instances

### Important

Amazon ECS Managed Instances uses a different security model than Fargate. By default, multiple tasks can run on the same instance, which might expose tasks to vulnerabilities from other tasks. Review your security requirements before migrating.

## Step 1: Update the cluster to use Amazon ECS Managed Instances

Create a capacity provider. When you create a capacity provider with Amazon ECS Managed Instances, it becomes available only within the specified cluster.

For more information, see [Creating a capacity provider for Amazon ECS Managed Instances](#).

## Step 2: Update the task definition to have the Amazon ECS Managed Instances capability

Update the task definition so that it has the `requiresCapabilities` for Amazon ECS Managed Instances.

For more information, see [Updating an Amazon ECS task definition using the console](#).

## Step 3: Update the service to use the Amazon ECS Managed Instances capacity provider

Update your existing Amazon ECS service to use the Amazon ECS Managed Instances capacity provider.

For more information, see [Updating an Amazon ECS service to use a capacity provider](#).

## Step 4: Migrate standalone tasks

For standalone tasks, specify the Amazon ECS Managed Instances capacity provider when running the task.

For more information, see [Running an application as an Amazon ECS task](#).

## Migrate from Amazon EC2 to Amazon ECS Managed Instances

Migrate existing workloads from Amazon EC2 to Amazon ECS Managed Instances. This migration allows you to access the full range of Amazon EC2 instance types, capacity reservations, and advanced capabilities while maintaining AWS-managed infrastructure.

### Migration considerations

Keep the following considerations in mind when migrating from Amazon EC2 to Amazon ECS Managed Instances:

#### Task compatibility

Existing task definitions configured for Amazon EC2 are mostly compatible with Amazon ECS Managed Instances. For a list of task definition differences, see [Amazon ECS task definition differences for Amazon ECS Managed Instances](#).

#### Security model changes

Amazon ECS Managed Instances allows multiple tasks per instance by default. Consider enabling single-task mode if your workloads require stronger isolation.

#### Instance lifecycle

Amazon ECS Managed Instances have a maximum lifetime of 14 days. Plan for task replacement and use Amazon ECS services for automatic task management.

#### Pricing changes

With Amazon ECS Managed Instances, you pay for the entire instance plus a management fee, with AWS handling the infrastructure management overhead.

## Maintenance windows

Configure maintenance windows using Amazon EC2 event windows to control when Amazon ECS Managed Instances are replaced for patching.

## Prerequisites

Before migrating to Amazon ECS Managed Instances, ensure you have:

- You have the required IAM roles for Amazon ECS Managed Instances. This includes:
  - **Infrastructure role** - Allows Amazon ECS to make calls to AWS services on your behalf to manage Amazon ECS Managed Instances infrastructure.

For more information, see [Amazon ECS infrastructure IAM role](#).

- **Instance profile** - Provides permissions for the Amazon ECS container agent and Docker daemon running on managed instances.

For more information, see [Amazon ECS Managed Instances instance profile](#).

- Understanding of the security model differences between Amazon EC2 and Amazon ECS Managed Instances

## Step 1: Update the cluster to use Amazon ECS Managed Instances

Create a capacity provider. When you create a capacity provider with Amazon ECS Managed Instances, it becomes available only within the specified cluster.

For more information, see [Creating a capacity provider for Amazon ECS Managed Instances](#).

## Step 2: Update the task definition to have the Amazon ECS Managed Instances capability

Update the task definition so that it has the `requiresCapabilities` for Amazon ECS Managed Instances.

For more information, see [Updating an Amazon ECS task definition using the console](#).

## Step 3: Update the service to use the Amazon ECS Managed Instances capacity provider

Update your existing Amazon ECS service to use the Amazon ECS Managed Instances capacity provider.

For more information, see [Updating an Amazon ECS service to use a capacity provider](#).

## Step 4: Migrate standalone tasks

For standalone tasks, specify the Amazon ECS Managed Instances capacity provider when running the task.

For more information, see [Running an application as an Amazon ECS task](#).

# Amazon ECS Managed Daemons

Amazon ECS Managed Daemons enable you to deploy and manage software agents, such as security, observability, and networking agents, across your container infrastructure on Amazon ECS Managed Instances. Managed Daemons decouple daemon lifecycle management from application operations. You can deploy, update, and monitor agents independently, without redeploying workloads or coordinating changes across services.

## Daemon criticality

You can configure each managed daemon as critical or non-critical, based on whether a daemon failure should cause Amazon ECS to drain the container instance.

- **Critical** - The default. Amazon ECS starts the daemon task before it places application tasks on the instance, and if the daemon task stops or becomes unhealthy, Amazon ECS drains and replaces the container instance.
- **Non-critical** - Set the `critical` parameter to `false`. The daemon task operates independently of container instance health. If a non-critical daemon task fails, stops, or becomes unhealthy, Amazon ECS keeps the container instance active. Existing application tasks keep running, and Amazon ECS keeps placing new application tasks on it. A non-critical daemon never blocks instance registration, so application tasks can be placed immediately even if the daemon fails to start.

## How Managed Daemons work

To use Managed Daemons, first register a daemon task definition. A daemon task definition is a template that describes the containers that form a daemon. After you register a daemon task definition, create a daemon and associate it with a cluster and one or more Amazon ECS Managed Instances capacity providers. Amazon ECS then ensures that exactly one daemon task runs on every Amazon EC2 instance provisioned through those capacity providers.

Daemons do not launch instances independently. When you run an application task on a Amazon ECS Managed Instances capacity provider, Amazon ECS provisions an Amazon EC2 instance, starts the daemon task, and only then transitions the application task to `RUNNING`. Amazon ECS uses this ordering for every daemon, regardless of criticality, so that cross-cutting functions like logging, tracing, and metrics collection are operational before your application begins processing requests.

Criticality controls what Amazon ECS does when a daemon task doesn't start, or stops later. For a critical daemon, a task that fails to start keeps the instance from becoming active. A task that stops or becomes unhealthy after the instance is active causes Amazon ECS to drain and replace the instance. This auto-repair behavior maintains reliable daemon coverage without manual intervention.

A non-critical daemon never blocks the instance and never triggers a drain. The instance becomes active even if the daemon task fails to start, and stays active if the daemon task stops or becomes unhealthy later. Your application tasks keep running, and Amazon ECS keeps placing new application tasks on the instance.

When you update a daemon to a new task definition revision, Amazon ECS performs a rolling deployment across all instances in the associated capacity providers. During the deployment, Amazon ECS drains a configurable percentage of instances simultaneously, provisions replacement instances with the updated daemon, and replaces your Amazon ECS service tasks automatically. Amazon ECS provides built-in circuit breaker protection. You can configure a bake time and CloudWatch alarms so that Amazon ECS monitors the deployment after it updates all instances and automatically rolls back if issues arise. Amazon ECS emits an EventBridge event and records a service action log when a daemon task fails to start, for both critical and non-critical daemons.

## Key benefits

- **Decoupled lifecycle management** - Update daemons independently from application deployments.
- **Guaranteed coverage** - Amazon ECS starts the daemon task before application tasks on every instance, so cross-cutting functions are operational before your application begins processing requests. For a critical daemon, a daemon task that fails to start also keeps the instance from registering, so an instance never serves application tasks without its daemon.
- **Reliable version updates** - When you update a daemon version, Amazon ECS rolls it out across all instances in the associated capacity providers, with built-in circuit breaker protection and automatic rollback to ensure every instance runs the target revision.
- **Improved resource utilization** - Running a single daemon task per instance eliminates the sidecar-per-task model, reducing resource overhead across your cluster.
- **Automatic instance repair** - For a critical daemon, if the daemon task stops or becomes unhealthy, Amazon ECS automatically drains and replaces that container instance. This maintains reliable daemon coverage without manual intervention.

- **Workload continuity** - Non-critical daemons keep your application workloads running uninterrupted, even if a daemon task fails, stops, or becomes unhealthy.

### Note

Amazon ECS offers a DAEMON scheduling strategy for Amazon ECS services for the Amazon EC2 launch type. Managed Daemons is a new capability built for Amazon ECS Managed Instances to simplify daemon deployments and provide stronger daemon coverage guarantees.

## Getting started

To get started, register a daemon task definition specifying your container image, then create a daemon with associated capacity providers in your cluster. You can use the AWS Management Console, AWS CLI, CloudFormation, or AWS SDKs. For step-by-step instructions, see [Creating and managing daemons](#).

## Daemon task definitions

A daemon task definition is the blueprint for your daemon. Amazon ECS Managed Daemons use a dedicated daemon task definition resource, distinct from standard Amazon ECS task definitions. You register a daemon task definition to specify the container image, resource requirements, and configuration for your daemon.

## Creating a daemon task definition

You can create a daemon task definition by using the AWS Management Console or the AWS CLI.

### Using the AWS Management Console

1. Open the Amazon ECS console. In the navigation pane, choose **Daemon task definitions**.
2. Choose **Create new daemon task definition**.
3. For **Daemon task definition family**, enter a unique name. The name can contain up to 255 alphanumeric characters, hyphens, and underscores.
4. (Optional) For **Task role**, choose an IAM role that grants permissions to the applications running in your containers. Leave this blank if your containers do not call AWS APIs.

5. (Optional) For **Task execution role**, select `ecsTaskExecutionRole`. Amazon ECS requires this role to pull container images and publish logs.
6. (Optional) For **Task size**, specify the CPU and memory to reserve for your daemon. For example, `0.25` vCPU and 512 MB memory.
7. Configure your container details:
  - **Container name** - Enter a name for your container. The name can contain up to 255 alphanumeric characters, hyphens, and underscores.
  - **Essential container** - Select **Yes**. Each daemon task definition requires at least one essential container. If an essential container fails, Amazon ECS stops the entire task.
  - **Image URI** - Enter the Docker image URI. You can browse Amazon ECR images or use public images from Docker Hub or other registries.
8. (Optional) Configure resource allocation, health check, environment variables, log collection, and tags as needed.
9. Review your configuration and choose **Create**.

## Using the AWS CLI

Register a daemon task definition by creating a JSON file and using the `register-daemon-task-definition` command.

The following is an example JSON file:

```
{
  "family": "my-daemon-task",
  "containerDefinitions": [
    {
      "name": "daemon-container",
      "image": "public.ecr.aws/docker/library/busybox:latest",
      "essential": true,
      "command": ["sh", "-c", "while true; do echo 'Daemon running'; sleep 30;
done"],
      "memoryReservation": 512
    }
  ]
}
```

Run the following command to register the daemon task definition:

```
aws ecs register-daemon-task-definition --cli-input-json file://daemon-taskdef.json
```

## Daemon task definition parameters

You can use the following parameters when you register a daemon task definition.

### Required parameters

- **family** - The task definition family name. This groups multiple revisions of the same daemon task definition.
- **containerDefinitions** - An array of `DaemonContainerDefinition` objects that describe the containers in your daemon task.

### Optional parameters

- **cpu** - Task-level CPU units as a string (for example, "256").
- **memory** - Task-level memory in MiB as a string (for example, "512").
- **taskRoleArn** - The ARN of the IAM role that grants permissions to the containers in your daemon task.
- **executionRoleArn** - The ARN of the IAM role that the Amazon ECS container agent uses to make AWS API calls on your behalf (for example, pulling images from Amazon ECR).
- **volumes** - An array of `DaemonVolume` objects. Daemon volumes support only bind mounts with `host` and `sourcePath`. Daemon task definitions do not support Amazon EBS, Amazon EFS, FSx for Windows File Server, Docker volumes, or ephemeral storage.
- **tags** - An array of key-value pairs to tag your daemon task definition.
- **pidMode** - Controls the PID namespace mode for the daemon.
- **ipcMode** - Controls the IPC namespace mode for the daemon.

## Network mode

Daemons use a special `daemon_bridge` network mode that Amazon ECS sets automatically. You cannot specify a network mode in your daemon task definition. All daemons on an instance share a single network namespace and are accessible locally via a static daemon bridge IP address (169.254.172.2 for IPv4, or `fd00:ec2::172:2` for IPv6). Application tasks (non-daemons) can communicate with daemons at this address without additional network configuration.

Because daemons run in a separate network namespace from application tasks, non-daemon tasks don't need to worry about port conflicts with daemons. However, since all daemon tasks share the same namespace, daemons on the same instance cannot bind to the same port. When deploying multiple daemons, ensure each daemon uses a unique port.

## Privileged capabilities

On Amazon ECS Managed Instances, daemons support privileged Linux capabilities for system-level operations. Security agents, network monitoring tools, and observability agents often require kernel-level access to function correctly.

You can grant capabilities in two ways:

**Full privileged mode** grants all Linux capabilities to the container. Use this when your agent requires broad system access:

```
{
  "containerDefinitions": [{
    "name": "security-daemon",
    "image": "my-security-agent:latest",
    "privileged": true
  }]
}
```

**Individual capabilities** grant only the permissions your daemon needs, following the principle of least privilege. Use the `linuxParameters.capabilities` field to add individual capabilities such as `SYS_ADMIN`, `NET_ADMIN`, `SYS_PTRACE`, `BPF`, and `PERFMON`:

```
{
  "containerDefinitions": [{
    "name": "monitoring-daemon",
    "image": "my-monitoring-agent:latest",
    "linuxParameters": {
      "capabilities": {
        "add": ["NET_ADMIN", "SYS_PTRACE"]
      }
    }
  }]
}
```

## PID and IPC namespace sharing

On Amazon ECS Managed Instances, daemons support PID and IPC namespace sharing to enable use cases such as security agents, monitoring tools, and observability daemons that need visibility into application task processes or IPC resources.

### pidMode

Type: String

Required: No

Valid values: none | shared

Default: none

The PID namespace mode for the daemon. If none is specified or no value is provided, the daemon runs with its own PID namespace, isolated from other tasks. If shared is specified, the daemon joins the host PID namespace, making it accessible to non-daemon tasks that use `pidMode: "host"` or other daemons that use `pidMode: "shared"`.

### ipcMode

Type: String

Required: No

Valid values: none | shared

Default: none

The IPC namespace mode for the daemon. If none is specified or no value is provided, the daemon runs with its own IPC namespace, isolated from other tasks. If shared is specified, the daemon joins the host IPC namespace, making it accessible to non-daemon tasks that use `ipcMode: "host"` or other daemons that use `ipcMode: "shared"`.

The following example shows a daemon task definition with both PID and IPC namespace sharing enabled:

```
{
  "family": "my-monitoring-daemon",
  "pidMode": "shared",
  "ipcMode": "shared",
```

```
"containerDefinitions": [  
  {  
    "name": "monitoring-agent",  
    "image": "public.ecr.aws/my-company/monitoring-agent:latest",  
    "essential": true  
  }  
]  
}
```

To share the PID namespace with a daemon that has `pidMode` set to `shared`, a non-daemon task must specify `pidMode: "host"` in its task definition. This allows the task's containers to see the daemon's processes and enables use cases such as process monitoring and signal delivery.

To share the IPC namespace with a daemon that has `ipcMode` set to `shared`, a non-daemon task must specify `ipcMode: "host"` in its task definition. This allows the task's containers to access the daemon's IPC resources such as shared memory segments and message queues.

## Volumes

Managed Daemons support bind mounts using host volumes with a `sourcePath` specification. This allows daemon containers to mount host directories to access logs, metrics, and system information on the underlying Amazon EC2 instance. Log collection agents, metrics exporters, and security scanners commonly use this to gain visibility into host-level data.

The daemon task definition supports host volume specifications with `sourcePath`. Daemon volumes persist for the lifecycle of the underlying container instance.

### Note

Amazon EBS volumes, Amazon EFS volumes, FSx for Windows File Server volumes, Docker volumes, and ephemeral storage are not supported in daemon task definitions.

### Note

Daemons do not support volume sharing between each other. Each daemon operates with its own independent volume configuration.

The following example shows a log collector daemon with a bind mount:

```
{
  "containerDefinitions": [{
    "name": "log-collector",
    "image": "fluent/fluentd:latest",
    "mountPoints": [{
      "sourceVolume": "var-log",
      "containerPath": "/var/log"
    }]
  }],
  "volumes": [{
    "name": "var-log",
    "host": {
      "sourcePath": "/var/log"
    }
  }]
}
```

## Supported container parameters

Daemon container definitions support the following parameters:

- `image` (required) - Container image URI
- `name` (required) - Container name
- `cpu` - CPU units reserved for the container
- `memory` / `memoryReservation` - Hard and soft memory limits
- `essential` - Whether the container is essential (default: true)
- `command` / `entryPoint` - Override the container command or entry point
- `environment` / `environmentFiles` / `secrets` - Environment configuration
- `privileged` - Run the container in privileged mode
- `user` - User to run the container as
- `workingDirectory` - Working directory inside the container
- `readOnlyRootFilesystem` - Mount the root filesystem as read-only
- `mountPoints` - Volume mount points (bind mounts with host and sourcePath only)
- `logConfiguration` - Logging configuration (supports awslogs, splunk, awsfirelens)
- `healthCheck` - Container health check configuration
- `dependsOn` - Container startup dependencies

- `ulimits` - Resource limits
- `systemControls` - Kernel parameters
- `linuxParameters.capabilities` - Linux capabilities to add or drop
- `linuxParameters.initProcessEnabled` - Run an init process in the container
- `repositoryCredentials` - Credentials for private registries
- `restartPolicy` - Container restart policy

## Creating and managing daemons

After you register a daemon task definition, create a daemon to deploy it across your Amazon ECS Managed Instances capacity providers. Amazon ECS automatically places one daemon task on every Amazon EC2 instance in the associated capacity providers and manages the daemon lifecycle.

### Prerequisites

Before you create a daemon, verify that you have the following:

- An Amazon ECS cluster.
- One or more Amazon ECS Managed Instances capacity providers associated with the cluster.
- A registered daemon task definition.

## Creating a daemon

### AWS Management Console

1. Open the Amazon ECS console. In the navigation pane, choose **Clusters**, then select your cluster.
2. Choose the **Daemons** tab, then choose **Create**.
3. For **Daemon task definition family**, select your daemon task definition from the dropdown.
4. For **Daemon task definition revision**, select the revision to use. Leave blank to use the latest revision.
5. For **Daemon name**, enter a unique name. The name can contain up to 255 alphanumeric characters, hyphens, and underscores.
6. For **Capacity providers**, select one or more Amazon ECS Managed Instances capacity providers. These determine which instances run your daemon tasks.

## 7. (Optional) Configure deployment settings:

- **Drain percentage** - Percentage of instances to drain simultaneously during updates. Default: 25.
- **Use CloudWatch alarm(s)** - Turn on to monitor deployment health and automatically roll back if alarms trigger.
- **Bake time** - The number of minutes that Amazon ECS waits after it updates all instances to the new daemon revision before it completes the deployment. During this period, Amazon ECS monitors CloudWatch alarms and automatically rolls back the deployment if any alarm triggers. Default: 0.

8. (Optional) For **Critical**, choose whether the daemon is critical to instance health.

9. (Optional) Add tags.

10. (Optional) Turn on **Enable ECS Exec** to run interactive commands in your daemon containers for troubleshooting.

11. Review your configuration and choose **Create**.

## AWS CLI

Create a JSON file with your daemon configuration and run the `create-daemon` command.

The following is an example JSON file:

```
{
  "clusterArn": "arn:aws:ecs:us-east-1:123456789012:cluster/my-daemon-cluster",
  "daemonName": "my-monitoring-daemon",
  "daemonTaskDefinitionArn": "arn:aws:ecs:us-east-1:123456789012:daemon-task-definition/my-daemon-task:1",
  "capacityProviderArns": [
    "arn:aws:ecs:us-east-1:123456789012:capacity-provider/my-daemon-capacity-provider"
  ],
  "critical": true
}
```

Run the following command to create the daemon:

```
aws ecs create-daemon --cli-input-json file://create-daemon.json
```

## Required fields

- `daemonName` - A unique name for the daemon.
- `clusterArn` - The ARN of the cluster.
- `daemonTaskDefinitionArn` - The ARN of the daemon task definition.
- `capacityProviderArns` - An array of Amazon ECS Managed Instances capacity provider ARNs.

### Optional fields

- `deploymentConfiguration` - A `DaemonDeploymentConfiguration` object to customize deployment behavior.
- `critical` - Whether the daemon is critical to instance health.
- `tags` - Key-value pairs for tagging.
- `propagateTags` - Tag propagation setting.
- `clientToken` - An idempotency token.

## Verifying daemon deployment

After you create a daemon, verify its status by using the AWS Management Console or the AWS CLI.

### AWS Management Console

1. Open the Amazon ECS console. In the navigation pane, choose **Clusters**, then select your cluster.
2. Choose the **Daemons** tab.
3. Verify that your daemon shows **Active** status.
4. Choose the **Tasks** tab to confirm that one daemon task runs on each container instance.

### AWS CLI

Run the following commands to verify daemon status:

```
aws ecs list-daemons \
  --cluster-arn arn:aws:ecs:us-east-1:123456789012:cluster/my-daemon-cluster
```

```
aws ecs describe-daemons \
  --daemon-arn arn:aws:ecs:us-east-1:123456789012:daemon/my-daemon-cluster/my-
  monitoring-daemon
```

## Updating a daemon

To update a daemon with a new task definition revision or to add capacity providers, use the AWS Management Console or the AWS CLI. This triggers a rolling deployment across all instances.

### AWS Management Console

1. Open the Amazon ECS console. In the navigation pane, choose **Clusters**, then select your cluster.
2. Choose the **Daemons** tab, then select the daemon you want to update.
3. Choose **Update**.
4. For **Daemon task definition revision**, select the new revision.
5. (Optional) Update the capacity providers or deployment settings.
6. Choose **Update** to start the rolling deployment.

### AWS CLI

Run the `update-daemon` command:

```
aws ecs update-daemon \
  --daemon-arn arn:aws:ecs:us-east-1:123456789012:daemon/my-daemon-cluster/my-
monitoring-daemon \
  --daemon-task-definition-arn arn:aws:ecs:us-east-1:123456789012:daemon-task-
definition/my-daemon-task:2 \
  --capacity-provider-arns arn:aws:ecs:us-east-1:123456789012:capacity-provider/my-
daemon-capacity-provider \
  --no-critical
```

#### Important

When you provide daemon configuration settings in an `UpdateDaemon` request, Amazon ECS uses your specified settings instead of the defaults. Daemon configuration settings, including tags and the `enableExecuteCommand` flag, are not persisted between updates. Each call to `UpdateDaemon` must include the full set of configuration settings you want applied. Any settings omitted from the request revert to their default values. The `critical` parameter defaults to `true`, so if you omit it from an `UpdateDaemon` request, the daemon becomes critical.

## Deleting a daemon

To delete a daemon, use the AWS Management Console or the AWS CLI. Wait for all daemon tasks to stop before you delete the capacity provider or cluster.

### AWS Management Console

1. Open the Amazon ECS console. In the navigation pane, choose **Clusters**, then select your cluster.
2. Choose the **Daemons** tab, then select the daemon you want to delete.
3. Choose **Delete**.
4. In the confirmation dialog, choose **Delete** to confirm.

### AWS CLI

Run the `delete-daemon` command:

```
aws ecs delete-daemon \
    --daemon-arn arn:aws:ecs:us-east-1:123456789012:daemon/my-daemon-cluster/my-
    monitoring-daemon
```

## Daemon deployments

When you create or update a daemon, Amazon ECS performs a rolling deployment to run daemon tasks on all instances in the associated capacity providers. This section describes how daemon deployments work and how to configure deployment behavior.

### How daemon deployments work

A daemon deployment follows a drain-provision-replace pattern. When you create a daemon on a capacity provider with existing instances, or update a daemon to a new task definition revision, Amazon ECS drains a batch of instances, provisions replacement instances with the updated daemon, and replaces application tasks automatically. This process repeats until all instances run the new daemon revision.

The deployment lifecycle transitions through the following states:

1. **PENDING** - Amazon ECS has created the deployment and is preparing to begin.
2. **IN\_PROGRESS** - Amazon ECS is actively draining instances and provisioning replacements.

3. **SUCCESSFUL** - All instances are running the target daemon revision.
4. **STOPPED** - Amazon ECS has stopped the deployment because it failed or was replaced by a new deployment. The daemon may be in a mixed state where some instances run the old revision and others run the new revision.

Amazon ECS automatically rolls back to the previous daemon revision if the deployment circuit breaker detects failures or if a CloudWatch alarm triggers during the deployment.

During a deployment, a non-critical daemon task failure doesn't drain or replace the instance, so the instance stays active and continues to run your application tasks. Daemon task launch failures still count toward the deployment circuit breaker, which can roll back an unstable target revision.

## Deployment configuration parameters

You can customize deployment behavior by using the `deploymentConfiguration` parameter when you create or update a daemon.

- `drainPercent` (1.0–100.0) - The percentage of instances to drain simultaneously during the deployment. Higher values speed up deployments but may temporarily reduce available capacity. For example, a value of `20.0` drains 20% of instances at a time. If not specified, the default is `25.0`.
- `alarms` (`DaemonAlarmConfiguration`) - CloudWatch alarms to monitor during the deployment. Amazon ECS evaluates the specified alarms during the deployment and automatically rolls back if any alarm enters the ALARM state. Amazon ECS ignores alarms that are already in the ALARM state when the deployment begins.
- `bakeTimeInMinutes` (0–1440) - The number of minutes that Amazon ECS waits after it updates all instances to the new daemon revision before it completes the deployment. During this period, Amazon ECS monitors CloudWatch alarms and automatically rolls back the deployment if any alarm triggers. If not specified, the default is `0`.

### Example with deployment configuration:

```
aws ecs create-daemon \  
  --cluster-arn arn:aws:ecs:us-east-1:123456789012:cluster/my-daemon-cluster \  
  --daemon-name my-monitoring-daemon \  
  --daemon-task-definition-arn arn:aws:ecs:us-east-1:123456789012:daemon-task-  
definition/my-daemon-task:1 \  

```

```
--capacity-provider-arns arn:aws:ecs:us-east-1:123456789012:capacity-provider/my-  
daemon-capacity-provider \  
--deployment-configuration '{"drainPercent":20.0,"bakeTimeInMinutes":5}'
```

## Monitoring deployments

Track deployment progress by using the following commands:

```
aws ecs list-daemon-deployments \  
--daemon-arn arn:aws:ecs:us-east-1:123456789012:daemon/my-daemon-cluster/my-  
monitoring-daemon
```

```
aws ecs describe-daemon-deployments \  
--daemon-deployment-arns arn:aws:ecs:us-east-1:123456789012:daemon-deployment/my-  
daemon-cluster/abc123
```

The describe-daemon-deployments response includes the deployment status, the target daemon revision, and the totalRunningInstanceCount field that indicates how many instances run the target daemon.

## Daemon deployment scenarios

This section walks through common deployment scenarios for Managed Daemons.

- [Deploy a daemon on an empty capacity provider](#)
- [Deploy a daemon on a capacity provider with existing instances](#)
- [Add a capacity provider to an existing daemon](#)
- [Update a daemon to a new revision](#)

### Deploy a daemon on an empty capacity provider

In this scenario, you deploy a daemon on a capacity provider with no existing instances. Instances launch when you schedule application tasks.

**Prerequisites:** A cluster and a Amazon ECS Managed Instances capacity provider with no running instances.

1. Register your daemon task definition.

2. Create the daemon. Amazon ECS completes the creation immediately even though no instances exist yet.

```
aws ecs create-daemon \
  --cluster-arn arn:aws:ecs:us-east-1:123456789012:cluster/my-daemon-cluster \
  --daemon-name my-monitoring-daemon \
  --daemon-task-definition-arn arn:aws:ecs:us-east-1:123456789012:daemon-task-
definition/my-daemon-task:1 \
  --capacity-provider-arns arn:aws:ecs:us-east-1:123456789012:capacity-provider/my-
daemon-capacity-provider
```

3. Create a service that uses the same capacity provider. When Amazon ECS provisions an instance for the service, it starts the daemon task first, then transitions the application task to RUNNING.

```
aws ecs create-service \
  --cluster my-daemon-cluster \
  --service-name my-app-service \
  --task-definition my-app-task \
  --desired-count 2 \
  --capacity-provider-strategy capacityProvider=my-daemon-capacity-
provider,weight=1
```

4. Verify that the daemon task is running on each instance by using the `describe-daemons` command or by checking the **Daemons** tab in the console.

#### Note

The daemon deployment may remain in PENDING state briefly while Amazon ECS provisions instances and starts daemon tasks. Wait for the deployment to reach SUCCESSFUL before verifying daemon task placement.

## Deploy a daemon on a capacity provider with existing instances

In this scenario, you deploy a daemon on a capacity provider that already has running instances and application tasks.

**Prerequisites:** A cluster with a Amazon ECS Managed Instances capacity provider that has running instances.

1. Register your daemon task definition.
2. Create the daemon. Amazon ECS starts a rolling deployment to place daemon tasks on all existing instances.

```
aws ecs create-daemon \  
  --cluster-arn arn:aws:ecs:us-east-1:123456789012:cluster/my-daemon-cluster \  
  --daemon-name my-monitoring-daemon \  
  --daemon-task-definition-arn arn:aws:ecs:us-east-1:123456789012:daemon-task-  
definition/my-daemon-task:1 \  
  --capacity-provider-arns arn:aws:ecs:us-east-1:123456789012:capacity-provider/my-  
daemon-capacity-provider \  
  --deployment-configuration '{"drainPercent":25.0,"bakeTimeInMinutes":3}'
```

Amazon ECS drains a batch of existing instances (based on the `drainPercent`), provisions replacement instances with the daemon, and replaces application tasks. This process repeats until all instances run the daemon.

3. Monitor the deployment progress:

```
aws ecs list-daemon-deployments \  
  --daemon-arn arn:aws:ecs:us-east-1:123456789012:daemon/my-daemon-cluster/my-  
monitoring-daemon
```

## Add a capacity provider to an existing daemon

In this scenario, you add a second capacity provider to an existing daemon. The daemon automatically deploys to instances in the new capacity provider.

**Prerequisites:** A daemon running on a first capacity provider, and a second capacity provider created and associated with the cluster.

1. Update the daemon to include both capacity providers:

```
aws ecs update-daemon \  
  --daemon-arn arn:aws:ecs:us-east-1:123456789012:daemon/my-daemon-cluster/my-  
monitoring-daemon \  
  --daemon-task-definition-arn arn:aws:ecs:us-east-1:123456789012:daemon-task-  
definition/my-daemon-task:1 \  
  --capacity-provider-arns \  

```

```
arn:aws:ecs:us-east-1:123456789012:capacity-provider/my-daemon-capacity-  
provider \  
arn:aws:ecs:us-east-1:123456789012:capacity-provider/my-daemon-capacity-  
provider-2
```

2. Monitor the deployment and verify that daemon tasks run on instances in both capacity providers.

## Update a daemon to a new revision

In this scenario, you update an existing daemon to use a new task definition revision.

1. Register a new revision of your daemon task definition with the updated container image or configuration.
2. Update the daemon to use the new revision:

```
aws ecs update-daemon \  
  --daemon-arn arn:aws:ecs:us-east-1:123456789012:daemon/my-daemon-cluster/my-  
monitoring-daemon \  
  --daemon-task-definition-arn arn:aws:ecs:us-east-1:123456789012:daemon-task-  
definition/my-daemon-task:2
```

Amazon ECS performs a rolling deployment. It drains instances running the old revision, provisions replacement instances with the new revision, and replaces application tasks automatically. If the circuit breaker detects failures, Amazon ECS rolls back to the previous revision.

3. Monitor the deployment and verify that all instances run the new revision:

```
aws ecs describe-daemon-deployments \  
  --daemon-deployment-arns arn:aws:ecs:us-east-1:123456789012:daemon-deployment/my-  
daemon-cluster/deployment-id
```

## Daemon events

Amazon ECS sends daemon events to provide visibility into daemon task management and deployment lifecycle changes. You can use these events to monitor daemon health, track deployment progress, and trigger automated workflows.

Amazon ECS supports the following daemon event types:

- [Daemon service action events](#) - Events related to daemon task placement and startup issues.
- [Daemon deployment state change events](#) - Events related to daemon deployment lifecycle transitions.

To learn how to create rules for these events, see [Creating rules for daemon events](#).

## Daemon service action events

Amazon ECS sends daemon service action events with the detail type `ECS Daemon Service Action`. These events notify you when Amazon ECS encounters issues starting daemon tasks on your container instances. Amazon ECS emits an EventBridge event when a daemon task fails to start, for both critical and non-critical daemons.

### DAEMON\_TASK\_START\_IMPAIRED

Amazon ECS sends the `DAEMON_TASK_START_IMPAIRED` event when it is unable to successfully start a daemon task on a container instance. The event includes a `failureType` field that indicates the cause of the failure:

- `TASK_FAILED_TO_RUN` - The daemon task was created but failed to reach `RUNNING` status. Common causes include container image pull failures, container health check failures, or essential container exits. The `taskArn` field is present in the event.
- `TASK_CREATION_FAILED` - The daemon task could not be created on the container instance. Common causes include insufficient CPU, memory, or other resources on the instance. The `taskArn` field is not present in the event because no task was created.

### Example: TASK\_FAILED\_TO\_RUN event

The following event shows a daemon task that was created but failed to reach `RUNNING` status due to a container image pull failure.

```
{
  "version": "0",
  "id": "12345678-1234-1234-1234-123456789012",
  "detail-type": "ECS Daemon Service Action",
  "source": "aws.ecs",
```

```

"account": "123456789012",
"time": "2026-03-24T12:00:00Z",
"region": "us-west-2",
"resources": [
  "arn:aws:ecs:us-west-2:123456789012:task/my-cluster/a1b2c3d4e5f6"
],
"detail": {
  "eventType": "WARNING",
  "eventName": "DAEMON_TASK_START_IMPAIRED",
  "clusterArn": "arn:aws:ecs:us-west-2:123456789012:cluster/my-cluster",
  "containerInstanceArn": "arn:aws:ecs:us-west-2:123456789012:container-
instance/my-cluster/a1b2c3d4e5f6",
  "taskArn": "arn:aws:ecs:us-west-2:123456789012:task/my-cluster/a1b2c3d4e5f6",
  "daemonRevisionArn": "arn:aws:ecs:us-west-2:123456789012:daemon-revision/my-

    "failureType": "TASK_CREATION_FAILED",
    "createdAt": "2026-03-24T12:01:00.000Z",
    "reason": "RESOURCE:CPU - Unable to place daemon task on container instance:
insufficient CPU"
  }
}

```

## Daemon deployment state change events

Amazon ECS sends daemon deployment state change events with the detail type `ECS Daemon Deployment State Change`. Amazon ECS emits these events each time the state of a daemon deployment changes.

### Deployment state change event types

Amazon ECS categorizes deployment state change events by the following event types:

#### INFO events

- `DAEMON_DEPLOYMENT_PENDING` - Amazon ECS has initiated a daemon deployment.
- `DAEMON_DEPLOYMENT_IN_PROGRESS` - Amazon ECS has started the deployment and is actively replacing daemon tasks.
- `DAEMON_DEPLOYMENT_SUCCESSFUL` - Amazon ECS has successfully completed the deployment with all daemon tasks running and healthy.
- `DAEMON_DEPLOYMENT_STOPPED` - Amazon ECS has stopped the deployment. This occurs when a deployment has failed or has been replaced by a new deployment.
- `DAEMON_DEPLOYMENT_STOP_REQUESTED` - Amazon ECS has stopped the deployment from moving forward and will now start to roll back.
- `DAEMON_DEPLOYMENT_ROLLBACK_IN_PROGRESS` - Amazon ECS has initiated a rollback due to deployment failure or circuit breaker trigger.

- **DAEMON\_DEPLOYMENT\_ROLLBACK\_SUCCESSFUL** - Amazon ECS has successfully completed the deployment rollback.

## ERROR events

- **DAEMON\_DEPLOYMENT\_ROLLBACK\_FAILED** - Amazon ECS was unable to complete the deployment rollback.

## Example: Deployment pending event

The following event shows a daemon deployment that Amazon ECS has initiated.

```
{
  "version": "0",
  "id": "3329f79b-3dca-07f8-b1c2-5fe99f0b5e87",
  "detail-type": "ECS Daemon Deployment State Change",
  "source": "aws.ecs",
  "account": "111122223333",
  "time": "2026-03-05T15:54:41Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:ecs:us-west-2:111122223333:daemon/my-cluster/my-daemon"
  ],
  "detail": {
    "eventType": "INFO",
    "eventName": "DAEMON_DEPLOYMENT_PENDING",
    "clusterArn": "arn:aws:ecs:us-west-2:111122223333:cluster/my-cluster",
    "daemonArn": "arn:aws:ecs:us-west-2:111122223333:daemon/my-cluster/my-daemon",
    "daemonDeploymentArn": "arn:aws:ecs:us-west-2:111122223333:daemon-deployment/my-cluster/my-daemon/0EYSiB0qap8xf0N76FsbE",
    "targetDaemonRevisionArn": "arn:aws:ecs:us-west-2:111122223333:daemon-revision/my-cluster/my-daemon/85707969-3732-4b6a-a37d-5cefddd7d7dd",
    "updatedAt": "2026-03-05T15:54:41.618059641Z"
  }
}
```

## Creating rules for daemon events

You can create rules to receive notifications when daemon events occur. For more information about creating rules, see [Creating a rule](#) in the *Amazon EventBridge User Guide*.

The following example event patterns show how to filter daemon events.

### Example: Match all daemon service action events

```
{
  "source": ["aws.ecs"],
  "detail-type": ["ECS Daemon Service Action"]
}
```

### Example: Match a specific failure type

```
{
  "source": ["aws.ecs"],
  "detail-type": ["ECS Daemon Service Action"],
  "detail": {
    "eventName": ["DAEMON_TASK_START_IMPAIRED"],
    "failureType": ["TASK_CREATION_FAILED"]
  }
}
```

### Example: Match events for a specific cluster

```
{
  "source": ["aws.ecs"],
  "detail-type": ["ECS Daemon Service Action"],
  "detail": {
    "eventName": ["DAEMON_TASK_START_IMPAIRED"],
    "clusterArn": ["arn:aws:ecs:us-west-2:123456789012:cluster/my-cluster"]
  }
}
```

### Example: Match all deployment state change events

```
{
  "source": ["aws.ecs"],
  "detail-type": ["ECS Daemon Deployment State Change"]
}
```

## Daemon metrics

Amazon ECS publishes CloudWatch metrics for Managed Daemons. You can use these metrics to track CPU and memory utilization for daemon tasks across your cluster.

Daemon metrics use the same AWS/ECS namespace as service metrics. Amazon ECS distinguishes daemon metrics from service metrics by the `ServiceName` dimension value, which uses the prefix `daemon:` followed by the daemon name (for example, `daemon:my-daemon`).

## Daemon utilization metrics

Amazon ECS measures daemon CPU and memory utilization as the percentage of resources used by daemon tasks compared to the resources specified in the daemon task definition.

CloudWatch provides the following statistics for daemon utilization metrics:

- **Average** - The average utilization across all daemon tasks in the cluster.
- **Minimum** - The utilization of the daemon task with the lowest resource usage.
- **Maximum** - The utilization of the daemon task with the highest resource usage.

## Utilization formulas

Amazon ECS calculates the Average statistic using the following formulas:

$$\text{Daemon CPU utilization} = \frac{(\text{Total CPU units used by daemon tasks}) \times 100}{(\text{Total CPU units specified in daemon task definition}) \times (\text{Number of daemon tasks})}$$

$$\text{Daemon memory utilization} = \frac{100 \times (\text{Total MiB of memory used by daemon tasks})}{(\text{Total MiB of memory specified in daemon task definition}) \times (\text{Number of daemon tasks})}$$

These formulas apply only to the Average statistic. The Minimum and Maximum statistics represent the individual daemon task with the lowest and highest resource utilization, respectively.

The Amazon ECS container agent samples CPU and memory usage for each running daemon task every 20 seconds. Each minute, the agent reports three samples to Amazon ECS. Amazon ECS aggregates the samples across all daemon tasks in the cluster and publishes the Average, Minimum, and Maximum values to CloudWatch as a percentage of the total resources specified in the daemon task definition.

## Example: Utilization calculation

A daemon task definition specifies 256 CPU units and 512 MiB of memory. The daemon has 2 running tasks across 2 container instances. One daemon task uses 200 CPU units and 400 MiB of memory. The other uses 100 CPU units and 256 MiB of memory. Amazon ECS reports the following metrics:

- Average CPU utilization:  $((200 + 100) \times 100) / (256 \times 2) = 58.6\%$
- Average memory utilization:  $((400 + 256) \times 100) / (512 \times 2) = 64.1\%$

## Viewing daemon metrics

You can view daemon metrics by using the AWS Management Console or the AWS CLI.

### AWS Management Console

1. Open the CloudWatch console.
2. In the navigation pane, choose **Metrics**, then choose **All metrics**.
3. Choose the **AWS/ECS** namespace.
4. Choose the **ClusterName, ServiceName** dimension.
5. Filter for ServiceName values that begin with `daemon:` to locate your daemon metrics.

### AWS CLI

Run the `get-metric-statistics` command to retrieve daemon metrics from CloudWatch. Specify the `ServiceName` dimension with the `daemon:` prefix.

## Example: Viewing daemon CPU utilization

The following command retrieves the average CPU utilization for a daemon over a 12-hour period with 5-minute intervals.

```
aws cloudwatch get-metric-statistics \
  --namespace AWS/ECS \
  --metric-name CPUUtilization \
  --dimensions Name=ClusterName,Value=my-cluster Name=ServiceName,Value=daemon:my-daemon \
  --start-time 2026-03-24T00:00:00Z \
  --end-time 2026-03-24T12:00:00Z \
  --period 300 \
  --statistics Average
```

## Example: Viewing daemon memory utilization

The following command retrieves the average memory utilization for a daemon over a 12-hour period with 5-minute intervals.

```
aws cloudwatch get-metric-statistics \
  --namespace AWS/ECS \
  --metric-name MemoryUtilization \
  --dimensions Name=ClusterName,Value=my-cluster Name=ServiceName,Value=daemon:my-daemon \
  --start-time 2026-03-24T00:00:00Z \
  --end-time 2026-03-24T12:00:00Z \
  --period 300 \
  --statistics Average
```

## Daemon auto repair

A daemon can be critical or non-critical to instance health, which you control with the `critical` parameter when you create or update the daemon. The `critical` parameter defaults to `true`, so a daemon is critical unless you set `critical` to `false`.

For a critical daemon, if the daemon task stops or becomes unhealthy, Amazon ECS considers the instance impaired and automatically drains and replaces it. The daemon auto repair actions for a critical daemon are as follows:

1. Amazon ECS detects when a daemon task stops or becomes unhealthy.
2. Amazon ECS marks the instance as draining, which prevents it from accepting new application tasks.
3. Amazon ECS provisions a replacement instance and starts the daemon task on it.

4. After the daemon task reaches a healthy state, Amazon ECS schedules the application tasks from the draining instance onto the replacement.
5. Amazon ECS terminates the original instance.

For a non-critical daemon, the daemon task operates independently of container instance health. If the daemon task fails, stops, or becomes unhealthy, Amazon ECS keeps the container instance active. A non-critical daemon never blocks instance registration, so application tasks can be placed immediately even if the daemon fails to start.

 **Important**

Daemon health checks are optional but highly recommended. Without a health check, Amazon ECS can only detect failures when the daemon task stops.

You can monitor daemon health using the `DescribeContainerInstances` API or `DescribeTasks` API.

For a non-critical daemon, Amazon ECS keeps the instance active when the daemon task is not running. The following fields report how many instances are in that state:

- `DescribeDaemon` returns `withoutDaemonCount` for each capacity provider, and `totalWithoutDaemonCount` for the revision across all capacity providers.
- `DescribeDaemonDeployments` returns `withoutDaemonInstanceCount` for each capacity provider, and `totalWithoutDaemonInstanceCount` for the revision across all capacity providers.

 **Note**

The without-daemon counts are separate from the running counts. `DescribeDaemon` reports `runningCount` and `totalRunningCount`. `DescribeDaemonDeployments` reports `runningInstanceCount` and `totalRunningInstanceCount`. An instance appears in one set or the other, never both, so do not add the two sets together.

# Architect for AWS Fargate for Amazon ECS

AWS Fargate is a technology that you can use with Amazon ECS to run [containers](#) without having to manage servers or clusters of Amazon EC2 instances. With AWS Fargate, you no longer have to provision, configure, or scale clusters of virtual machines to run containers. This removes the need to choose server types, decide when to scale your clusters, or optimize cluster packing.

When you run your tasks and services with Fargate, you package your application in containers, specify the CPU and memory requirements, define networking and IAM policies, and launch the application. Each Fargate task has its own isolation boundary and does not share the underlying kernel, CPU resources, memory resources, or elastic network interface with another task. You configure your task definitions for Fargate by setting the `requiresCompatibilities` task definition parameter to `FARGATE`. For more information, see [Capacity](#).

Fargate offers platform versions for Amazon Linux 2 (platform version 1.3.0), Bottlerocket operating system (platform version 1.4.0), and Microsoft Windows 2019 Server Full and Core editions. Unless otherwise specified, the information applies to all Fargate platforms.

For information about the Regions that support Linux containers on Fargate, see [the section called “Linux containers on AWS Fargate”](#).

For information about the Regions that support Windows containers on Fargate, see [the section called “Windows containers on AWS Fargate”](#).

## Walkthroughs

For information about how to get started using the console, see:

- [Learn how to create an Amazon ECS Linux task for Fargate](#)
- [Learn how to create an Amazon ECS Windows task for Fargate](#)

For information about how to get started using the AWS CLI, see:

- [Creating an Amazon ECS Linux task for the Fargate with the AWS CLI](#)
- [Creating an Amazon ECS Windows task for the Fargate with the AWS CLI](#)

# Capacity providers

The following capacity providers are available:

- Fargate
- Fargate Spot - Run interruption tolerant Amazon ECS tasks at a discounted rate compared to the AWS Fargate price. Fargate Spot runs tasks on spare compute capacity. When AWS needs the capacity back, your tasks will be interrupted with a two-minute warning. For more information, see [Amazon ECS clusters for Fargate](#).

## Task definitions

Fargate tasks don't support all of the Amazon ECS task definition parameters that are available. Some parameters aren't supported at all, and others behave differently for Fargate tasks. For more information, see [Task CPU and memory](#).

## Platform versions

AWS Fargate platform versions are used to refer to a specific runtime environment for Fargate task infrastructure. It is a combination of the kernel and container runtime versions. You select a platform version when you run a task or when you create a service to maintain a number of identical tasks.

New revisions of platform versions are released as the runtime environment evolves, for example, if there are kernel or operating system updates, new features, bug fixes, or security updates. A Fargate platform version is updated by making a new platform version revision. Each task runs on one platform version revision during its lifecycle. If you want to use the latest platform version revision, then you must start a new task. A new task that runs on Fargate always runs on the latest revision of a platform version, ensuring that tasks are always started on secure and patched infrastructure.

If a security issue is found that affects an existing platform version, AWS creates a new patched revision of the platform version and retires tasks running on the vulnerable revision. In some cases, you may be notified that your tasks on Fargate have been scheduled for retirement. For more information, see [Task retirement and maintenance for AWS Fargate on Amazon ECS](#).

For more information see [Fargate platform versions for Amazon ECS](#).

## Service load balancing

Your Amazon ECS service on AWS Fargate can optionally be configured to use Elastic Load Balancing to distribute traffic evenly across the tasks in your service.

Amazon ECS services on AWS Fargate support the Application Load Balancer, Network Load Balancer, and Gateway Load Balancer load balancer types. Application Load Balancers are used to route HTTP/HTTPS (or layer 7) traffic. Network Load Balancers are used to route TCP or UDP (or layer 4) traffic. For more information, see [Use load balancing to distribute Amazon ECS service traffic](#).

When you create a target group for these services, you must choose `ip` as the target type, not `instance`. This is because tasks that use the `awsvpc` network mode are associated with an elastic network interface, not an Amazon EC2 instance. For more information, see [Use load balancing to distribute Amazon ECS service traffic](#).

Using a Network Load Balancer to route UDP traffic to your Amazon ECS on AWS Fargate tasks is only supported when using platform version 1.4 or later.

## Usage metrics

You can use CloudWatch usage metrics to provide visibility into your accounts usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

AWS Fargate usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about AWS Fargate service quotas, [Amazon ECS endpoints and quotas](#) in the *Amazon Web Services General Reference*.

For more information about AWS Fargate usage metrics, see [AWS Fargate usage metrics](#).

## Amazon ECS security considerations for when to use Fargate

We recommend that customers looking for strong isolation for their tasks use Fargate. Fargate runs each task in a hardware virtualization environment. This ensures that these containerized workloads do not share network interfaces, Fargate ephemeral storage, CPU, or memory with other tasks.

# Fargate security best practices in Amazon ECS

We recommend that you take into account the following best practices when you use AWS Fargate.

## Use AWS KMS to encrypt ephemeral storage for Fargate

You should have your ephemeral storage encrypted by either AWS KMS or your own customer managed keys. For tasks that are hosted on Fargate using platform version 1.4.0 or later, each task receives 20 GiB of ephemeral storage. For more information, see [customer managed key \(CMK\)](#). You can increase the total amount of ephemeral storage, up to a maximum of 200 GiB, by specifying the `ephemeralStorage` parameter in your task definition. For such tasks that were launched on May 28, 2020 or later, the ephemeral storage is encrypted with an AES-256 encryption algorithm using an encryption key managed by Fargate.

For more information, see [Storage options for Amazon ECS tasks](#).

### Example: Launching an task on Fargate platform version 1.4.0 with ephemeral storage encryption

The following command will launch a task on Fargate platform version 1.4. Because this task is launched as part of the cluster, it uses the 20 GiB of ephemeral storage that's automatically encrypted.

```
aws ecs run-task --cluster clustername \  
  --task-definition taskdefinition:version \  
  --count 1 \  
  --launch-type "FARGATE" \  
  --platform-version 1.4.0 \  
  --network-configuration \  
  "awsvpcConfiguration={subnets=[subnetid],securityGroups=[securitygroupid]}" \  
  --region region
```

## SYS\_PTRACE capability for kernel syscall tracing with Fargate

The default configuration of Linux capabilities that are added or removed from your container are provided by Docker.

Tasks that are launched on Fargate only support adding the SYS\_PTRACE kernel capability.

The following video shows how to use this feature through the Sysdig [Falco](#) project.

## [#ContainersFromTheCouch - Troubleshooting your Fargate Task using SYS\\_PTRACE capability](#)

The code discussed in the previous video can be found on GitHub [here](#).

## Use Amazon GuardDuty with Fargate Runtime Monitoring

Amazon GuardDuty is a threat detection service that helps protect your accounts, containers, workloads, and the data within your AWS environment. Using machine learning (ML) models, and anomaly and threat detection capabilities, GuardDuty continuously monitors different log sources and runtime activity to identify and prioritize potential security risks and malicious activities in your environment.

Runtime Monitoring in GuardDuty protects workloads running on Fargate by continuously monitoring AWS log and networking activity to identify malicious or unauthorized behavior. Runtime Monitoring uses a lightweight, fully managed GuardDuty security agent that analyzes on-host behavior, such as file access, process execution, and network connections. This covers issues including escalation of privileges, use of exposed credentials, or communication with malicious IP addresses, domains, and the presence of malware on your Amazon EC2 instances and container workloads. For more information, see [GuardDuty Runtime Monitoring](#) in the *GuardDuty User Guide*.

## Fargate security considerations for Amazon ECS

Each task has a dedicated infrastructure capacity because Fargate runs each workload on an isolated virtual environment. Workloads that run on Fargate do not share network interfaces, ephemeral storage, CPU, or memory with other tasks. You can run multiple containers within a task including application containers and sidecar containers, or simply sidecars. A *sidecar* is a container that runs alongside an application container in an Amazon ECS task. While the application container runs core application code, processes running in sidecars can augment the application. Sidecars help you segregate application functions into dedicated containers, making it easier for you to update parts of your application.

Containers that are part of the same task share resources for Fargate launch type because these containers will always run on the same host and share compute resources. These containers also share the ephemeral storage provided by Fargate. Linux containers in a task share network namespaces, including the IP address and network ports. Inside a task, containers that belong to the task can inter-communicate over localhost.

The runtime environment in Fargate prevents you from using certain controller features that are supported on EC2 instances. Consider the following when you architect workloads that run on Fargate:

- **No privileged containers or access** - Features such as privileged containers or access are currently unavailable on Fargate. This will affect use cases such as running Docker in Docker.
- **Limited access to Linux capabilities** - The environment in which containers run on Fargate is locked down. Additional Linux capabilities, such as `CAP_SYS_ADMIN` and `CAP_NET_ADMIN`, are restricted to prevent a privilege escalation. Fargate supports adding the [CAP\\_SYS\\_PTRACE](#) Linux capability to tasks to allow observability and security tools deployed within the task to monitor the containerized application.
- **No access to the underlying host** - Neither customers nor AWS operators can connect to a host running customer workloads. You can use ECS exec to run commands in or get a shell to a container running on Fargate. You can use ECS exec to help collect diagnostic information for debugging. Fargate also prevents containers from accessing the underlying host's resources, such as the file system, devices, networking, and container runtime.
- **Networking** - You can use security groups and network ACLs to control inbound and outbound traffic. Fargate tasks receive an IP address from the configured subnet in your VPC.

## Fargate platform versions for Amazon ECS

AWS Fargate platform versions are used to refer to a specific runtime environment for Fargate task infrastructure. It is a combination of the kernel and container runtime versions. You select a platform version when you run a task or when you create a service to maintain a number of identical tasks.

New revisions of platform versions are released as the runtime environment evolves, for example, if there are kernel or operating system updates, new features, bug fixes, or security updates. A Fargate platform version is updated by making a new platform version revision. Each task runs on one platform version revision during its lifecycle. If you want to use the latest platform version revision, then you must start a new task. A new task that runs on Fargate always runs on the latest revision of a platform version, ensuring that tasks are always started on secure and patched infrastructure.

If a security issue is found that affects an existing platform version, AWS creates a new patched revision of the platform version and retires tasks running on the vulnerable revision. In some cases, you may be notified that your tasks on Fargate have been scheduled for retirement. For more information, see [Task retirement and maintenance for AWS Fargate on Amazon ECS](#).

You specify the platform version when you run a task, or deploy a service.

Consider the following when specifying a platform version:

- You can specify a specific version number, for example 1.4.0, or LATEST.

The **LATEST** Linux platform version is 1.4.0.

The **LATEST** Windows platform version is 1.0.0.

- If you want to update the platform version for a service, create a deployment. For example, assume that you have a service that runs tasks on the Linux platform version 1.3.0. To change the service to run tasks on the Linux platform version 1.4.0, you update your service and specify a new platform version. Your tasks are redeployed with the latest platform version and the latest platform version revision. For more information about deployments, see [Amazon ECS services](#).
- If your service is scaled up without updating the platform version, those tasks receive the platform version that was specified on the service's current deployment. For example, assume that you have a service that runs tasks on the Linux platform version 1.3.0. If you increase the desired count of the service, the service scheduler starts the new tasks using the latest platform version revision of platform version 1.3.0.
- New tasks always run on the latest revision of a platform version. This ensures tasks are always on secured and patched infrastructure.
- The platform version numbers for Linux containers and Windows containers on Fargate are independent. For example, the behavior, features, and software used in platform version 1.0.0 for Windows containers on Fargate aren't comparable to those of platform version 1.0.0 for Linux containers on Fargate.
- The following applies to Fargate Windows platform versions.

Microsoft Windows Server container images must be created from a specific version of Windows Server. You must select the same version of Windows Server in the `platformFamily` when you run a task or create a service that matches the Windows Server container image. Additionally, you can provide a matching `operatingSystemFamily` in the task definition to prevent tasks from being run on the wrong Windows version. For more information, see [Matching container host version with container image versions](#) on the Microsoft Learn website.

## Migrating to Linux platform version 1.4.0 on Amazon ECS

Consider the following when migrating your Amazon ECS on Fargate tasks from platform version 1.0.0, 1.1.0, 1.2.0, or 1.3.0 to platform version 1.4.0. It is best practice to confirm your task works properly on platform version 1.4.0 before you migrate the tasks.

- The network traffic behavior to and from tasks has been updated. Starting with platform version 1.4.0, all Amazon ECS on Fargate tasks receive a single elastic network interface (referred to as the task ENI) and all network traffic flows through that ENI within your VPC. The traffic is visible to you through your VPC flow logs. For more information see [Amazon ECS task networking options for Fargate](#).
- If you use interface VPC endpoints, consider the following.
  - For container images hosted with Amazon ECR, you need the following endpoints. For more information, see [Amazon ECR interface VPC endpoints \(AWS PrivateLink\)](#) in the *Amazon Elastic Container Registry User Guide*.
    - **com.amazonaws.*region*.ecr.dkr** Amazon ECR VPC endpoint
    - **com.amazonaws.*region*.ecr.api** Amazon ECR VPC endpoint
    - Amazon S3 gateway endpoint
  - When your task definition references Secrets Manager secrets to retrieve sensitive data for your containers, you must create the interface VPC endpoints for Secrets Manager. For more information, see [Using Secrets Manager with VPC Endpoints](#) in the *AWS Secrets Manager User Guide*.
  - When your task definition references Systems Manager Parameter Store parameters to retrieve sensitive data for your containers, you must create the interface VPC endpoints for Systems Manager. For more information, see [Improve the security of EC2 instances by using VPC endpoints for Systems Manager](#) in the *AWS Systems Manager User Guide*.
  - The security group for the Elastic Network Interface (ENI) associated with your task needs the security group rules to allow traffic between the task and the VPC endpoints.

## Fargate Linux platform version change log

The following are the available Linux platform versions. For information about platform version deprecation, see [AWS Fargate Linux platform version deprecation](#).

## 1.4.0

The following is the changelog for platform version 1.4.0.

- Beginning on November 5, 2020, any new Amazon ECS task launched on Fargate using platform version 1.4.0 will be able to use the following features:
  - When using Secrets Manager to store sensitive data, you can inject a specific JSON key or a specific version of a secret as an environment variable or in a log configuration. For more information, see [Pass sensitive data to an Amazon ECS container](#).
  - Specify environment variables in bulk using the `environmentFiles` container definition parameter. For more information, see [Pass an individual environment variable to an Amazon ECS container](#).
  - Tasks run in a VPC and subnet enabled for IPv6 will be assigned both a private IPv4 address and an IPv6 address. For more information, see [Amazon ECS task networking options for Fargate](#).
  - The task metadata endpoint version 4 provides additional metadata about your task and container including the task launch type, the Amazon Resource Name (ARN) of the container, and the log driver and log driver options used. When querying the `/stats` endpoint you also receive network rate stats for your containers. For more information, see [Task metadata endpoint version 4](#).
- Beginning on July 30, 2020, any new Amazon ECS task launched on Fargate using platform version 1.4.0 will be able to route UDP traffic using a Network Load Balancer to their Amazon ECS on Fargate tasks. For more information, see [Use load balancing to distribute Amazon ECS service traffic](#).
- Beginning on May 28, 2020, any new Amazon ECS task launched on Fargate using platform version 1.4.0 will have its ephemeral storage encrypted with an AES-256 encryption algorithm using an AWS owned encryption key. For more information, see [Fargate task ephemeral storage for Amazon ECS](#) and [Storage options for Amazon ECS tasks](#).
- Added support for using Amazon EFS file system volumes for persistent task storage. For more information, see [Use Amazon EFS volumes with Amazon ECS](#).
- The ephemeral task storage has been increased to a minimum of 20 GB for each task. For more information, see [Fargate task ephemeral storage for Amazon ECS](#).
- The network traffic behavior to and from tasks has been updated. Starting with platform version 1.4.0, all Fargate tasks receive a single elastic network interface (referred to as the task ENI) and all network traffic flows through that ENI within your VPC and will be visible to you through your

VPC flow logs. For more information about networking for the Amazon EC2 launch type, see [Amazon ECS task networking options for EC2](#). For more information about networking for the Fargate, see [Amazon ECS task networking options for Fargate](#).

- Task ENIs add support for jumbo frames. Network interfaces are configured with a maximum transmission unit (MTU), which is the size of the largest payload that fits within a single frame. The larger the MTU, the more application payload can fit within a single frame, which reduces per-frame overhead and increases efficiency. Supporting jumbo frames will reduce overhead when the network path between your task and the destination supports jumbo frames, such as all traffic that remains within your VPC.
- CloudWatch Container Insights will include network performance metrics for Fargate tasks. For more information, see [Monitor Amazon ECS containers using Container Insights with enhanced observability](#).
- Added support for the task metadata endpoint version 4 which provides additional information for your Fargate tasks, including network stats for the task and which Availability Zone the task is running in. For more information, see [Amazon ECS task metadata endpoint version 4](#) and [Amazon ECS task metadata endpoint version 4 for tasks on Fargate](#).
- Added support for the SYS\_PTRACE Linux parameter in container definitions. For more information, see [Linux parameters](#).
- The Fargate container agent replaces the use of the Amazon ECS container agent for all Fargate tasks. Usually, this change does not have an effect on how your tasks run.
- The container runtime is now using Containerd instead of Docker. Most likely, this change does not have an effect on how your tasks run. You will notice that some error messages that originate with the container runtime changes from mentioning Docker to more general errors. For more information, see [Amazon ECS stopped task error messages](#).
- Based on Amazon Linux 2.

## AWS Fargate Linux platform version deprecation

The following table lists Linux platform versions that AWS Fargate has deprecated or have been scheduled for deprecation. These platform versions remain available until the published deprecation date.

A *force update date* is provided for each platform version scheduled for deprecation. On the force update date, any service using the LATEST platform version that is pointed to a platform version that is scheduled for deprecation will be updated using the force new deployment option. When

the service is updated using the force new deployment option, all tasks running on a platform version scheduled for deprecation are stopped and new tasks are launched using the platform version that the LATEST tag points to at that time. Standalone tasks or services with an explicit platform version set are not affected by the force update date.

For information about how to migrate to latest platform version, see [Migrating to Linux platform version 1.4.0 on Amazon ECS](#).

After a platform version reaches the *deprecation date*, the platform version will no longer be available for new tasks or services. Any standalone tasks or services which explicitly use a deprecated platform version will continue using that platform version until the tasks are stopped. After the deprecation date, a deprecated platform version will no longer receive any security updates or bug fixes.

| Platform version | Force update date | Deprecation date  |
|------------------|-------------------|-------------------|
| 1.0.0            | October 26, 2020  | December 14, 2020 |
| 1.1.0            | October 26, 2020  | December 14, 2020 |
| 1.2.0            | October 26, 2020  | December 14, 2020 |
| 1.3.0            |                   | June 15, 2026     |

For information about current platform versions, see [Fargate platform versions for Amazon ECS](#).

## Deprecated Fargate Linux versions change log

### 1.3.0

The following is the changelog for platform version 1.3.0.

- Beginning on Sept 30, 2019, any new Fargate task that is launched supports the `awsfirelens` log driver. Configure the FireLens for Amazon ECS to use task definition parameters to route logs to an AWS service or AWS Partner Network (APN) destination for log storage and analytics. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).
- Added task recycling for Fargate tasks, which is the process of refreshing tasks that are a part of an Amazon ECS service. For more information, [Task retirement and maintenance for AWS Fargate on Amazon ECS](#).

- Beginning on March 27, 2019, any new Fargate task that is launched can use additional task definition parameters that you use to define a proxy configuration, dependencies for container startup and shutdown as well as a per-container start and stop timeout value. For more information, see [Proxy configuration](#), [Container dependency](#), and [Container timeouts](#).
- Beginning on April 2, 2019, any new Fargate task that is launched supports injecting sensitive data into your containers by storing your sensitive data in either AWS Secrets Manager secrets or AWS Systems Manager Parameter Store parameters and then referencing them in your container definition. For more information, see [Pass sensitive data to an Amazon ECS container](#).
- Beginning on May 1, 2019, any new Fargate task that is launched supports referencing sensitive data in the log configuration of a container using the `secretOptions` container definition parameter. For more information, see [Pass sensitive data to an Amazon ECS container](#).
- Beginning on May 1, 2019, any new Fargate task that is launched supports the `splunk` log driver in addition to the `awslogs` log driver. For more information, see [Storage and logging](#).
- Beginning on July 9, 2019, any new Fargate tasks that is launched supports CloudWatch Container Insights. For more information, see [Monitor Amazon ECS containers using Container Insights with enhanced observability](#).
- Beginning on December 3, 2019, the Fargate Spot capacity provider is supported. For more information, see [Amazon ECS clusters for Fargate](#).
- Based on Amazon Linux 2.

### 1.2.0

The following is the changelog for platform version 1.2.0.

#### Note

Platform version 1.2.0 is no longer available. For information about platform version deprecation, see [AWS Fargate Linux platform version deprecation](#).

- Added support for private registry authentication using AWS Secrets Manager. For more information, see [Using non-AWS container images in Amazon ECS](#).

### 1.1.0

The following is the changelog for platform version 1.1.0.

**Note**

Platform version 1.1.0 is no longer available. For information about platform version deprecation, see [AWS Fargate Linux platform version deprecation](#).

- Added support for the Amazon ECS task metadata endpoint. For more information, see [Amazon ECS task metadata available for tasks on Fargate](#).
- Added support for Docker health checks in container definitions. For more information, see [Health check](#).
- Added support for Amazon ECS service discovery. For more information, see [Use service discovery to connect Amazon ECS services with DNS names](#).

**1.0.0**

The following is the changelog for platform version 1.0.0.

**Note**

Platform version 1.0.0 is no longer available. For information about platform version deprecation, see [AWS Fargate Linux platform version deprecation](#).

- Based on Amazon Linux 2017.09.
- Initial release.

## Fargate Windows platform version change log

The following are the available platform versions for Windows containers.

**1.0.0**

The following is the changelog for platform version 1.0.0.

- Initial release for support on the following Microsoft Windows Server operating systems:
  - Windows Server 2019 Full

- Windows Server 2019 Core
- Windows Server 2022 Full
- Windows Server 2022 Core

## Windows containers on Fargate considerations for Amazon ECS

The following are the differences and considerations to know when you run Windows containers on AWS Fargate.

If you need to run tasks on Linux and Windows containers, then you need to create separate task definitions for each operating system.

AWS handles the operating system license management, so you do not need any additional Microsoft Windows Server licenses.

Windows containers on AWS Fargate supports the following operating systems:

- Windows Server 2019 Full
- Windows Server 2019 Core
- Windows Server 2022 Full
- Windows Server 2022 Core

Windows containers on AWS Fargate supports the awslogs driver. For more information, see [the section called “Send logs to CloudWatch”](#).

The following features are not supported on Windows containers on Fargate:

- Amazon FSx
- ENI trunking
- gMSAs for Windows Containers
- App Mesh service and proxy integration for tasks
- Firelens log router integration for tasks
- EFS volumes
- EBS volumes
- The following task definition parameters:

- `maxSwap`
- `swappiness`
- `environmentFiles`
- `ephemeralStorage`
- The Fargate Spot capacity provider
- Image volumes

The Dockerfile `volume` option is ignored. Instead, use bind mounts in your task definition. For more information, see [Use bind mounts with Amazon ECS](#).

- The task-level CPU and memory parameters are ignored for Windows containers. We recommend specifying container-level resources for Windows containers.
- `memory` for task
- `memoryReservation` on containers
- Restart policies on containers
- You can't update the `platformFamily` of a service.

## Linux containers on Fargate container image pull behavior for Amazon ECS

Every Fargate task runs on its own single use, single tenant instance. When you run Linux containers on Fargate, container images or container image layers are not cached on the instance. Therefore, for each container image defined in the task, the whole container image needs to be pulled from the container image registry for each Fargate task. The time it takes to pull the images is directly correlated to the time taken to start a Fargate task.

Take the following into account to optimize the image pull time.

### Container image proximity

To reduce the time it takes to download container images, locate the data as close to the compute as possible. Pulling a container image over the internet or across AWS Regions might impact the download time. We recommend that you store the container image in the same Region where the task will run. If you store the container image in Amazon ECR, use a VPC interface endpoint to further reduce the image pull time. For more information, see [Amazon ECR interface VPC endpoints \(AWS PrivateLink\)](#) in the *Amazon ECR User Guide*.

## Container image size reduction

The size of a container image directly impacts the download time. Reducing the size of the container image or the number of container image layers, can reduce the time it takes for an image to download. Lightweight base images (such as the minimal Amazon Linux 2023 container image) can be significantly smaller than those based on traditional operating system base images. For more information about the minimal image, see [AL2023 Minimal container image](#) in the *Amazon Linux 2023 User Guide*.

## Alternative compression algorithms

Container image layers are often compressed when pushed to a container image registry. Compressing the container image layer reduces the amount of data that has to be transferred across the network and stored in the container image registry. After a container image layer has been downloaded to an instance by the container runtime, that layer is decompressed. The compression algorithm used and the amount of vCPUs available to the runtime impact the time it takes to decompress the container image. On Fargate, you can increase the size of the task or leverage the more performant zstd compression algorithm to reduce the time taken for decompression. For more information, see [zstd](#) on GitHub. For information about how to implement the images for Fargate, see [Reducing AWS Fargate Startup Times with zstd Compressed Container Images](#).

## Lazy Loading container images

For large container images (> 250mb), it might be optimal to lazy load a container image rather than downloading all of the container image. On Fargate, you can use Seekable OCI (SOCI) to lazy load a container image from a container image registry. For more information, see [soci-snapshotter](#) on GitHub and [Lazy loading container images using Seekable OCI \(SOCI\)](#).

# Windows containers on Fargate container image pull behavior for Amazon ECS

Fargate Windows caches the most recent month's, and the previous month's, servercore base image provided by Microsoft. These images match the KB/Build number patches updated each Patch Tuesday. For example, on April 9, 2024, Microsoft released KB5036896 (17763.5696) for Windows Server 2019. The previous month KB on March 12, 2024 was KB5035849 (17763.5576). So for the platforms `WINDOWS_SERVER_2019_CORE` and `WINDOWS_SERVER_2019_FULL` the following container images were cached::

- `mcr.microsoft.com/windows/servercore:ltsc2019`
- `mcr.microsoft.com/windows/servercore:10.0.17763.5696`
- `mcr.microsoft.com/windows/servercore:10.0.17763.5576`

Additionally, on April 9, 2024, Microsoft released KB5036909 (20348.2402) for Windows Server 2022. The previous month KB on March 12, 2024 was KB5035857 (20348.2340). So for the platforms `WINDOWS_SERVER_2022_CORE` and `WINDOWS_SERVER_2022_FULL` the following container images were cached:

- `mcr.microsoft.com/windows/servercore:ltsc2022`
- `mcr.microsoft.com/windows/servercore:10.0.20348.2402`
- `mcr.microsoft.com/windows/servercore:10.0.20348.2340`

## Fargate task ephemeral storage for Amazon ECS

When provisioned, each Amazon ECS task hosted on Linux containers on AWS Fargate receives the following ephemeral storage for bind mounts. This can be mounted and shared among containers that use the `volumes`, `mountPoints`, and `volumesFrom` parameters in the task definition. This isn't supported for Windows containers on AWS Fargate.

### Fargate Linux container platform versions

#### Version 1.4.0 or later

By default, Amazon ECS tasks that are hosted on Fargate using platform version `1.4.0` or later receive a minimum of 20 GiB of ephemeral storage. The total amount of ephemeral storage can be increased, up to a maximum of 200 GiB. You can do this by specifying the `ephemeralStorage` parameter in your task definition.

The pulled, compressed, and the uncompressed container image for the task is stored on the ephemeral storage. To determine the total amount of ephemeral storage your task has to use, you must subtract the amount of storage your container image uses from the total amount of ephemeral storage your task is allocated.

For tasks that use platform version `1.4.0` or later that are launched on May 28, 2020 or later, the ephemeral storage is encrypted with an AES-256 encryption algorithm. This algorithm uses

an AWS owned encryption key, or you can create your own customer managed key. For more information, see [Customer managed keys for AWS Fargate ephemeral storage](#).

For tasks that use platform version 1.4.0 or later that are launched on November 18, 2022 or later, the ephemeral storage usage is reported through the task metadata endpoint. Your applications in your tasks can query the task metadata endpoint version 4 to get their ephemeral storage reserved size and the amount used.

Additionally, the ephemeral storage reserved size and the amount used are sent to Amazon CloudWatch Container Insights if you turn on Container Insights.

 **Note**

Fargate reserves space on disk. It is only used by Fargate. You aren't billed for it. It isn't shown in these metrics. However, you can see this additional storage in other tools such as `df`.

## Version 1.3.0 or earlier

For Amazon ECS on Fargate tasks that use platform version 1.3.0 or earlier, each task receives the following ephemeral storage.

- 10 GB of Docker layer storage

 **Note**

This amount includes both compressed and uncompressed container image artifacts.

- An additional 4 GB for volume mounts. This can be mounted and shared among containers that use the `volumes`, `mountPoints`, and `volumesFrom` parameters in the task definition.

## Customer managed keys for AWS Fargate ephemeral storage for Amazon ECS

AWS Fargate supports customer managed keys to encrypt data for Amazon ECS tasks stored in ephemeral storage to help regulation-sensitive customers meet their internal security policies. Customers still get the serverless benefit of Fargate, while giving enhanced visibility on self-managed storage encryption to compliance auditors. While Fargate has Fargate-managed

ephemeral storage encryption by default, customers can also use their own self-managed keys when encrypting sensitive data like financial or health related information.

You can import your own keys into AWS KMS or create the keys in AWS KMS. These self-managed keys are stored in AWS KMS and perform standard AWS KMS lifecycle actions such as rotate, disable, and delete. You can audit key access and usage in CloudTrail logs.

By default, KMS key supports 50,000 grants per key. Fargate uses a single AWS KMS grant per customer managed key task, so it supports up to 50,000 concurrent tasks for a key. If you want to increase this number, you can ask for a limit increase, which is approved on a case-by-case basis.

Fargate doesn't charge anything extra for using customer managed keys. You're only charged the standard price for using AWS KMS keys for storage and API requests.

## Topics

- [Create an encryption key for Fargate ephemeral storage for Amazon ECS](#)
- [Managing AWS KMS keys for Fargate ephemeral storage for Amazon ECS](#)

## Create an encryption key for Fargate ephemeral storage for Amazon ECS

Create a customer managed key to encrypt data stored on Fargate ephemeral storage.

### Note

Fargate ephemeral storage encryption with customer managed keys isn't available for Windows task clusters.

Fargate ephemeral storage encryption with customer managed keys isn't available on platformVersions earlier than 1.4.0.

Fargate reserves space on an ephemeral storage that's only used by Fargate, and you're not billed for the space. Allocation might differ from non-customer managed key tasks, but the total space remains the same. You can view this change in tools like `df`.

Multi-Region keys are not supported for Fargate ephemeral storage.

KMS key aliases are not supported for Fargate ephemeral storage.

To create a customer managed key (CMK) to encrypt ephemeral storage for Fargate in AWS KMS, follow these steps.

1. Navigate to the <https://console.aws.amazon.com/kms>.

2. Follow the instructions for [Creating Keys](#) in the [AWS Key Management Service Developer Guide](#).
3. When creating your AWS KMS key, make sure to provide Fargate service relevant AWS KMS operation permissions in the key policies. The following API operations must be permitted in the policy to use your customer managed key with your Amazon ECS cluster resources.
  - `kms:GenerateDataKeyWithoutPlainText` - Call `GenerateDataKeyWithoutPlainText` to generate an encrypted data key from the provided AWS KMS key.
  - `kms:CreateGrant` - Adds a grant to a customer managed key. Grants control access to a specified AWS KMS key, which allows access to grant operations that Amazon ECS Fargate requires. For more information about [Using Grants](#), see the [AWS Key Management Service Developer Guide](#). This allows Amazon ECS Fargate to do the following:
    - Call `Decrypt` to AWS KMS to get the encryption key to decrypt the ephemeral storage data.
    - Set up a retiring principal to allow the service to `RetireGrant`.
  - `kms:DescribeKey` - Provides the customer managed key details to allow Amazon ECS to validate the key if it's symmetric and enabled.

The following example shows a AWS KMS key policy that you would apply to the target key for encryption. To use the example policy statements, replace the *user input placeholders* with your own information. As always, only configure the permissions that you need, but you'll need to provide AWS KMS with permissions to at least one user to avoid errors.

```
{
  "Sid": "Allow generate data key access for Fargate tasks.",
  "Effect": "Allow",
  "Principal": { "Service": "fargate.amazonaws.com" },
  "Action": [
    "kms:GenerateDataKeyWithoutPlaintext"
  ],
  "Condition": {
    "StringEquals": {
      "kms:EncryptionContext:aws:ecs:clusterAccount": [
        "customerAccountId"
      ],
      "kms:EncryptionContext:aws:ecs:clusterName": [
        "clusterName"
      ]
    }
  }
}
```

```

        ]
      }
    },
    "Resource": "*"
  },
  {
    "Sid": "Allow grant creation permission for Fargate tasks.",
    "Effect": "Allow",
    "Principal": { "Service": "fargate.amazonaws.com" },
    "Action": [
      "kms:CreateGrant"
    ],
    "Condition": {
      "StringEquals": {
        "kms:EncryptionContext:aws:ecs:clusterAccount": [
          "customerAccountId"
        ],
        "kms:EncryptionContext:aws:ecs:clusterName": [
          "clusterName"
        ]
      }
    },
    "ForAllValues:StringEquals": {
      "kms:GrantOperations": [
        "Decrypt"
      ]
    }
  },
  {
    "Resource": "*"
  },
  {
    "Sid": "Allow describe key permission for cluster operator - CreateCluster and UpdateCluster.",
    "Effect": "Allow",
    "Principal": { "AWS": "arn:aws:iam::customerAccountId:role/customer-chosen-role" },
    "Action": [
      "kms:DescribeKey"
    ],
    "Resource": "*"
  }
}

```

Fargate tasks use the `aws:ecs:clusterAccount` and `aws:ecs:clusterName` encryption context keys for cryptographic operations with the key. Customers should add these

permissions to restrict access to a specific account and/or cluster. Use the cluster name and not the ARN when you specify the cluster.

For more information, see [Encryption context](#) in the [AWS KMS Developer Guide](#).

When creating or updating a cluster, you have the option to use the condition key `fargateEphemeralStorageKmsKeyId`. This condition key allows customers to have more granular control of the IAM policies. Updates to the `fargateEphemeralStorageKmsKeyId` configuration only take effect on new service deployments.

The following is an example of allowing customers to grant permissions to only a specific set of approved AWS KMS keys.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:CreateCluster",
        "ecs:UpdateCluster"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "ecs:fargate-ephemeral-storage-kms-key": "a1b2c3d4-5678-90ab-cdef-  
EXAMPLE11111"
        }
      }
    }
  ]
}
```

Next is an example for denying attempts to remove AWS KMS keys that are already associated with a cluster.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": [
      "ecs:CreateCluster",
      "ecs:UpdateCluster"
    ],
    "Resource": "*",
    "Condition": {
      "Null": {
        "ecs:fargate-ephemeral-storage-kms-key": "true"
      }
    }
  }
}
```

Customers can see if their unmanaged tasks or service tasks are encrypted using the key by using the AWS CLI `describe-tasks`, `describe-cluster`, or `describe-services` commands.

For more information, see [Condition keys for AWS KMS](#) in the [AWS KMS Developer Guide](#).

### AWS Management Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. Choose **Clusters** in the navigation pane and either **Create cluster**, or choose an existing cluster. For an existing cluster, choose **Update cluster**.
3. Under the **Encryption** section of the workflow, you'll have the option to select your AWS KMS key under **Managed storage** and **Fargate ephemeral storage**. You can also choose to **Create an AWS KMS key** from here.
4. Choose **Create** once you finish creating your new cluster or **Update**, if you were updating an existing one.

## AWS CLI

The following is an example of creating a cluster and configuring your Fargate ephemeral storage using the AWS CLI (replace the *red* values with your own):

```
aws ecs create-cluster --cluster clusterName \
--configuration '{"managedStorageConfiguration":
{"fargateEphemeralStorageKmsKeyId":"arn:aws:kms:us-
west-2:012345678901:key/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"}}'
{
  "cluster": {
    "clusterArn": "arn:aws:ecs:us-west-2:012345678901:cluster/clusterName",
    "clusterName": "clusterName",
    "configuration": {
      "managedStorageConfiguration": {
        "fargateEphemeralStorageKmsKeyId": "arn:aws:kms:us-
west-2:012345678901:key/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
      }
    },
    "status": "ACTIVE",
    "registeredContainerInstancesCount": 0,
    "runningTasksCount": 0,
    "pendingTasksCount": 0,
    "activeServicesCount": 0,
    "statistics": [],
    "tags": [],
    "settings": [],
    "capacityProviders": [],
    "defaultCapacityProviderStrategy": []
  },
  "clusterCount": 5
}
```

## CloudFormation

The following is an example template of creating a cluster and configuring your Fargate ephemeral storage using the CloudFormation (replace the *red* values with your own):

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  MyCluster:
    Type: AWS::ECS::Cluster
    Properties:
```

```
ClusterName: "clusterName"
Configuration:
  ManagedStorageConfiguration:
    FargateEphemeralStorageKmsKeyId: "arn:aws:kms:us-west-2:012345678901:key/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
```

## Managing AWS KMS keys for Fargate ephemeral storage for Amazon ECS

After creating or importing your AWS KMS key to encrypt your Fargate ephemeral storage, you manage it the same way you would any other AWS KMS key.

### Automatic rotation of AWS KMS keys

You can enable automatic key rotation or rotate them manually. Automatic key rotation rotates the key for you yearly by generating new cryptographic material for the key. AWS KMS also saves all previous versions of the cryptographic material, so you'll be able to decrypt any data that used the earlier key versions. Any rotated material won't be deleted by AWS KMS until you delete the key.

Automatic key rotation is optional and can be enabled or disabled at any time.

### Disabling or revoking AWS KMS keys

If you disable a customer managed key in AWS KMS, it doesn't have any impact on running tasks, and they continue to function through their lifecycle. If a new task uses the disabled or revoked key, the task fails since it can't access the key. You should set a CloudWatch alarm or similar to make sure a disabled key is never needed to decrypt already encrypted data.

### Deleting AWS KMS keys

Deleting keys should always be a last resort and should only be done if you're certain the deleted key is never needed again. New tasks that try to use the deleted key will fail because they can't access it. AWS KMS advises disabling a key instead of deleting it. If you feel it's necessary to delete a key, we suggest disabling it first and setting a CloudWatch alarm to make sure it isn't needed. If you do delete a key, AWS KMS supplies at least seven days to change your mind.

### Auditing AWS KMS key access

You can use CloudTrail logs to audit access to your AWS KMS key. You're able to check the AWS KMS operations `CreateGrant`, `GenerateDataKeyWithoutPlaintext`, and `Decrypt`. These

operations also show the `aws:ecs:clusterAccount` and `aws:ecs:clusterName` as part of the `EncryptionContext` logged in CloudTrail.

The following are example CloudTrail events for `GenerateDataKeyWithoutPlaintext`, `GenerateDataKeyWithoutPlaintext (DryRun)`, `CreateGrant`, `CreateGrant (DryRun)`, and `RetireGrant` (replace the *red* values with your own).

#### GenerateDataKeyWithoutPlaintext

```
{
  "eventVersion": "1.08",
  "userIdentity": {
    "type": "AWSService",
    "invokedBy": "ec2-frontend-api.amazonaws.com"
  },
  "eventTime": "2024-04-23T18:08:13Z",
  "eventSource": "kms.amazonaws.com",
  "eventName": "GenerateDataKeyWithoutPlaintext",
  "awsRegion": "us-west-2",
  "sourceIPAddress": "ec2-frontend-api.amazonaws.com",
  "userAgent": "ec2-frontend-api.amazonaws.com",
  "requestParameters": {
    "numberOfBytes": 64,
    "keyId": "arn:aws:kms:us-west-2:account-id:key/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "encryptionContext": {
      "aws:ecs:clusterAccount": "account-id",
      "aws:ebs:id": "vol-xxxxxxx",
      "aws:ecs:clusterName": "cluster-name"
    }
  },
  "responseElements": null,
  "requestID": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
  "eventID": "a1b2c3d4-5678-90ab-cdef-EXAMPLE33333",
  "readOnly": true,
  "resources": [
    {
      "accountId": "AWS Internal",
      "type": "AWS::KMS::Key",
      "ARN": "arn:aws:kms:us-west-2:account-id:key/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
    }
  ],
}
```

```

    "eventType": "AwsApiCall",

## Task retirement and maintenance for AWS Fargate on Amazon ECS

AWS is responsible for maintaining the underlying infrastructure for AWS Fargate. AWS determines when a platform version revision needs to be replaced with a new revision for the infrastructure. This is known as task retirement. AWS sends a task retirement notification when a platform version revision is retired. We routinely update our supported platform versions to introduce a new revision containing updates to the Fargate runtime software and underlying dependencies such as the operating system and container runtime. After a newer revision is made available, we retire the older revision in order to ensure all customer workloads run on the most up to date revision of the Fargate platform version. When a revision is retired, all tasks running on that revision are stopped.

Amazon ECS tasks can be categorized as either service tasks or standalone tasks. Service tasks are deployed as part of a service and controlled by the Amazon ECS scheduler. For more information, see [Amazon ECS services](#). Standalone tasks are tasks started by the Amazon ECS RunTask API, either directly or by an external scheduler such as scheduled tasks (which are started by Amazon EventBridge), AWS Batch, or AWS Step Functions. You do not need to take any actions in response to task retirement for your service tasks because the Amazon ECS scheduler automatically replaces the tasks.

For standalone tasks, you may need to perform additional handling in response to task retirement. For more information, see [Can Amazon ECS automatically handle standalone tasks?](#).

For service tasks, you do not need to take any action to task retirement unless you want to replace these tasks before AWS does. When the Amazon ECS scheduler stops the tasks, it uses the `maximumPercent` and launches a new task in an attempt to maintain the desired count for the service. Follow best practices to minimize the impact of task retirement. The default `maximumPercent` value for a service using the REPLICA service scheduler is 200%. Therefore, when AWS Fargate starts retiring tasks, Amazon ECS first schedules a new task, and then waits for it to be running, before retiring an old task. When you set the `maximumPercent` value to 100%, Amazon ECS stops the task first, then replaces it.

For standalone task retirement, AWS stops the task on or after the task retirement date. Amazon ECS doesn't launch a replacement task when a task is stopped. If you need these tasks to continue to run, you need to stop the running tasks and launch a replacement task before the time indicated in the notification. Therefore, we recommend that customers monitor the state of standalone tasks and if required, implement logic to replace the stopped tasks.

When a task is stopped in any of the scenarios, you can run `describe-tasks`. The `stoppedReason` in the response is `ECS is performing maintenance on the underlying infrastructure hosting the task`.

Task maintenance applies when there is a new platform version revision needs to be replaced with a new revision. If there is an issue with an underlying Fargate host, Amazon ECS replaces the host without a task retirement notice.

## Task retirement notice overview

When AWS marks a platform version revision as needing to be retired, we identify all of the tasks that are running on that platform version revision in all Regions.

The following illustration shows the lifecycle of a Fargate platform version revision from a new revision launch to the platform revision retirement.

The following information provides details.

- After a new platform version revision is launched, all new tasks are scheduled on this revision.
- Existing tasks that have been scheduled and running remain on the revision they were originally placed on for the duration of the task and aren't migrated to the new revision.
- New tasks, for example as part of an update to a service or Fargate task retirement, are placed on to latest platform version revision available at the time of launch.

Task retirement notifications are sent through AWS Health Dashboard as well as through an email to the registered email address and includes the following information:

- The task retirement date - The task is stopped on or after this date.
- For standalone tasks, the IDs of the tasks.
- For service tasks, the ID of the cluster where the service runs and the IDs of the service.
- The next steps you need to take.

Typically, we send one notification each for service and standalone tasks in each AWS Region. However, in certain cases you might receive more than one event for each task type, for example when there are too many tasks to be retired that will surpass limits in our notification mechanisms.

You can identify tasks scheduled for retirement in the following ways:

- The Health Dashboard

AWS Health notifications can be sent through Amazon EventBridge to archival storage such as Amazon Simple Storage Service, take automated actions such as run an AWS Lambda function, or other notification systems such as Amazon Simple Notification Service. For more information, see [Monitoring AWS Health events with Amazon EventBridge](#). For sample configuration to send notifications to Amazon Chime, Slack, or Microsoft Teams, see the [AWS Health Aware](#) repository on GitHub.

The following is a sample EventBridge event.

      "eventDescription": [
        {
          "language": "en_US",
          "latestDescription": "\\nA software update has been deployed to
Fargate which includes CVE patches or other critical patches. No action is required
on your part. All new tasks launched automatically uses the latest software
version. For existing tasks, your tasks need to be restarted in order for these
updates to apply. Your tasks running as part of the following ECS Services will
be automatically updated beginning Wed, 16 Aug 2023 23:18:51 GMT.\\n\\nAfter Wed,
16 Aug 2023 23:18:51 GMT, the ECS scheduler will gradually replace these tasks,
respecting the deployment settings for your service. Typically, services should
see little to no interruption during the update and no action is required. When AWS
stops tasks, AWS uses the minimum healthy percent (1) and launches a new task in
an attempt to maintain the desired count for the service. By default, the minimum
healthy percent of a service is 100 percent, so a new task is started first before
a task is stopped. Service tasks are routinely replaced in the same way when
you scale the service or deploy configuration changes or deploy task definition
revisions. If you would like to control the timing of this restart you can update
the service before Wed, 16 Aug 2023 23:18:51 GMT, by running the update-service
command from the ECS command-line interface specifying force-new-deployment for
services using Rolling update deployment type. For example:\\n\\n$ aws ecs update-
service -service service_name \\n--cluster cluster_name -force-new-deployment\\
\\n\\nFor services using Blue/Green deployment type with AWS CodeDeploy:\\nPlease
refer to create-deployment document (2) and create new deployment using same task
definition revision.\\n\\nFor further details on ECS deployment types, please
refer to ECS Deployment Developer Guide (1).\\nFor further details on Fargate's
update process, please refer to the AWS Fargate User Guide (3).\\nIf you have
any questions or concerns, please contact AWS Support (4).\\n\\n(1) https://
docs.aws.amazon.com/AmazonECS/latest/developerguide/deployment-types.html\\n(2)
https://docs.aws.amazon.com/cli/latest/reference/deploy/create-deployment.html\\n(3)
https://docs.aws.amazon.com/AmazonECS/latest/userguide/task-maintenance.html\\n(4)
https://aws.amazon.com/support\\n\\nA list of your affected resources(s) can be
found in the 'Affected resources' tab in the 'Cluster/ Service' format in the AWS
Health Dashboard. \\n\\n"
        }

      }
    ]
  }
}
```

- Email

An email is sent to the registered email for the AWS account ID.

For information about how to prepare for task retirement, see [Prepare for AWS Fargate task retirement on Amazon ECS](#).

## Affected resource status in a task retirement notice

Each affected resource listed in a task retirement notice has a status that reflects whether that task is still waiting to be retired. While a task's retirement is pending, its status is *Impaired*. This indicates that the task is still running on the platform version revision that is scheduled for retirement.

After a task stops running, the status changes to *Resolved* automatically, typically within 24 hours. This applies whether AWS retired the task as part of task maintenance, or you stopped or replaced the task yourself before the scheduled retirement. After all of the affected resources in a notice are *Resolved*, AWS closes the retirement notice.

## Can I opt-out of task retirement?

No. As part of the AWS shared responsibility model, AWS is responsible for managing and maintaining the underlying infrastructure for AWS Fargate. This includes performing periodic platform updates to ensure security and stability. These updates are automatically applied by AWS and are not something customers can opt-out of. This is a key benefit of using a AWS Fargate compared to running your workloads on EC2 instances, the responsibility for maintaining the

underlying platform is handled by AWS. This model allows you to focus on your applications rather than infrastructure maintenance. By automatically applying these platform updates, AWS is able to keep the Fargate environment up-to-date and secure, without any action required from you as the customer. This helps provide a reliable and secure containerized environment for running your workloads on Fargate.

## Can I get task retirement notifications through other AWS services?

AWS sends a task retirement notification to the Health Dashboard and to the primary email contact on the AWS account. The Health Dashboard provides a number of integrations into other AWS services, including EventBridge. You can use EventBridge to automate the visibility of the notices (For example, forwarding the message to a ChatOps tool). For more information, see [Solution overview: Capturing task retirement notifications](#).

## Can I change a task retirement after it is scheduled?

No. The schedule is based on the task retirement wait time which has a default of 7 days. If you need more time, you can choose to configure the wait period to 14 days. For more information, see [Step 2: Capture task retirement notifications to alert teams and take actions](#).

As of 12/18/2025, Amazon ECS enables you to configure [Amazon EC2 event windows](#) for your Fargate tasks. If you need precise control over the exact timing of task retirements, for example, scheduling them over weekends to avoid disruption during business hours, you can configure Amazon EC2 event windows for your tasks, services, or clusters, see [Step 1: Set the task wait time or use Amazon EC2 event windows](#). Note that the change in this configuration applies to retirements that will be scheduled in the future. Currently scheduled retirements are not impacted. Furthermore, when you configure an Amazon EC2 event window for your Fargate tasks, it takes precedence over your task retirement wait time configuration. If you have any further concerns, contact Support.

## How does Amazon ECS handle tasks that are part of a service?

For service tasks, you do not need to take any action in response to task retirement unless you want to replace these tasks before AWS does. When the Amazon ECS scheduler stops the tasks, it uses the minimum healthy percent and launches a new task in an attempt to maintain the desired count for the service. To minimize the impact of Fargate task retirement, workloads should be deployed following Amazon ECS best practices. For example, when deploying a stateless application as an Amazon ECS service, such as a web or API server, customers should deploy

multiple task replicas and set the `minimumHealthyPercent` to 100%. By default, the minimum healthy percent of a service is 100 percent. Therefore, when Fargate starts retiring tasks, Amazon ECS first schedules a new task and waits for it to be running, before retiring an old task. Service tasks are routinely replaced as part of task retirement in the same way when you scale the service, deploy configuration changes, or deploy task definition revisions. To prepare for the task retirement process, see [Prepare for AWS Fargate task retirement on Amazon ECS](#).

## Can Amazon ECS automatically handle standalone tasks?

No. AWS can't create a replacement task for standalone tasks which are started by `RunTask`, scheduled tasks (for example through EventBridge Scheduler), AWS Batch, or AWS Step Functions. Amazon ECS manages only tasks that are part of a service.

## Troubleshooting service availability during task retirement

If Amazon ECS cannot start a replacement task during task retirement, your service availability may be impacted. This can occur due to incorrect customer configuration, such as:

- Missing or incorrectly configured IAM roles
- Insufficient capacity in the target subnets
- Security group misconfigurations
- Task definition errors

When Amazon ECS cannot launch replacement tasks, the retired tasks are stopped without replacement, reducing your service's available capacity and potentially causing service disruption. Monitor your service's task count and Amazon CloudWatch metrics to ensure replacement tasks are successfully launched during retirement events.

## Prepare for AWS Fargate task retirement on Amazon ECS

In order to prepare for task retirement, perform the following operations:

1. Set the task retirement wait period or use Amazon EC2 event windows.
2. Capture task retirement notifications to notify team members.
3. You can ensure all your services' tasks run on the latest platform revision by updating the service with the force-deployment option. This step is optional.

## Step 1: Set the task wait time or use Amazon EC2 event windows

You have two account settings options to configure the time that Fargate starts task retirements: `fargateTaskRetirementWaitPeriod` and `fargateEventWindows`.

### Using `fargateTaskRetirementWaitPeriod` account setting

You can configure the time that Fargate starts the task retirement. The default wait period is 7 days. For workloads that require immediate application of the updates, choose the immediate setting (0). If you need more time, configure the 7, or 14 day option.

We recommend that you choose a shorter waiting period in order to pick up newer platform versions revisions sooner.

Configure the wait period by running `put-account-setting-default` or `put-account-setting` as the root user or an administrative user. Use the `fargateTaskRetirementWaitPeriod` option for the name and the value option set to one of the following values:

- 0 - AWS sends the notification, and immediately starts to retire the affected tasks.
- 7 - AWS sends the notification, and waits 7 calendar days before starting to retire the affected tasks. This is the default.
- 14 - AWS sends the notification, and waits 14 calendar days before starting to retire the affected tasks.

For more information, see, [put-account-setting-default](#) and [put-account-setting](#) in the *Amazon Elastic Container Service API Reference*.

### Using `fargateEventWindows` account setting

As of 12/18/2025, Amazon ECS enables you to configure [Amazon EC2 event windows](#) for your Fargate tasks. If you need precise control over the exact timing of task retirements, for example, scheduling them over weekends to avoid disruption during business hours, you can configure Amazon EC2 event windows for your tasks, services, or clusters.

When you use event windows, Fargate ensures that your tasks run for at least 3 days before they are retired within the next available window, unless stopped by user-initiated actions or critical health events such as degradation of the underlying hardware.

Set the `fargateEventWindows` account setting to enabled. You can use one of the following APIs: `put-account-setting-default` or `put-account-setting` as the root user or an administrative user.

Each Amazon EC2 event window must be open for at least 4 hours per week, and each time range must be at least 2 hours long. For large clusters and services we recommend configuring event windows with either long durations (8 hours or more) or more frequent time ranges that occur at least once every 3 days. You can further review considerations for Amazon EC2 event windows in the [user guide](#). AWS Fargate ensures that your tasks run for at least 3 days before they are retired, unless stopped by user-initiated actions or critical health events such as degradation of the underlying hardware.

**⚠ Important**

Replacement of tasks within event window is best effort. If you notice tasks being retired outside of your event windows, consider expanding the duration (8 hours or more) or increasing frequency (at least once every 3 days).

To apply Amazon EC2 event windows to your Fargate task retirements:

- Set the `fargateEventWindows` account setting to enabled. You can use one of the following APIs: `put-account-setting-default` or `put-account-setting` as the root user or an administrative user. Note that this is a one-time enablement for usage of the Amazon EC2 event windows feature for your Fargate tasks.
- Create an Amazon EC2 event window through the AWS console or the AWS CLI. To create an event window using CLI, use EC2 `create-instance-event-window` API with time ranges or cron expressions. Take note of the `InstanceEventWindowId` from the response.

```
aws ec2 create-instance-event-window \
    --time-range
    StartWeekDay=monday,StartHour=2,EndWeekDay=wednesday,EndHour=8 \
    --tag-specifications "ResourceType=instance-event-
window,Tags=[{Key=K1,Value=V1" \
    --name myEventWindowName
```

Alternatively, you can use cron expressions when creating EC2 event windows.

```
aws ec2 create-instance-event-window \
```

```
--cron-expression "* 21-23 * * 2,3" \  
--tag-specifications "ResourceType=instance-event-  
window,Tags=[{Key=K1,Value=V1" \  
--name myEventWindowName
```

- You can then associate the event window with specific services, clusters or all tasks in your account using EC2 `associate-instance-event-window` API.
- For ECS service tasks

```
aws ec2 associate-instance-event-window \  
--instance-event-window-id iew-0abcdef1234567890 \  
--association-target "InstanceTags=[{Key=aws:ecs:serviceArn,Value=your-service-  
arn}]"
```

- For ECS clusters

```
aws ec2 associate-instance-event-window \  
--instance-event-window-id iew-0abcdef1234567890 \  
--association-target "InstanceTags=[{Key=aws:ecs:clusterArn,Value=your-cluster-  
arn}]"
```

- To associate an event window with all tasks in the account

```
aws ec2 associate-instance-event-window \  
--instance-event-window-id iew-0abcdef1234567890 \  
--association-target "InstanceTags=[{Key=aws:ecs:fargateTask,Value=true}]"
```

You can use more than one key-value pair to associate an event window with multiple services or clusters.

Fargate will choose the event window for each task in the following order:

- If there is an event window associated with the task's service, it will be used. This is not applicable for standalone or unmanaged tasks.
- If there is an event window associated with the task's cluster, it will be used.
- If there is an event window set for all Fargate tasks, it will be used.

- The `fargateTaskRetirementWaitPeriod` setting will be used if none of the event windows match with the task.

## Configuring event windows for Fargate task maintenance

Consider a case when you are running multiple ECS services on Fargate with different availability requirements. You want precise control over task retirements. You can configure multiple event windows as follows:

- **Default maintenance for all Fargate tasks:** Create an event window for routine maintenance during off-peak hours (12AM to 4AM daily) and associate it with all Fargate tasks using the `aws:ecs:fargateTask` tag.
- **Weekend-only maintenance for development cluster:** For a development cluster with services that can tolerate disruption on weekends, create a 24-hour weekend window (Saturday and Sunday, all day) and associate it with the cluster using the `aws:ecs:clusterArn` tag with your cluster ARN.
- **Restricted window for mission-critical service:** For a mission-critical payment processing service that requires high uptime during weekdays, restrict maintenance to weekend early morning hours (Saturday and Sunday, 12AM to 4AM) and associate it with the specific service using the `aws:ecs:serviceArn` tag with your service ARN.

With this configuration, the payment service uses its specific weekend-only window, the development cluster services and tasks use the weekend 24-hour window, and all other Fargate tasks use the default daily maintenance window.

For more information, see, [put-account-setting-default](#) and [put-account-setting](#) in the *Amazon Elastic Container Service API Reference*.

## Step 2: Capture task retirement notifications to alert teams and take actions

When there is an upcoming task retirement, AWS sends a task retirement notification to the AWS Health Dashboard, and to the primary email contact on the AWS account. The AWS Health Dashboard provides a number of integrations into other AWS services, including Amazon EventBridge. You can use EventBridge to build automations from a task retirement notification, such as increasing the visibility of the upcoming retirement by forwarding the message to a ChatOps tool. AWS Health Aware is a resource that shows the power of the AWS Health Dashboard

and how notifications can be distributed throughout an organization. You can forward a task retirement notification to a chat application, such as Slack.

The following illustration shows the solution overview.

The following information provides details.

- Fargate sends the task retirement notification to the AWS Health Dashboard.
- The AWS Health Dashboard sends mail to the primary email contact on the AWS account, and notifies EventBridge.
- EventBridge has a rule that captures the retirement notification.

The rule looking for events with the Event Detail Type: "AWS Health Event" and the Event Detail Type Code: "AWS\_ECS\_TASK\_PATCHING\_RETIREMENT"

- The rule triggers a Lambda function that forwards the information to Slack using a Slack Incoming Webhook. For more information, see [Incoming Webhooks](#).

For a code example, see [Capturing AWS Fargate Task Retirement Notifications](#) on Github.

### Step 3: Control the replacement of tasks

You can't control the exact timing of a task retirement, however, you can define a wait time. If you want control over replacing tasks at your own schedule, you can capture the task retirement notice to first understand the task retirement date. You can then redeploy your service to launch replacement tasks, and likewise replace any standalone tasks. For services that use rolling

deployment, you update the service using `update-service` with the `force-deployment` option before the retirement start time.

The following `update-service` example uses the `force-deployment` option.

```
aws ecs update-service --service service_name \  
  --cluster cluster_name \  
  --force-new-deployment
```

For services that use the blue/green deployment, you need to create a new deployment in AWS CodeDeploy. For information about how to create the deployment, see [create-deployment](#) in the *AWS Command Line Interface Reference*.

## Supported Regions for Amazon ECS on AWS Fargate

You can use the following tables to verify the Region support for Linux containers on AWS Fargate and Windows containers on AWS Fargate.

### Linux containers on AWS Fargate

Amazon ECS Linux containers on AWS Fargate are supported in the following AWS Regions. The supported Availability Zone IDs are noted when applicable.

| Region Name             | Region                               |
|-------------------------|--------------------------------------|
| US East (Ohio)          | us-east-2                            |
| US East (N. Virginia)   | us-east-1                            |
| US West (N. California) | us-west-1 (usw1-az1 & usw1-az3 only) |
| US West (Oregon)        | us-west-2                            |
| Canada (Central)        | ca-central-1                         |
| Canada West (Calgary)   | ca-west-1                            |
| Mexico (Central)        | mx-central-1                         |
| Africa (Cape Town)      | af-south-1                           |

| Region Name              | Region                                                    |
|--------------------------|-----------------------------------------------------------|
| Asia Pacific (Hong Kong) | ap-east-1                                                 |
| Asia Pacific (Mumbai)    | ap-south-1                                                |
| Asia Pacific (Tokyo)     | ap-northeast-1 (apne1-az1 , apne1-az2 , & apne1-az4 only) |
| Asia Pacific (Seoul)     | ap-northeast-2                                            |
| Asia Pacific (Osaka)     | ap-northeast-3                                            |
| Asia Pacific (Hyderabad) | ap-south-2                                                |
| Asia Pacific (Singapore) | ap-southeast-1                                            |
| Asia Pacific (Sydney)    | ap-southeast-2                                            |
| Asia Pacific (Thailand)  | ap-southeast-7                                            |
| Asia Pacific (Jakarta)   | ap-southeast-3                                            |
| Asia Pacific (Melbourne) | ap-southeast-4                                            |
| Asia Pacific (Malaysia)  | ap-southeast-5                                            |
| Canada (Central)         | ca-central-1                                              |
| Canada West (Calgary)    | ca-west-1                                                 |
| China (Beijing)          | cn-north-1 (cnn1-az1 & cnn1-az2 only)                     |
| China (Ningxia)          | cn-northwest-1                                            |
| Europe (Frankfurt)       | eu-central-1                                              |
| Europe (Zurich)          | eu-central-2                                              |
| Europe (Ireland)         | eu-west-1                                                 |
| Europe (London)          | eu-west-2                                                 |

| Region Name               | Region        |
|---------------------------|---------------|
| Europe (Paris)            | eu-west-3     |
| Europe (Milan)            | eu-south-1    |
| Europe (Spain)            | eu-south-2    |
| Europe (Stockholm)        | eu-north-1    |
| South America (São Paulo) | sa-east-1     |
| Israel (Tel Aviv)         | il-central-1  |
| Middle East (Bahrain)     | me-south-1    |
| Middle East (UAE)         | me-central-1  |
| AWS GovCloud (US-East)    | us-gov-east-1 |
| AWS GovCloud (US-West)    | us-gov-west-1 |

## Windows containers on AWS Fargate

Amazon ECS Windows containers on AWS Fargate are supported in the following AWS Regions. The supported Availability Zone IDs are noted when applicable.

| Region Name             | Region                                                             |
|-------------------------|--------------------------------------------------------------------|
| US East (Ohio)          | us-east-2                                                          |
| US East (N. Virginia)   | us-east-1 (use1-az1, use1-az2, use1-az4, use1-az5, & use1-az6only) |
| US West (N. California) | us-west-1 (usw1-az1 & usw1-az3 only)                               |
| US West (Oregon)        | us-west-2                                                          |
| Africa (Cape Town)      | af-south-1                                                         |

| Region Name              | Region                                                    |
|--------------------------|-----------------------------------------------------------|
| Asia Pacific (Hong Kong) | ap-east-1                                                 |
| Asia Pacific (Mumbai)    | ap-south-1                                                |
| Asia Pacific (Hyderabad) | ap-south-2                                                |
| Asia Pacific (Osaka)     | ap-northeast-3                                            |
| Asia Pacific (Seoul)     | ap-northeast-2                                            |
| Asia Pacific (Singapore) | ap-southeast-1                                            |
| Asia Pacific (Sydney)    | ap-southeast-2                                            |
| Asia Pacific (Melbourne) | ap-southeast-4                                            |
| Asia Pacific (Malaysia)  | ap-southeast-5                                            |
| Asia Pacific (Tokyo)     | ap-northeast-1 (apne1-az1 , apne1-az2 , & apne1-az4 only) |
| Canada (Central)         | ca-central-1 (cac1-az1 & cac1-az2 only)                   |
| Canada West (Calgary)    | ca-west-1                                                 |
| China (Beijing)          | cn-north-1 (cnn1-az1 & cnn1-az2 only)                     |
| China (Ningxia)          | cn-northwest-1                                            |
| Europe (Frankfurt)       | eu-central-1                                              |
| Europe (Zurich)          | eu-central-2                                              |
| Europe (Ireland)         | eu-west-1                                                 |
| Europe (London)          | eu-west-2                                                 |
| Europe (Paris)           | eu-west-3                                                 |
| Europe (Milan)           | eu-south-1                                                |

| Region Name               | Region       |
|---------------------------|--------------|
| Europe (Spain)            | eu-south-2   |
| Europe (Stockholm)        | eu-north-1   |
| South America (São Paulo) | sa-east-1    |
| Israel (Tel Aviv)         | il-central-1 |
| Middle East (UAE)         | me-central-1 |
| Middle East (Bahrain)     | me-south-1   |

# Architect for EC2 capacity for Amazon ECS

Use EC2 capacity for large workloads that must be price optimized.

When considering how to model task definitions and services using EC2, we recommend that you consider what processes must run together and how you might go about scaling each component.

As an example, suppose that an application consists of the following components:

- A frontend service that displays information on a webpage
- A backend service that provides APIs for the frontend service
- A data store

For this example, create task definitions that group the containers that are used for a common purpose together. Separate the different components into multiple task definitions. The following example cluster has three container instances that are running three front-end service containers, two backend service containers, and one data store service container.

You can group related containers in a task definition, such as linked containers that must be run together. For example, add a log streaming container to your front-end service and include it in the same task definition.

After you have your task definitions, you can create services from them to maintain the availability of your desired tasks. For more information, see [Creating an Amazon ECS rolling update deployment](#). In your services, you can associate containers with Elastic Load Balancing load balancers. For more information, see [Use load balancing to distribute Amazon ECS service traffic](#). When your application requirements change, you can update your services to scale the number of desired tasks up or down. Or, you can update your services to deploy newer versions of the containers in your tasks. For more information, see [Updating an Amazon ECS service](#).

## Container image pull behavior for EC2 and external instances on Amazon ECS

The time that it takes a container to start up varies, based on the underlying container image. For example, a fatter image (full versions of Debian, Ubuntu, and Amazon1/2) might take longer to start up because there are a more services that run in the containers compared to their respective slim versions (Debian-slim, Ubuntu-slim, and Amazon-slim) or smaller base images (Alpine).

When the Amazon ECS agent starts a task, it pulls the Docker image from its remote registry, and then caches a local copy. When you use a new image tag for each release of your application, this behavior is unnecessary.

The `ECS_IMAGE_PULL_BEHAVIOR` agent parameter determines the image pull behavior. The following options are available:

- `ECS_IMAGE_PULL_BEHAVIOR: default`

The image will be pulled remotely. If the pull fails, the cached image in the instance is used.

- `ECS_IMAGE_PULL_BEHAVIOR: always`

The image will be pulled remotely. If the pull fails, the task fails.

To speed up deployment, set the Amazon ECS agent parameter to one of the following values:

- `ECS_IMAGE_PULL_BEHAVIOR: once`

The image is pulled remotely only if it wasn't pulled by a previous task on the same container instance or if the cached image was removed by the automated image cleanup process.

Otherwise, the cached image on the instance is used. This ensures that no unnecessary image pulls are attempted.

- `ECS_IMAGE_PULL_BEHAVIOR: prefer-cached`

The image is pulled remotely if there is no cached image. Otherwise, the cached image on the instance is used. Automated image cleanup is turned off for the container to ensure that the cached image isn't removed.

Setting the `ECS_IMAGE_PULL_BEHAVIOR` parameter to either of the preceding values can save time because the Amazon ECS agent uses the existing downloaded image. For larger Docker images, the download time might take 10-20 seconds to pull over the network.

## External (Amazon ECS Anywhere) for Amazon ECS

Amazon ECS Anywhere provides support for registering an *external instance* such as an on-premises server or virtual machine (VM), to your Amazon ECS cluster. External instances are optimized for running applications that generate outbound traffic or process data. If your application requires inbound traffic, the lack of Elastic Load Balancing support makes running these workloads less efficient. Amazon ECS added a new EXTERNAL launch type that you can use to create services or run tasks on your external instances.

The following provides a high-level system architecture overview of Amazon ECS Anywhere. Your on-premises server has both the Amazon ECS agent and the SSM agent installed.

For more information, see [Amazon ECS clusters for external instances](#).

# Amazon ECS Express Mode

An Amazon ECS Express Mode service reduces the complexity of deploying containerized applications by providing sensible defaults and automating the configuration of supporting AWS services. Instead of managing configuration parameters across multiple services, an Express Mode service requires only three things to get started:

- A container image
- A task execution role
- An infrastructure role

Amazon ECS Express Mode orchestrates and configures all necessary infrastructure: a Fargate-based ECS service with a unique accessible URL, load balancer with SSL/TLS, auto scaling policies, monitoring, and networking components.

Use Amazon ECS Express Mode services in the following scenarios:

- Web applications and APIs - Stateless containerized applications that serve HTTP requests
- Rapid prototyping - Quickly deploy and test applications without infrastructure setup overhead
- Developer productivity - Enable application teams to deploy independently without deep AWS knowledge
- Platform team efficiency - Reduce maintenance overhead by providing self-service deployment capabilities

Amazon ECS Express Mode services support either public or private HTTPS applications and automatically scale based on utilization or traffic.

## Benefits of Amazon ECS Express Mode services

Amazon ECS Express Mode services provide several key advantages for deploying and managing containerized applications on AWS.

- Simplified deployment - Deploy containerized applications with production-ready defaults across multiple AWS services.
- No compromise on capabilities - All underlying AWS resources remain accessible for direct management when you need fine-grained control or advanced features.

- **Cost optimization** - Shares Application Load Balancers across multiple Express Mode services using the same networking configuration to reduce costs.
- **Transparent infrastructure** - All resources are created in your AWS account with full visibility and accessibility through the AWS console and APIs.

## Pricing

There is no additional charge for using an Amazon ECS Express Mode service. You pay only for the underlying AWS resources that are created to run your application, including:

- Fargate compute resources
- Application Load Balancer
- CloudWatch logs and metrics
- Data transfer charges

## Availability

Amazon ECS Express Mode is available in all AWS Regions where Amazon ECS and Fargate are supported. You can create and manage Express Mode services using any of the following:

- The Amazon ECS console
- AWS CLI
- AWS SDKs
- CloudFormation
- Terraform
- AWS Labs MCP Server for Amazon ECS

## Creating an Amazon ECS Express Mode service

An Amazon ECS Express Mode service reduces the complexity of deploying containerized applications by providing sensible defaults and automating the configuration of supporting AWS services. Instead of managing configuration parameters across multiple services, an Express Mode service requires only a container image, task execution role and infrastructure role to get started.

After your deployment completes you will be returned a unique URL for your application. You can find the service you just deployed in *Clusters*, and if you did not specify a cluster it will be in the `Default` cluster.

## Prerequisites

Before creating an Express Mode service, ensure you have one of the following:

- A container image stored in Amazon ECR.
- Or a container image stored in a private registry. To use a private registry, configure a Secrets Manager secret. For more information, see [Create an AWS Secrets Manager secret](#) in the *AWS Secrets Manager User Guide*.

### Note

IAM Roles are also required, but is covered in the [Console](#) and [CLI](#) guides separately. The Amazon ECS Console has automated flows for role creation.

## Walkthroughs

- For a simplified first-run experience using the console, see [the section called “Create your first Express Mode service in the console”](#).
- To create an Express Mode service using the AWS CLI, see [the section called “Create your first Express Mode service using the AWS CLI”](#).
- To learn more about what Express Mode creates and how it works, see [the section called “Resources created by Express Mode services”](#).

## Customizing

When creating an Express Mode service, Amazon ECS selects defaults for your Amazon ECS and other AWS resources. Customize the application when needed by using the optional parameters. Take advantage of an Express Mode service and customize the following:

- Service name
- Amazon ECS Cluster

- Container settings - port and health check path
- Environment variables and secrets
- Custom commands
- Task role - This role allows your application code (on the container) to use other AWS services.

You need this role when your application accesses other AWS services, such as Amazon S3.

- Compute resources - CPU and memory allocation
- CPU architecture - x86 or ARM64 (AWS Graviton) compute
- Network configuration - subnets and service security group
- Application Auto Scaling policies - metrics, target values, and task limits
- CloudWatch Logs configuration
- Resource tags
- Task definition – use your own custom task definition

## Create your first Amazon ECS Express Mode service in the console

The console experience for Express Mode service provides a streamlined way to deploy your containerized application with minimal configuration required. Read more about prerequisites in [Amazon ECS Express Mode](#). To learn more about what Express Mode creates and how it works, see [the section called “Resources created by Express Mode services”](#).

### Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Express mode**.
3. Under **Let's set up your app**:
  - a. Specify the image to use for your application. For **Image URI**, enter the URI for your image. To browse your Amazon ECR images, choose **Browse ECR images**, and then do the following:
    - i. For **Private repository**, choose the Amazon ECR private repository.
    - ii. For **Image**, choose your image.

- iii. Choose how to identify the image. For **Select image by**, choose one of the following options:
  - AWS recommends that you choose **Image digest**.
  - To use the tag, choose **Image tag** and then choose the tag.
- b. If using a private registry, select **Private registry**. Then for **Secrets Manager ARN or name**, enter the Secrets Manager ARN you created in the prerequisites.
- c. For **Task execution role**, and **Infrastructure role**, choose the roles. If you've never created these roles in Amazon ECS before, you will see the option to **Create new role** in the drop down. When you select this option, the role will be created for you automatically once you click **Create**. For the **Task execution role**, the Permission details will display the link for additional details on the [AmazonECSTaskExecutionRolePolicy](#) in the AWS Managed Policy Reference Guide. For the **Infrastructure role**, the Permission details will display the link for additional details on the [AmazonECSInfrastructureRoleforExpressGatewayServices](#) Managed Policy in the AWS Managed Policy Reference Guide.

If you prefer to customize these roles, the **Create new role** button directs you to the IAM console where you can create the role, view, and edit the permissions attached to role. When you return to the Amazon ECS Express Mode console, refresh to view the role you created.

 **Note**

The first time you create a service in the Amazon ECS Console, some users may see an `Invalid Parameter Exception: Unable to assume the service linked role`. If this occurs, wait a few seconds and try again.

4. Choose **Create**. You've just created your first Amazon ECS Express Mode service!

## Next steps

After creating your first Express Mode service:

- Access your application using the provided Application URL once the deployment is complete.
- Monitor deployment progress in the Resources tab of the console. When the deployment is complete, your service is ready to receive traffic. For more information, see [the section called "Viewing the details of an Express Mode service"](#).

- To navigate back to your service, select from the navigation **Clusters**, then select the default Cluster if you did not specify one during the create. Amazon ECS Organizes services into logical groupings called clusters. This is an easy way to organize applications in your account.
- If you encounter any issues during deployment, see [the section called "Troubleshooting"](#).

## Customize

Optionally, you can also customize the configuration of your Express Mode service. Open the section titled **Additional configurations - optional**.

1. Select a **Cluster** from the drop down if there is a specific Amazon ECS Cluster where you want to deploy your service. If no cluster is specified, Express Mode will use the Default cluster. If you leave the Express Mode console to create a cluster, use the refresh button to populate the drop down.
2. Enter a **Name** for the service. If no name is specified, Express Mode will generate one from the container image name. This service name will be used across several resources, including the Application URL, Amazon ECS Service, Amazon ECS Task Definition, certificate, scaling target, and scaling policy.
3. Optionally specify details about your **Container**:
  - a. For **Container port**, enter the port your application listens on (default is 80).
  - b. For **Health check path**, enter the path for health checks (for example, `/health`). The default is `/`.
  - c. Under **Environment variables**, add key-value pairs for environment variables your application needs. For **Key**, enter the environment variable name. For **Value type**, choose **Environment variable** or **Secret**. For **Value or value from**, enter the value or reference. Choose **Add environment variable** to add more variables as needed. No defaults are provided.
  - d. For **Command**, optionally enter a custom command to override the Docker CMD instruction. No default is provided.
  - e. For **Task role**, choose an IAM role that grants permissions to your application. No default is provided.
4. Optionally specify details about your **Compute and Auto scaling**:
  - a. For **CPU**, choose the vCPU allocation for your tasks (the default is 1 vCPU).

- b. For **Memory**, choose the Memory allocation for your tasks (the default is 2 GB).
  - c. For **CPU architecture**, choose **X86\_64** or **ARM64** (the default is **X86\_64**). Choose **ARM64** to run your tasks on AWS Graviton-powered compute.
  - d. For **ECS service metric**, choose the metric to scale on (the default is **Average CPU Utilization**).
  - e. For **Target value**, choose the target percentage for scaling (the default is **60**.)
  - f. For **Minimum number of tasks** and **Maximum number of tasks**, set the scaling limits. (The defaults are **1** and **20**)
5. Check the box to **Customize networking configurations**. If you do not customize these configurations, Express Mode will use the Default VPC.
  - a. Select a **VPC** to help quickly navigate to the **Subnets** where your services will run. Optionally, leave the Amazon ECS Console to create a new VPC, and come back to refresh and find that VPC in the drop down.
  - b. For **Security groups**, choose or create security groups to allow additional inbound network access to your service.
6. Under **Logs**:
  - a. For **Amazon CloudWatch log group**, enter the preferred log group name for your application logs. The default log group is named according to your cluster and service names.
  - b. For **Amazon CloudWatch log stream prefix**, enter a preferred prefix for log streams. The default stream prefix is `ecs/Main/`.
7. Under **Tags**, add key-value pairs to tag your resources. For **Key**, enter the tag key. For **Value**, enter the tag value. Choose **Add new item** to add more tags as needed. Tags can only be added on create.

## Create your first Express Mode service using the AWS CLI

This tutorial shows you how to create an Express Mode service application using the AWS CLI. You'll deploy a simple web application that demonstrates the core capabilities of Express Mode service.

## Prerequisites

Before you begin, ensure you have:

- An AWS account with appropriate permissions
- The AWS CLI installed and configured
- A container image stored in Amazon ECR or a private registry
- A default VPC with public subnets in the AWS Region where you create the service. By default, Express Mode service creates an internet-facing load balancer in your account's default VPC and public subnets. If your account does not have a default VPC, create one before you begin, or specify your own subnets when you create the service. For more information, see [Default VPCs](#) in the *Amazon VPC User Guide*.

## Step 1: Create IAM Roles

An Express Mode service requires two IAM roles. The Task Execution Role allows Amazon ECS to pull container images and write logs on your behalf. Create a task execution role and infrastructure role with the following policies:

```
#Create the roles with ECS trust policies
aws iam create-role --role-name ecsTaskExecutionRole \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "ecs-tasks.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
      }
    ]
  }'

aws iam create-role --role-name ecsInfrastructureRoleForExpressServices \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
```

```

        "Sid": "AllowAccessInfrastructureForECSExpressServices",
        "Effect": "Allow",
        "Principal": {
            "Service": "ecs.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    }
]
}'

```

```

#Attach the AWS managed policies
aws iam attach-role-policy --role-name ecsTaskExecutionRole \
    --policy-arn arn:aws:iam::aws:policy/service-role/AmazonECSTaskExecutionRolePolicy
aws iam attach-role-policy --role-name ecsInfrastructureRoleForExpressServices \
    --policy-arn arn:aws:iam::aws:policy/service-role/
AmazonECSInfrastructureRoleforExpressGatewayServices

```

For more information, see [the section called “Task execution IAM role”](#).

### Note

IAM roles are eventually consistent, so a newly created role might not be usable immediately. If your first `create-express-gateway-service` call fails with `Unable to assume the service linked role` (or a similar `assume-role` error) right after you create these roles, wait a short time (about a minute) for the roles to propagate, and then retry the command.

## Step 2: Create your first Express Mode service application

Create an Express Mode service application with the minimum required parameters:

```

aws ecs create-express-gateway-service \
    --primary-container "image"="public.ecr.aws/nginx/nginx:latest" \
    --execution-role-arn arn:aws:iam::123456789012:role/ecsTaskExecutionRole \
    --infrastructure-role-arn arn:aws:iam::123456789012:role/
ecsInfrastructureRoleForExpressServices \
    --monitor-resources

```

This command creates an Express Mode service application with:

- A unique service name generated from the image name
- 1 vCPU and 2 GB memory
- Port 80 for HTTPS traffic
- Auto scaling based on CPU utilization
- An internet-facing Application Load Balancer in the default VPC and public subnets
- A URL unique to this service in the format `servicename.ecs.region.on.aws`

The command continuously monitors resources as they are being provisioned and returns status. Once the service deployment is complete, the Application URL is ready to receive traffic. When you interrupt the monitoring, the information about the created service is returned, including the service ARN and URL:

```
{
  "service": {
    "cluster": "arn:aws:ecs:region:123456789012:cluster/default",
    "serviceName": "nginx-1234",
    "serviceArn": "arn:aws:ecs:region:123456789012:service/default/nginx-1234",
    "infrastructureRoleArn": "arn:aws:iam::123456789012:role/
ecsInfrastructureRoleForExpressServices",
    "status": {
      "statusCode": "ACTIVE"
    },
    "createdAt": "UNIXTIMESTAMP"
  }
}
```

## Step 3: Create an Express Mode service application with custom settings

You can customize your Express Mode service application by specifying additional parameters:

```
aws ecs create-express-gateway-service \
  --execution-role-arn arn:aws:iam::123456789012:role/ecsTaskExecutionRole \
  --infrastructure-role-arn arn:aws:iam::123456789012:role/
ecsInfrastructureRoleForExpressServices \
  --primary-container '{"image":"123456789012.dkr.ecr.region.amazonaws.com/my-
app:latest","containerPort":8080,"environment":[{"name":"ENV","value":"production"},
{"name":"DEBUG","value":"false"}]}' \
```

```
--service-name "my-web-app" \  
--cpu 2 \  
--memory 4 \  
--cpu-architecture ARM64 \  
--health-check-path "/health" \  
--scaling-target '{"minTaskCount":3,"maxTaskCount":100}' \  
--monitor-resources
```

This creates an application with:

- A custom name "my-web-app"
- 2 vCPU and 4 GB memory
- The ARM64 CPU architecture, which runs on AWS Graviton-powered compute
- Port 8080 for application traffic
- Custom health check endpoint
- Environment variables
- Minimum 3 tasks, maximum 100 tasks for auto scaling

## Create an Express Mode service with your own task definition

You can also create an Express Mode service with your own task definition. With your own task definition, you have full control over task-level configuration. Express Mode continues to manage infrastructure, including load balancing, auto scaling, and canary deployments.

The following AWS Command Line Interface (AWS CLI) command creates an Express Mode service with a custom task definition:

```
aws ecs create-express-gateway-service \  
  --infrastructure-role-arn arn:aws:iam::123456789012:role/  
ecsInfrastructureRoleForExpressServices \  
  --task-definition-arn arn:aws:ecs:us-west-2:123456789012:task-definition/my-td:3 \  
  --health-check-path "/health" \  
  --monitor-resources
```

Your task definition must meet the following requirements:

- A container named `Main`
- The `Main` container must have a single TCP port mapping with a container port and port name

- The task definition must have FARGATE in its compatibilities

### Note

The `taskDefinitionArn` parameter cannot be specified with `primaryContainer`, `executionRoleArn`, `taskRoleArn`, `cpu`, or `memory` in the same API call. Express Mode derives these values from the provided task definition.

## Step 4: Monitor your deployment

The `--monitor-resources` flag works on any Create, Update or Delete call to your Express Mode services. But in addition, you can monitor the resources in a service at any time, separate from a mutating action. Deployment time can vary depending on the resources that need to be provisioned. Once the status changes to `ACTIVE`, your application is ready to receive traffic.

```
aws ecs monitor-express-gateway-service --service-arn
arn:aws:ecs:region:123456789012:service/default/app-23d97h88
```

You can also find current configuration and status of your Express Mode service application:

```
aws ecs describe-express-gateway-service --service-arn
arn:aws:ecs:region:123456789012:service/default/app-23d97h88
```

## Step 5: Access your application

Access the Express Mode service application using the provided URL when it becomes active. The URL format is:

```
https://<service-name>.ecs.<region>.on.aws/
```

For example:

```
https://app-23d97h88.ecs.us-west-2.on.aws/
```

Your application is now running with:

- Automatic SSL/TLS termination
- Load balancing across multiple Availability Zones
- Auto scaling based on CPU utilization
- CloudWatch logging and monitoring
- 5XX Rollback Alarms and Canary Deployments for future updates

## Resources created by Amazon ECS Express Mode services

An Express Mode service reduces the complexity of deploying containerized applications by providing sensible defaults and automating the configuration of supporting AWS services. Instead of managing hundreds of configuration parameters across multiple services, an Express Mode service requires only a container image, task execution role and infrastructure role to get started.

Express Mode services have simplified procedures for provisioning and configuring an Amazon ECS Service that bundles together the preferred infrastructure for getting a production web application running. Express Mode services automatically incorporate operational and configuration best practices. The following resources are created:

- The ECS default cluster (if it does not already exist) with Fargate capacity providers
- A task definition with container, logging, and networking configurations
- A service with canary deployment and auto scaling
- Application Load Balancer with HTTPS listener, listener rules, and target groups
- Security groups with minimal required ingress
- Service Linked Roles for auto-scaling and load balancing
- Application Auto Scaling scalable target and target tracking scaling policy.

The scaling policy adds or removes service tasks as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target tracking scaling policy also adjusts to the fluctuations in the metric due to a fluctuating load pattern and minimizes rapid fluctuations in the number of tasks running in your service.

- Log group specific to the service
- Metric alarm for detecting faulty deployments
- ACM certificate

Use the defaults to get started with Express Mode services, or configure your application using a minimal set of parameters.

## Cluster defaults

The following defaults are configurable from within Express Mode for the Cluster:

- `clusterName`: Uses the default cluster.

You can customize this option by using the **Additional configurations** option in the console, or by specifying `create-express-gateway-service --cluster`.

The following defaults are set by Express Mode but can be updated in the Cluster directly.

- `capacityProviders`: ["FARGATE"] - Uses Fargate

## Task definition defaults

The following defaults are configurable from within Express Mode for the task definition:

- `cpu`: 1024 - 1 vCPU unit allocated to the task

You can customize this option by using the **Additional configurations** option in the console, or by running `create-express-gateway-service --cpu`.

- `memory`: 2048 - 2 GB of memory allocated to the task

You can customize this option by using the **Additional configurations** option in the console, or by running `create-express-gateway-service --memory`.

- `cpuArchitecture`: "X86\_64" - The default x86\_64 processor architecture. To use the 64-bit ARM architecture, choose ARM64, which runs on AWS Graviton-powered compute.

The following defaults are set by Express Mode but can be updated in the Task Definition directly.

- `networkMode`: "awsvpc" - Uses awsvpc networking mode
- `operatingSystemFamily`: "LINUX" - Runs on Linux operating system
- `requiresCompatibilities`: ["FARGATE"] - Compatible with Fargate launch type
- `platformVersion`: "LATEST" - Uses the latest Fargate platform version

You can also provide a custom task definition using the `taskDefinitionArn` parameter. Express Mode uses your task definition as-is, including CPU, memory, container definitions, and any additional containers or settings you define.

## Container definition defaults

The following defaults are configurable from within Express Mode for the container:

- `port: 80` - Default port for container traffic

The following defaults are set by Express Mode but can be updated in the Task Definition - Container Definition directly:

- `essential: true` - Container is marked as essential for task health
- `protocol: "tcp"` - Default protocol for load balancer communication
- `name: "Main"` - Default name for the primary container

Changing the name of the default container can effect Express Mode's ability to make subsequent updates to your service. This is not recommended if you intend to continue using the Express Mode Console or APIs

- `versionConsistency: enabled` - Resolves image tags to digest IDs for consistent deployments
- `initProcessEnabled: true` - Enables Docker init process support.
- `stopTimeout: 30 seconds` - Time between SIGTERM and SIGKILL signals.

## Logging defaults

The following defaults are configurable from within Express Mode for the CloudWatch Logs:

- `awslogs-group: "/aws/ecs/<cluster>/<name>-####"` - Log group name derived from cluster and service name

You can customize this option by using the **Additional configurations** option in the console, or by running `create-express-gateway-service --primary-container "awsLogsConfiguration"=[{"logGroup":"/my/logGroup/"}]`.

- `awslogs-stream-prefix: "ecs"` - Prefix for log stream names

You can customize this option by using the **Additional configurations** option in the console, or by running `create-express-gateway-service --primary-container "awsLogsConfiguration"=[{"logStreamPrefix"="myprefix"}]`.

The following defaults are set by Express Mode but can be updated in the Task Definition - Log Configuration directly:

- `logDriver`: "awslogs" - Uses CloudWatch Logs
- `awslogs-region`: current Region - Uses the same Region as the Express Mode service
- `mode`: "non-blocking" - Logging mode set to non-blocking
- `max-buffer-size`: "25m" - Maximum buffer size for log writes

When you provide a custom task definition using the `taskDefinitionArn` parameter, you configure logging within the task definition.

## Service defaults

The following defaults are configurable from within Express Mode for the Amazon ECS Service:

- `serviceName`: Express Mode service → Name - Name of the service (customer provided or derived from the image name)

Name can only be configured on create, and is not available to be configured on updates.

- `cluster`: Express Mode service → Cluster - ECS cluster for this service (customer provided or default)

Cluster can only be configured on create, and is not available to be configured on updates.

- `desiredCount`: Express Mode service → MinTasks - Desired count for service (default is 1)

You can customize this option by using the **Additional configurations** option in the console, or by running `create-express-gateway-service --scaling-target '{"minTaskCount":3}'`,

- `tags`: Express Mode service Tags for AWS tagging (customer provided)

You can customize this option by using the **Additional configurations** option in the console, or by running `create-express-gateway-service --tags`. Tags can only be added on the create of a new resource.

The following defaults are set by Express Mode but can be updated in the Amazon ECS Service directly:

- `availabilityZoneRebalancing`: `true` - Enables automatic AZ rebalancing
- `CapacityProviderStrategy`: `{"base": 1, "capacityProvider": "FARGATE", "weight": 1}` - Uses Fargate for compute capacity
- `deploymentConfiguration`: Canary by default - Express Mode service uses Canary deployments

Note that deployment strategy can not be updated on Express Mode services.

- `enableECSTags`: `true` - Enables ECS-managed resource tagging
- `healthCheckGracePeriodSeconds`: `300` - Grace period before Scheduler looks at ELB or Lattice health checks (aligns with ELB health check grace period default)
- `launchType`: `<Not set>` - Uses capacity providers
- `loadBalancers`: Load balancer configuration handled by ECS

Note that load balancer configurations can not be updated on Express Mode services.

- `placementStrategy`: `Not set` - Uses Fargate at launch (should always be AZ Spread)
- `platformVersion`: `LATEST` - Fargate platform version (hard coded to LATEST)
- `propagateTags`: `"SERVICE"` - Propagates tags from the service to tasks
- `schedulingStrategy`: `"REPLICA"` - Express Mode services are REPLICA services
- `taskDefinition`: Express Mode service created - The task definition to use (provided by Express Mode service)

## Network configuration defaults

The following defaults are configurable from within Express Mode for the Amazon ECS Service - Network Configuration:

- `networkConfiguration.Subnets`: If none are provided, Express Mode will use the default public subnets in the default VPC.

The default VPC must have at least two public subnets, in at least two availability zones, with at least 8 free IPs available, per assigned CIDR block, per subnet.

If you provide custom public subnets, Express Mode will provision an internet-facing ALB and turn on `assignPublicIP` for your tasks. If you provide private subnets (subnets without an internet gateway in their route table), Express Mode will provision an internal ALB.

If you specify subnets, the first Express Mode service for a VPC defines the subnets associated with either the internet-facing or internal load balancer for that VPC. Subsequent Express Mode services that launch in the same VPC must have subnets that match the availability zones supported by the load balancer. Because of this, we recommend creating Express Mode services with subnets from all availability zones.

- `networkConfiguration.SecurityGroups`: If none are provided, Express Mode creates both a Service Security Group and a Load Balancer Security Group

The Service Security Group allows outbound traffic to the public internet, but this may be restricted depending on other aspects of your networking, such as your subnet configuration.

**The Load Balancer Security Group** The Load Balancer Security Group allows inbound traffic for HTTPS resolution and outbound traffic to your Service Security Group on the container port you specify (default 80). And is automatically updated to match the container port provided in your Express Mode Create or Update calls.

You can customize this option by using the **Additional configurations** option in the console, or by running `create-express-gateway-service --network-configuration '{"securityGroup": ["sg-xxxxxxx"]}'`. When you provide a security group you are providing an additional ingress path to your service.

The following defaults are set by Express Mode but can be updated in the Amazon ECS Service - Network Configuration directly:

- `assignPublicIp`: Based on subnet type - Enabled for public subnets to ensure users of the default VPC are able to access the public internet, we enable public IPs on each task by default. This is disabled if you provide a private subnet, and you are then responsible for configuring a NAT gateway if your tasks need internet access.

## IAM role defaults

The following IAM roles are configurable for an Express Mode Service with automatic creation of service-linked roles where appropriate.

- `executionRoleArn`: Task Execution Role (required parameter)

While the required permissions are in the managed policy, additional policies and permissions can be attached. Additional details on the [AmazonECSTaskExecutionRolePolicy](#) in the AWS Managed Policy Reference Guide

- `infrastructureRoleArn`: Infrastructure Role for Express Gateway Services (required parameter)

While the required permissions are in the managed policy, additional policies and permissions can be attached. Additional details on the [AmazonECSInfrastructureRoleforExpressGatewayServices](#) Managed Policy in the AWS Managed Policy Reference Guide

- `taskRoleArn`: Task Role for calls from container application code (optional)

You can customize this option by using the **Additional configurations** option in the console, or by running `create-express-gateway-service --task-role-arn`.

You must create the new IAM role before you create or update the Express Mode service.

The following IAM roles are configured by Express Mode automatically.

- `ecsServiceRoleForECS`: Allows Amazon ECS to manage your cluster
- `AWSServiceRoleForElasticLoadBalancing`: Calls other AWS services for you on your behalf - created automatically by Elastic Load Balancing
- `AWSServiceRoleForApplicationAutoScaling_ECSService`: Calls other AWS services on your behalf - created automatically by Application Auto Scaling

When you provide a custom task definition using the `taskDefinitionArn` parameter, the task execution role and task role are read from your task definition.

## Application Auto Scaling defaults

You can configure the following Application Auto Scaling settings in Express Mode:

- `autoScalingTargetValue`: 60 - Target CPU utilization percentage for scaling
- `autoScalingMetric`: "CPUUtilization" - Metric used for auto scaling decisions
- `desiredMinTaskCount`: 1 - Minimum number of tasks to maintain
- `desiredMaxTaskCount`: 20 - Maximum number of tasks to scale to (can be increased or decreased)

The following settings can be configured in Application Auto Scaling directly:

- `policyType`: "TargetTrackingScaling" - Uses target tracking scaling policy
- `disableScaleIn`: false - Allows scaling down when demand decreases

## Application scaling target defaults

Application Auto Scaling targets define the scalable resource and capacity limits for automatic scaling operations. The following can be modified in Express Mode:

- `MaxCapacity`: Express Mode service → `MaxTasks` - Maximum tasks the service will scale up to (default from `CreateLoadBalancedService` or customer provided)
- `MinCapacity`: Express Mode service → `MinTasks` - Minimum tasks the service will scale down to (default from `CreateLoadBalancedService` or customer provided)
- `ScalableDimension`: `ecs:service:DesiredCount` - The property to scale
- `Tags`: Derived from the tags passed in `CreateLoadBalancedService` - Resource tags for this resource

The following defaults can be modified in Application Auto Scaling scalable target:

- `DynamicScalingInSuspended`: false - Indicates if scaling in is suspended
- `DynamicScalingOutSuspended`: false - Indicates if scaling out is suspended
- `ScheduledScalingSuspended`: false - Indicates if scheduled scaling is suspended

## Application scaling policy defaults

Scaling policies implement target tracking algorithms that monitor CPU utilization and adjust task count to maintain optimal performance. The following can be modified from Express Mode:

- **TargetValue:** 60% - The target value for the tracking policy (Express Mode service → scaling-target-value)
- **PredefinedMetricType:** ECSServiceAverageCPUUtilization - The name type of metric being tracked (Express Mode service → scaling-metric)

Express Mode provides scaling metrics for Average CPUUtilization, Average Memory Utilization, and Request Count per Target. Request Count per Target comes from the Application Load Balancer and can be set up to 65536 requests per target per second, which is your Amazon ECS Service in the Application Load Balancer target group.

The following defaults are set by Express Mode but can be changed in the Application Auto Scaling policy:

- **PolicyName:** <ServiceName><"TargetMetric"> - Name of this scaling policy (derived from ECS Service name and Target Metric)
- **PolicyType:** TargetTrackingScaling - The type of scaling being done (predefined default)
- **ScalableDimension:** "ecs:service:DesiredCount" - The property to be scaled (predefined default)
- **DisableScaleIn:** false - Indicates if scale in is disabled

## Application Load Balancer defaults

You can configure the following Application Load Balancer defaults in Express Mode:

- **scheme:** depends on subnets - Creates an Internet-facing load balancer with public IP addresses when public subnets are provided. Creates an Internal load balancer with private IP addresses when private subnets are provided.
- **ip-address-type:** depends on subnets - Creates an IPv4 only Application Load Balancer when addresses are IPv4. When there are IPv6-enabled subnets, a dual-stack Application Load Balancer will be created. Note that if you have IPv6-enabled subnets, the first Express Mode service in a VPC defines the internal or internet-facing load balancer for that VPC. Because of this, we recommend creating your IPv6-only subnets first, or in a new VPC.

The following defaults are set in Express Mode and you can configure them in Application Load Balancer:

- **desync-mitigation-mode:** Off - HTTP desync mitigation is disabled

- `access-logs.enabled`: false - Access logging is disabled
- `listener-configurations.protocol`: https - Uses HTTPS protocol for secure communication
- `listener-configurations.port`: 443 - Listens on standard HTTPS port
- `listener-configurations.rule-type`: host-header - Routes traffic based on host header rules

## Target group defaults

You can configure the following Amazon EC2 Target Group defaults in Express Mode:

- `health-check-path`: (default `"/"`) Express Mode service health check path - URL path for health check requests
- `port`: (default 80) - Port on which targets receive traffic
- `health-check-port`: (default 80) - Port for health check requests

The following defaults are set by Express Mode and you can configure them in Amazon EC2 Target Groups:

- `protocol`: HTTP - Protocol for routing traffic to targets
- `protocol-version`: HTTP1 - HTTP protocol version for communication
- `vpc-id`: default is the default VPC - Virtual Private Cloud identifier for the target group, but will be derived from the subnets provided
- `health-check-protocol`: Same as Protocol - Protocol for health check requests
- `health-check-enabled`: Always enabled - Health checks are automatically enabled
- `health-check-interval-seconds`: 30 - Time between health checks of individual targets
- `health-check-timeout-seconds`: 5 - Timeout duration for health check responses
- `healthy-threshold-count`: 5 - Consecutive successful health checks required for healthy status
- `unhealthy-threshold-count`: 2 - Consecutive failed health checks required for unhealthy status
- `target-type`: ip - Targets are registered by IP address
- `ip-address-type`: ipv4 - Uses IPv4 addresses for target registration

## Resource sharing and cost optimization

Express Mode services automatically share resources when possible to optimize costs:

- **Load balancer sharing** - Up to 25 Express Mode services in the same VPC can share an Application Load Balancer. Express Mode will provision additional Application Load Balancers as necessary depending on the amount of Express Mode services you have provisioned. And as you reduce the amount of Express Mode services in your VPC, Express Mode will also deprovision unused Application Load Balancers. This sharing reduces the effective cost per application as you deploy more Express Mode services.
- **Cluster sharing** - Express Mode services can be grouped together in Amazon ECS Clusters. Express Mode services can also share Amazon ECS Clusters with Amazon ECS Services not managed by Express Mode.

## Viewing the details of an Amazon ECS Express Mode service

You can view details about your Express Mode service to monitor its status, configuration, and performance metrics. The service details page provides comprehensive information about your service's current state, running tasks, deployment history, and operational metrics.

### To view an Express Mode service (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the name of the cluster that contains your Express Mode service.
4. On the cluster details page, choose the **Services** tab.
5. Configure a filter to view your Express Mode services. For **Filter resource management type**, choose **ECS**.

An Express Mode service has a **Express** badge next to the name.

6. Select the name of your Express Mode service to navigate to the service detail page for your Express Mode service.
7. Review the service information displayed on the service details page:
  - a. **Express service Overview** - View basic service information including Application URL, Service status, Pending and Running Tasks, and Active Deployments.
  - b. **Observability** - View CloudWatch metrics for CPU Utilization (min, max, average) Memory Utilization (min, max, average), Target Response time (p50,p90,p99), RequestCount, 4xx Statuses and 5xx Statuses.

- c. **Logs** - View logs from the containers in your tasks.
- d. **Resources** - Your AWS Resources created for your Express Mode service. The Timeline view updates automatically after a Create or Update and shows status and events. The Table view provides a searchable table with the status and full ARNs for each resource.
- e. **Deployments** - Track deployment history and current deployment status, include the service revision and tasks which provide valuable information during updates. The events panel lets you know when your Express Mode service has reached a steady state.
- f. **Configuration** - View service configuration, including the cluster, roles, container configuration, compute, auto scaling and networking configuration.
- g. **Tags** - Manage your tags.

## Updating an Amazon ECS Express Mode service

The Express Mode service simplifies the service update process by providing configurable options for networking, load balancing, and Application Auto Scaling and orchestrating changes across these services.

You can update your Express Mode service to modify container images, adjust resource allocation, or change configuration settings. Updates are deployed using canary deployments with alarm based rollback alarms to maintain availability.

### Deployment behavior

An Express Mode service uses canary deployments by default to ensure safe updates and quick rollbacks:

- A new environment is created and tasks deployed with your changes
- 5% of traffic is shifted to the new environment
- Alarm Based Rollbacks will trigger if sum of 4xx and 5xx errors percentage is > 1 for 2 datapoints within 3 minutes
- Health checks verify the new tasks are healthy
- After 3 minutes bake time, 100% of traffic is shifted to new environment
- After 3 minutes bake time for monitoring, old tasks are gradually stopped and replaced

For more information, see [Amazon ECS canary deployments](#)

## Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the name of the cluster that contains your Express Mode service.
4. On the cluster details page, choose the **Services** tab.
5. Configure a filter to view your Express Mode services. For **Filter resource management type**, choose **ECS**.

An Express Mode service has a **Express** badge next to the name.

6. Under **Configuration**:
  - a. Specify the image to use for your application. For **Image URI**, enter the URI for your image. To browse your Amazon ECR images, choose **Browse ECR images**, and then do the following:
    - i. For **Private repository**, choose the Amazon ECR private repository.
    - ii. For **Image**, choose your image.
    - iii. Choose how to identify the image. For **Select image by**, choose one of the following options:
      - AWS recommends that you choose **Image digest**.
      - To use the tag, choose **Image tag** and then choose the tag.
  - b. To use a private registry, select **Private registry**. Then, for **Secrets Manager ARN or name**, enter the Secrets Manager ARN you created in the prerequisites.
  - c. For **Task execution role**, choose the roles or create a new role and refresh. You can update the task execution role when you need to add additional permissions.
7. Under **Additional configurations**, customize your service.
  - a. Under **Container**:
    - i. For **Container port**, update the port your application listens on (default is 80).
    - ii. For **Health check path**, update the path for health checks (for example, `/health`).
  - b. Under **Environment variables**, add key-value pairs for environment variables your application needs:

- i. For **Key**, enter the environment variable name.
    - ii. For **Value type**, choose **Environment variable** or **Secret**.
    - iii. For **Value or value from**, enter the value or reference.
    - iv. Choose **Add environment variable** to add more variables as needed.
  - c. For **Command**, optionally enter a custom command to override the Docker CMD instruction.
  - d. For **Task role**, add an IAM role that grants permissions to your application running in your containers. This allows your application to make API calls to AWS services.
  - e. Under **Compute**:
    - i. For **CPU**, update the vCPU allocation for your tasks (for example, 1 vCPU).
    - ii. For **Memory**, update the memory allocation for your tasks (for example, 2 GB).
    - iii. For **CPU architecture**, choose **X86\_64** or **ARM64**. Choose **ARM64** to run your tasks on AWS Graviton-powered compute. When you change the CPU architecture, a new deployment starts and replaces the running tasks.
  - f. Under **Auto Scaling**:
    - i. For **ECS service metric**, choose the metric to scale on (for example, **ECS Service Average Memory Utilization** or **Request count per target**).
    - ii. For **Target value**, enter the target for scaling (for example, **60** or **1000**).
    - iii. For **Minimum number of tasks** and **Maximum number of tasks**, update the scaling limits.
  - g. Under **Logs**:
    - i. For **Amazon CloudWatch log group**, update the log group name for your application logs. Note this will not move existing logs, but begin writing logs from the new service revision.
    - ii. For **Amazon CloudWatch log stream prefix**, enter a new prefix for log streams.
8. Choose **Update** to update your Express Mode service.

## Updating with a custom task definition

You can update your Express Mode service with a custom task definition by specifying the `taskDefinitionArn` parameter. Express Mode uses your task definition as-is and continues to manage the rest of the infrastructure.

On subsequent updates, you can either:

- Create a new revision of your task definition and update the `taskDefinitionArn`. Express Mode uses the new revision for the next service deployment.
- Update Express Mode parameters directly:
  - For parameters unrelated to the task definition (such as `healthCheckPath`, `networkConfiguration`, or `scalingTarget`), Express Mode applies the changes without modifying the task definition.
  - For task-definition related parameters (such as `image`, `CPU`, or `memory` using `primaryContainer` or `cpu/memory`), Express Mode creates a new managed task definition with your changes while preserving your other task-level configuration.

### To update with a custom task definition (Amazon ECS console)

1. Open the Amazon ECS console and navigate to your Express Mode service.
2. Choose the dropdown arrow next to **Update service**, then choose **Update with custom task definition**.
3. For **Task definition family**, select an existing task definition family. To create a new task definition, choose the **Task definitions** link.
4. For **Task definition revision**, select the revision to use, or leave blank to use the latest revision.
5. (Optional) Expand **Additional configurations** to update health check path, networking, or auto scaling settings.
6. Choose **Update**.

The following AWS CLI command updates your Express Mode service with a custom task definition:

```
aws ecs update-express-gateway-service \  
  --service-arn arn:aws:ecs:us-west-2:123456789012:service/default/my-service \  
  --task-definition-arn arn:aws:ecs:us-west-2:123456789012:task-definition/my-td:4
```

**Note**

If you use CloudFormation and are adding `taskDefinitionArn` to your Express Mode service for the first time, redeploy your stack once first. This ensures rollback compatibility.

## Delete Amazon ECS Express Mode services

When you delete an Express Mode service, you remove the service and delete its associated resources including the cluster, load balancer, and other infrastructure components.

**Important**

Deleting an Express Mode service will stop all running tasks and make your application unavailable. This action cannot be undone.

The following resources may be deleted depending on your selection:

- The Amazon ECS cluster (if no other services are running)
- The Amazon ECS service, task definition, and any running tasks
- Service security group
- CloudWatch log group
- Metric alarm
- ACM Certificate
- The Application Load Balancer (if no other services are configured), target group, security group, listener, and listener rule
- Auto Scaling policy, scalable target

Consider the following::

- Ensure you have backed up any important data before deletion
- Consider scaling the service to zero tasks before deletion to gracefully stop traffic
- Review dependencies that might be affected by the deletion

## Difference between deleting an Express Mode service and a service

When you delete a service, Amazon ECS will delete the service if there are no running tasks. Amazon ECS does not delete target groups associated with the service or the default cluster (if it was used). When you delete an Express Mode service, Amazon ECS will delete the service as well as any resources that are distinct to the Express Mode service. For example, if the Express Mode service created the load balancer and is the only service using the load balancer it will delete the associated load balancer. If the load balancer is being shared, even with resources not managed by Express Mode, it will not be deleted.

### Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, select the cluster for the service.
3. On the **Clusters** page, choose the cluster.
4. Choose the **Services** tab.
5. Select the services to delete.
6. Choose **Delete**.
7. In the **Delete confirmation** dialog box:
  - Enter **delete** to confirm the deletion.
8. Choose **Delete** to confirm.
9. Stay on the page to monitor deletion progress and view a list of resources that have been removed, as well as those that have been retained and may require manual cleanup.

## Best practices for Amazon ECS Express Mode services

Learn about best practices and recommendations for using Express Mode service effectively in production environments.

### Security best practices

#### Secrets management

- **Use Secrets Manager for secrets** - Store sensitive data in Secrets Manager (e.g. private repository or database credentials).

For more information about Secrets Manager best practices, see [Secrets Manager best practices](#) in the *Secrets Manager User Guide*.

- **Enable encryption at rest** - Ensure secrets are encrypted when stored in AWS services.

Using a service such as Secrets Manager allows you to encrypt using either an AWS managed or customer provided key.

- **Implement secret rotation** - Use automatic rotation for database passwords and API keys.

Using a service such as Secrets Manager can manage secret rotation for services like Amazon Aurora and Amazon RDS

Example of using secrets in Express Mode service:

```
aws ecs update-express-gateway-service \
  --primary-container \
    '{"environment":[{"name":"DB_PASSWORD","value":"arn:aws:secretsmanager:us-
west-2:123456789012:secret:prod/db/password"}, \
    {"name":"API_KEY","value":"arn:aws:ssm:us-west-2:123456789012:parameter/prod/
api-key"}]}' \
```

## Network security

- **Use private subnets for sensitive applications** - Deploy applications that don't need direct internet access in private subnets.

For more information about recommended architectures, see [Connect Amazon ECS application to the internet](#).

- **Configure security groups to be minimally permissive** - Restrict inbound and outbound traffic to only necessary ports and sources.

To restrict the outbound traffic of the Express Mode Service Security Group, you can edit this directly in Amazon EC2 Security Groups Console by modifying the Outbound rules, or use the following commands:

```
aws ec2 authorize-security-group-egress
```

```
--group-id sg-xxxxxxx \
--protocol tcp \
--port 443 \
--cidr 0.0.0.0/0

aws ec2 revoke-security-group-egress
--group-id sg-xxxxxxx \
--protocol tcp \
--port 443 \
--cidr 0.0.0.0/0
```

- **Enable Amazon VPC Flow Logs** - Monitor network traffic for security analysis and troubleshooting.

You can enable this in each subnet in use by your Express Mode applications in the VPC Subnet Console, or use `aws ec2 create-flow-logs --resource-ids subnet-xxx`

- **Use AWS WAF for web applications** - Protect against common web exploits and attacks.

You can enable this by creating a Web ACL and then associating it to the Application Load Balancer used by your Express Mode service. In Console, Create a web ACL in the WAF & Shield Service and associate to your Application Load Balancer. Or, use `aws wafv2 create-web-acl` and `aws wafv2 associate-web-acl --resource-arn <alb>`.

## Performance and Compute optimization

### Resource sizing

- **Right-size CPU and memory** - Monitor application performance and adjust CPU and memory allocations based on actual usage patterns.

AWS Compute Optimizer generates recommendations for Amazon ECS task and container sizes. For more information, see [What is AWS Compute Optimizer?](#) in the *AWS Compute Optimizer User Guide*.

- **Performance test your application** - To ensure your application operates at scale and with the given scaling thresholds and resources allocations, perform load testing.

## Auto scaling configuration

- **Set appropriate scaling thresholds** - Configure CPU or memory thresholds that trigger scaling before performance degrades.

You can modify the service metric's target value in your Express Mode service console.

Consider adding a predictive scaling policy, especially if your traffic follows a time-based pattern. For more information, see [Use historical patterns to scale Amazon ECS services with predictive scaling](#).

- **Use multiple scaling metrics** - Consider using both CPU or Memory and request-based scaling for more responsive scaling.

You can add multiple policies to a service. Express Mode adds one by default, but you can attach additional policies to your service directly.

- **Configure minimum and maximum limits of tasks** - Set reasonable bounds to control costs and ensure availability.

For production workloads, once initial testing is complete - we recommend running in three availability zones to follow availability best practices. You can update the **Minimum number of tasks** in the Express Mode Console, or by using `update-express-gateway-service --scaling-target '{"minTaskCount":3}'`.

## Health checks

- **Implement meaningful health checks** - Create health check endpoints that verify critical application dependencies.

You can update the **Health check path** in the Express Mode Console. Or by using `update-express-gateway-service --health-check-path "/health"`.

For more information on forming health checks for your application, refer to [Implementing Health Checks](#)

- **Keep health checks lightweight** - Avoid expensive operations in health check endpoints.

Examples might include external API calls, CPU or memory intensive operations, or long running operations with the potential to timeout.

- **Use appropriate timeouts** - Configure health check timeouts that allow for normal response times while detecting failures quickly.

Health check timeouts for Express Mode is configurable on the Application Load Balancer target group. In the Amazon EC2 Console, Navigate to the **Target Groups** section and select your Express Mode target group. Select the **Health Checks** Tab and click **Edit**, under **Advanced health check settings** you can adjust the timeout. Or, use `aws elbv2 modify-target-group --target-group-arn <targetgroup> --health-check-timeout`.

- **Return proper HTTP status codes** - Use 200 for healthy and 4xx/5xx for unhealthy states.

## Operational best practices

### Monitoring and logging

- **Enable Enhanced Container Insights** - Use CloudWatch; Enhanced Container Insights for comprehensive monitoring of your Express Mode service applications.

For more information, see [Setting up Container Insights on Amazon ECS](#).

- **Set up custom metrics** - Publish application-specific metrics to CloudWatch; for business logic monitoring.

For more information, see [Publish custom metrics](#) in the *CloudWatch User Guide*.

- **Configure log retention** - Set appropriate log retention periods to balance cost and compliance requirements.

CloudWatch Log Groups created by Express Mode are configured to never expire and are retained when the Express Mode service is deleted. You can adjust this setting in the CloudWatch Log Group.

- **Create dashboards and alerts** - Set up CloudWatch; dashboards and alarms for proactive monitoring.

### Deployment strategies

- **Implement bake times** - Express Mode implements a canary bake time to ensure deployments have time to stabilize while reducing blast radius of problematic deployments. If your application needs more time to stabilize, you can configure this in the Amazon ECS Service definition of your Express Mode service. For more information, see [Creating an Amazon ECS canary deployment](#).

- **Implement rollback procedures** - Have a plan to quickly revert to previous versions if issues occur.

Meaningful health checks and alarm based rollbacks can both help with rollback. Express Mode's canary deployment strategy combined with alarm based rollbacks on 4xx and 5xx traffic sets up your deployments for fast rollbacks in the event of faulty application code or configuration.

## When to use a custom task definition

Consider providing your own custom task definition only when:

- Your team has standardized task definitions with security agents, logging sidecars, or compliance configurations that must be present on all services.
- You need task-level settings not directly configurable through Express Mode, such as container health checks, custom log drivers (for example, FireLens), Linux parameters (`initProcessEnabled`, `tmpfs` mounts), or additional sidecar containers.
- You use infrastructure as code and want to define your task definition in your templates and pass it to your Express Mode service.

## Troubleshooting Amazon ECS Express Mode services

This section helps you identify and resolve common issues when deploying and managing Express Mode services.

### Deployment issues

#### Service stuck in **ACTIVE** or **DRAINING** status

**Symptoms:** `DescribeServiceRevisions` shows resources are still provisioning or deprovisioning. `DescribeServices` shows deployment not stabilized

#### Possible causes and solutions:

- **Insufficient IAM permissions** - Verify that the task execution role and infrastructure role have the necessary permissions as shown in their respective managed policies.

```
# Check if the role has the required managed policy
aws iam list-attached-role-policies --role-name ecsTaskExecutionRole
```

- **Image pull failures** - Ensure the container image exists and is accessible.

```
# Test image pull manually
docker pull 123456789012.dkr.ecr.us-west-2.amazonaws.com/my-app:latest
```

- **Network connectivity issues** - Check that subnets have internet access or Amazon VPC endpoints for AWS services.
- **Resource limits** - Verify that your account has sufficient Fargate capacity and hasn't reached service quotas.

### Diagnostic steps:

1. Use `DescribeExpressGatewayService` to get your current Service Revision followed by `DescribeServiceRevisions` for the `ServiceRevision` to get status on the provisioning or deprovisioning
2. Check the service events in the Amazon ECS console for detailed error messages.
3. Check the container port was set correctly
4. Check AWS service quotas for Amazon ECS and Fargate.

## Task startup failures

**Symptoms:** Tasks fail to start or immediately stop after starting.

### Common causes:

- **Application errors** - The container application exits due to configuration or runtime errors.
- **Health check failures** - The application doesn't respond to health checks on the expected port or path.
- **Resource constraints** - Insufficient CPU or memory allocation for the application.
- **Missing environment variables or secrets** - Required configuration is not available to the application.

### Resolution steps:

1. Check application logs in CloudWatch Logs, obtain the log group name from `DescribeServiceRevisions`:

```
aws logs describe-log-streams --log-group-name /ecs/express-service-my-app
aws logs get-log-events --log-group-name /ecs/express-service-my-app --log-stream-
name stream-name
```

2. Verify that the health check path returns HTTP 200 status.
3. Test the container image locally to ensure it starts correctly.
4. Review and adjust CPU and memory allocations if needed.

## Custom task definition errors

Service creation or update fails with an `InvalidParameterException` when using the `taskDefinitionArn` parameter.

**"taskDefinitionArn cannot be provided with primaryContainer, executionRoleArn, taskRoleArn, cpu, or memory."**

The `taskDefinitionArn` parameter cannot be specified with `primaryContainer`, `executionRoleArn`, `taskRoleArn`, `cpu`, or `memory` in the same API call. Express Mode derives these values from the provided task definition.

**"Task definition must contain a container named 'Main' with a single TCP port mapping."**

Your task definition does not meet Express Mode requirements. Ensure it has:

- A container named `Main`
- The `Main` container has exactly one TCP port mapping with a container port and port name defined
- The task definition has `FARGATE` in its compatibilities

## Connectivity issues

### Application unreachable via load balancer

**Symptoms:** The application URL returns timeouts or connection errors.

**Troubleshooting steps:**

1. Validate your resources have finished provisioning
2. Verify that tasks are running and healthy:

```
aws ecs describe-services --cluster my-cluster --services my-express-service
```

3. Check Application Load Balancer target group health:

```
aws elbv2 describe-target-health --target-group-arn  
arn:aws:elasticloadbalancing:region:account:targetgroup/name/id
```

4. Ensure the application is listening on the correct port inside the container.

## Performance issues

### Slow response times

**Symptoms:** Application responses are slower than expected.

**Diagnostic approach:**

1. Monitor CPU and memory utilization:

```
# Check CloudWatch metrics for the service  
aws cloudwatch get-metric-statistics \  
    --namespace AWS/ECS \  
    --metric-name CPUUtilization \  
    --dimensions Name=ServiceName,Value=my-express-service Name=ClusterName,Value=my-  
cluster \  
    --start-time 2024-01-01T00:00:00Z \  
    --end-time 2024-01-01T00:00:00Z
```

```
--end-time 2024-01-01T01:00:00Z \  
--period 300 \  
--statistics Average
```

2. Review application logs for errors or performance warnings.
3. Check if auto scaling is responding appropriately to load.
4. Analyze load balancer metrics for request distribution.

### Optimization strategies:

- Increase CPU or memory allocation if resources are constrained.
- Adjust auto scaling thresholds to scale out earlier.
- Optimize application code and database queries.

## Auto scaling not working as expected

**Symptoms:** The service doesn't scale up during high load or doesn't scale down during low load.

### Troubleshooting steps:

1. Check auto scaling policies and their configuration:

```
aws application-autoscaling describe-scaling-policies \  
  --service-namespace ecs \  
  --resource-id service/my-cluster/my-express-service
```

2. Review CloudWatch metrics to ensure scaling triggers are being met.
3. Verify that the service has permission to scale (check IAM roles).
4. Check for any scaling activities and their outcomes.

## Monitoring and debugging tools

### Using CloudWatch Container Insights

Enable Container Insights for comprehensive monitoring:

```
aws ecs put-account-setting --name containerInsights --value enabled
```

Container Insights provides:

- CPU, memory, disk, and network metrics
- Performance monitoring dashboards
- Log correlation and analysis
- Anomaly detection

## Updating Resources Outside of Express Mode

Express Mode simplifies deployment by automatically provisioning and managing AWS resources on your behalf, but it's important to understand the responsibility model. While Express Mode creates and configures resources like Amazon ECS services, load balancers, and auto scaling policies, all resources remain in your AWS account and are fully accessible for direct management. You can modify these resources outside of Express Mode using the AWS Console, AWS CLI, or APIs, but doing so may affect Express Mode's ability to manage your service. This section explains which resources Express Mode manages, how to safely make changes outside of Express Mode, and what happens when you do.

## Understanding the shared responsibility model

The responsibility boundary in Express Mode is defined by API usage. Express Mode APIs manage resources on your behalf with coordinated updates across multiple AWS services. Standard AWS service APIs give you direct control over individual resources. This allows you to go beyond the set of parameters that Express Mode provides for configuration, and gives you control over every parameter of every resource. Both sets of APIs operate on the same underlying infrastructure in your account, and both will execute the operations you request. AWS has the responsibility of performing the operation you request. Express Mode does not validate whether resource modifications using direct APIs will conflict with Express Mode configuration, nor does it prevent changes that might disrupt service functionality. This also means that you have the ability to make changes, and those changes will persist. Express Mode will not overwrite changes unless requested as part of an Express Mode update. You're responsible for understanding how modifications using

direct APIs interact with Express Mode's configuration and for resolving any resulting conflicts or service issues.

For more information about the defaults that Express Mode sets and the resources it orchestrates, see [the section called “Resources created by Express Mode services”](#).

## Do I need to do anything before I can take advantage of Amazon ECS features in my Express Mode service?

No, there is no graduation path or break glass for Express Mode. The entire Amazon ECS feature set is always available for your Express Mode service. If you'd like to make sure no further Express Mode updates can occur on your service, there are several options. By removing the Managed Tag on your resources, Amazon ECS will no longer be able to identify and operate on it as an Express Mode service. Alternatively, you can also use IAM to restrict user permissions to the Express Mode APIs.

## Example Updates Outside of Express Mode

### Adding a sidecar to an Express Mode service

You can add any sidecar container to your service. This example shows how to add a Fluent Bit logging sidecar.

You can define a task definition with sidecar containers and provide it to your Express Mode service using the `taskDefinitionArn` parameter. Express Mode uses your task definition as-is, including any sidecar containers you configured. For more information, see [the section called “Create an Express Mode service with your own task definition”](#).

Alternatively, you can add a sidecar by editing the Express Mode created task definition directly, as described in the following procedure.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. Select the cluster where your Express Mode service is located, and in the **Services** panel, select it.
4. Go to the **Resources** tab and select the task definition.
5. Select the **JSON** tab, and then select the down arrow in the top button labeled **Create New Revision**. Here you'll find an action called **Create New Revision with JSON**.

6. Add the sidecar container before or after your primary container definition. For more information, see [Example Amazon ECS task definition: Route logs to FireLens](#).
7. If you have a logging sidecar, like in this example, you'll want to change the `logDriver` in the primary container:

```
"logConfiguration": {  
  "logDriver": "awsfirelens"  
}
```

8. Assuming the default settings for an Express Mode service, set the primary container `memoryReservation` to 1998 and the Fluent Bit container `memoryReservation` to 50. This ensures the total memory reservation across the two containers does not exceed the amount you have running on your Fargate task (2048 for a default Express Mode service).
9. Create your new revision.
10. Click the drop down that says **Deploy** and select **Update Service**.
11. Select the **Cluster** and **Service** that you're updating, and then select **Force new deployment**. The task definition revision you just created should be auto-selected. Select **Update**.
12. Watch your deployment take place. Tasks in this service will now have two containers. Additional updates through the Express Mode Console or APIs will not overwrite the changes to the task definition, unless they are in direct conflict - for example in this case, if you gave Express Mode a new Log Group and Log Stream name, the `logDriver` would be updated back to `awslogs`.

## Adding a custom domain to your service

**Prerequisites:** This guide assumes your domain is a hosted zone managed by Route 53 with an ACM certificate. If your domain is hosted elsewhere, you will need a CNAME to point to the Application Load Balancer DNS record.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. Select the cluster where your Express Mode service is located, and in the **Services** panel, select it.
4. Go to the **Resources** tab and select the listener rule.

5. Select **Action** and **Edit Rule**.
6. Copy the current Host header value (your Application URL), then **Remove** the rule since there can only be one of each type.
7. Add a condition of type **Host header**, paste your Application URL back in as the Host header condition value.
8. Click **Add OR condition value**.
9. Enter your custom domain here.
10. Click **Next** and **Save Changes**.
11. Now select the **Certificates** tab of the Application Load Balancer listener.
12. Click **Add certificate**. Here you can import the certificate to the listener.
13. In your Route 53 hosted zone, click **Create record** to create a routing record to your service.
14. Select a simple routing record.
15. Add a record name.
16. Select a record type.
17. Route traffic to an **Alias to Application and Classic Load Balancer**.
18. Select your Region.
19. Select the load balancer your Express Mode service uses.

After a few minutes for propagation, your service will begin to receive traffic on the custom domain. If you are adding many certificates to your Application Load Balancer or servicing many Express Mode services from your Application Load Balancer, you may want to consider raising the service limit for certificates on the Application Load Balancer.

# Amazon ECS Gateway

Amazon ECS Gateway simplifies ingress networking for containerized applications. It automatically provisions and manages the infrastructure that routes traffic to your Amazon Elastic Container Service (Amazon ECS) services. Instead of configuring Application Load Balancers, listeners, target groups, security groups, and certificates for each service, you define ingress settings once on a gateway and share that infrastructure across many services.

You create a gateway with your desired networking configuration and associate it with one or more Amazon ECS clusters. Each service then opts in by adding a gateway connector parameter. Amazon ECS then provisions and manages the ingress infrastructure in your AWS account, giving each connected service a unique HTTPS hostname.

To get started, see [Create and manage a gateway](#). To connect a service to a gateway that already exists, see [Connect services to a gateway](#).

## How Amazon ECS Gateway works

Amazon ECS Gateway separates infrastructure management from application deployment. It supports two primary personas:

- **Platform teams** own the gateway. They create and configure gateways, and associate them with Amazon ECS clusters. A gateway's configuration applies to every service connected to it and includes settings across networking, security, and operations:
  - **Networking**, such as whether services are reachable from the internet or only from inside the VPC, and which subnets the load balancers use
  - **Security**, such as which security group controls inbound traffic, and which AWS WAF web ACL applies
  - **Operations**, such as where access logs go, how much load balancer capacity to allow, and which request header identifies test traffic during progressive deployments.

You cannot change several of these settings after you create the gateway. For more information, see [the section called “Customizing a gateway”](#).

- **Application teams** opt their services into a gateway by adding a gateway connector parameter when they create or update a service. The connector names the container port that receives traffic, and can also set an access type filter and health checks.

Setting up ingress through a gateway takes three steps:

1. **Create a gateway.** The platform team creates a gateway and defines its ingress configuration, including the networking and security settings.
2. **Associate the gateway with clusters.** The platform team associates the gateway with one or more Amazon ECS clusters, which makes it available to the services in those clusters.
3. **Connect services.** Each service opts in individually. An application team adds a gateway connector when it creates or updates a service, naming the container port that receives traffic.

Amazon ECS provisions no infrastructure until the first service connects. It then creates or reuses the shared resources, creates the per-service resources, and creates a gateway route that directs traffic to the service at a unique HTTPS URL.

## Benefits of Amazon ECS Gateway

Gateways simplify setting up and managing Application Load Balancers for your applications. Amazon ECS Gateway provides the following benefits:

- **Centralized configuration.** Platform teams define networking, security, and traffic management settings once, and every service that connects to the gateway inherits them across clusters. Application teams get ingress for their services without configuring any resources themselves or needing networking expertise.
- **Automated infrastructure management.** Amazon ECS provisions and manages Application Load Balancers, listeners, target groups, security groups, certificates, and DNS hostnames as services opt in to a gateway.
- **Cost optimization.** Share Application Load Balancers across multiple services using the same networking configuration to reduce costs.
- **Transparent infrastructure.** Amazon ECS creates all resources in your AWS account, where you can view and manage them with the AWS Management Console and the AWS APIs.

## Key concepts

The following table describes the concepts you work with when you use Amazon ECS Gateway.

| Concept                            | Description                                                                                                                                                                                                                                                                                                         |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Gateway</b>                     | An account-level resource, with its own ARN, that defines the ingress configuration and manages the underlying infrastructure for the services connected to it. Gateway names are unique within an account and Region.                                                                                              |
| <b>Gateway-cluster association</b> | A link between a gateway and a cluster that makes the gateway available to the services in that cluster. Associations are many-to-many: one gateway can serve multiple clusters, and one cluster can use multiple gateways. For more information, see <a href="#">the section called “Gateway Service Limits”</a> . |
| <b>Gateway connector</b>           | An opt-in parameter on a service that connects it to all compatible gateways associated with its cluster. The connector specifies the name of the container port to expose and includes optional access type and health check settings.                                                                             |
| <b>Gateway route</b>               | A resource with its own ARN that represents one connection between a service and a gateway. Amazon ECS creates a route when the service connects and deletes it when the service disconnects. The route reports the connection status, the service's URL, and the underlying service-specific resources.            |

## Infrastructure managed by Amazon ECS Gateway

Amazon ECS provisions two categories of ingress infrastructure in your account.

| Resource type                          | Managed resources                                                               | Description                                                                      |
|----------------------------------------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <b>Shared infrastructure</b>           | Application Load Balancer, load balancer listener, load balancer security group | Resources that a gateway manages and shares across multiple Amazon ECS services. |
| <b>Service-specific infrastructure</b> | AWS Certificate Manager certificate, DNS hostname, listener rule,               | Resources that Amazon ECS creates for each gateway route to                      |

| Resource type | Managed resources                    | Description                                  |
|---------------|--------------------------------------|----------------------------------------------|
|               | target group, service security group | direct traffic to the corresponding service. |

Amazon ECS uses host-based routing to direct requests from a shared Application Load Balancer to the appropriate service. Each service gets a generated hostname in the form `https://<unique-id>.ecs.<region>.on.aws`. The domain varies by AWS partition.

A gateway provisions nothing when you create it or associate it with a cluster. When the first service connects, Amazon ECS provisions the first load balancer, its listener, and its security group, then adds that service's own resources. As more services connect, Amazon ECS reuses a load balancer that has capacity, or provisions another one. Up to 25 services share one Application Load Balancer, and each service has its own hostname, certificate, and listener rules.

Amazon ECS tags the resources it manages with `AmazonECSManaged=true` and with the system tag `aws:ecs:gateway-arn`, whose value is the gateway's ARN. The target group, listener rules, and service security group that Amazon ECS creates for each gateway route also carry `aws:ecs:gateway-route-arn`. Use these tags to find the resources in the Elastic Load Balancing, Amazon EC2, and AWS Certificate Manager consoles.

## Pricing

There is no additional charge for using Amazon ECS Gateway. You pay only for the underlying AWS resources provisioned in your account when services connect to a gateway, including applicable Application Load Balancer, Amazon CloudWatch logs and metrics, and data transfer charges.

## Availability

Amazon ECS Gateway is available in all commercial AWS Regions. It supports Amazon ECS services that use the `awsvpc` network mode, on all launch types: Amazon ECS EC2, Fargate, and Amazon ECS Managed Instances. You can create and manage gateways using the Amazon ECS console, the AWS CLI, the AWS SDKs, and CloudFormation.

## Gateway Service Limits

The following table lists the service quotas for Amazon ECS Gateway.

| Limit                                        | Value  |
|----------------------------------------------|--------|
| Max Gateway-Cluster Associations Per Cluster | 5      |
| Max Clusters Per Gateway                     | 10,000 |
| Max Gateway Connectors Per Service           | 1      |
| Max Services Per Application Load Balancer   | 25     |
| Max Application Load Balancers Per Gateway   | 200    |

The underlying AWS resources are also subject to their own service quotas. Refer to [Quotas for your Application Load Balancers](#).

## Considerations

Review the following before you adopt Amazon ECS Gateway.

**A gateway serves HTTPS traffic only.** A gateway uses Application Load Balancers with host-based routing, so it serves web applications and APIs addressed by hostname. The listener uses only the HTTPS protocol on port 443. No other protocol is supported.

**A service must use the awsvpc network mode.** A service that uses the bridge, host, or none network mode cannot connect to a gateway.

**A gateway works within a single account.** A gateway and its clusters must be in the same AWS account. You cannot associate a gateway with a cluster in another account.

**A gateway does not work with Express Mode services.** It serves only Amazon ECS services.

**A service has one gateway connector.** You cannot add a second connector to a service. One connector can still connect the service to several gateways.

**A service cannot choose a gateway by name.** A connector connects the service to every compatible gateway associated with its cluster. A gateway is compatible when it matches the access type filter if the service sets one, in the same VPC as the service, and covers every Availability Zone the service runs in. Amazon ECS excludes every gateway that does not match,

and the request fails when there is no compatible gateway in the cluster that meets all three conditions. For more information, see [the section called “How Amazon ECS selects compatible gateways”](#).

**Some gateway settings are immutable after creation.** You cannot change a gateway's name, type, scheme, listener port, listener protocol, subnets, or IP address type after you create it. To change any of these, create a new gateway and move services to it. For more information, see [the section called “Update a gateway”](#).

**Amazon ECS does not consolidate load balancers.** A gateway adds load balancers when the existing ones are full and removes them when they become empty. It does not move services between load balancers, so several partly filled load balancers can remain after services leave.

**Amazon ECS does not repair changes made outside it.** If you modify or delete a resource that a gateway manages, Amazon ECS does not restore it. Traffic to the affected services can stop, and later service deployments, gateway updates, and cleanup operations can fail. For more information, see [the section called “Changes made outside Amazon ECS”](#).

## Create and manage an Amazon ECS Gateway

An Amazon ECS Gateway is an account-level resource that holds the ingress configuration and security standards that connected services inherit. The platform team creates gateways, configures networking policies, and associates them with target Amazon ECS clusters. Application teams then opt in their services and the services then connect to the compatible gateways on the cluster. For more information, see [the section called “Connect services to a gateway”](#).

Creating a gateway does not immediately provision infrastructure. Amazon ECS provisions the first Application Load Balancer only when the first service connects to an associated gateway.

### Prerequisites

Before you create a gateway, ensure that you have the following:

- An infrastructure IAM role that Amazon ECS can assume to provision and manage ingress resources.
- A default VPC in the AWS Region where you create the gateway. If you do not have a default VPC, you can specify your own subnets when creating the gateway.

## Infrastructure IAM role for Amazon ECS Gateway

Amazon ECS requires an infrastructure role to create, configure, and manage load balancers, listeners, target groups, security groups, and AWS Certificate Manager certificates in your account.

Create an IAM role with a trust policy that allows the `ecs.amazonaws.com` service principal to assume it, and attach the AWS managed policy `AmazonECSInfrastructureRoleForGatewayHostSharedALB`. You can see the permissions that this policy grants in the [AWS Managed Policy Reference](#).

```
aws iam create-role \
  --role-name ecsInfrastructureRoleForGateways \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "ecs.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
      }
    ]
  }'
```

```
aws iam attach-role-policy \
  --role-name ecsInfrastructureRoleForGateways \
  --policy-arn arn:aws:iam::aws:policy/
AmazonECSInfrastructureRoleForGatewayHostSharedALB
```

The IAM user or role that creates or updates a gateway must have permission to pass the infrastructure role to Amazon ECS. The following policy scopes `iam:PassRole` to that specific infrastructure role rather than granting it broadly.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::123456789012:role/
ecsInfrastructureRoleForGateways"
```

```
    }  
  ]  
}
```

An application team needs neither `iam:PassRole` nor the gateway operations to give its service an HTTPS endpoint. The team does not need permission to create load balancers either, because those permissions live in the infrastructure role.

#### Note

IAM roles are eventually consistent, so a newly created role might not be usable immediately. Right after you create these roles, your first `create-gateway` call can fail with an error such as `The infrastructureRoleArn could not be assumed`. Verify the role exists and its trust policy allows ECS to assume it. Wait a short time (about a minute) for the role to propagate, and then retry the command.

#### Important

Amazon ECS tags all resources it creates with `AmazonECSManaged=true`. If you modify or remove this tag from a managed Application Load Balancer, security group, or listener rule, Amazon ECS can no longer update or clean up that resource.

## Create a gateway

When creating a gateway, you must specify a unique name, the infrastructure role ARN, and the `hostSharedAlb` configuration object. A `hostSharedAlb` gateway shares Application Load Balancers across services and uses host-based routing to direct incoming traffic to connected ECS services. Every setting inside the configuration is optional, so `--configuration '{"hostSharedAlb": {}}'` creates a gateway that uses default values. `CreateGateway` is a synchronous operation: it returns a status of `ACTIVE`, and Amazon ECS provisions no infrastructure until the first service connects.

### To create a gateway

```
aws ecs create-gateway \  
  --name my-gateway \  
  --configuration '{"hostSharedAlb": {}}'
```

```
--infrastructure-role-arn arn:aws:iam::123456789012:role/
ecsInfrastructureRoleForGateways \
--configuration '{
    "hostSharedAlb": {
        "scheme": "internet-facing",
        "networkConfiguration": {
            "subnets": ["subnet-abc123", "subnet-def456"]
        }
    }
}'
```

Output:

```
{
  "gatewayArn": "arn:aws:ecs:us-west-2:123456789012:gateway/my-gateway/a1b2c3d4",
  "name": "my-gateway",
  "status": "ACTIVE"
}
```

To confirm the gateway and read its configuration back, run `aws ecs describe-gateway --gateway my-gateway`. For more information, see [the section called “View gateway status”](#).

## Customizing a gateway

Amazon ECS selects a default for every setting you do not provide. To customize a gateway, set the optional fields inside the configuration.

Where a setting has an equivalent in Elastic Load Balancing, the field names and values match the Elastic Load Balancing API.

A gateway listener uses HTTPS on port 443. No other protocol or port is supported.

The following settings are immutable once a gateway is created. To change an immutable setting, you must create a new gateway, update your services to connect to it, and delete the previous gateway.

- **Name.** The name must be unique in your account and can be up to 255 characters.
- **Subnets.** Specify the subnets that the load balancers use. The default is the subnets of your default VPC. A gateway's subnets determine which VPC and which Availability Zones it covers. A service connects only to gateways that cover the VPC and Availability Zones it runs in, so your

choice decides which services can use the gateway. If your service does not run in your default VPC, set subnets when you create the gateway.

- **IP address type.** Choose `ipv4`, `dualstack`, or `dualstack-without-public-ipv4`. The default is `dualstack`.
- **Scheme.** Choose `internet-facing` or `internal`. The default is `internet-facing`. Amazon ECS derives the gateway's access type from the scheme, so `internet-facing` gives an access type of `PUBLIC` and `internal` gives `PRIVATE`. A service connects only to gateways whose access type it accepts. For more information, see [the section called “Connect services to a gateway”](#).

You can change the following settings at any time.

- **Inbound security group.** Supply a security group if you want to control inbound traffic to the load balancers yourself. Otherwise, Amazon ECS creates one and manages its inbound rules.
- **Maximum load balancer count.** Enter the number of Application Load Balancers that the gateway can manage. The default is 10.
- **AWS WAF web ACL.** Enter the ARN of a web ACL to associate with every load balancer that the gateway manages. There is no default.
- **HTTP desync mitigation mode.** Choose `monitor`, `defensive`, or `strictest`. The default is `defensive`.
- **Access logs.** Access logs are disabled by default. To enable them, supply an Amazon S3 bucket that you own.
- **Test traffic rules.** Enter the header that routes test traffic to a new service revision. There is no default. A change applies to each service on that service's next deployment.
- **Deletion protection.** Deletion protection is enabled by default, and the gateway propagates it to the load balancers that it manages. You cannot delete the gateway until you disable it.
- **Tag propagation.** The gateway applies its tags to the infrastructure that it manages. To keep your tags on the gateway only, set tag propagation to `NONE`.

## Associate a gateway with Amazon ECS clusters

A cluster's services can use a gateway only after you associate the gateway with their cluster. A gateway and the clusters it serves must be in the same AWS Region and account. Associating a gateway does not route any traffic on its own. It does not change how existing services receive

traffic. Services in this cluster opt in separately, and start using the gateway on their next deployment.

### To associate a gateway with a cluster

```
aws ecs associate-gateway-with-cluster \
  --gateway my-gateway \
  --cluster my-cluster
```

Associations are many-to-many. You can associate a gateway with up to 10,000 clusters, and a cluster with up to 5 gateways. You manage associations only through `AssociateGatewayWithCluster` and `DisassociateGatewayFromCluster`.

When a service with a gateway connector is deployed, Amazon ECS evaluates the gateways associated with its cluster. The service connects to compatible gateways based on its access type, VPC, and Availability Zones. Plan subnet coverage carefully, because it decides a gateway's reach. A gateway serves only the services in the VPC and Availability Zones that its subnets cover. Narrow coverage leaves the rest of the services in the cluster unable to use it. For more information, see [the section called “How Amazon ECS selects compatible gateways”](#).

#### Note

When you associate a gateway with a cluster, existing services are not affected until their next deployment. Adding another gateway to a cluster does not automatically connect services that are already running.

### To list a gateway's cluster associations

```
aws ecs list-gateway-cluster-associations --gateway my-gateway
```

The response includes the gateway ARN, cluster ARN, and association status. An association can have the following statuses:

- **ACTIVE:** The gateway is associated with the cluster
- **DISASSOCIATING:** The association is being removed. Existing gateway routes can continue serving traffic until they are removed.

These are association statuses, not gateway statuses. A gateway has its own set of statuses. You can filter this list by gateway, by cluster, or by status. Pass `--cluster` to see which gateways a cluster has, or filter by status to find every association that is still `DISASSOCIATING`. This is how you check whether a disassociation is pending before you delete a gateway. The results are paginated, 100 per page by default.

## Update a gateway

Updating a gateway changes the settings that every connected service inherits, including the services and infrastructure already behind it. Some settings cannot be changed after you create a gateway. [the section called “Customizing a gateway”](#) describes the available settings and identifies those you cannot change.

### Important

`UpdateGateway` replaces the gateway's configuration with the one in your request. Omitting a setting clears it rather than leaving it unchanged. Before you update, run `describe-gateway` to retrieve the current configuration, and include every setting you want to keep in the request, not only the one you are changing.

### Step 1: Get the current configuration

```
aws ecs describe-gateway --gateway my-gateway
```

```
{
  "gateway": {
    "gatewayArn": "arn:aws:ecs:us-west-2:123456789012:gateway/my-gateway/a1b2c3d4",
    "name": "my-gateway",
    "status": "ACTIVE",
    "accessType": "PUBLIC",
    "deletionProtection": true,
    "infrastructureRoleArn": "arn:aws:iam::123456789012:role/ecsInfrastructureRoleForGateways",
    "propagateTags": "GATEWAY",
    "configuration": {
      "hostSharedAlb": {
        "scheme": "internet-facing",
        "protocol": "HTTPS",
        "port": 443,
```

```

        "maxAlbCount": 10,
        "currentAlbCount": 2,
        "httpDesync": "monitor",
        "networkConfiguration": {
            "subnets": ["subnet-abc123", "subnet-def456"],
            "ipAddressType": "dualstack"
        }
    },
    "tags": [],
    "createdAt": 1760000000.0,
    "updatedAt": 1760400000.0
}

```

## Step 2: Choose the settings to include

Specify the new value for the setting you are changing, and include every other setting with its current value. Amazon ECS does not preserve a setting you leave out. The following table shows where each setting goes and what happens if you leave it out.

| Setting                                   | Where to pass it | If you omit it                                     |
|-------------------------------------------|------------------|----------------------------------------------------|
| infrastructureRoleArn                     | Top level        | The request fails (required)                       |
| configuration.hostSharedAlb               | Top level        | The request fails (required)                       |
| deletionProtection                        | Top level        | Reset to true                                      |
| propagateTags                             | Top level        | Reset to GATEWAY                                   |
| networkConfiguration.inboundSecurityGroup | hostSharedAlb    | Removed. Amazon ECS resumes managing inbound rules |
| webACLArn                                 | hostSharedAlb    | Removed. The web ACL is disassociated              |
| httpDesync                                | hostSharedAlb    | Reset to defensive                                 |

| Setting          | Where to pass it  | If you omit it                        |
|------------------|-------------------|---------------------------------------|
| accessLogs       | hostShare<br>dAlb | Removed. Access logging is turned off |
| testTrafficRules | hostShare<br>dAlb | Removed                               |
| maxAlbCount      | hostShare<br>dAlb | Reset to 10                           |

The gateway's name, scheme, protocol, port, subnets, and ipAddressType are fixed when you create a gateway and cannot be changed. currentAlbCount is a value Amazon ECS reports rather than a setting. Leave all of these out of the request.

#### Note

The infrastructure role is required in every UpdateGateway request. A request without it returns a validation error. If you omit deletion protection or tag propagation, Amazon ECS resets them to their default values.

### Step 3: Update the gateway

This example changes maxAlbCount from 10 to 25. It also includes httpDesync, which is not changing. Omitting it would return the gateway to the default of defensive.

```
aws ecs update-gateway \
  --gateway my-gateway \
  --infrastructure-role-arn arn:aws:iam::123456789012:role/
ecsInfrastructureRoleForGateways \
  --configuration '{
    "hostSharedAlb": {
      "maxAlbCount": 25,
      "httpDesync": "monitor"
    }
  }'
```

Immutable settings describe infrastructure that Amazon ECS cannot rebuild without interrupting traffic. To change an immutable setting, create a new gateway with the configuration you want, associate it with the cluster, move services to it, and then disassociate and delete the old gateway.

When you modify mutable parameters with `UpdateGateway`, Amazon ECS applies the changes across all load balancers managed by the gateway asynchronously. Changes to shared infrastructure take effect as the update runs. The gateway enters `UPDATE_IN_PROGRESS`. Amazon ECS performs rolling updates to all active ALBs. When updates complete, the status becomes `UPDATE_COMPLETE`.

If an update cannot be applied to one or more load balancers (such as an invalid WAF ARN or missing IAM permissions), the gateway status changes to `UPDATE_FAILED`. Use `describe-gateway` to inspect the failure.

### To check the progress of an update

```
aws ecs describe-gateway \
  --gateway my-gateway \
  --query 'gateway.{name:name,status:status}'
```

#### Note

While a gateway is updating, its load balancers hold a mix of the old and the new configuration, because Amazon ECS has applied the change to some of them and not yet to others. Repeat the command until the status changes.

An update can succeed for some load balancers and fail for others. Amazon ECS makes a best effort to update every resource rather than stopping at the first failure. A gateway that reports `UPDATE_FAILED` explains the status in `statusReason`. In `failures`, it records each resource it could not update, and why. Each entry names the resource that failed and the operations, error codes, and messages associated with each failure. A gateway records failures for up to 200 resources, with up to 5 errors each. Resolve the underlying issue, such as missing IAM permissions or an externally modified resource and retry the `update-gateway` operation.

For a gateway's full description, including its configuration and the number of load balancers it currently has, see [the section called “View gateway status”](#).

**⚠ Important**

Until an update reports `UPDATE_COMPLETE`, do not assume that all managed resources have the requested configuration.

The following sections describe the settings you can change. Each shows only its own configuration. Add it to the configuration you retrieved in Step 1, and include the infrastructure role in the request.

## Control inbound traffic

By default, Amazon ECS creates a security group for the gateway's load balancers and allows inbound HTTPS traffic from all IP addresses on port 443. To control inbound traffic yourself, provide your own security group. Amazon ECS attaches the specified security group to the load balancers, removes the existing inbound rules it previously managed, and stops managing inbound rules.

**⚠ Important**

Before specifying an inbound security group, ensure that it allows the required traffic for your services. Otherwise, existing services connected to the gateway might become unreachable.

## To provide your own inbound security group

```
"networkConfiguration": {  
    "inboundSecurityGroup": "sg-085c0f8be53138a08"  
}
```

The load balancers are shared, so changes to inbound security group rules can affect every service using those load balancers. The inbound security group is the only network configuration setting you can change after you create a gateway. The subnets and IP address type cannot be changed.

## Associate an AWS WAF web ACL

Amazon ECS applies the web ACL to every load balancer the gateway manages. The web ACL then protects every service behind the gateway without each team configuring it. The web ACL must be a regional web ACL in the same AWS Region as the gateway.

### To associate a web ACL

```
"webACLArn": "arn:aws:wafv2:us-west-2:123456789012:regional/webacl/my-waf/a1b2c3d4"
```

## Set the HTTP desync mitigation mode

By default, load balancers use defensive mode, which protects against most request smuggling while allowing requests that do not strictly conform to HTTP. Use `strictest` to reject any non-conforming request, or `monitor` to allow all requests and record which ones it would have blocked.

If you are considering `strictest`, start with `monitor` so that you can see what it would reject before it rejects anything. To review the results, enable access logs.

### To set the desync mitigation mode

```
"httpDesync": "strictest"
```

## Enable access logs

Access logs are disabled until you provide an Amazon S3 bucket. Amazon ECS does not create a bucket for you, and no separate setting turns logging on. Supplying a bucket enables access logs.

### To enable access logs

```
"accessLogs": {  
  "destination": {  
    "s3": { "bucket": "my-gateway-logs", "prefix": "alb" }  
  }  
}
```

The bucket must be in the same AWS Region as the gateway, and its bucket policy must allow Elastic Load Balancing to write to it. The infrastructure role is not involved in these writes, so

granting it Amazon S3 permissions has no effect. Because the load balancers are shared, one bucket receives logs for every service on the gateway. Use the hostname in each log record to identify which service a request went to.

## Configure test traffic rules

During a progressive deployment, a new service revision needs to receive traffic before production traffic shifts to it. Test traffic rules identify the requests that reach the new revision.

You configure these rules on the gateway rather than on individual services, so every service behind the gateway uses the same rule. Amazon ECS matches requests by header, and you must provide both the header name and at least one value.

### To configure test traffic rules

```
"testTrafficRules": {  
  "header": { "name": "x-test-traffic", "values": ["canary"] }  
}
```

A request carrying `x-test-traffic: canary` reaches the new revision during a deployment. All other requests reach the production revision. Header matching is the only mechanism. You cannot send a percentage of traffic to the new revision.

Outside a deployment, no new revision exists, so a request carrying the test header reaches the production revision like any other request.

#### Important

A change to test traffic rules does not apply to running services when you make it. It applies to each service on that service's next deployment.

Amazon ECS does not rewrite an existing rule's match conditions. Changing the header creates a new rule for the new revision. A deployment that fails removes only the rule it created and leaves the rule serving the current revision unchanged. As a result, a gateway can have some services matching an old test header and others matching the new one until each service redeploys. Application teams must redeploy their services to pick up a new header. Amazon ECS does not redeploy those services, so coordinate a header change with the service owners.

## Set the maximum load balancer count

`maxAlbCount` limits how many Application Load Balancers the gateway can create. The default is 10.

### To raise the maximum load balancer count

```
"maxAlbCount": 50
```

Two separate limits decide how many services a gateway can serve.

- **Services per load balancer.** A `hostSharedAlb` gateway places up to 25 services on one Application Load Balancer. This is a fixed property of the Application Load Balancer with host-based routing and you cannot change it.
- **Load balancers per gateway.** `maxAlbCount` is the ceiling you set on how many load balancers the gateway can create. The default is 10.

Amazon ECS fills a load balancer to 25 services, then provisions another, up to `maxAlbCount`. When the last service leaves a load balancer, Amazon ECS removes it. Together, the two limits cap a gateway at  $25 \times \text{maxAlbCount}$  services, or 250 at the default.

Raise the maximum before you need it. If a service opts in when every load balancer is full and the gateway is at its maximum, Amazon ECS cannot provision ingress for that service. The failure happens during that service's deployment. Raising the maximum afterward does not retry the deployment that failed, so the service owner must deploy the service again.

To see how many load balancers a gateway has against its maximum, describe the gateway and compare `currentAlbCount` with `maxAlbCount`. To see the load balancers themselves and the gateway routes on each, see [the section called “Inspect managed infrastructure \(platform view\)”](#).

## Disassociate a gateway from a cluster

Disassociate a gateway from a cluster when you no longer want services in that cluster to connect to the gateway. Disassociating prevents new service connections through that association. It does not remove existing service connections immediately.

**⚠ Important**

Before you disassociate a gateway, verify that the affected services have an alternative ingress path if they must remain accessible. Removing gateway routes can make services unreachable through that gateway.

**To disassociate a gateway from a cluster**

```
aws ecs disassociate-gateway-from-cluster \
  --gateway my-gateway \
  --cluster my-cluster
```

The association enters the `DISASSOCIATING` state. While the association is in `DISASSOCIATING` state:

- New services cannot connect to the gateway through the cluster.
- Existing services continue receiving traffic through their gateway routes.
- Services disconnect from the gateway when they are updated or redeployed.
- The association remains `DISASSOCIATING` until all gateway routes have been removed.

Amazon ECS does not automatically redeploy services when a gateway is disassociated from their cluster. Application teams must update or redeploy their services to disconnect from the disassociating gateway. If no other gateways are available on the cluster, remove the gateway connector before redeploying the service. When the last gateway route is removed, Amazon ECS removes the association.

**View gateway routes that prevent disassociation**

Use the `list-gateway-routes` command to identify services that still have gateway routes associated with the cluster.

**To find the gateway routes blocking a disassociation**

```
aws ecs list-gateway-routes --gateway my-gateway --cluster my-cluster
```

The response identifies the gateway routes that are still connected. If routes remain, update or redeploy the affected services to disconnect them from the disassociating gateway.

Besides gateway and cluster, you can filter routes by service, by container port name, and by status. Filtering by status finds routes that are stuck rather than still in use. A route ARN leads to `DescribeGatewayRoute`, which reports the hostname and the service-specific infrastructure for that one connection. For more information, see [the section called “Monitor a gateway”](#).

#### Note

Filtering by a service name alone is not allowed, because service names are unique only within a cluster. Pass either a full service ARN or a service name together with its cluster.

## Cancel a gateway disassociation

While an association is in the `DISASSOCIATING` state, you can reactivate it. Associate the gateway with the same cluster again, and Amazon ECS returns the association to `ACTIVE`.

### To reactivate an association

```
aws ecs associate-gateway-with-cluster \  
  --gateway my-gateway \  
  --cluster my-cluster
```

What a service keeps depends on whether it redeployed while the association was disassociating.

- **Services that have not redeployed** keep their existing gateway routes and DNS hostnames, and continue serving traffic without interruption.
- **Services that redeployed while the association was disassociating** lost their gateway routes. Each one needs another deployment to receive a route again, and that route carries a new DNS hostname.

After a disassociation completes, the association is permanently gone and cannot be reactivated. If the original association has already been fully removed, to use the same gateway with that cluster again, create a new association. Previously connected services receive new gateway routes, with new DNS hostnames, on their next deployment.

## Delete a gateway

You can delete a gateway when it is no longer needed. Before you delete a gateway, the following conditions must be met:

- Deletion protection is disabled.
- The gateway has no cluster associations in the ACTIVE or DISASSOCIATING state.

### Step 1: Disable deletion protection

Deletion protection is enabled by default, so make sure that it is disabled before you continue.

```
aws ecs update-gateway --gateway my-gateway --no-deletion-protection
```

### Step 2: Disassociate the gateway from each of its clusters

Run the following command for each associated cluster.

```
aws ecs disassociate-gateway-from-cluster \  
  --gateway my-gateway \  
  --cluster my-cluster
```

Each association stays in DISASSOCIATING until every gateway route for that gateway in the cluster is removed. Amazon ECS removes a route only when the service that owns it is redeployed or deleted, and it does not redeploy services for you. Coordinate with the service owners to redeploy each service.

To find the routes that are holding an association open, run the following command.

```
aws ecs list-gateway-routes --gateway my-gateway --cluster my-cluster
```

### Step 3: Confirm that no associations remain

Amazon ECS removes an association after its last route is gone. When the list is empty, you can delete the gateway.

```
aws ecs list-gateway-cluster-associations --gateway my-gateway
```

### Step 4: Delete the gateway

```
aws ecs delete-gateway --gateway my-gateway
```

The `DeleteGateway` operation is synchronous. When the operation succeeds, Amazon ECS returns the gateway information with a status of `DELETED`, and subsequent requests for the gateway return a `GatewayNotFoundException`. If the prerequisites are not met, the operation fails.

Nothing remains to clean up. Amazon ECS removes a service's gateway route and its resources when the service disconnects, and removes a load balancer when its last service leaves.

## Connect Amazon ECS services to a gateway

You can connect an Amazon ECS service to a gateway by configuring a gateway connector when you create or update the service. A gateway connector identifies the named container port that receives traffic. You can also configure health checks and specify which gateway access types the service can use.

Amazon ECS connects the service to compatible gateways associated with its cluster. For each connection, Amazon ECS creates a gateway route and provides a unique HTTPS hostname.

### Prerequisites

Before you add a gateway connector to a service, make sure you have the following:

- A gateway is associated with your service's ECS cluster, and the association is `ACTIVE`. If no gateway is associated, Amazon ECS rejects the request, so you find out immediately instead of waiting for a service that deploys without a URL.
- Your service has a task definition that uses `awsvpc` network mode and defines a named port on the container that should receive traffic. For more information, see [Amazon ECS task networking options](#).
- At least one gateway on the cluster is compatible with your service. A gateway is compatible when it is in the same VPC as your service's subnets, matches your access type filter, and covers every Availability Zone your service runs in.

## Connect a service to a gateway

Add a gateway connector to the service and set `portName` to the container port in your task definition that should receive traffic.

### To connect a service to a gateway

```
aws ecs update-service \  
  --cluster my-cluster \  
  --service my-service \  
  --gateway-connectors '[{"portName": "web"}]'
```

During deployment, Amazon ECS selects the compatible gateways, provisions or reuses the required ingress infrastructure, creates the certificate, hostname, listener rules, and target groups, and creates a gateway route for each connection. Each route has its own HTTPS hostname. If more than one gateway is compatible, the service connects to all of them. A service has at most one gateway connector.

## Customize a gateway connector

The `portName` is required. It refers to a named port in your task definition. Amazon ECS uses that port's number, protocol, and protocol version to configure the target group. If the name does not match a port in the task definition your service uses, the request fails. Health check settings and an access type filter are optional.

### Access type filter

The `filters.accessTypes` narrows the gateways your service connects to. Set it to `PUBLIC`, `PRIVATE`, or both, and omit it to accept either. A `PUBLIC` gateway is reachable from the internet. A `PRIVATE` gateway is reachable only from a network that can reach its internal load balancer, so a request from the internet does not arrive. The filter controls gateway selection only. It does not configure traffic rules or security rules.

### To connect only to private gateways

```
aws ecs update-service \  
  --cluster my-cluster \  
  --service my-service \  
  --gateway-connectors '[{  
    "portName": "web",  
    "filters": { "accessTypes": ["PRIVATE"] }  
  }]'
```

Narrowing the filter takes effect on the deployment it starts. Your service drops its connections to the gateways that no longer match, and their URLs stop working.

**⚠ Important**

A service that should never be reachable from the internet must filter on PRIVATE. Without the filter, associating an internet-facing gateway with the cluster later exposes the service on its next deployment.

## Health checks

Amazon ECS configures health checks on the target group it creates for each gateway route, and forwards traffic only to targets that pass. By default, a gateway sends an HTTP request to `/` on the port that `portName` names, every 30 seconds, and expects a 200 response within 5 seconds. A service that answers 200 at `/` needs no health check configuration.

Set a different path if `/` is slow or does real work, such as querying a database or rendering a full page. A health check repeats that work every 30 seconds for each target, and a slow response can exceed the health check timeout and mark a healthy target unhealthy. A lightweight endpoint such as `/health` avoids both.

### To set a health check path

```
aws ecs update-service \
  --cluster my-cluster \
  --service my-service \
  --gateway-connectors '[{
    "portName": "web",
    "healthCheck": { "healthCheckPath": "/health" }
  }]'
```

For what each setting controls, see [Health checks for Application Load Balancer target groups](#) in the *Application Load Balancers User Guide*.

**⚠ Important**

A health check change replaces the target group, so you cannot make one on a service that uses the ROLLING deployment strategy. The request fails with `Target group properties cannot be changed with ROLLING deployment strategy`. Use a BLUE\_GREEN or CANARY deployment strategy on the service, or set the health check configuration when you first connect the service.

## How Amazon ECS selects compatible gateways

During a service deployment, Amazon ECS evaluates the gateways associated with the service's cluster, up to 5 per cluster, and narrows those candidates. It ignores the gateways that do not match rather than failing your deployment.

Amazon ECS matches on three dimensions:

| Dimension         | How Amazon ECS determines eligibility                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access type       | The gateway matches the gateway connector's <code>filters.accessTypes</code> . If you omit the filter, both PUBLIC and PRIVATE gateways are eligible.                                           |
| VPC               | The gateway is in the same VPC as your service's subnets. A gateway in another VPC is not eligible.                                                                                             |
| Availability Zone | The gateway must have configured subnets in every Availability Zone used by the service's configured subnets. A gateway that overlaps with only some of the Availability Zones is not eligible. |

Amazon ECS connects the service to every eligible gateway. An incompatible gateway does not by itself fail the deployment, if another associated gateway is eligible. If no eligible gateway remains, the request fails because the service cannot establish a gateway connection.

Availability Zone coverage must be complete, not partial. A gateway reaches only the Availability Zones where it has subnets. A task that launches in an Availability Zone the gateway does not cover never passes its health checks, and Amazon ECS replaces it. Full Availability Zone coverage ensures tasks launched in any of the service's configured Availability Zones can register with healthy targets behind the connected gateway.

For example, consider two gateways, Gateway 1 (GW1) and Gateway 2 (GW2), and a service (S1) in the same VPC:

| Resource | Configured Availability Zones        | Eligible for service                                     |
|----------|--------------------------------------|----------------------------------------------------------|
| GW1      | us-west-2a , us-west-2b , us-west-2c | Yes. It covers both of the service's Availability Zones. |

| Resource | Configured Availability Zones | Eligible for service               |
|----------|-------------------------------|------------------------------------|
| GW2      | us-west-2a , us-west-2b       | No. It does not cover us-west-2c . |
| S1       | us-west-2b , us-west-2c       |                                    |

Assuming the access type filter also matches, Amazon ECS connects the service to Gateway 1 only. Gateway 1 covers both us-west-2b and us-west-2c, while Gateway 2 does not cover us-west-2c. Connecting the service to Gateway 2 can cause tasks launched in us-west-2c to fail load balancer health checks and be replaced.

### Important

A gateway connector does not select an individual gateway by name or ARN. The service connects to every gateway on the cluster that passes the three checks. A gateway spanning more Availability Zones than your service needs is the safer configuration. To connect a service to a particular gateway, configure that gateway to cover every Availability Zone where the service's tasks run. Coordinate changes to cluster associations with your platform team, because they can affect multiple services.

## Understand service deployment

Creating or updating a service with a gateway connector starts a deployment. Amazon ECS creates the gateway route and its service-specific resources during that deployment. The first connection to a gateway can take longer, because Amazon ECS might need to create a shared Application Load Balancer before it can create your service's resources. Later services reuse that load balancer, its listener, and its security group.

When you update a gateway connector, or deploy the service after a cluster association changes, Amazon ECS reevaluates which gateways are eligible. The deployment establishes routes to newly eligible gateways and removes connections that no longer match.

### How test traffic reaches a new revision

During a progressive deployment, requests carrying the gateway's test traffic header and value reach the new service revision while everything else continues to reach the current one. The

platform team sets that header on the gateway, not on your service, so every service behind the gateway uses the same one. Ask them what it is.

A change to the header reaches your service only on its next deployment, so your service can still be matching a previous header. For more information, see [the section called “Configure test traffic rules”](#).

## Verify the connection and find the service URL

Each eligible gateway produces a separate connection and its own HTTPS hostname. These connections belong to a service revision, so one call returns every connection on the revision you name, along with each connection's URL, access type, and status. During a deployment, more than one revision exists, and each one carries its own connections.

You get a revision ARN from the service's deployment. `describe-service-deployments` returns the ARN of the revision that a deployment is moving to, under `targetServiceRevision.arn`. For more information, see [Viewing Amazon ECS service revision details](#).

### To verify a connection and get the service URL

```
aws ecs describe-service-revisions \
  --service-revision-arns arn:aws:ecs:us-west-2:123456789012:service-revision/my-
cluster/my-service/1234567890123456789 \
  --query 'serviceRevisions[0].ecsManagedResources.gatewayConnections'
```

Each connection carries `serviceUrl`, the HTTPS hostname to send traffic to, alongside `accessType`, which tells you how far that hostname reaches, and `status`. A hostname takes the form `https://<unique-id>.ecs.<region>.on.aws`. The domain varies by AWS partition. The hostname's identifier is random. It is not derived from your service name, so a service that you delete and recreate under the same name gets a different URL.

Read `status` on every connection, and wait until a connection reports `ACTIVE` before you direct client traffic to its URL. `status` reports `CREATE_IN_PROGRESS` while Amazon ECS provisions and `ACTIVE` once that connection is ready, so run the command again until the connections you need report `ACTIVE`. A service connected to two gateways has two connections to check. A connection that reports `CREATE_FAILED` means provisioning failed rather than that it is still running, and waiting longer will not change it. For more information, see [the section called “The service hostname does not respond”](#).

Gateway settings appear in `DescribeServiceRevisions`, because connectors change between deployments and a revision records what was configured when it deployed. For route status, resource inspection, and walking a route through every resource in its path, see [the section called “Monitor gateway routes”](#).

## Migrate a service

**To migrate a service that already has its own load balancer**, add a gateway connector to it. Amazon ECS provisions a gateway route and a new hostname, and it neither removes nor modifies your existing load balancer configuration. Both ingress paths serve traffic at once, so you can validate the gateway URL before you remove your own load balancer in a later update.

**To move a service from one gateway to another**, coordinate with your platform team. Because the connector does not specify a gateway ARN, a migration is controlled through cluster associations and access type filters. That is also why a setting that is fixed on a gateway, such as its scheme, subnets, listener port, or protocol, cannot be changed in place, and creating a replacement gateway and moving services to it is the only way to get a different value.

1. Create and associate the destination gateway. Confirm that its access type and VPC match the service, and that its subnets cover every Availability Zone the service's tasks run in. A gateway that covers only some of them is not eligible and the service will not connect to it.
2. Redeploy the service so that it connects to the destination gateway. If the original gateway remains eligible, both routes can coexist during the transition.
3. Confirm that the service's connection to the destination gateway reports `ACTIVE`, then update the clients that address the old hostname.
4. Have the platform team disassociate the old gateway when it is no longer needed. Redeploy affected services to remove the old routes.

### Important

Disassociating a gateway affects all services using that cluster association. Plan the change with other application teams. The old generated hostname stops working after its gateway route is removed.

## Disconnect a service from gateways

### To disconnect a service from all gateways

```
aws ecs update-service \  
  --cluster my-cluster \  
  --service my-service \  
  --gateway-connectors '[]'
```

To keep only certain gateway access types, update `filters.accessTypes` instead. During the next deployment, Amazon ECS removes the routes for gateways that no longer match. You cannot use an access type filter to remove one specific gateway while retaining another eligible gateway of the same access type.

When a service disconnects, Amazon ECS removes its gateway routes and service-specific ingress resources. The gateway and its cluster associations remain available to other services. Deleting a connected Amazon ECS service also removes its gateway connections. If no services remain on a managed load balancer, Amazon ECS removes that load balancer. A cluster association remains in the `DISASSOCIATING` state until every gateway route on that cluster is removed, and Amazon ECS then removes the association. For more information, see [the section called “Disassociate a gateway from a cluster”](#).

Disconnecting takes effect on the deployment it starts, so the service keeps serving traffic through the gateway until that deployment finishes.

#### Important

Removing the gateway connector makes the service inaccessible through its gateway hostnames after the corresponding routes are removed. Ensure that the service has another ingress path if it must remain accessible.

## Monitor a gateway

You can monitor Amazon ECS Gateway to view the status of a gateway, identify the infrastructure that it manages, and inspect the connections between gateways and Amazon ECS services. You can also use Amazon CloudWatch and Elastic Load Balancing to monitor request traffic and the health of the targets receiving that traffic.

Gateway monitoring includes three types of information:

- **Gateway and association status:** Whether the gateway is available, whether a configuration update succeeded, and which clusters are associated with it.
- **Gateway route status:** Whether Amazon ECS provisioned or updated the ingress infrastructure for a particular service connection.
- **Traffic and target health:** Whether the load balancer receives requests and whether the targets serving a service are healthy.

These statuses are independent. A gateway can be ACTIVE even if an individual gateway route failed to provision. A gateway route can be ACTIVE even if its application targets are unhealthy.

## View gateway status

Use `describe-gateway` to view the configuration and current status of a gateway.

```
aws ecs describe-gateway \  
  --gateway my-gateway
```

The response includes the gateway's status, infrastructure IAM role, and configuration. Use it to confirm whether a change to the gateway's managed infrastructure has completed. Once an update begins, `statusReason` reports how many load balancers were updated out of the total. For example, 12/12 load balancers updated when every load balancer succeeded, or 10/12 load balancers updated, 2 load balancers failed update when some did not. A gateway that has never been updated has no `statusReason`. `failures` appears only when the gateway is in a failure state, so inspect it to identify the affected resources. A failure entry identifies the resource ARN and the failed operation, along with an error code and message. To resolve an update failure, see [the section called "Gateway update failures"](#). A gateway's cluster associations and routes are not part of this response.

To list the gateways in your account and Region, use `list-gateways`:

```
aws ecs list-gateways
```

To view the Amazon ECS clusters associated with a gateway, use `list-gateway-cluster-associations`:

```
aws ecs list-gateway-cluster-associations \  
  --gateway my-gateway
```

```
--gateway my-gateway
```

An ACTIVE association makes a gateway available to compatible services in the cluster. An association in DISASSOCIATING remains until the gateway routes for that cluster are removed.

## Gateway, association, and route status

The following table shows which Amazon ECS operation to use for each resource and the status values it reports.

| Resource                           | API operations                 | Status values            | What the status indicates                                                                                        |
|------------------------------------|--------------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Gateway</b>                     | DescribeGateway                | ACTIVE                   | The gateway's configuration state and the outcome of updates to its managed infrastructure.                      |
|                                    | ListGateways                   | UPDATE_IN_PROGRESS       |                                                                                                                  |
|                                    |                                | UPDATE_COMPLETE          |                                                                                                                  |
|                                    |                                | UPDATE_FAILED            |                                                                                                                  |
|                                    |                                | DELETED                  |                                                                                                                  |
| <b>Gateway cluster association</b> | ListGatewayClusterAssociations | ACTIVE<br>DISASSOCIATING | Whether the association can be used for new service connections or is waiting for existing routes to be removed. |
| <b>Gateway route</b>               | DescribeGatewayRoute           | ACTIVE                   | The provisioning or removal state of a service-to-gateway connection and its ingress resources.                  |
|                                    |                                | CREATE_IN_PROGRESS       |                                                                                                                  |
|                                    | ListGatewayRoutes              | CREATE_FAILED            |                                                                                                                  |
|                                    |                                | UPDATE_IN_PROGRESS       |                                                                                                                  |
|                                    |                                | UPDATE_FAILED            |                                                                                                                  |
|                                    |                                | DELETE_IN_PROGRESS       |                                                                                                                  |
|                                    |                                | DELETE_FAILED            |                                                                                                                  |

A **gateway** is **ACTIVE** from creation until its first update. An update moves it to **UPDATE\_IN\_PROGRESS** and then to **UPDATE\_COMPLETE** or **UPDATE\_FAILED**. Of these, **UPDATE\_FAILED** is the only state that needs you to act: read `statusReason` and the `failures` list to see which load balancers were not updated and why. **DELETED** is terminal, and a later request for the gateway returns `GatewayNotFoundException`.

A **gateway cluster association** is **ACTIVE** once you create it and **DISASSOCIATING** after you remove it. It stays **DISASSOCIATING** until every gateway route for that cluster is gone, so a long-lived **DISASSOCIATING** is a sign that services are still connected, not that anything failed.

A **gateway route** moves through its own create, update, and delete lifecycle and is **ACTIVE** while it carries traffic. The three `*_FAILED` states are where a per-service provisioning problem surfaces. `list-gateway-routes --status CREATE_FAILED UPDATE_FAILED` is how you find them. A connection in the application view does not have a separate status: its `status` is the status of its gateway route, so it uses these same values.

#### Note

A gateway reporting **ACTIVE** does not mean every service behind it is healthy. Gateway status describes the gateway's own configuration. A service deployment that fails to provision ingress shows up on the gateway route, and an unhealthy application shows up in target group health, neither of which changes gateway status.

## Inspect managed infrastructure (platform view)

Use `describe-gateway-resources` to identify the ingress resources that a gateway manages for you.

```
aws ecs describe-gateway-resources \  
  --gateway my-gateway
```

For a `hostSharedAlb` gateway, the response groups resources by Application Load Balancer. Each group identifies the load balancer, its listener, its security group, and the associated gateway routes. Use this view to find which load balancers belong to a gateway and which service connections share each load balancer.

The response returns ARNs of resources that Amazon ECS manages, not live status of the resources. If the response returned state, that state could be stale or contradict what the owning service

reports. For the real state of a resource, use the ARN with the owning AWS service to inspect current resource state. For example, to describe a managed Application Load Balancer, run:

```
aws elbv2 describe-load-balancers \
  --load-balancer-arns arn:aws:elasticloadbalancing:us-
west-2:123456789012:loadbalancer/app/example/0123456789abcdef
```

You can inspect listeners, listener rules, and target groups the same way with the relevant Elastic Load Balancing operations, and security groups with Amazon EC2. Because a gateway reports only its own record and not a live reading, it does not detect when something it manages is changed outside Amazon ECS. For more information, see [the section called “Changes made outside Amazon ECS”](#).

## Monitor gateway routes

Use gateway routes to monitor individual service connections. Each route has its own provisioning status and generated service URL, even when several routes share an Application Load Balancer.

### List gateway routes

To see all service connections through a gateway, run:

```
aws ecs list-gateway-routes \
  --gateway my-gateway
```

To find the routes for a particular service, specify the cluster and service:

```
aws ecs list-gateway-routes \
  --cluster my-cluster \
  --service my-service
```

The response identifies the route ARN, the associated service and gateway, and the route status. You can filter routes by gateway, cluster, service, container port name, or status. To filter by service, pass either a full service ARN or a service name together with its cluster. A service name on its own is ambiguous, because service names are unique only within a cluster, so Amazon ECS returns an error. Use the status filter to find routes whose provisioning or update failed:

```
aws ecs list-gateway-routes \
```

```
--gateway my-gateway \  
--status CREATE_FAILED UPDATE_FAILED
```

A route in `CREATE_IN_PROGRESS` is still provisioning ingress resources, and a route in `ACTIVE` has finished. If a route is in a failed state, inspect it with `describe-gateway-route`, and see [the section called “Troubleshoot a gateway”](#) for recovery guidance.

## Inspect a gateway route

To inspect a particular connection, run `describe-gateway-route` with the route ARN:

```
aws ecs describe-gateway-route \  
  --gateway-route-arn arn:aws:ecs:us-west-2:123456789012:gateway-route/my-gateway/  
a1b2c3d4/9f8e7d6c
```

The response includes the route's status and service URL, along with the identifiers of the ingress resources for that connection: the certificate, the load balancer and its listener, the listener rule for production traffic, the listener rule for test traffic, the load balancer's security groups, and the service security group where the gateway manages the ingress rule. Use these identifiers to follow a request from the shared load balancer to the service. A route normally lists one test listener rule, and lists more only while it is moving from one test header configuration to another. To find the target group that receives production traffic, or the alternate target group that a progressive deployment uses, inspect the service revision instead.

## View gateway connections for a service revision (application view)

Application teams can inspect the gateway connections recorded for a deployed Amazon ECS service revision. Use `describe-service-revisions`:

```
aws ecs describe-service-revisions \  
  --service-revision-arns arn:aws:ecs:us-west-2:123456789012:service-revision/my-  
cluster/my-service/1234567890123456789 \  
  --query 'serviceRevisions[0].ecsManagedResources.gatewayConnections'
```

Each connection identifies the gateway and route, the container port name, the access type, the connection status, and the generated HTTPS service URL. A connection's status is the status of its gateway route, so it reports the gateway route status values. A connection also names the ingress resources for that service: the certificate, the load balancer and its listener, the listener rules for production and test traffic, the load balancer's security groups, and the production and alternate

target groups. A progressive deployment registers the new revision in the alternate target group while the current revision keeps serving from the production one. Inspect a service revision when you want to verify which connections a particular deployment was configured with. Comparing two revisions shows what changed about a service's ingress between deployments. For instructions to create, change, or remove service connections, see [the section called “Connect services to a gateway”](#).

## Monitor traffic and target health

After you connect a service, you watch two things: the traffic reaching it and the health of the targets serving it. Amazon ECS Gateway does not publish metrics of its own for this. Instead, you use the Application Load Balancer metrics that Elastic Load Balancing publishes to Amazon CloudWatch, and you read target health directly from Elastic Load Balancing.

### Choose the right metric dimensions

A gateway can place up to 25 services on one Application Load Balancer, so a metric reported for the whole load balancer combines every service on it. To see one service on its own, query the metric with the target group dimension instead of the load balancer dimension. Choose the dimensions that match what you want to see.

| Monitoring scope              | Recommended dimensions                                                        | Useful metrics                                                                                        |
|-------------------------------|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| Individual service connection | TargetGroup with LoadBalancer                                                 | RequestCount , TargetResponseTime , HTTPCode_Target_5XX_Count , HealthyHostCount , UnHealthyHostCount |
| Shared load balancer          | LoadBalancer                                                                  | HTTPCode_ELB_5XX_Count , ActiveConnectionCount , RejectedConnectionCount , ConsumedLCUs               |
| Availability Zone             | AvailabilityZone with the applicable load balancer or target group dimensions | Target health and request metrics, to tell whether an issue is limited to one Availability Zone       |

Application teams should use the target group dimension. A request spike or a rise in 5XX responses on the load balancer dimension might come from another service that shares the load balancer, and you cannot attribute it to yours. Find your service's target group in its gateway connection, which `describe-service-revisions` returns. For the full list of metrics and the statistics each supports, see [CloudWatch metrics for your Application Load Balancer](#) in the *Application Load Balancers User Guide*.

### Note

Elastic Load Balancing publishes a metric only while traffic is flowing, and it does not count health check requests. A newly connected service that has not received traffic yet shows no request metrics. This is expected and does not indicate a problem.

## Check target health

Metrics show trends over time. To see the health of your targets right now, read the target group directly:

```
aws elbv2 describe-target-health \  
  --target-group-arn arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/  
example/0123456789abcdef
```

The response gives the current state of each registered target, and a reason when a target is unhealthy, such as a failed health check and the response code it received. A gateway route in ACTIVE status means Amazon ECS finished provisioning the ingress. It does not mean the targets behind it are healthy, so check target health separately. If targets stay unhealthy, see [the section called “Service connectivity and target health”](#).

## Configure CloudWatch alarms

Create alarms on the metrics that matter to your application, such as unhealthy targets, rising target response time, and target 5XX errors. Platform teams can also alarm on load balancer 5XX errors and rejected connections for the shared infrastructure.

A gateway adds load balancers as services connect and removes them as services disconnect, so an alarm tied to a single load balancer or target group ARN can quietly stop measuring anything when that resource goes away. Amazon ECS tags every load balancer it creates with the gateway's

ARN. Select resources by that tag so your alarms and dashboards keep following the gateway as its infrastructure changes. For more information, see [Using resource tags for telemetry](#) in the *Amazon CloudWatch User Guide*. Account for metrics that are not emitted in every period by choosing how an alarm treats missing data.

## View traffic and operation logs

### Application Load Balancer access logs

When access logging is enabled for a gateway's managed load balancers, Elastic Load Balancing delivers request records to the configured Amazon S3 bucket. Access logs capture request and response information that helps you examine traffic patterns and investigate individual requests.

Because the load balancers are shared, one load balancer's access logs can include requests for several services. Use the hostname in each log record to tell one service's requests from another's. Access logs are disabled by default. For how to turn them on, see [the section called "Enable access logs"](#). For the log format and delivery behavior, see [Access logs for your Application Load Balancer](#) in the *Application Load Balancers User Guide*.

### Locate failure details

When a monitoring operation reports a failure, use the following table to find where the failure is recorded.

| Failure observed                                            | Where to look              | Information available                                                                                      |
|-------------------------------------------------------------|----------------------------|------------------------------------------------------------------------------------------------------------|
| A gateway configuration update reports UPDATE_FAILED        | describe-gateway           | statusReason and failures identify the affected managed resources and the operations that did not succeed. |
| A service connection reports CREATE_FAILED or UPDATE_FAILED | describe-gateway-route     | The route's status and the ingress resources for that connection.                                          |
| A service deployment does not reach the expected state      | describe-service-revisions | The service revision's gateway connections and context about the deployment operations.                    |

| Failure observed                                   | Where to look                                                                          | Information available                                                             |
|----------------------------------------------------|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Requests fail or application targets are unhealthy | Elastic Load Balancing target health, CloudWatch metrics, and access logs (if enabled) | Target health states, request metrics, and information about individual requests. |

Use these sources to determine which resource or connection is affected. For symptoms, likely causes, and recovery procedures, see [the section called “Troubleshoot a gateway”](#).

## Troubleshoot a gateway

Use this topic to troubleshoot issues with Amazon ECS Gateway, including service connection failures, gateway route provisioning failures, gateway configuration updates, and connectivity issues.

Amazon ECS gateways, gateway routes, and application targets report their status independently. A gateway can remain ACTIVE even when a gateway route fails to provision, and a gateway route can be ACTIVE even when its application targets are unhealthy. To identify the cause of a failure, review the error returned by the API operation or inspect the status and failure details of the affected gateway or gateway route.

Before investigating further, verify that you are using the correct resource name or ARN, AWS account, and Region. Ensure that Amazon ECS Gateway is supported in your Region and that you have the required permissions. For service connection issues, verify that the service's task definition uses the `awsvpc` network mode.

If the issue persists, use the following troubleshooting procedures to identify and resolve the failure.

## Service connection and deployment failures

### No gateways are associated with the cluster

A `CreateService` or `UpdateService` request that includes a gateway connector fails when no gateways are associated with the service's cluster. Amazon ECS reports `gatewayConnectors` were specified but no gateways are associated with `cluster` and rejects the

request rather than deploying a service it cannot give a URL. Check the cluster's gateway associations to verify that at least one gateway is associated with the service's cluster.

```
aws ecs list-gateway-cluster-associations \
  --cluster my-cluster
```

If no association is available, contact your platform team to associate a gateway before you deploy the service with a connector. A gateway whose association has entered `DISASSOCIATING` is not available for new connections. You also see this error after the platform team deletes the last gateway on your cluster. Remove the connector from your service, or wait for a replacement gateway, before your next update.

## No compatible gateway matches the service

Amazon ECS evaluates the gateways associated with the cluster and connects the service to every gateway that meets all of the following conditions:

- **Access type.** The gateway's access type matches the `filters.accessTypes` setting in the service's gateway connector. If you omit this filter, both `PUBLIC` and `PRIVATE` gateways are eligible.
- **VPC.** The gateway and the service are in the same VPC.
- **Availability Zones.** The gateway covers all Availability Zones used by the service's configured subnets. The subnet IDs themselves do not need to match, but the gateway must have subnet coverage in every Availability Zone the service uses.

A gateway that does not meet these conditions is excluded. If at least one compatible gateway is available, the service connects to it. If no compatible gateways are available, the request fails. Amazon ECS reports has associated gateways but none are in the service's VPC when no associated gateway is in the service's VPC, and none of the gateways associated with `cluster` match when the access type filter excludes every remaining gateway.

## To identify and resolve a compatibility mismatch

1. **Check the service's access type filter.** Verify that `filters.accessTypes` matches the access type of the gateway you want to connect to.
2. **Retrieve the service's configured subnets.** Use `list-service-deployments` to identify the relevant service revision ARN.

```
aws ecs list-service-deployments \  
  --cluster my-cluster \  
  --service my-service \  
  --query 'serviceDeployments[].targetServiceRevisionArn'
```

Then use `describe-service-revisions` to retrieve its configured subnets.

```
aws ecs describe-service-revisions \  
  --service-revision-arns <service-revision-arn> \  
  --query 'serviceRevisions[0].networkConfiguration.awsVpcConfiguration.subnets'
```

3. **Retrieve the gateway's configured subnets.** Use `describe-gateway` to view the gateway's networking configuration.

```
aws ecs describe-gateway \  
  --gateway my-gateway
```

4. **Compare the VPCs and Availability Zones.** Use `describe-subnets` to retrieve the VPC ID and Availability Zone for the service and gateway subnets.

```
aws ec2 describe-subnets \  
  --subnet-ids <subnet-ids> \  
  --query 'Subnets[0].  
{SubnetId:SubnetId,VpcId:VpcId,AvailabilityZone:AvailabilityZone}'
```

Verify that the service and gateway are in the same VPC and that the gateway covers all Availability Zones used by the service.

5. **Resolve the mismatch.** Update the service's access type filter or subnet configuration as appropriate. If no compatible gateway is available, contact your platform team to configure or associate a gateway that matches the service's access type, VPC, and Availability Zone requirements.

After resolving the mismatch, retry the service creation or update.

#### Note

For greater flexibility when connecting ECS services, configure gateways with subnets that cover all Availability Zones where your services might run. Broader Availability Zone

coverage allows a gateway to support more services and reduces the need to create additional gateways. Gateway subnets cannot be changed after creation.

## Gateway connector references an invalid container port

A gateway connector's `portName` must match the name of a port mapping in the service's task definition. It is the name of the port, not the numeric container port. When no container in the task definition has a port mapping with that name, Amazon ECS reports `InvalidConfiguration: "portName not found in task definition portMappings"`. To inspect the named port mappings, run:

```
aws ecs describe-task-definition \
  --task-definition my-task-definition:1 \
  --query 'taskDefinition.containerDefinitions[].portMappings[].name'
```

Correct the connector or the task definition so the names match, and then retry the service operation. Check this again after you update a task definition, because a previously valid port name might no longer exist.

## Updating health checks fails with the ROLLING deployment strategy

Updating a gateway connector's health check settings returns an error stating that target group properties cannot be changed with the ROLLING deployment strategy. Changing those settings requires a replacement target group, and a service that uses the ROLLING deployment strategy does not support that replacement during an update.

Keep the existing health check settings, or use a blue/green or canary deployment strategy for the change. If you must disconnect and reconnect the service to replace the target group, plan for the removal and recreation of its gateway route and hostname. For connector configuration, see [the section called "Connect services to a gateway"](#).

## Gateway route provisioning failures

A service connection can have a gateway route in `CREATE_FAILED` or `UPDATE_FAILED` state, or a service deployment can fail to finish provisioning ingress. A route level failure does not necessarily change the gateway's overall status or affect another service's existing route.

1. Find the failed gateway routes.

```
aws ecs list-gateway-routes \  
  --gateway my-gateway \  
  --status CREATE_FAILED UPDATE_FAILED
```

2. Identify the service that each failed route belongs to, and the resources the gateway created for it.

```
aws ecs describe-gateway-route \  
  --gateway-route-arn arn:aws:ecs:us-west-2:123456789012:gateway-route/my-gateway/  
a1b2c3d4/9f8e7d6c
```

3. Check the service's deployment status and service events for the failure reason. Determine from the reason whether certificate issuance, a listener rule, a target group, a security group, or another resource failed.
4. Correct the underlying issue and retry the affected service deployment. A gateway configuration change does not necessarily restart a service deployment that already failed.

#### Note

A gateway route reports a failure status but not the reason for it. Amazon ECS records the reason on the service deployment that triggered the provisioning, and in the service's events.

Common causes include insufficient infrastructure role permissions, load balancer capacity or service quotas, subnet IP exhaustion, and resources deleted or changed outside Amazon ECS. Two reasons you may see are `InsufficientAvailabilityZones`, which means the gateway's subnets are in fewer than two Availability Zones, the minimum for an Application Load Balancer, and `InvalidSubnet`, which means a configured subnet does not exist, belongs to a different VPC, or has no free IP addresses left. The sections that follow describe how to investigate the permission, capacity, and out-of-band conditions. For the monitoring procedures, see [the section called "Monitor a gateway"](#).

For the permissions the hostSharedALB gateway type requires, see [AmazonECSInfrastructureRoleForGatewayHostSharedALB](#) in the *AWS Managed Policy Reference*.

## Capacity and quota issues

For the quota values, see [the section called “Gateway Service Limits”](#).

### The cluster has reached its gateway association limit

A cluster can associate with at most 5 gateways. When it reaches that limit, Amazon ECS reports `Cluster has reached the maximum number of gateway associations (5)`. Disassociate a gateway the cluster no longer needs, which requires disconnecting the services still using it first.

### The gateway has reached its maximum number of load balancers

When a gateway's existing load balancers cannot accept another service connection, Amazon ECS provisions another load balancer until it reaches the gateway's `maxAlbCount` setting, which defaults to 10. A load balancer can serve up to 25 ECS services. When every load balancer is full and the gateway is at `maxAlbCount`, a new service's deployment fails. Check the `currentAlbCount` against `maxAlbCount` and inspect the managed resources:

```
aws ecs describe-gateway --gateway my-gateway
aws ecs describe-gateway-resources --gateway my-gateway
```

If `maxAlbCount` is the limiting factor, increase it within the supported limit. For example:

```
aws ecs update-gateway \
  --gateway my-gateway \
  --configuration '{"hostSharedAlb":{"maxAlbCount":25}}'
```

Wait for the gateway update to complete, and then redeploy the affected service. Increasing `maxAlbCount` does not automatically retry a failed service deployment.

### An underlying AWS resource quota was reached

The resources provisioned by ECS Gateway are subject to their owning services' quotas, including load balancers, target groups, listener rules, certificates, and security group rules. Provisioning can also fail if the configured subnets do not have enough available IP addresses. You may see the following reasons:

- `LoadBalancerQuotaExceeded` and `TargetGroupQuotaExceeded`, for the account's limits in the Region.

- `ResourceQuotaExceeded`, for a per load balancer limit such as listener rules or certificates.
- `CertificateQuotaExceeded`, for the account's certificate limit.
- `CertificateAnnualLimitExceeded`, for certificates requested in the last 365 days. Deleting certificates does not reduce this count, so this one needs a quota increase through AWS Support.
- `SecurityGroupCapacityExceeded` and `SecurityGroupRuleCapacityExceeded`, for security groups per VPC and rules per security group.
- `TestRuleLimitExceeded`, for test traffic rules on one service.
- `TagLimitExceeded`, for a combination of gateway tags and service tags that exceeds what a resource allows, or for tags an account tag policy rejects. Amazon ECS also applies its own `AmazonECSManaged` tag, which uses one slot.

Use the failure reason to identify the constrained resource and then check the applicable service quota. Request a quota increase, release unused capacity, or use a supported alternative configuration, and then retry the service deployment. For Elastic Load Balancing limits, see [Quotas for your Application Load Balancers](#).

## IAM and permissions issues

Gateway operations involve two different identities: the IAM principal that makes the API request, and the infrastructure IAM role that Amazon ECS assumes to manage AWS resources. A permission problem on one is not fixed by changing the other.

### The caller cannot pass the infrastructure role

`CreateGateway` and `UpdateGateway` fail with a permissions error that involves `iam:PassRole` when the caller cannot pass the role provided in `infrastructureRoleArn`. This is the most common first-run failure, because the call fails even when the caller is allowed to create gateways. Confirm that the caller has `iam:PassRole` permission on the exact role ARN in `infrastructureRoleArn`, and check permissions boundaries, service control policies, and explicit denies. Adding permissions to the infrastructure role does not resolve a missing permission on the calling identity. For IAM role setup, see [the section called "Infrastructure IAM role for Amazon ECS Gateway"](#).

### Amazon ECS cannot assume the infrastructure role

Amazon ECS could reach the role but could not assume it. Verify that the IAM role exists and that its trust policy permits `ecs.amazonaws.com` to call `sts:AssumeRole`.

```
aws iam get-role --role-name ecsInfrastructureRoleForGateways
```

The role's trust policy must match the following.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessInfrastructureForECSGateways",
      "Effect": "Allow",
      "Principal": {
        "Service": "ecs.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

If the role was just created or modified, allow time for the IAM change to propagate before you retry. A missing or incorrect trust relationship is not fixed by granting the caller `iam:PassRole` alone. Confirm as well that the role is in the same account and partition as the gateway. A related failure, AWS STS is not activated for this account in a Region, means AWS Security Token Service is not enabled for that Region. Activate it, and then retry.

## The infrastructure role cannot manage a resource

A gateway route or a gateway update reports an access denied error for an Elastic Load Balancing, Amazon EC2, or AWS Certificate Manager operation when the infrastructure role is missing a permission. Verify that the role has the permissions required by the gateway configuration. For the `hostSharedAlb` gateway type, check the attached AWS managed policy.

```
aws iam list-attached-role-policies --role-name ecsInfrastructureRoleForGateways
```

Attach the `AmazonECSInfrastructureRoleForGatewayHostSharedALB` managed policy, or, if you replaced it with a policy of your own, compare that policy against the IAM action named in the failure. You can see the permissions that this policy grants in the [AWS Managed Policy Reference](#). Check also whether a permissions boundary or another account restriction prevents the action. The exact failed operation and resource ARN are more useful than an undifferentiated `AccessDenied` message.

# Service connectivity and target health

## The service hostname does not respond

When requests to a gateway-generated HTTPS hostname time out or fail, check the connection from the gateway route to the application.

1. **Check the gateway route status.** Find the route for the service and confirm that it is ACTIVE. A route in CREATE\_IN\_PROGRESS has not finished provisioning, and a route in a \*\_FAILED state has a provisioning failure. Inspect the route failure before troubleshooting the application:

```
aws ecs list-gateway-routes --cluster my-cluster --service my-service
```

2. **Check gateway access.** An internal gateway requires network connectivity to the internal load balancer. Verify that you are testing from a network that can reach it.
3. **Check target health.** Get the target group ARN from the service's gateway connection, which describe-service-revisions returns, then inspect its registered targets.

```
aws elbv2 describe-target-health \  
  --target-group-arn arn:aws:elasticloadbalancing:us-  
west-2:123456789012:targetgroup/my-service/0123456789abcdef
```

A target group can report unhealthy targets when the application returns an unexpected status code, times out, listens on a different port, or cannot be reached by the load balancer. The response includes each target's health state and, when relevant, a reason and description. For example, a reason of Target.ResponseCodeMismatch indicates that the response did not match the configured success code range. Check the health check path, the application response, and the target port before you modify any gateway infrastructure. For the health check reason codes, see [Health checks for Application Load Balancer target groups](#).

An ACTIVE gateway route means that ingress provisioning succeeded. It does not mean that the application targets are healthy.

4. **Check the security groups.** Confirm that the load balancer's inbound security group allows traffic from the intended clients, and that the task security group allows traffic from the load balancer on the container port. When the platform team supplies the gateway's inbound security group, Amazon ECS does not manage its inbound rules.
5. **Check the application and traffic controls.** Verify the container's listening port and health endpoint. If an AWS WAF web ACL is configured, check whether a rule is blocking the request.

Use load balancer access logs and CloudWatch metrics to tell load balancer errors apart from application responses.

## Gateway update failures

DescribeGateway reports UPDATE\_FAILED after a gateway configuration update that Amazon ECS could not apply to every load balancer. Amazon ECS applies an update to each managed load balancer in turn and makes a best effort to update them all rather than stopping at the first failure, so some load balancers might accept the change while others fail. Do not assume the update was rolled back across the gateway. Retrieve the status and the failure information.

```
aws ecs describe-gateway --gateway my-gateway
```

Inspect statusReason and failures for the resources and operations that could not be updated. For example, an error for an invalid security group identifier points to the gateway's configured inbound security group, and an access denied error points to the permissions available to the infrastructure role. For how to read the failures list, see [the section called “Locate failure details”](#). Correct the reported cause and retry the requested update. Wait until the gateway reports a successful update before you assume every managed load balancer has the new configuration, and wait for the update to complete before retrying.

### Important

A partial gateway update can leave different load balancers with different configurations, which can change traffic or policy behavior for the services behind them. Treat the update as partially applied until the gateway reports UPDATE\_COMPLETE, and validate the affected resources after recovery.

## Disassociation and deletion issues

### A cluster association remains DISASSOCIATING

A gateway cluster association remains in DISASSOCIATING until all gateway routes associated with that cluster are removed. Amazon ECS does not automatically redeploy connected services or remove their existing routes when you disassociate a gateway.

To identify the services that are still connected, use the following command:

```
aws ecs list-gateway-routes --gateway my-gateway --cluster my-cluster
```

Coordinate with the application teams to update or redeploy the affected services so they disconnect from the gateway. When the last route is removed, the disassociation completes.

## The gateway cannot be deleted

A gateway cannot be deleted while deletion protection is enabled or while it has cluster associations in the ACTIVE or DISASSOCIATING state. Check the gateway's cluster associations and ensure that all remaining gateway routes are removed so disassociation can complete. After all associations are removed, make sure that deletion protection is disabled, and then retry deleting the gateway. For the complete procedure, see [the section called “Delete a gateway”](#).

```
aws ecs update-gateway --gateway my-gateway --no-deletion-protection
aws ecs delete-gateway --gateway my-gateway
```

## Changes made outside Amazon ECS

Amazon ECS does not automatically repair or recreate gateway-managed resources that are modified or deleted outside Amazon ECS. Modifying or deleting managed resources such as load balancers, listeners, listener rules, target groups, certificates, or security groups outside Amazon ECS can interrupt traffic or cause subsequent service deployments, gateway updates, or cleanup operations to fail.

If a gateway-managed resource was modified or deleted outside Amazon ECS, take the following steps:

1. **Identify the affected resource:** Use `describe-gateway-resources` or `describe-gateway-route` to identify the managed resources. Inspect their current configuration in the corresponding AWS service to identify missing or modified resources. A change made outside Amazon ECS can surface as one of the following failure reasons:
  - `ManagedResourceDeleted`, when a resource Amazon ECS created for the service was deleted outside Amazon ECS.
  - `ConflictingListener`, when a listener on the gateway's port exists on the load balancer and Amazon ECS did not create it.
  - `SecurityGroupNameInUse`, when a security group with the name Amazon ECS wants exists and is not managed by Amazon ECS. Amazon ECS does not reconfigure or delete it.

- `InvalidSecurityGroup`, when the gateway's inbound security group no longer exists.
2. **Recover the affected service:** If a resource was modified, restore its original configuration and redeploy the service. If a resource was deleted, remove the gateway connector from the service and deploy, then add the connector back and deploy again. The second deployment provisions fresh resources and a new gateway route. Because the service receives a new generated hostname, update any clients or DNS records that point at the old one.
  3. **Verify connectivity:** Confirm that the service's gateway route is `ACTIVE` and its targets are healthy before you redirect traffic to it.

 **Important**

Do not modify or remove the `AmazonECSManaged` tag from gateway-managed resources. Amazon ECS uses it to identify the resources it manages, and without it Amazon ECS can no longer update or clean up that resource. Make supported configuration changes through Amazon ECS Gateway operations rather than modifying the underlying resources directly.

# Amazon ECS task definitions

A *task definition* is a blueprint for your application. It is a text file in JSON format that describes the parameters and one or more containers that form your application.

The following are some of the parameters that you can specify in a task definition:

- The capacity to use, which determines the infrastructure that your tasks are hosted on
- The Docker image to use with each container in your task
- How much CPU and memory to use with each task or each container within a task
- The memory and CPU requirements
- The operating system of the container that the task runs on
- The Docker networking mode to use for the containers in your task
- The logging configuration to use for your tasks
- Whether the task continues to run if the container finishes or fails
- The command that the container runs when it's started
- Any data volumes that are used with the containers in the task
- The IAM role that your tasks use

For a complete list of task definition parameters, see [Amazon ECS task definition parameters for Fargate](#).

After you create a task definition, you can run the task definition as a task or a service.

- A *task* is the instantiation of a task definition within a cluster. After you create a task definition for your application within Amazon ECS, you can specify the number of tasks to run on your cluster.
- An Amazon ECS *service* runs and maintains your desired number of tasks simultaneously in an Amazon ECS cluster. How it works is that, if any of your tasks fail or stop for any reason, the Amazon ECS service scheduler launches another instance based on your task definition. It does this to replace it and thereby maintain your desired number of tasks in the service.

- [Example Amazon ECS task definitions](#)

## Amazon ECS task definition states

A task definition changes states when you create, deregister, or delete it. You can view the task definition state in the console, or by using `DescribeTaskDefinition`.

The following are the possible states for a task definition:

### ACTIVE

A task definition is **ACTIVE** after it is registered with Amazon ECS. You can use task definitions in the **ACTIVE** state to run tasks, or create services.

### INACTIVE

A task definition transitions from the **ACTIVE** state to the **INACTIVE** state when you deregister a task definition. You can retrieve an **INACTIVE** task definition by calling `DescribeTaskDefinition`. You cannot run new tasks or create new services with a task definition in the **INACTIVE** state. There is no impact on existing services or tasks.

### DELETE\_IN\_PROGRESS

A task definition transitions from the **INACTIVE** state to the **DELETE\_IN\_PROGRESS** state after you submitted the task definition for deletion. After the task definition is in the

DELETE\_IN\_PROGRESS state, Amazon ECS periodically verifies that the target task definition is not being referenced by any active tasks or deployments, and then deletes the task definition permanently. You cannot run new tasks or create new services with a task definition in the DELETE\_IN\_PROGRESS state. A task definition can be submitted for deletion at any moment without impacting existing tasks and services.

Task definitions that are in the DELETE\_IN\_PROGRESS state can be viewed in the console and you can retrieve the task definition by calling `DescribeTaskDefinition`.

When you delete all INACTIVE task definition revisions, the task definition name is not displayed in the console and not returned in the API. If a task definition revision is in the DELETE\_IN\_PROGRESS state, the task definition name is displayed in the console and returned in the API. The task definition name is retained by Amazon ECS and the revision is incremented the next time you create a task definition with that name.

If you use AWS Config to manage your task definitions, AWS Config charges you for all task definition registrations. You are only charged for deregistering the latest ACTIVE task definition. There is no charge for deleting a task definition. For more information about pricing, see [AWS Config Pricing](#).

## Amazon ECS resources that can block a deletion

A task definition deletion request will not complete when there are any Amazon ECS resources that depend on the task definition revision. The following resources might prevent a task definition from being deleted:

- Amazon ECS standalone tasks - The task definition is required in order for the task to remain healthy.
- Amazon ECS service tasks - The task definition is required in order for the task to remain healthy.
- Amazon ECS service deployments and task sets - The task definition is required when a scaling event is initiated for an Amazon ECS deployment or task set.

If your task definition remains in the DELETE\_IN\_PROGRESS state, you can use the console, or the AWS CLI to identify, and then stop the resources which block the task definition deletion.

## Task definition deletion after the blocked resource is removed

The following rules apply after you remove the resources that block the task definition deletion:

- Amazon ECS tasks - The task definition deletion can take up to 1 hour to complete after the task is stopped.
- Amazon ECS service deployments and task sets - The task definition deletion can take up to 24 hours to complete after the deployment or task set is deleted.

## Architect your application for Amazon ECS

You architect your application by creating a task definition for your application. The task definition contains the parameters that define information about the application, including:

- The capacity to use, which determines the infrastructure that your tasks are hosted on.

When you use the EC2 capacity provider, you also choose the instance type. When you use the Amazon ECS Managed Instances capacity provider, you can provide instance requirements for Amazon ECS to manage compute capacity. For some instance types, such as GPU, you need to set specific parameters. For more information, see [Amazon ECS task definition use cases](#).

- The container image, which holds your application code and all the dependencies that your application code requires to run.
- The networking mode to use for the containers in your task.

The networking mode determines how your task communicates over the network.

For tasks that run on EC2 instances and Amazon ECS Managed Instances, there are multiple options, but we recommend that you use the awsvpc network mode. The awsvpc network mode simplifies container networking by giving you more control over how your applications communicate with each other and other services within your VPCs.

For tasks that run on Fargate, you must use the awsvpc network mode.

- The logging configuration to use for your tasks.
- Any data volumes that are used with the containers in the task.

For a complete list of task definition parameters, see [Amazon ECS task definition parameters for Fargate](#).

Use the following guidelines when you create your task definitions:

- Use each task definition family for only one business purpose.

If you group multiple types of application containers together in the same task definition, you can't independently scale those containers. For example, a website and an API typically require different scaling patterns. As traffic increases, you might need a different number of web containers than API containers. If these two containers are deployed in the same task definition, every task runs the same number of web containers and API containers.

- Match each application version with a task definition revision within a task definition family.

Within a task definition family, each task definition revision represents a point-in-time snapshot of the settings for a particular container image. This is similar to how the container is a snapshot of all the components needed to run a particular version of your application code.

Create a one-to-one mapping between a version of application code, a container image tag, and a task definition revision. A typical release process involves a git commit that gets turned into a container image that's tagged with the git commit SHA. Then, that container image tag gets its own Amazon ECS task definition revision. Last, the Amazon ECS service is updated to deploy the new task definition revision.

- Use different IAM roles for each task definition family.

Define each task definition with its own IAM role. Implement this practice along with providing each business component its own task definition family. By implementing both of these best practices, you can limit how much access each service has to resources in your AWS account. For example, you can give your authentication service access to connect to your passwords database. At the same time, you can ensure that only your order service has access to the credit card payment information.

## Best practices for Amazon ECS task sizes

Your container and task sizes are both essential for scaling and capacity planning. In Amazon ECS, CPU and memory are two resource metrics used for capacity. CPU is measured in units of 1/1024 of a full vCPU (where 1024 units is equal to 1 whole vCPU). Memory is measured in mebibytes. In your task definition, you can configure resource reservations and limits.

When you configure a reservation, you're setting the minimum amount of resources that a task requires. Your task receives at least the amount of resources requested. Your application might be able to use more CPU or memory than the reservation that you declare. However, this is subject to any limits that you also declared. Using more than the reservation amount is known as bursting. In Amazon ECS, reservations are guaranteed. For example, if you use Amazon EC2 instances to

provide capacity, Amazon ECS doesn't place a task on an instance where the reservation can't be fulfilled.

A limit is the maximum amount of CPU units or memory that your container or task can use. Any attempt to use more CPU more than this limit results in throttling. Any attempt to use more memory results in your container being stopped.

Choosing these values can be challenging. This is because the values that are the most well suited for your application greatly depend on the resource requirements of your application. Load testing your application is the key to successful resource requirement planning and better understanding your application's requirements.

## Stateless applications

For stateless applications that scale horizontally, such as an application behind a load balancer, we recommend that you first determine the amount of memory that your application consumes when it serves requests. To do this, you can use traditional tools such as `ps` or `top`, or monitoring solutions such as CloudWatch Container Insights.

When determining a CPU reservation, consider how you want to scale your application to meet your business requirements. You can use smaller CPU reservations, such as 256 CPU units (or 1/4 vCPU), to scale out in a fine-grained way that minimizes cost. But, they might not scale fast enough to meet significant spikes in demand. You can use larger CPU reservations to scale in and out more quickly and therefore match demand spikes more quickly. However, larger CPU reservations are more costly.

## Other applications

For applications that don't scale horizontally, such as singleton workers or database servers, available capacity and cost represent your most important considerations. You should choose the amount of memory and CPU based on what load testing indicates you need to serve traffic to meet your service-level objective. Amazon ECS ensures that the application is placed on a host that has adequate capacity.

## Amazon ECS task networking for Amazon ECS Managed Instances

The networking behavior of Amazon ECS tasks running on Amazon ECS Managed Instances is determined by the *network mode* specified in the task definition. You must specify a network mode in the task definition. You will not be able to run tasks on Amazon ECS Managed Instances using

a task definition that doesn't specify a network mode. Amazon ECS Managed Instances supports the following networking modes, ensuring backward compatibility for migrating workloads from Fargate or Amazon ECS on Amazon EC2:

| Network mode | Description                                                                                                                                                                                                                                          |  |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| awsvpc       | Each task receives its own elastic network interface (ENI) and private IPv4 address. This provides the same networking properties as Amazon EC2 instances and is compatible with traditional Fargate tasks. Uses ENI trunking for high task density. |  |
| host         | Tasks share the host's network namespace directly. Container networking is tied to the underlying host instance.                                                                                                                                     |  |

## Using a VPC in IPv6-only mode

In an IPv6-only configuration, your Amazon ECS tasks communicate exclusively over IPv6. To set up VPCs and subnets for an IPv6-only configuration, you must add an IPv6 CIDR block to the VPC and create subnets that include only an IPv6 CIDR block. For more information see [Add IPv6 support for your VPC](#) and [Create a subnet](#) in the *Amazon VPC User Guide*. You must also update route tables with IPv6 targets and configure security groups with IPv6 rules. For more information, see [Configure route tables](#) and [Configure security group rules](#) in the *Amazon VPC User Guide*.

The following considerations apply:

- You can update an IPv4-only or dualstack Amazon ECS service to an IPv6-only configuration by either updating the service directly to use IPv6-only subnets or by creating a parallel IPv6-only service and using Amazon ECS blue-green deployments to shift traffic to the new service. For more information about Amazon ECS blue-green deployments, see [Amazon ECS blue/green deployments](#).
- An IPv6-only Amazon ECS service must use dualstack load balancers with IPv6 target groups. If you're migrating an existing Amazon ECS service that's behind a Application Load Balancer or a Network Load Balancer, you can create a new dualstack load balancer and shift traffic from the old load balancer, or update the IP address type of the existing load balancer.

For more information about Network Load Balancers, see [Create a Network Load Balancer](#) and [Update the IP address types for your Network Load Balancer](#) in the *User Guide for Network Load Balancers*. For more information about Application Load Balancers, see [Create an Application Load Balancer](#) and [Update the IP address types for your Application Load Balancer](#) in the *User Guide for Application Load Balancers*.

- For Amazon ECS tasks in an IPv6-only configuration to communicate with IPv4-only endpoints, you can set up DNS64 and NAT64 for network address translation from IPv6 to IPv4. For more information, see [DNS64 and NAT64](#) in the *Amazon VPC User Guide*.
- Amazon ECS workloads in an IPv6-only configuration must use Amazon ECR dualstack image URI endpoints when pulling images from Amazon ECR. For more information, see [Getting started with making requests over IPv6](#) in the *Amazon Elastic Container Registry User Guide*.

**Note**

Amazon ECR doesn't support dualstack interface VPC endpoints that tasks in an IPv6-only configuration can use. For more information, see [Getting started with making requests over IPv6](#) in the *Amazon Elastic Container Registry User Guide*.

- Amazon ECS Exec isn't supported in an IPv6-only configuration.

## Allocate a network interface for tasks on Amazon ECS Managed Instances

Using the `awsvpc` network mode in Amazon ECS Managed Instances simplifies container networking because you have more control over how your applications communicate with each other and other services within your VPCs. The `awsvpc` network mode also provides greater security for your containers by allowing you to use security groups and network monitoring tools at a more granular level within your tasks.

By default, every Amazon ECS Managed Instances instance has a trunk Elastic Network Interface (ENI) attached during launch as a primary ENI when the instance type supports trunking. For more information about instance types that support ENI trunking, see [Supported instances for increased Amazon ECS container network interfaces](#).

**Note**

When the chosen instance type doesn't support trunk ENIs, the instance will be launched with a regular ENI.

Each task that runs on the instance receives its own ENI attached to the trunk ENI, with a primary private IP address. If your VPC is configured for dual-stack mode and you use a subnet with an IPv6 CIDR block, the ENI also receives an IPv6 address. When using a public subnet, you can optionally assign a public IP address to the Amazon ECS Managed Instance primary ENI by enabling IPv4 public addressing for the subnet. For more information, see [Modify the IP addressing attributes of your subnet](#) in *Amazon VPC User Guide*. A task can only have one ENI that's associated with it at a time.

Containers that belong to the same task can also communicate over the `localhost` interface. For more information about VPCs and subnets, see [How Amazon VPC works](#) in the *Amazon VPC User Guide*.

The following operations use the primary ENI attached to the instance:

- **Image downloads** - Container images are downloaded from Amazon ECR through the primary ENI.
- **Secrets retrieval** - Secrets Manager secrets and other credentials are retrieved through the primary ENI.
- **Log uploads** - Logs are uploaded to CloudWatch through the primary ENI.
- **Environment file downloads** - Environment files are downloaded through the primary ENI.

Application traffic flows through the task ENI.

Because each task gets its own ENI, you can use networking features such as VPC Flow Logs, which you can use to monitor traffic to and from your tasks. For more information, see [VPC Flow Logs](#) in the *Amazon VPC User Guide*.

You can also take advantage of AWS PrivateLink. You can configure a VPC interface endpoint so that you can access Amazon ECS APIs through private IP addresses. AWS PrivateLink restricts all network traffic between your VPC and Amazon ECS to the Amazon network. You don't need an internet gateway, a NAT device, or a virtual private gateway. For more information, see [Amazon ECS interface VPC endpoints \(AWS PrivateLink\)](#).

The `awsvpc` network mode also allows you to leverage Amazon VPC Traffic Mirroring for security and monitoring of network traffic when using instance types that don't have trunk ENIs attached. For more information, see [What is Traffic Mirroring?](#) in the *Amazon VPC Traffic Mirroring Guide*.

### Considerations for `awsvpc` mode

- Tasks require the Amazon ECS service-linked role for ENI management. This role is created automatically when you create a cluster or service.
- Task ENIs are managed by Amazon ECS and cannot be manually detached or modified.
- Assigning a public IP address to the task ENI using `assignPublicIp` when running a standalone task (`RunTask`) or creating or updating a service (`CreateService/UpdateService`) is not supported.

- When you configure `awsvpc` networking at the task level, you must use the same VPC that you specified as part of the Amazon ECS Managed Instances capacity provider's launch template. You can use different subnets and security groups from those specified in the launch template.
- For `awsvpc` network mode tasks, use `ip` target type when configuring load balancer target groups. Amazon ECS automatically manages target group registration for supported networking modes.

## Using a VPC in dual-stack mode

When using a VPC in dual-stack mode, your tasks can communicate over IPv4, or IPv6, or both. IPv4 and IPv6 addresses are independent of each other. Therefore you must configure routing and security in your VPC separately for IPv4 and IPv6. For more information about how to configure your VPC for dual-stack mode, see [Migrating to IPv6](#) in the *Amazon VPC User Guide*.

If you configured your VPC with an internet gateway or an outbound-only internet gateway, you can use your VPC in dual-stack mode. By doing this, tasks that are assigned an IPv6 address can access the internet through an internet gateway or an egress-only internet gateway. NAT gateways are optional. For more information, see [Internet gateways](#) and [Egress-only internet gateways](#) in the *Amazon VPC User Guide*.

Amazon ECS tasks are assigned an IPv6 address if the following conditions are met:

- The Amazon ECS Managed Instances instance that hosts the task is using version `1.45.0` or later of the container agent. For information about how to check the agent version your instance is using, and updating it if needed, see [Updating the Amazon ECS container agent](#).
- The `dualStackIPv6` account setting is enabled. For more information, see [Access Amazon ECS features with account settings](#).
- Your task is using the `awsvpc` network mode.
- Your VPC and subnet are configured for IPv6. The configuration includes the network interfaces that are created in the specified subnet. For more information about how to configure your VPC for dual-stack mode, see [Migrating to IPv6](#) and [Modify the IPv6 addressing attribute for your subnet](#) in the *Amazon VPC User Guide*.

## Host network mode

In host mode, tasks share the host's network namespace directly. The container's networking configuration is tied to the underlying Amazon ECS Managed Instances host instance that you

specify using the `networkConfiguration` parameter when you create an Amazon ECS Managed Instances capacity provider.

There are significant drawbacks to using this network mode. You can't run more than a single instantiation of a task on each host. This is because only the first task can bind to its required port on the Amazon EC2 instance. There's also no way to remap a container port when it's using host network mode. For example, if an application needs to listen on a particular port number, you can't remap the port number directly. Instead, you must manage any port conflicts through changing the application configuration.

There are also security implications when using the host network mode. This mode allows containers to impersonate the host, and it allows containers to connect to private loopback network services on the host.

Use host mode only when you need direct access to host networking or when migrating applications that require host-level network access.

## Amazon ECS task networking options for EC2

The networking behavior of Amazon ECS tasks that are hosted on Amazon EC2 instances is dependent on the *network mode* that's defined in the task definition. We recommend that you use the `awsvpc` network mode unless you have a specific need to use a different network mode.

The following are the available network modes.

| Network mode        | Linux containers on EC2 | Windows containers on EC2 | Description                                                                                                                                                                           |
|---------------------|-------------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>awsvpc</code> | Yes                     | Yes                       | The task is allocated its own elastic network interface (ENI) and a primary private IPv4 or IPv6 address. This gives the task the same networking properties as Amazon EC2 instances. |
| <code>bridge</code> | Yes                     | No                        | The task uses Docker's built-in virtual network on Linux, which runs inside each Amazon EC2 instance that hosts the task. The built-                                                  |

| Network mode | Linux containers on EC2 | Windows containers on EC2 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|-------------------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              |                         |                           | in virtual network on Linux uses the bridge Docker network driver. This is the default network mode on Linux if a network mode isn't specified in the task definition.                                                                                                                                                                                                                                                                                                                                                |
| host         | Yes                     | No                        | The task uses the host's network which bypasses Docker's built-in virtual network by mapping container ports directly to the ENI of the Amazon EC2 instance that hosts the task. Dynamic port mappings can't be used in this network mode. A container in a task definition that uses this mode must specify a specific <code>hostPort</code> number. A port number on a host can't be used by multiple tasks. As a result, you can't run multiple tasks of the same task definition on a single Amazon EC2 instance. |
| none         | Yes                     | No                        | The task has no external network connectivity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| default      | No                      | Yes                       | The task uses Docker's built-in virtual network on Windows, which runs inside each Amazon EC2 instance that hosts the task. The built-in virtual network on Windows uses the <code>nat</code> Docker network driver. This is the default network mode on Windows if a network mode isn't specified in the task definition.                                                                                                                                                                                            |

For more information about Docker networking on Linux, see [Networking overview](#) in the *Docker Documentation*.

For more information about Docker networking on Windows, see [Windows container networking](#) in the *Microsoft Containers on Windows Documentation*.

## Using a VPC in IPv6-only mode

In an IPv6-only configuration, your Amazon ECS tasks communicate exclusively over IPv6. To set up VPCs and subnets for an IPv6-only configuration, you must add an IPv6 CIDR block to the VPC and create new subnets that include only an IPv6 CIDR block. For more information see [Add IPv6 support for your VPC](#) and [Create a subnet](#) in the *Amazon VPC User Guide*.

You must also update route tables with IPv6 targets and configure security groups with IPv6 rules. For more information, see [Configure route tables](#) and [Configure security group rules](#) in the *Amazon VPC User Guide*.

The following considerations apply:

- You can update an IPv4-only or dualstack Amazon ECS service to an IPv6-only configuration by either updating the service directly to use IPv6-only subnets or by creating a parallel IPv6-only service and using Amazon ECS blue-green deployments to shift traffic to the new service. For more information about Amazon ECS blue-green deployments, see [Amazon ECS blue/green deployments](#).
- An IPv6-only Amazon ECS service must use dualstack load balancers with IPv6 target groups. If you're migrating an existing Amazon ECS service that's behind a Application Load Balancer or a Network Load Balancer, you can create a new dualstack load balancer and shift traffic from the old load balancer, or update the IP address type of the existing load balancer.

For more information about Network Load Balancers, see [Create a Network Load Balancer](#) and [Update the IP address types for your Network Load Balancer](#) in the *User Guide for Network Load Balancers*. For more information about Application Load Balancers, see [Create an Application Load Balancer](#) and [Update the IP address types for your Application Load Balancer](#) in the *User Guide for Application Load Balancers*.

- IPv6-only configuration isn't supported on Windows. You must use Amazon ECS-optimized Linux AMIs to run tasks in an IPv6-only configuration. For more information about Amazon ECS-optimized Linux AMIs, see [Amazon ECS-optimized Linux AMIs](#).
- When you launch a container instance for running tasks in an IPv6-only configuration, you must set a primary IPv6 address for the instance by using the `--enable-primary-ipv6` EC2 parameter.

**Note**

Without a primary IPv6 address, tasks running on the container instance in the host or bridge network modes will fail to register with load balancers or with AWS Cloud Map.

For more information about the `--enable-primary-ipv6` for running Amazon EC2 instances, see [run-instances](#) in the *AWS CLI Command Reference*.

For more information about launching container instances using the AWS Management Console, see [Launching an Amazon ECS Linux container instance](#).

- By default, the Amazon ECS container agent will try to detect the container instance's compatibility for an IPv6-only configuration by looking at the instance's default IPv4 and IPv6 routes. To override this behavior, you can set the `ECS_INSTANCE_IP_COMPATIBILITY` parameter to `ipv4` or `ipv6` in the instance's `/etc/ecs/ecs.config` file.
- Tasks must use version 1.99.1 or later of the container agent. For information about how to check the agent version your instance is using and updating it if needed, see [Updating the Amazon ECS container agent](#).
- For Amazon ECS tasks in an IPv6-only configuration to communicate with IPv4-only endpoints, you can set up DNS64 and NAT64 for network address translation from IPv6 to IPv4. For more information, see [DNS64 and NAT64](#) in the *Amazon VPC User Guide*.
- Amazon ECS workloads in an IPv6-only configuration must use Amazon ECR dualstack image URI endpoints when pulling images from Amazon ECR. For more information, see [Getting started with making requests over IPv6](#) in the *Amazon Elastic Container Registry User Guide*.

**Note**

Amazon ECR doesn't support dualstack interface VPC endpoints that tasks in an IPv6-only configuration can use. For more information, see [Getting started with making requests over IPv6](#) in the *Amazon Elastic Container Registry User Guide*.

- Amazon ECS Exec isn't supported in an IPv6-only configuration.

## AWS Regions that support IPv6-only mode for Amazon ECS

You can run tasks in an IPv6-only configuration in the following AWS regions that Amazon ECS is available in:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (London)
- Europe (Milan)
- Europe (Paris)
- Europe (Spain)
- Israel (Tel Aviv)
- Middle East (Bahrain)

- Middle East (UAE)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

## Allocate a network interface for an Amazon ECS task

The task networking features that are provided by the `awsvpc` network mode give Amazon ECS tasks the same networking properties as Amazon EC2 instances. Using the `awsvpc` network mode simplifies container networking, because you have more control over how your applications communicate with each other and other services within your VPCs. The `awsvpc` network mode also provides greater security for your containers by allowing you to use security groups and network monitoring tools at a more granular level within your tasks. You can also use other Amazon EC2 networking features such as VPC Flow Logs to monitor traffic to and from your tasks. Additionally, containers that belong to the same task can communicate over the `localhost` interface.

The task elastic network interface (ENI) is a fully managed feature of Amazon ECS. Amazon ECS creates the ENI and attaches it to the host Amazon EC2 instance with the specified security group. The task sends and receives network traffic over the ENI in the same way that Amazon EC2 instances do with their primary network interfaces. Each task ENI is assigned a private IPv4 address by default. If your VPC is enabled for dual-stack mode and you use a subnet with an IPv6 CIDR block, the task ENI will also receive an IPv6 address. Each task can only have one ENI.

These ENIs are visible in the Amazon EC2 console for your account. Your account can't detach or modify the ENIs. This is to prevent accidental deletion of an ENI that is associated with a running task. You can view the ENI attachment information for tasks in the Amazon ECS console or with the [DescribeTasks](#) API operation. When the task stops or if the service is scaled down, the task ENI is detached and deleted.

When you need increased ENI density, use the `awsvpcTrunking` account setting. Amazon ECS also creates and attaches a "trunk" network interface for your container instance. The trunk network is fully managed by Amazon ECS. The trunk ENI is deleted when you either terminate or deregister your container instance from the Amazon ECS cluster. For more information about the `awsvpcTrunking` account setting, see [Prerequisites](#).

You specify `awsvpc` in the `networkMode` parameter of the task definition. For more information, see [Network mode](#).

Then, when you run a task or create a service, use the `networkConfiguration` parameter that includes one or more subnets to place your tasks in and one or more security groups to attach to an ENI. For more information, see [Network configuration](#). The tasks are placed on compatible Amazon EC2 instances in the same Availability Zones as those subnets, and the specified security groups are associated with the ENI that's provisioned for the task.

## Linux considerations

Consider the following when using the Linux operating system.

- If you use a p5.48xlarge instance in awsvpc mode, you can't run more than 1 task on the instance.
- Tasks and services that use the awsvpc network mode require the Amazon ECS service-linked role to provide Amazon ECS with the permissions to make calls to other AWS services on your behalf. This role is created for you automatically when you create a cluster or if you create or update a service, in the AWS Management Console. For more information, see [Using service-linked roles for Amazon ECS](#). You can also create the service-linked role with the following AWS CLI command:

```
aws iam create-service-linked-role --aws-service-name ecs.amazonaws.com
```

- Your Amazon EC2 Linux instance requires version 1.15.0 or later of the container agent to run tasks that use the awsvpc network mode. If you're using an Amazon ECS-optimized AMI, your instance needs at least version 1.15.0-4 of the `ecs-init` package as well.
- Amazon ECS populates the hostname of the task with an Amazon-provided (internal) DNS hostname when both the `enableDnsHostnames` and `enableDnsSupport` options are enabled on your VPC. If these options aren't enabled, the DNS hostname of the task is set to a random hostname. For more information about the DNS settings for a VPC, see [Using DNS with Your VPC](#) in the *Amazon VPC User Guide*.
- Each Amazon ECS task that uses the awsvpc network mode receives its own elastic network interface (ENI), which is attached to the Amazon EC2 instance that hosts it. There's a default quota for the number of network interfaces that can be attached to an Amazon EC2 Linux instance. The primary network interface counts as one toward that quota. For example, by default, a c5.large instance might have only up to three ENIs that can be attached to it. The primary network interface for the instance counts as one. You can attach an additional two ENIs to the instance. Because each task that uses the awsvpc network mode requires an ENI, you can typically only run two such tasks on this instance type. For more information about the default

ENI limits for each instance type, see [IP addresses per network interface per instance type](#) in the *Amazon EC2 User Guide*.

- Amazon ECS supports the launch of Amazon EC2 Linux instances that use supported instance types with increased ENI density. When you opt in to the `awsvpcTrunking` account setting and register Amazon EC2 Linux instances that use these instance types to your cluster, these instances have higher ENI quota. Using these instances with this higher quota means that you can place more tasks on each Amazon EC2 Linux instance. To use the increased ENI density with the trunking feature, your Amazon EC2 instance must use version 1.28.1 or later of the container agent. If you're using an Amazon ECS-optimized AMI, your instance also requires at least version 1.28.1-2 of the `ecs-init` package. For more information about opting in to the `awsvpcTrunking` account setting, see [Access Amazon ECS features with account settings](#). For more information about ENI trunking, see [Increasing Amazon ECS Linux container instance network interfaces](#).
- When hosting tasks that use the `awsvpc` network mode on Amazon EC2 Linux instances, your task ENIs aren't given public IP addresses. To access the internet, tasks must be launched in a private subnet that's configured to use a NAT gateway. For more information, see [NAT gateways](#) in the *Amazon VPC User Guide*. Inbound network access must be from within a VPC that uses the private IP address or routed through a load balancer from within the VPC. Tasks that are launched within public subnets do not have access to the internet.
- Amazon ECS recognizes only the ENIs that it attaches to your Amazon EC2 Linux instances. If you manually attached ENIs to your instances, Amazon ECS might attempt to add a task to an instance that doesn't have enough network adapters. This can result in the task timing out and moving to a deprovisioning status and then a stopped status. We recommend that you don't attach ENIs to your instances manually.
- Amazon EC2 Linux instances must be registered with the `ecs.capability.task-eni` capability to be considered for placement of tasks with the `awsvpc` network mode. Instances running version 1.15.0-4 or later of `ecs-init` are registered with this attribute automatically.
- The ENIs that are created and attached to your Amazon EC2 Linux instances cannot be detached manually or modified by your account. This is to prevent the accidental deletion of an ENI that is associated with a running task. To release the ENIs for a task, stop the task.
- There is a limit of 16 subnets and 5 security groups that are able to be specified in the `awsVpcConfiguration` when running a task or creating a service that uses the `awsvpc` network mode. For more information, see [AwsVpcConfiguration](#) in the *Amazon Elastic Container Service API Reference*.

- When a task is started with the `awsvpc` network mode, the Amazon ECS container agent creates an additional pause container for each task before starting the containers in the task definition. It then configures the network namespace of the pause container by running the [amazon-ecs-cni-plugins](#) CNI plugins. The agent then starts the rest of the containers in the task so that they share the network stack of the pause container. This means that all containers in a task are addressable by the IP addresses of the ENI, and they can communicate with each other over the `localhost` interface.
- Services with tasks that use the `awsvpc` network mode only support Application Load Balancer and Network Load Balancer. When you create any target groups for these services, you must choose `ip` as the target type. Do not use `instance`. This is because tasks that use the `awsvpc` network mode are associated with an ENI, not with an Amazon EC2 Linux instance. For more information, see [Use load balancing to distribute Amazon ECS service traffic](#).
- If your VPC is updated to change the DHCP options set it uses, you can't apply these changes to existing tasks. Start new tasks with these changes applied to them, verify that they are working correctly, and then stop the existing tasks in order to safely change these network configurations.

## Windows considerations

The following are considerations when you use the Windows operating system:

- Container instances using the Amazon ECS optimized Windows Server 2016 AMI can't host tasks that use the `awsvpc` network mode. If you have a cluster that contains Amazon ECS optimized Windows Server 2016 AMIs and Windows AMIs that support `awsvpc` network mode, tasks that use `awsvpc` network mode aren't launched on the Windows 2016 Server instances. Rather, they're launched on instances that support `awsvpc` network mode.
- Your Amazon EC2 Windows instance requires version `1.57.1` or later of the container agent to use CloudWatch metrics for Windows containers that use the `awsvpc` network mode.
- Tasks and services that use the `awsvpc` network mode require the Amazon ECS service-linked role to provide Amazon ECS with the permissions to make calls to other AWS services on your behalf. This role is created for you automatically when you create a cluster, or if you create or update a service, in the AWS Management Console. For more information, see [Using service-linked roles for Amazon ECS](#). You can also create the service-linked role with the following AWS CLI command.

```
aws iam create-service-linked-role --aws-service-name ecs.amazonaws.com
```

- Your Amazon EC2 Windows instance requires version 1.54.0 or later of the container agent to run tasks that use the `awsvpc` network mode. When you bootstrap the instance, you must configure the options that are required for `awsvpc` network mode. For more information, see [the section called “Bootstrapping container instances”](#).
- Amazon ECS populates the hostname of the task with an Amazon provided (internal) DNS hostname when both the `enableDnsHostnames` and `enableDnsSupport` options are enabled on your VPC. If these options aren't enabled, the DNS hostname of the task is a random hostname. For more information about the DNS settings for a VPC, see [Using DNS with Your VPC](#) in the *Amazon VPC User Guide*.
- Each Amazon ECS task that uses the `awsvpc` network mode receives its own elastic network interface (ENI), which is attached to the Amazon EC2 Windows instance that hosts it. There is a default quota for the number of network interfaces that can be attached to an Amazon EC2 Windows instance. The primary network interface counts as one toward this quota. For example, by default a `c5.large` instance might have only up to three ENIs attached to it. The primary network interface for the instance counts as one of those. You can attach an additional two ENIs to the instance. Because each task using the `awsvpc` network mode requires an ENI, you can typically only run two such tasks on this instance type. For more information about the default ENI limits for each instance type, see [IP addresses per network interface per instance type](#) in the *Amazon EC2 User Guide*.
- When hosting tasks that use the `awsvpc` network mode on Amazon EC2 Windows instances, your task ENIs aren't given public IP addresses. To access the internet, launch tasks in a private subnet that's configured to use a NAT gateway. For more information, see [NAT gateways](#) in the *Amazon VPC User Guide*. Inbound network access must be from within the VPC that is using the private IP address or routed through a load balancer from within the VPC. Tasks that are launched within public subnets don't have access to the internet.
- Amazon ECS recognizes only the ENIs that it has attached to your Amazon EC2 Windows instance. If you manually attached ENIs to your instances, Amazon ECS might attempt to add a task to an instance that doesn't have enough network adapters. This can result in the task timing out and moving to a deprovisioning status and then a stopped status. We recommend that you don't attach ENIs to your instances manually.
- Amazon EC2 Windows instances must be registered with the `ecs.capability.task-eni` capability to be considered for placement of tasks with the `awsvpc` network mode.
- You can't manually modify or detach ENIs that are created and attached to your Amazon EC2 Windows instances. This is to prevent you from accidentally deleting an ENI that's associated with a running task. To release the ENIs for a task, stop the task.

- You can only specify up to 16 subnets and 5 security groups in `awsVpcConfiguration` when you run a task or create a service that uses the `awsvpc` network mode. For more information, see [AwsVpcConfiguration](#) in the *Amazon Elastic Container Service API Reference*.
- When a task is started with the `awsvpc` network mode, the Amazon ECS container agent creates an additional pause container for each task before starting the containers in the task definition. It then configures the network namespace of the pause container by running the [amazon-ecs-cni-plugins](#) CNI plugins. The agent then starts the rest of the containers in the task so that they share the network stack of the pause container. This means that all containers in a task are addressable by the IP addresses of the ENI, and they can communicate with each other over the `localhost` interface.
- Services with tasks that use the `awsvpc` network mode only support Application Load Balancer and Network Load Balancer. When you create any target groups for these services, you must choose `ip` as the target type, not `instance`. This is because tasks that use the `awsvpc` network mode are associated with an ENI, not with an Amazon EC2 Windows instance. For more information, see [Use load balancing to distribute Amazon ECS service traffic](#).
- If your VPC is updated to change the DHCP options set it uses, you can't apply these changes to existing tasks. Start new tasks with these changes applied to them, verify that they are working correctly, and then stop the existing tasks in order to safely change these network configurations.
- The following are not supported when you use `awsvpc` network mode in an EC2 Windows configuration:
  - Dual-stack configuration
  - IPv6
  - ENI trunking

## Using a VPC in dual-stack mode

When using a VPC in dual-stack mode, your tasks can communicate over IPv4, or IPv6, or both. IPv4 and IPv6 addresses are independent of each other. Therefore you must configure routing and security in your VPC separately for IPv4 and IPv6. For more information about how to configure your VPC for dual-stack mode, see [Migrating to IPv6](#) in the *Amazon VPC User Guide*.

If you configured your VPC with an internet gateway or an outbound-only internet gateway, you can use your VPC in dual-stack mode. By doing this, tasks that are assigned an IPv6 address can access the internet through an internet gateway or an egress-only internet gateway. NAT gateways

are optional. For more information, see [Internet gateways](#) and [Egress-only internet gateways](#) in the *Amazon VPC User Guide*.

Amazon ECS tasks are assigned an IPv6 address if the following conditions are met:

- The Amazon EC2 Linux instance that hosts the task is using version 1.45.0 or later of the container agent. For information about how to check the agent version your instance is using, and updating it if needed, see [Updating the Amazon ECS container agent](#).
- The dualStackIPv6 account setting is enabled. For more information, see [Access Amazon ECS features with account settings](#).
- Your task is using the awsvpc network mode.
- Your VPC and subnet are configured for IPv6. The configuration includes the network interfaces that are created in the specified subnet. For more information about how to configure your VPC for dual-stack mode, see [Migrating to IPv6](#) and [Modify the IPv6 addressing attribute for your subnet](#) in the *Amazon VPC User Guide*.

## Map Amazon ECS container ports to the EC2 instance network interface

The host network mode is only supported for Amazon ECS tasks hosted on Amazon EC2 instances. It's not supported when using Amazon ECS on Fargate.

The host network mode is the most basic network mode that's supported in Amazon ECS. Using host mode, the networking of the container is tied directly to the underlying host that's running the container.

Assume that you're running a Node.js container with an Express application that listens on port 3000 similar to the one illustrated in the preceding diagram. When the host network mode is used, the container receives traffic on port 3000 using the IP address of the underlying host Amazon EC2 instance. We do not recommend using this mode.

There are significant drawbacks to using this network mode. You can't run more than a single instantiation of a task on each host. This is because only the first task can bind to its required port on the Amazon EC2 instance. There's also no way to remap a container port when it's using host network mode. For example, if an application needs to listen on a particular port number, you can't remap the port number directly. Instead, you must manage any port conflicts through changing the application configuration.

There are also security implications when using the host network mode. This mode allows containers to impersonate the host, and it allows containers to connect to private loopback network services on the host.

## Use Docker's virtual network for Amazon ECS Linux tasks

The bridge network mode is only supported for Amazon ECS tasks hosted on Amazon EC2 instances.

With bridge mode, you're using a virtual network bridge to create a layer between the host and the networking of the container. This way, you can create port mappings that remap a host port to a container port. The mappings can be either static or dynamic.

With a static port mapping, you can explicitly define which host port you want to map to a container port. Using the preceding example, port 80 on the host is being mapped to port 3000 on the container. To communicate to the containerized application, you send traffic to port 80 to the Amazon EC2 instance's IP address. From the containerized application's perspective it sees that inbound traffic on port 3000.

If you only want to change the traffic port, then static port mappings is suitable. However, this still has the same disadvantage as using the host network mode. You can't run more than a single instantiation of a task on each host. This is because a static port mapping only allows a single container to be mapped to port 80.

To solve this problem, consider using the bridge network mode with a dynamic port mapping as shown in the following diagram.

By not specifying a host port in the port mapping, you can have Docker choose a random, unused port from the ephemeral port range and assign it as the public host port for the container. For example, the Node.js application listening on port 3000 on the container might be assigned a random high number port such as 47760 on the Amazon EC2 host. Doing this means that you can run multiple copies of that container on the host. Moreover, each container can be assigned its own port on the host. Each copy of the container receives traffic on port 3000. However, clients that send traffic to these containers use the randomly assigned host ports.

Amazon ECS helps you to keep track of the randomly assigned ports for each task. It does this by automatically updating load balancer target groups and AWS Cloud Map service discovery to have the list of task IP addresses and ports. This makes it easier to use services operating using bridge mode with dynamic ports.

However, one disadvantage of using the bridge network mode is that it's difficult to lock down service to service communications. Because services might be assigned to any random, unused port, it's necessary to open broad port ranges between hosts. However, it's not easy to create specific rules so that a particular service can only communicate to one other specific service. The services have no specific ports to use for security group networking rules.

## Configuring bridge networking mode for IPv6-only workloads

To configure bridge mode for communication over IPv6, you must update Docker daemon settings. Update `/etc/docker/daemon.json` with the following:

```
{
  "ipv6": true,
  "fixed-cidr-v6": "2001:db8:1::/64",
  "ip6tables": true,
  "experimental": true
}
```

After updating Docker daemon settings, you will need to restart the daemon.

### Note

When you update and restart the daemon, Docker enables IPv6 forwarding on the instance, which can result in the loss of default routes on instances that use an Amazon Linux 2 AMI. To avoid this, use the following command to add a default route via the subnet's IPv6 gateway.

```
ip route add default via FE80:EC2::1 dev eth0 metric 100
```

## Amazon ECS task networking options for Fargate

By default, every Amazon ECS task on Fargate is provided an elastic network interface (ENI) with a primary private IP address. When using a public subnet, you can optionally assign a public IP address to the task's ENI. If your VPC is configured for dual-stack mode and you use a subnet with an IPv6 CIDR block, your task's ENI also receives an IPv6 address. A task can only have one ENI that's associated with it at a time. Containers that belong to the same task can also communicate over the `localhost` interface. For more information about VPCs and subnets, see [How Amazon VPC works](#) in the *Amazon VPC User Guide*.

For a task on Fargate to pull a container image, the task must have a route to the internet. The following describes how you can verify that your task has a route to the internet.

- When using a public subnet, you can assign a public IP address to the task ENI.
- When using a private subnet, the subnet can have a NAT gateway attached.
- When using container images that are hosted in Amazon ECR, you can configure Amazon ECR to use an interface VPC endpoint and the image pull occurs over the task's private IPv4 address. For more information, see [Amazon ECR interface VPC endpoints \(AWS PrivateLink\)](#) in the *Amazon Elastic Container Registry User Guide*.

Because each task gets its own ENI, you can use networking features such as VPC Flow Logs, which you can use to monitor traffic to and from your tasks. For more information, see [VPC Flow Logs](#) in the *Amazon VPC User Guide*.

You can also take advantage of AWS PrivateLink. You can configure a VPC interface endpoint so that you can access Amazon ECS APIs through private IP addresses. AWS PrivateLink restricts all network traffic between your VPC and Amazon ECS to the Amazon network. You don't need an internet gateway, a NAT device, or a virtual private gateway. For more information, see [Amazon ECS interface VPC endpoints \(AWS PrivateLink\)](#).

For examples of how to use the NetworkConfiguration resource with CloudFormation, see [the section called "Example CloudFormation templates"](#).

The ENIs that are created are fully managed by AWS Fargate. Moreover, there's an associated IAM policy that's used to grant permissions for Fargate. For tasks using Fargate platform version 1.4.0 or later, the task receives a single ENI (referred to as the task ENI) and all network traffic flows through that ENI within your VPC. This traffic is recorded in your VPC flow logs. For tasks that use Fargate platform version 1.3.0 and earlier, in addition to the task ENI, the task also receives a separate Fargate owned ENI, which is used for some network traffic that isn't visible in the VPC flow logs. The following table describes the network traffic behavior and the required IAM policy for each platform version.

| Action                                                     | Traffic flow with Linux platform version 1.3.0 and earlier | Traffic flow with Linux platform version 1.4.0 | Traffic flow with Windows platform version 1.0.0 | IAM permission          |
|------------------------------------------------------------|------------------------------------------------------------|------------------------------------------------|--------------------------------------------------|-------------------------|
| Retrieving Amazon ECR login credentials                    | Fargate owned ENI                                          | Task ENI                                       | Task ENI                                         | Task execution IAM role |
| Image pull                                                 | Task ENI                                                   | Task ENI                                       | Task ENI                                         | Task execution IAM role |
| Sending logs through a log driver                          | Task ENI                                                   | Task ENI                                       | Task ENI                                         | Task execution IAM role |
| Sending logs through FireLens for Amazon ECS               | Task ENI                                                   | Task ENI                                       | Task ENI                                         | Task IAM role           |
| Retrieving secrets from Secrets Manager or Systems Manager | Fargate owned ENI                                          | Task ENI                                       | Task ENI                                         | Task execution IAM role |
| Amazon EFS file system traffic                             | Not available                                              | Task ENI                                       | Task ENI                                         | Task IAM role           |
| Application traffic                                        | Task ENI                                                   | Task ENI                                       | Task ENI                                         | Task IAM role           |

## Considerations

Consider the following when using task networking.

- The Amazon ECS service-linked role is required to provide Amazon ECS with the permissions to make calls to other AWS services on your behalf. This role is created for you when you

create a cluster or if you create or update a service in the AWS Management Console. For more information, see [Using service-linked roles for Amazon ECS](#). You can also create the service-linked role using the following AWS CLI command.

```
aws iam create-service-linked-role --aws-service-name ecs.amazonaws.com
```

- Amazon ECS populates the hostname of the task with an Amazon provided DNS hostname when both the `enableDnsHostnames` and `enableDnsSupport` options are enabled on your VPC. If these options aren't enabled, the DNS hostname of the task is set to a random hostname. For more information about the DNS settings for a VPC, see [Using DNS with Your VPC](#) in the *Amazon VPC User Guide*.
- You can only specify up to 16 subnets and 5 security groups for `awsVpcConfiguration`. For more information, see [AwsVpcConfiguration](#) in the *Amazon Elastic Container Service API Reference*.
- You can't manually detach or modify the ENIs that are created and attached by Fargate. This is to prevent the accidental deletion of an ENI that's associated with a running task. To release the ENIs for a task, stop the task.
- If a VPC subnet is updated to change the DHCP options set it uses, you can't also apply these changes to existing tasks that use the VPC. Start new tasks, which will receive the new setting to smoothly migrate while testing the new change and then stop the old ones, if no rollback is required.
- The following applies to tasks run on Fargate platform version `1.4.0` or later for Linux or `1.0.0` for Windows. Tasks launched in dual-stack subnets receive an IPv4 address and an IPv6 address. Tasks launched in IPv6-only subnets receive only an IPv6 address.
- For tasks that use platform version `1.4.0` or later for Linux or `1.0.0` for Windows, the task ENIs support jumbo frames. Network interfaces are configured with a maximum transmission unit (MTU), which is the size of the largest payload that fits within a single frame. The larger the MTU, the more application payload can fit within a single frame, which reduces per-frame overhead and increases efficiency. Supporting jumbo frames reduces overhead when the network path between your task and the destination supports jumbo frames.
- Services with tasks that use Fargate only support Application Load Balancer and Network Load Balancer. Classic Load Balancer isn't supported. When you create any target groups, you must choose `ip` as the target type, not `instance`. For more information, see [Use load balancing to distribute Amazon ECS service traffic](#).

## Using a VPC in dual-stack mode

When using a VPC in dual-stack mode, your tasks can communicate over IPv4 or IPv6, or both. IPv4 and IPv6 addresses are independent of each other and you must configure routing and security in your VPC separately for IPv4 and IPv6. For more information about configuring your VPC for dual-stack mode, see [Migrating to IPv6](#) in the *Amazon VPC User Guide*.

If the following conditions are met, Amazon ECS tasks on Fargate are assigned an IPv6 address:

- Your Amazon ECS `dualStackIPv6` account setting is turned on (enabled) for the IAM principal launching your tasks in the Region you're launching your tasks in. This setting can only be modified using the API or AWS CLI. You have the option to turn this setting on for a specific IAM principal on your account or for your entire account by setting your account default setting. For more information, see [Access Amazon ECS features with account settings](#).
- Your VPC and subnet are enabled for IPv6. For more information about how to configure your VPC for dual-stack mode, see [Migrating to IPv6](#) in the *Amazon VPC User Guide*.
- Your subnet is enabled for auto-assigning IPv6 addresses. For more information about how to configure your subnet, see [Modify the IPv6 addressing attribute for your subnet](#) in the *Amazon VPC User Guide*.
- The task or service uses Fargate platform version `1.4.0` or later for Linux.

For Amazon ECS tasks on Fargate running in a VPC in dual-stack mode, to communicate with dependency services used in task launch process such as ECR, SSM and SecretManager, the public subnet's route table needs IPv4 (0.0.0.0/0) route to an internet gateway and the private subnet's route table needs IPv4 (0.0.0.0/0) route to an NAT gateway. For more information, see [Internet gateways](#) and [NAT gateways](#) in the *Amazon VPC User Guide*.

For examples of how to configure a dual-stack VPC, see [Example dual-stack VPC configuration](#).

## Using a VPC in IPv6-only mode

In an IPv6-only configuration, your Amazon ECS tasks communicate exclusively over IPv6. To set up VPCs and subnets for an IPv6-only configuration, you must add an IPv6 CIDR block to the VPC and create subnets that include only an IPv6 CIDR block. For more information see [Add IPv6 support for your VPC](#) and [Create a subnet](#) in the *Amazon VPC User Guide*. You must also update route tables with IPv6 targets and configure security groups with IPv6 rules. For more information, see [Configure route tables](#) and [Configure security group rules](#) in the *Amazon VPC User Guide*.

The following considerations apply:

- You can update an IPv4-only or dualstack Amazon ECS service to an IPv6-only configuration by either updating the service directly to use IPv6-only subnets or by creating a parallel IPv6-only service and using Amazon ECS blue-green deployments to shift traffic to the new service. For more information about Amazon ECS blue-green deployments, see [Amazon ECS blue/green deployments](#).
- An IPv6-only Amazon ECS service must use dualstack load balancers with IPv6 target groups. If you're migrating an existing Amazon ECS service that's behind a Application Load Balancer or a Network Load Balancer, you can create a new dualstack load balancer and shift traffic from the old load balancer, or update the IP address type of the existing load balancer.

For more information about Network Load Balancers, see [Create a Network Load Balancer](#) and [Update the IP address types for your Network Load Balancer](#) in the *User Guide for Network Load Balancers*. For more information about Application Load Balancers, see [Create an Application Load Balancer](#) and [Update the IP address types for your Application Load Balancer](#) in the *User Guide for Application Load Balancers*.

- IPv6-only configuration isn't supported on Windows.
- For Amazon ECS tasks in an IPv6-only configuration to communicate with IPv4-only endpoints, you can set up DNS64 and NAT64 for network address translation from IPv6 to IPv4. For more information, see [DNS64 and NAT64](#) in the *Amazon VPC User Guide*.
- IPv6-only configuration is supported on Fargate platform version 1.4.0 or later.
- Amazon ECS workloads in an IPv6-only configuration must use Amazon ECR dualstack image URI endpoints when pulling images from Amazon ECR. For more information, see [Getting started with making requests over IPv6](#) in the *Amazon Elastic Container Registry User Guide*.

**Note**

Amazon ECR doesn't support dualstack interface VPC endpoints that tasks in an IPv6-only configuration can use. For more information, see [Getting started with making requests over IPv6](#) in the *Amazon Elastic Container Registry User Guide*.

- Amazon ECS Exec isn't supported in an IPv6-only configuration.
- Amazon CloudWatch doesn't support a dualstack FIPS endpoint that can be used to monitor Amazon ECS tasks in IPv6-only configuration that use FIPS-140 compliance. For more

information about FIPS-140, see [AWS Fargate Federal Information Processing Standard \(FIPS-140\)](#).

## **AWS Regions that support IPv6-only mode for Amazon ECS**

You can run tasks in an IPv6-only configuration in the following AWS Regions that Amazon ECS is available in:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (London)
- Europe (Milan)
- Europe (Paris)
- Europe (Spain)

- Israel (Tel Aviv)
- Middle East (Bahrain)
- Middle East (UAE)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

## Storage options for Amazon ECS tasks

Amazon ECS provides you with flexible, cost effective, and easy-to-use data storage options depending on your needs. Amazon ECS supports the following data volume options for containers:

| Data volume                             | Supported capacity                                | Supported operating systems         | Storage persistence                                                                                             | Use cases                                                                                                                                                                                                                                                       |

|-------------|---------------------------------------------------|-----------------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bind mounts | Fargate, Amazon EC2, Amazon ECS Managed Instances | Windows, Linux              | Ephemeral           | Bind mounts consist of a file or directory on the host, such as an Amazon EC2 instance or AWS Fargate, that is mounted onto a container . Common use cases for bind mounts include sharing a volume from a source container with other containers in the same task, or mounting a host volume or an empty volume in one or more containers. For more information, see <a href="#">Use bind mounts with Amazon ECS</a> . |

Use Amazon EBS volumes with Amazon ECS

Amazon Elastic Block Store (Amazon EBS) volumes provide highly available, cost-effective, durable, high-performance block storage for data-intensive workloads. Amazon EBS volumes can be used

with Amazon ECS tasks for high throughput and transaction-intensive applications. For more information about Amazon EBS volumes, see [Amazon EBS volumes](#) in the *Amazon EBS User Guide*.

Amazon EBS volumes that are attached to Amazon ECS tasks are managed by Amazon ECS on your behalf. During standalone task launch, you can provide the configuration that will be used to attach one EBS volume to the task. During service creation or update, you can provide the configuration that will be used to attach one EBS volume per task to each task managed by the Amazon ECS service. You can either configure new, empty volumes for attachment, or you can use snapshots to load data from existing volumes.

 **Note**

When you use snapshots to configure volumes, you can specify a `volumeInitializationRate`, in MiB/s, at which data is fetched from the snapshot to create volumes that are fully initialized in a predictable amount of time. For more information about volume initialization, see [Initialize Amazon EBS volumes](#) in the *Amazon EBS User Guide*. For more information about configuring Amazon EBS volumes, see [Defer volume configuration to launch time in an Amazon ECS task definition](#) and [Specify Amazon EBS volume configuration at Amazon ECS deployment](#).

Volume configuration is deferred to launch time using the `configuredAtLaunch` parameter in the task definition. By providing volume configuration at launch time rather than in the task definition, you get to create task definitions that aren't constrained to a specific data volume type or specific EBS volume settings. You can then reuse your task definitions across different runtime environments. For example, you can provide more throughput during deployment for your production workloads than your pre-prod environments.

Amazon EBS volumes attached to tasks can be encrypted with AWS Key Management Service (AWS KMS) keys to protect your data. For more information see, [Encrypt data stored in Amazon EBS volumes attached to Amazon ECS tasks](#).

To monitor your volume's performance, you can also use Amazon CloudWatch metrics. For more information about Amazon ECS metrics for Amazon EBS volumes, see [Amazon ECS CloudWatch metrics](#) and [Amazon ECS Container Insights metrics](#).

Attaching an Amazon EBS volume to a task is supported in all commercial and China [AWS Regions](#) that support Amazon ECS.

## Supported operating systems and capacity

The following table provides the supported operating system and capacity configurations.

| Capacity                     | Linux                                                                                                                                                                                                                                                                                                                                                                                                                                | Windows                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fargate                      | Amazon EBS volumes are supported on platform version 1.4.0 or later (Linux). For more information, see <a href="#">Fargate platform versions for Amazon ECS</a> .                                                                                                                                                                                                                                                                    | Not supported                                                                                                                                                                                                                                                                                                                                                                                           |
| EC2                          | <p>Amazon EBS volumes are supported for tasks hosted on Nitro-based instances with Amazon ECS-optimized Amazon Machine Images (AMIs). | Amazon ECS Managed Instances | Amazon EBS volumes are supported for tasks hosted on Amazon ECS Managed Instances on Linux.                                                                                                                                                                                                                                                                                                                                          | Not supported                                                                                                                                                                                                                                                                                                                                                                                           |

## Considerations

Consider the following when using Amazon EBS volumes:

- You can't configure Amazon EBS volumes for attachment to Fargate Amazon ECS tasks in the `us-east-1-az3` Availability Zone.
- The magnetic (standard) Amazon EBS volume type is not supported for tasks hosted on Fargate. For more information about Amazon EBS volume types, see [Amazon EBS volumes](#) in the *Amazon EC2 User Guide*.
- An Amazon ECS infrastructure IAM role is required when creating a service or a standalone task that is configuring a volume at deployment. You can attach the AWS managed `AmazonECSInfrastructureRolePolicyForVolumes` IAM policy to the role, or you can use the managed policy as a guide to create and attach your own policy with permissions that meet your specific needs. For more information, see [Amazon ECS infrastructure IAM role](#).
- You can attach at most one Amazon EBS volume to each Amazon ECS task, and it must be a new volume. You can't attach an existing Amazon EBS volume to a task. However, you can configure a new Amazon EBS volume at deployment using the snapshot of an existing volume.
- To use Amazon EBS volumes with Amazon ECS services, the deployment controller must be ECS. Both rolling and blue/green deployment strategies are supported when using this deployment controller.
- For a container in your task to write to the mounted Amazon EBS volume, the container must have appropriate file system permissions. When you specify a non-root user in your container definition, Amazon ECS automatically configures the volume with group-based permissions that allow the specified user to read and write to the volume. If no user is specified, the container runs as root and has full access to the volume.
- Amazon ECS automatically adds the reserved tags `AmazonECSCreated` and `AmazonECSManaged` to the attached volume. If you remove these tags from the volume, Amazon ECS won't be able to manage the volume on your behalf. For more information about tagging Amazon EBS volumes, see [Tagging Amazon EBS volumes](#). For more information about tagging Amazon ECS resources, see [Tagging your Amazon ECS resources](#).
- Provisioning volumes from a snapshot of an Amazon EBS volume that contains partitions isn't supported.
- Volumes that are attached to tasks that are managed by a service aren't preserved and are always deleted upon task termination.
- You can't configure Amazon EBS volumes for attachment to Amazon ECS tasks that are running on AWS Outposts.

## Non-root user behavior

When you specify a non-root user in your container definition, Amazon ECS automatically configures the Amazon EBS volume with group-based permissions that allow the specified user to read and write to the volume. The volume is mounted with the following characteristics:

- The volume is owned by the root user and root group.
- Group permissions are set to allow read and write access.
- The non-root user is added to the appropriate group to access the volume.

Follow these best practices when using Amazon EBS volumes with non-root containers:

- Use consistent user IDs (UIDs) and group IDs (GIDs) across your container images to ensure consistent permissions.
- Pre-create mount point directories in your container image and set appropriate ownership and permissions.
- Test your containers with Amazon EBS volumes in a development environment to confirm that file system permissions work as expected.
- If multiple containers in the same task share a volume, ensure they either use compatible UIDs/GIDs or mount the volume with consistent access expectations.

## Defer volume configuration to launch time in an Amazon ECS task definition

To configure an Amazon EBS volume for attachment to your task, you must specify the mount point configuration in your task definition and name the volume. You must also set `configuredAtLaunch` to `true` because Amazon EBS volumes can't be configured for attachment in the task definition. Instead, Amazon EBS volumes are configured for attachment during deployment.

To register the task definition by using the AWS Command Line Interface (AWS CLI), save the template as a JSON file, and then pass the file as an input for the [register-task-definition](#) command.

To create and register a task definition using the AWS Management Console, see [Creating an Amazon ECS task definition using the console](#).

The following task definition shows the syntax for the `mountPoints` and `volumes` objects in the task definition. For more information about task definition parameters, see [Amazon ECS task](#)

[definition parameters for Fargate](#). To use this example, replace the *user input placeholders* with your own information.

## Linux

```
{

"networkMode": "awsvpc"  
}
```

## mountPoints

Type: Object array

Required: No

The mount points for the data volumes in your container. This parameter maps to Volumes in the create-container Docker API and the `--volume` option to `docker run`.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`. Windows containers cannot mount directories on a different drive, and mount points cannot be used across drives. You must specify mount points to attach an Amazon EBS volume directly to an Amazon ECS task.

### sourceVolume

Type: String

Required: Yes, when `mountPoints` are used

The name of the volume to mount.

### containerPath

Type: String

Required: Yes, when `mountPoints` are used

The path in the container where the volume will be mounted.

## readOnly

Type: Boolean

Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

For tasks that run on EC2 instances running the Windows operating system, leave the value as the default of `false`.

## name

Type: String

Required: No

The name of the volume. Up to 255 letters (uppercase and lowercase), numbers, hyphens (-), and underscores (\_) are allowed. This name is referenced in the `sourceVolume` parameter of the container definition `mountPoints` object.

## configuredAtLaunch

Type: Boolean

Required: Yes, when you want to use attach an EBS volume directly to a task.

Specifies whether a volume is configurable at launch. When set to `true`, you can configure the volume when you run a standalone task, or when you create or update a service. When set to `false`, you won't be able to provide another volume configuration in the task definition. This parameter must be provided and set to `true` to configure an Amazon EBS volume for attachment to a task.

## Encrypt data stored in Amazon EBS volumes attached to Amazon ECS tasks

You can use AWS Key Management Service (AWS KMS) to make and manage cryptographic keys that protect your data. Amazon EBS volumes are encrypted at rest by using AWS KMS keys. The following types of data are encrypted:

- Data stored at rest on the volume

- Disk I/O
- Snapshots created from the volume
- New volumes created from encrypted snapshots

Amazon EBS volumes that are attached to tasks can be encrypted by using either a default AWS managed key with the alias `alias/aws/ebs`, or a symmetric customer managed key specified in the volume configuration. Default AWS managed keys are unique to each AWS account per AWS Region and are created automatically. To create a symmetric customer managed key, follow the steps in [Creating symmetric encryption KMS keys](#) in the *AWS KMS Developer Guide*.

You can configure Amazon EBS encryption by default so that all new volumes created and attached to a task in a specific AWS Region are encrypted by using the KMS key that you specify for your account. For more information about Amazon EBS encryption and encryption by default, see [Amazon EBS encryption](#) in the *Amazon EBS User Guide*.

### Amazon ECS Managed Instances behavior

You encrypt Amazon EBS volumes by enabling encryption, either using encryption by default or by enabling encryption when you create a volume that you want to encrypt. For information about how to enable encryption by default (at the account-level, see [Encryption by default](#) in the *Amazon EBS User Guide*.

You can configure any combination of these keys. The order of precedence of KMS keys is as follows:

1. The KMS key specified in the volume configuration. When you specify a KMS key in the volume configuration, it overrides the Amazon EBS default and any KMS key that is specified at the account level.
2. The KMS key specified at the account level. When you specify a KMS key for cluster-level encryption of Amazon ECS managed storage, it overrides Amazon EBS default encryption but does not override any KMS key that is specified in the volume configuration.
3. Amazon EBS default encryption. Default encryption applies when you don't specify either a account-level KMS key or a key in the volume configuration. If you enable Amazon EBS encryption by default, the default is the KMS key you specify for encryption by default. Otherwise, the default is the AWS managed key with the alias `alias/aws/ebs`.

**Note**

If you set `encrypted` to `false` in your volume configuration, specify no account-level KMS key, and enable Amazon EBS encryption by default, the volume will still be encrypted with the key specified for Amazon EBS encryption by default.

## Non-Amazon ECS Managed Instances behavior

You can also set up Amazon ECS cluster-level encryption for Amazon ECS managed storage when you create or update a cluster. Cluster-level encryption takes effect at the task level and can be used to encrypt the Amazon EBS volumes attached to each task running in a specific cluster by using the specified KMS key. For more information about configuring encryption at the cluster level for each task, see [ManagedStorageConfiguration](#) in the *Amazon ECS API reference*.

You can configure any combination of these keys. The order of precedence of KMS keys is as follows:

1. The KMS key specified in the volume configuration. When you specify a KMS key in the volume configuration, it overrides the Amazon EBS default and any KMS key that is specified at the cluster level.
2. The KMS key specified at the cluster level. When you specify a KMS key for cluster-level encryption of Amazon ECS managed storage, it overrides Amazon EBS default encryption but does not override any KMS key that is specified in the volume configuration.
3. Amazon EBS default encryption. Default encryption applies when you don't specify either a cluster-level KMS key or a key in the volume configuration. If you enable Amazon EBS encryption by default, the default is the KMS key you specify for encryption by default. Otherwise, the default is the AWS managed key with the alias `alias/aws/ebs`.

**Note**

If you set `encrypted` to `false` in your volume configuration, specify no cluster-level KMS key, and enable Amazon EBS encryption by default, the volume will still be encrypted with the key specified for Amazon EBS encryption by default.

## Customer managed KMS key policy

To encrypt an EBS volume that's attached to your task by using a customer managed key, you must configure your KMS key policy to ensure that the IAM role that you use for volume configuration has the necessary permissions to use the key. The key policy must include the `kms:CreateGrant` and `kms:GenerateDataKey*` permissions. The `kms:ReEncryptTo` and `kms:ReEncryptFrom` permissions are necessary for encrypting volumes that are created using snapshots. If you want to configure and encrypt only new, empty volumes for attachment, you can exclude the `kms:ReEncryptTo` and `kms:ReEncryptFrom` permissions.

The following JSON snippet shows key policy statements that you can attach to your KMS key policy. Using these statements will provide access for Amazon ECS to use the key for encrypting the EBS volume. To use the example policy statements, replace the *user input placeholders* with your own information. As always, only configure the permissions that you need.

```
{
  "Effect": "Allow",
  "Principal": { "AWS": "arn:aws:iam::111122223333:role/ecsInfrastructureRole" },
  "Action": "kms:DescribeKey",
  "Resource": "*"
},
{
  "Effect": "Allow",
  "Principal": { "AWS": "arn:aws:iam::111122223333:role/ecsInfrastructureRole" },
  "Action": [
    "kms:GenerateDataKey*",
    "kms:ReEncryptTo",
    "kms:ReEncryptFrom"
  ],
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "kms:CallerAccount": "aws_account_id",
      "kms:ViaService": "ec2.region.amazonaws.com"
    },
    "ForAnyValue:StringEquals": {
      "kms:EncryptionContextKeys": "aws:ebs:id"
    }
  }
},
{
  "Effect": "Allow",
```

```

    "Principal": { "AWS": "arn:aws:iam::111122223333:role/ecsInfrastructureRole" },
    "Action": "kms:CreateGrant",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "kms:CallerAccount": "aws_account_id",
        "kms:ViaService": "ec2.region.amazonaws.com"
      },
      "ForAnyValue:StringEquals": {
        "kms:EncryptionContextKeys": "aws:ebs:id"
      },
      "Bool": {
        "kms:GrantIsForAWSResource": true
      }
    }
  }
}

```

For more information about key policies and permissions, see [Key policies in AWS KMS](#) and [AWS KMS permissions](#) in the *AWS KMS Developer Guide*. For troubleshooting EBS volume attachment issues related to key permissions, see [Troubleshooting Amazon EBS volume attachments to Amazon ECS tasks](#).

## Specify Amazon EBS volume configuration at Amazon ECS deployment

After you register a task definition with the `configuredAtLaunch` parameter set to `true`, you can configure an Amazon EBS volume at deployment when you run a standalone task, or when you create or update a service. For more information about deferring volume configuration to launch time using the `configuredAtLaunch` parameter, see [Defer volume configuration to launch time in an Amazon ECS task definition](#).

To configure a volume, you can use the Amazon ECS APIs, or you can pass a JSON file as input for the following AWS CLI commands:

- [run-task](#) to run a standalone ECS task.
- [start-task](#) to run a standalone ECS task in a specific container instance. This command is not applicable for Fargate tasks.
- [create-service](#) to create a new ECS service.
- [update-service](#) to update an existing service.

**Note**

For a container in your task to write to the mounted Amazon EBS volume, the container must have appropriate file system permissions. When you specify a non-root user in your container definition, Amazon ECS automatically configures the volume with group-based permissions that allow the specified user to read and write to the volume. If no user is specified, the container runs as root and has full access to the volume.

You can also configure an Amazon EBS volume by using the AWS Management Console. For more information, see [Running an application as an Amazon ECS task](#), [Creating an Amazon ECS rolling update deployment](#), and [Updating an Amazon ECS service](#).

The following JSON snippet shows all the parameters of an Amazon EBS volume that can be configured at deployment. To use these parameters for volume configuration, replace the *user input placeholders* with your own information. For more information about these parameters, see [Volume configurations](#).

```
"volumeConfigurations": [
  {
    "name": "ebs-volume",
    "managedEBSVolume": {
      "encrypted": true,
      "kmsKeyId": "arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "volumeType": "gp3",
      "sizeInGiB": 10,
      "snapshotId": "snap-12345",
      "volumeInitializationRate": 100,
      "iops": 3000,
      "throughput": 125,
      "tagSpecifications": [
        {
          "resourceType": "volume",
          "tags": [
            {
              "key": "key1",
              "value": "value1"
            }
          ]
        }
      ],
      "propagateTags": "NONE"
    }
  }
]
```

```

        }
    ],
    "roleArn": "arn:aws:iam::1111222333:role/ecsInfrastructureRole",
    "terminationPolicy": {
        "deleteOnTermination": true//can't be configured for service-
managed tasks, always true
    },
    "filesystemType": "ext4"
}
}
]

```

### Important

Ensure that the `volumeName` you specify in the configuration is the same as the `volumeName` you specify in your task definition.

For information about checking the status of volume attachment, see [Troubleshooting Amazon EBS volume attachments to Amazon ECS tasks](#). For information about the Amazon ECS infrastructure AWS Identity and Access Management (IAM) role necessary for EBS volume attachment, see [Amazon ECS infrastructure IAM role](#).

The following are JSON snippet examples that show the configuration of Amazon EBS volumes. These examples can be used by saving the snippets in JSON files and passing the files as parameters (using the `--cli-input-json file://filename` parameter) for AWS CLI commands. Replace the *user input placeholders* with your own information.

### Configure a volume for a standalone task

The following snippet shows the syntax for configuring Amazon EBS volumes for attachment to a standalone task. The following JSON snippet shows the syntax for configuring the `volumeType`, `sizeInGiB`, `encrypted`, and `kmsKeyId` settings. The configuration specified in the JSON file is used to create and attach an EBS volume to the standalone task.

```

{
  "cluster": "mycluster",
  "taskDefinition": "mytaskdef",
  "volumeConfigurations": [
    {
      "name": "datadir",

```

```

        "managedEBSVolume": {
            "volumeType": "gp3",
            "sizeInGiB": 100,
            "roleArn": "arn:aws:iam::1111222333:role/ecsInfrastructureRole",
            "encrypted": true,
            "kmsKeyId":
"arn:aws:kms:region:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
        }
    ]
}

```

## Configure a volume at service creation

The following snippet shows the syntax for configuring Amazon EBS volumes for attachment to tasks managed by a service. The volumes are sourced from the snapshot specified using the `snapshotId` parameter at a rate of 200 MiB/s. The configuration specified in the JSON file is used to create and attach an EBS volume to each task managed by the service.

```

{
  "cluster": "mycluster",
  "taskDefinition": "mytaskdef",
  "serviceName": "mysvc",
  "desiredCount": 2,
  "volumeConfigurations": [
    {
      "name": "myEbsVolume",
      "managedEBSVolume": {
        "roleArn": "arn:aws:iam::1111222333:role/ecsInfrastructureRole",
        "snapshotId": "snap-12345",
        "volumeInitializationRate": 200
      }
    }
  ]
}

```

## Configure a volume at service update

The following JSON snippet shows the syntax for updating a service that previously did not have Amazon EBS volumes configured for attachment to tasks. You must provide the ARN of a task definition revision with `configuredAtLaunch` set to `true`. The following JSON snippet shows the syntax for configuring the `volumeType`, `sizeInGiB`, `throughput`, and `iops`, and

filesystemType settings. This configuration is used to create and attach an EBS volume to each task managed by the service.

```
{
  "cluster": "mycluster",
  "taskDefinition": "mytaskdef",
  "service": "mysvc",
  "desiredCount": 2,
  "volumeConfigurations": [
    {
      "name": "myEbsVolume",
      "managedEBSVolume": {
        "roleArn": "arn:aws:iam::1111222333:role/ecsInfrastructureRole",
        "volumeType": "gp3",
        "sizeInGiB": 100,
        "iops": 3000,
        "throughput": 125,
        "filesystemType": "ext4"
      }
    }
  ]
}
```

### Configure a service to no longer utilize Amazon EBS volumes

The following JSON snippet shows the syntax for updating a service to no longer utilize Amazon EBS volumes. You must provide the ARN of a task definition with `configuredAtLaunch` set to `false`, or a task definition without the `configuredAtLaunch` parameter. You must also provide an empty `volumeConfigurations` object.

```
{
  "cluster": "mycluster",
  "taskDefinition": "mytaskdef",
  "service": "mysvc",
  "desiredCount": 2,
  "volumeConfigurations": []
}
```

### Termination policy for Amazon EBS volumes

When an Amazon ECS task terminates, Amazon ECS uses the `deleteOnTermination` value to determine whether the Amazon EBS volume that's associated with the terminated task should

be deleted. By default, EBS volumes that are attached to tasks are deleted when the task is terminated. For standalone tasks, you can change this setting to instead preserve the volume upon task termination.

#### Note

Volumes that are attached to tasks that are managed by a service are not preserved and are always deleted upon task termination.

## Tag Amazon EBS volumes

You can tag Amazon EBS volumes by using the `tagSpecifications` object. Using the object, you can provide your own tags and set propagation of tags from the task definition or the service, depending on whether the volume is attached to a standalone task or a task in a service. The maximum number of tags that can be attached to a volume is 50.

#### Important

Amazon ECS automatically attaches the `AmazonECSCreated` and `AmazonECSManaged` reserved tags to an Amazon EBS volume. This means you can control the attachment of a maximum of 48 additional tags to a volume. These additional tags can be user-defined, ECS-managed, or propagated tags.

If you want to add Amazon ECS-managed tags to your volume, you must set `enableECSTags` to `true` in your `UpdateService`, `CreateService`, `RunTask` or `StartTask` call. If you turn on Amazon ECS-managed tags, Amazon ECS will tag the volume automatically with cluster and service information (`aws:ecs:clusterName` and `aws:ecs:serviceName`). For more information about tagging Amazon ECS resources, see [Tagging your Amazon ECS resources](#).

The following JSON snippet shows the syntax for tagging each Amazon EBS volume that is attached to each task in a service with a user-defined tag. To use this example for creating a service, replace the *user input placeholders* with your own information.

```
{
  "cluster": "mycluster",
```

```

"taskDefinition": "mytaskdef",
"serviceName": "mysvc",
"desiredCount": 2,
"enableECSManagedTags": true,
"volumeConfigurations": [
  {
    "name": "datadir",
    "managedEBSVolume": {
      "volumeType": "gp3",
      "sizeInGiB": 100,
      "tagSpecifications": [
        {
          "resourceType": "volume",
          "tags": [
            {
              "key": "key1",
              "value": "value1"
            }
          ]
        },
        {
          "propagateTags": "NONE"
        }
      ]
    },
    "roleArn": "arn:aws:iam:1111222333:role/ecsInfrastructureRole",
    "encrypted": true,
    "kmsKeyId":
      "arn:aws:kms:region:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
  }
]
}

```

### Important

You must specify a volume resource type to tag Amazon EBS volumes.

## Performance of Amazon EBS volumes for Fargate on-demand tasks

The baseline Amazon EBS volume IOPS and throughput available for a Fargate on-demand task depends on the total CPU units you request for the task. If you request 0.25, 0.5, or 1 virtual CPU unit (vCPU) for your Fargate task, we recommend that you configure a General Purpose SSD volume (gp2 or gp3) or a Hard Disk Drive (HDD) volume (st1 or sc1). If you request more than 1

vCPU for your Fargate task, the following baseline performance limits apply to an Amazon EBS volume attached to the task. You may temporarily get higher EBS performance than the following limits. However, we recommend that you plan your workload based on these limits.

| CPU units requested<br>(in vCPUs) | Baseline Amazon<br>EBS IOPS(16 KiB I/<br>O) | Baseline Amazon<br>EBS Throughput (in<br>MiBps, 128 KiB I/O) | Baseline bandwidth<br>(in Mbps) |
|-----------------------------------|---------------------------------------------|--------------------------------------------------------------|---------------------------------|
| 2                                 | 3,000                                       | 75                                                           | 360                             |
| 4                                 | 5,000                                       | 120                                                          | 1,150                           |
| 8                                 | 10,000                                      | 250                                                          | 2,300                           |
| 16                                | 15,000                                      | 500                                                          | 4,500                           |

 **Note**

When you configure an Amazon EBS volume for attachment to a Fargate task, the Amazon EBS performance limit for Fargate task is shared between the task's ephemeral storage and the attached volume.

## Performance of Amazon EBS volumes for EC2 tasks

Amazon EBS provides volume types, which differ in performance characteristics and price, so that you can tailor your storage performance and cost to the needs of your applications. For information about performance, including IOPS per volume and throughput per volume, see [Amazon EBS volume types](#) in the *Amazon Elastic Block Store User Guide*.

## Performance of Amazon EBS volumes for Amazon ECS Managed Instances tasks

Amazon EBS provides volume types, which differ in performance characteristics and price, so that you can tailor your storage performance and cost to the needs of your applications. For information about performance, including IOPS per volume and throughput per volume, see [Amazon EBS volume types](#) in the *Amazon Elastic Block Store User Guide*.

## Troubleshooting Amazon EBS volume attachments to Amazon ECS tasks

You might need to troubleshoot or verify the attachment of Amazon EBS volumes to Amazon ECS tasks.

### Check volume attachment status

You can use the AWS Management Console to view the status of an Amazon EBS volume's attachment to an Amazon ECS task. If the task starts and the attachment fails, you'll also see a status reason that you can use to troubleshoot. The created volume will be deleted and the task will be stopped. For more information about status reasons, see [Status reasons for Amazon EBS volume attachment to Amazon ECS tasks](#).

### To view a volume's attachment status and status reason using the console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster that your task is running in. The cluster's details page appears.
3. On the cluster's details page, choose the **Tasks** tab.
4. Choose the task that you want to view the volume attachment status for. You might need to use **Filter desired status** and choose **Stopped** if the task you want to examine has stopped.
5. On the task's details page, choose the **Volumes** tab. You will be able to see the attachment status of the Amazon EBS volume under **Attachment status**. If the volume fails to attach to the task, you can choose the status under **Attachment status** to display the cause of the failure.

You can also view a task's volume attachment status and associated status reason by using the [DescribeTasks](#) API.

### Service and task failures

You might encounter service or task failures that aren't specific to Amazon EBS volumes that can affect volume attachment. For more information, see

- [Service event messages](#)
- [Stopped task error codes](#)
- [API failure reasons](#)

## Container can't write to Amazon EBS volume

### Non-root user without proper permissions

When you specify a non-root user in your container definition, Amazon ECS automatically configures the volume with group-based permissions to allow write access. However, if you're still experiencing permission issues:

- Verify that the `user` parameter is correctly specified in your container definition using the format `uid:gid` (for example, `1001:1001`).
- Ensure your container image doesn't override the user permissions after the volume is mounted.
- Check that your application is running with the expected user ID by examining the container logs or using Amazon ECS Exec to inspect the running container.

### Root user with permission issues

If no user is specified in your container definition, the container runs as root and should have full access to the volume. If you're experiencing issues:

- Verify that the volume is properly mounted by checking the mount points inside the container.
- Ensure the volume isn't configured as read-only in your mount point configuration.

### Multi-container tasks with different users

In tasks with multiple containers running as different users, Amazon ECS automatically manages group permissions to allow all specified users to write to the volume. If containers can't write:

- Verify that all containers requiring write access have the `user` parameter properly configured.
- Check that the volume is mounted in all containers that need access to it.

For more information about configuring users in container definitions, see [Amazon ECS task definition parameters for Fargate](#).

## Status reasons for Amazon EBS volume attachment to Amazon ECS tasks

Use the following reference to fix issues that you might encounter in the form of status reasons in the AWS Management Console when you configure Amazon EBS volumes for attachment to

Amazon ECS tasks. For more information on locating these status reasons in the console, see [Check volume attachment status](#).

ECS was unable to assume the configured ECS Infrastructure Role 'arn:aws:iam::**111122223333**:role/*ecsInfrastructureRole*'. Please verify that the role being passed has the proper trust relationship with Amazon ECS

This status reason appears in the following scenarios.

- You provide an IAM role without the necessary trust policy attached. Amazon ECS can't access the Amazon ECS infrastructure IAM role that you provide if the role doesn't have the necessary trust policy. The task can get stuck in the DEPROVISIONING state. For more information about the necessary trust policy, see [Amazon ECS infrastructure IAM role](#).
- Your IAM user doesn't have permission to pass the Amazon ECS infrastructure role to Amazon ECS. The task can get stuck in the DEPROVISIONING state. To avoid this problem, you can attach the `PassRole` permission to your user. For more information, see [Amazon ECS infrastructure IAM role](#).
- Your IAM role doesn't have the necessary permissions for Amazon EBS volume attachment. The task can get stuck in the DEPROVISIONING state. For more information about the specific permissions necessary for attaching Amazon EBS volumes to tasks, see [Amazon ECS infrastructure IAM role](#).

 **Note**

You may also see this error message due to a delay in role propagation. If retrying to use the role after waiting for a few minutes doesn't fix the issue, you might have misconfigured the trust policy for the role.

ECS failed to set up the EBS volume. Encountered `IdempotentParameterMismatch`"; "The client token you have provided is associated with a resource that is already deleted. Please use a different client token."

The following AWS KMS key scenarios can lead to an `IdempotentParameterMismatch` message appearing:

- You specify a KMS key ARN, ID, or alias that isn't valid. In this scenario, the task might appear to launch successfully, but the task eventually fails because AWS authenticates the KMS key

asynchronously. For more information, see [Amazon EBS encryption](#) in the *Amazon EC2 User Guide*.

- You provide a customer managed key that lacks the permissions that allow the Amazon ECS infrastructure IAM role to use the key for encryption. To avoid key-policy permission issues, see the example AWS KMS key policy in [Data encryption for Amazon EBS volumes](#).

You can set up Amazon EventBridge to send Amazon EBS volume events and Amazon ECS task state change events to a target, such as Amazon CloudWatch groups. You can then use these events to identify the specific customer managed key related issue that affected volume attachment. For more information, see

- [How can I create a CloudWatch log group to use as a target for an EventBridge rule?](#) on AWS re:Post.
- [Task state change events](#).
- [Amazon EventBridge events for Amazon EBS](#) in the *Amazon EBS User Guide*.

ECS timed out while configuring the EBS volume attachment to your Task.

The following file system format scenarios result in this message.

- The file system format that you specify during configuration isn't compatible with the [task's operating system](#).
- You configure an Amazon EBS volume to be created from a snapshot, and the snapshot's file system format isn't compatible with the task's operating system. For volumes created from a snapshot, you must specify the same filesystem type that the volume was using when the snapshot was created.

You can utilize the Amazon ECS container agent logs to troubleshoot this message for EC2 tasks. For more information, see [Amazon ECS log file locations](#) and [Amazon ECS log collector](#).

## Use Amazon EFS volumes with Amazon ECS

Amazon Elastic File System (Amazon EFS) provides simple, scalable file storage for use with your Amazon ECS tasks. With Amazon EFS, storage capacity is elastic. It grows and shrinks automatically as you add and remove files. Your applications can have the storage they need and when they need it.

You can use Amazon EFS file systems with Amazon ECS to export file system data across your fleet of container instances. That way, your tasks have access to the same persistent storage, no

matter the instance on which they land. Your task definitions must reference volume mounts on the container instance to use the file system.

For a tutorial, see [Configuring Amazon EFS file systems for Amazon ECS using the console](#).

## Considerations

Consider the following when using Amazon EFS volumes:

- For tasks that run on EC2, Amazon EFS file system support was added as a public preview with Amazon ECS-optimized AMI version 20191212 with container agent version 1.35.0. However, Amazon EFS file system support entered general availability with Amazon ECS-optimized AMI version 20200319 with container agent version 1.38.0, which contained the Amazon EFS access point and IAM authorization features. We recommend that you use Amazon ECS-optimized AMI version 20200319 or later to use these features. For more information, see [Amazon ECS-optimized Linux AMIs](#).

### Note

If you create your own AMI, you must use container agent 1.38.0 or later, `ecs-init` version 1.38.0-1 or later, and run the following commands on your Amazon EC2 instance to enable the Amazon ECS volume plugin. The commands are dependent on whether you're using Amazon Linux 2 or Amazon Linux as your base image.

Amazon Linux 2

```
yum install amazon-efs-utils
systemctl enable --now amazon-ecs-volume-plugin
```

Amazon Linux

```
yum install amazon-efs-utils
sudo shutdown -r now
```

- For tasks that are hosted on Fargate, Amazon EFS file systems are supported on platform version 1.4.0 or later (Linux). For more information, see [Fargate platform versions for Amazon ECS](#).
- When using Amazon EFS volumes for tasks that are hosted on Fargate, Fargate creates a supervisor container that's responsible for managing the Amazon EFS volume. The supervisor container uses a small amount of the task's memory and CPU. The supervisor container is visible when querying the task metadata version 4 endpoint. Additionally, it is visible in CloudWatch

Container Insights as the container name `aws-fargate-supervisor`. For more information when using the EC2, see [Amazon ECS task metadata endpoint version 4](#). For more information when using the Fargate, see [Amazon ECS task metadata endpoint version 4 for tasks on Fargate](#).

- Using Amazon EFS volumes or specifying an `EFSVolumeConfiguration` isn't supported on external instances.
- Using Amazon EFS volumes is supported for tasks that run on Amazon ECS Managed Instances.
- We recommend that you set the `ECS_ENGINE_TASK_CLEANUP_WAIT_DURATION` parameter in the agent configuration file to a value that is less than the default (about 1 hour). This change helps prevent EFS mount credential expiration and allows for cleanup of mounts that are not in use. For more information, see [Amazon ECS container agent configuration](#).

## Use Amazon EFS access points

Amazon EFS access points are application-specific entry points into an EFS file system for managing application access to shared datasets. For more information about Amazon EFS access points and how to control access to them, see [Working with Amazon EFS Access Points](#) in the *Amazon Elastic File System User Guide*.

Access points can enforce a user identity, including the user's POSIX groups, for all file system requests that are made through the access point. Access points can also enforce a different root directory for the file system. This is so that clients can only access data in the specified directory or its subdirectories.

### Note

When creating an EFS access point, specify a path on the file system to serve as the root directory. When referencing the EFS file system with an access point ID in your Amazon ECS task definition, the root directory must either be omitted or set to `/`, which enforces the path set on the EFS access point.

You can use an Amazon ECS task IAM role to enforce that specific applications use a specific access point. By combining IAM policies with access points, you can provide secure access to specific datasets for your applications. For more information about how to use task IAM roles, see [Amazon ECS task IAM role](#).

## Best practices for using Amazon EFS volumes with Amazon ECS

Make note of the following best practice recommendations when you use Amazon EFS with Amazon ECS.

### Security and access controls for Amazon EFS volumes

Amazon EFS offers access control features that you can use to ensure that the data stored in an Amazon EFS file system is secure and accessible only from applications that need it. You can secure data by enabling encryption at rest and in-transit. For more information, see [Data encryption in Amazon EFS](#) in the *Amazon Elastic File System User Guide*.

In addition to data encryption, you can also use Amazon EFS to restrict access to a file system. There are three ways to implement access control in EFS.

- **Security groups**—With Amazon EFS mount targets, you can configure a security group that's used to permit and deny network traffic. You can configure the security group attached to Amazon EFS to permit NFS traffic (port 2049) from the security group that's attached to your Amazon ECS instances or, when using the awsvpc network mode, the Amazon ECS task.
- **IAM**—You can restrict access to an Amazon EFS file system using IAM. When configured, Amazon ECS tasks require an IAM role for file system access to mount an EFS file system. For more information, see [Using IAM to control file system data access](#) in the *Amazon Elastic File System User Guide*.

IAM policies can also enforce predefined conditions such as requiring a client to use TLS when connecting to an Amazon EFS file system. For more information, see [Amazon EFS condition keys for clients](#) in the *Amazon Elastic File System User Guide*.

- **Amazon EFS access points**—Amazon EFS access points are application-specific entry points into an Amazon EFS file system. You can use access points to enforce a user identity, including the user's POSIX groups, for all file system requests that are made through the access point. Access points can also enforce a different root directory for the file system. This is so that clients can only access data in the specified directory or its sub-directories.

### IAM policies

You can use IAM policies to control the access to the Amazon EFS file system.

You can specify the following actions for clients accessing a file system using a file system policy.

| Action                                          | Description                                                 |
|-------------------------------------------------|-------------------------------------------------------------|
| <code>elasticfilesystem:ClientMount</code>      | Provides read-only access to a file system.                 |
| <code>elasticfilesystem:ClientWrite</code>      | Provides write permissions on a file system.                |
| <code>elasticfilesystem:ClientRootAccess</code> | Provides use of the root user when accessing a file system. |

You need to specify each action in a policy. The policies can be defined in the following ways:

- Client-based - Attach the policy to the task role

Set the **IAM authorization** option when you create the task definition.

- Resource-based - Attach the policy to Amazon EFS file system

If the resource-based policy does not exist, by default at file system creation access is granted to all principals (\*).

When you set the **IAM authorization** option, we merge the the policy associated with the task role and the Amazon EFS resource-based. The **IAM authorization** option passes the task identity (the task role) with the policy to Amazon EFS. This allows the Amazon EFS resource-based policy to have context for the IAM user or role specified in the policy. If you do not set the option, the Amazon EFS resource-level policy identifies the IAM user as "anonymous".

Consider implementing all three access controls on an Amazon EFS file system for maximum security. For example, you can configure the security group attached to an Amazon EFS mount point to only permit ingress NFS traffic from a security group that's associated with your container instance or Amazon ECS task. Additionally, you can configure Amazon EFS to require an IAM role to access the file system, even if the connection originates from a permitted security group. Last, you can use Amazon EFS access points to enforce POSIX user permissions and specify root directories for applications.

The following task definition snippet shows how to mount an Amazon EFS file system using an access point.

```
"volumes": [  
  {
```

```
    "efsVolumeConfiguration": {
      "fileSystemId": "fs-1234",
      "authorizationConfig": {
        "accessPointId": "fsap-1234",
        "iam": "ENABLED"
      },
      "transitEncryption": "ENABLED",
      "rootDirectory": ""
    },
    "name": "my-filesystem"
  }
]
```

## Amazon EFS volume performance

Amazon EFS offers two performance modes: General Purpose and Max I/O. General Purpose is suitable for latency-sensitive applications such as content management systems and CI/CD tools. In contrast, Max I/O file systems are suitable for workloads such as data analytics, media processing, and machine learning. These workloads need to perform parallel operations from hundreds or even thousands of containers and require the highest possible aggregate throughput and IOPS. For more information, see [Amazon EFS performance modes](#) in the *Amazon Elastic File System User Guide*.

Some latency sensitive workloads require both the higher I/O levels that are provided by Max I/O performance mode and the lower latency that are provided by General Purpose performance mode. For this type of workload, we recommend creating multiple General Purpose performance mode file systems. That way, you can spread your application workload across all these file systems, as long as the workload and applications can support it.

## Amazon EFS volume throughput

All Amazon EFS file systems have an associated metered throughput that's determined by either the amount of provisioned throughput for file systems using *Provisioned Throughput* or the amount of data stored in the EFS Standard or One Zone storage class for file systems using *Bursting Throughput*. For more information, see [Understanding metered throughput](#) in the *Amazon Elastic File System User Guide*.

The default throughput mode for Amazon EFS file systems is bursting mode. With bursting mode, the throughput that's available to a file system scales in or out as a file system grows. Because file-based workloads typically spike, requiring high levels of throughput for periods of time and

lower levels of throughput the rest of the time, Amazon EFS is designed to burst to allow high throughput levels for periods of time. Additionally, because many workloads are read-heavy, read operations are metered at a 1:3 ratio to other NFS operations (like write).

All Amazon EFS file systems deliver a consistent baseline performance of 50 MB/s for each TB of Amazon EFS Standard or Amazon EFS One Zone storage. All file systems (regardless of size) can burst to 100 MB/s. File systems with more than 1TB of EFS Standard or EFS One Zone storage can burst to 100 MB/s for each TB. Because read operations are metered at a 1:3 ratio, you can drive up to 300 MiBs/s for each TiB of read throughput. As you add data to your file system, the maximum throughput that's available to the file system scales linearly and automatically with your storage in the Amazon EFS Standard storage class. If you need more throughput than you can achieve with your amount of data stored, you can configure Provisioned Throughput to the specific amount your workload requires.

File system throughput is shared across all Amazon EC2 instances connected to a file system. For example, a 1TB file system that can burst to 100 MB/s of throughput can drive 100 MB/s from a single Amazon EC2 instance or each drive 10 MB/s. For more information, see [Amazon EFS performance](#) in the *Amazon Elastic File System User Guide*.

## Optimizing cost for Amazon EFS volumes

Amazon EFS simplifies scaling storage for you. Amazon EFS file systems grow automatically as you add more data. Especially with Amazon EFS *Bursting Throughput* mode, throughput on Amazon EFS scales as the size of your file system in the standard storage class grows. To improve the throughput without paying an additional cost for provisioned throughput on an EFS file system, you can share an Amazon EFS file system with multiple applications. Using Amazon EFS access points, you can implement storage isolation in shared Amazon EFS file systems. By doing so, even though the applications still share the same file system, they can't access data unless you authorize it.

As your data grows, Amazon EFS helps you automatically move infrequently accessed files to a lower storage class. The Amazon EFS Standard-Infrequent Access (IA) storage class reduces storage costs for files that aren't accessed every day. It does this without sacrificing the high availability, high durability, elasticity, and the POSIX file system access that Amazon EFS provides. For more information, see [EFS storage classes](#) in the *Amazon Elastic File System User Guide*.

Consider using Amazon EFS lifecycle policies to automatically save money by moving infrequently accessed files to Amazon EFS IA storage. For more information, see [Amazon EFS lifecycle management](#) in the *Amazon Elastic File System User Guide*.

When creating an Amazon EFS file system, you can choose if Amazon EFS replicates your data across multiple Availability Zones (Standard) or stores your data redundantly within a single Availability Zone. The Amazon EFS One Zone storage class can reduce storage costs by a significant margin compared to Amazon EFS Standard storage classes. Consider using Amazon EFS One Zone storage class for workloads that don't require multi-AZ resilience. You can further reduce the cost of Amazon EFS One Zone storage by moving infrequently accessed files to Amazon EFS One Zone-Infrequent Access. For more information, see [Amazon EFS Infrequent Access](#).

## Amazon EFS volume data protection

Amazon EFS stores your data redundantly across multiple Availability Zones for file systems using Standard storage classes. If you select Amazon EFS One Zone storage classes, your data is redundantly stored within a single Availability Zone. Additionally, Amazon EFS is designed to provide 99.999999999% (11 9's) of durability over a given year.

As with any environment, it's a best practice to have a backup and to build safeguards against accidental deletion. For Amazon EFS data, that best practice includes a functioning, regularly tested backup using AWS Backup. File systems using Amazon EFS One Zone storage classes are configured to automatically back up files by default at file system creation unless you choose to disable this functionality. For more information, see [Backing up EFS file systems](#) in the *Amazon Elastic File System User Guide*.

## Specify an Amazon EFS file system in an Amazon ECS task definition

To use Amazon EFS file system volumes for your containers, you must specify the volume and mount point configurations in your task definition. The following task definition JSON snippet shows the syntax for the volumes and mountPoints objects for a container.

```
{
  "containerDefinitions": [
    {
      "name": "container-using-efs",
      "image": "public.ecr.aws/amazonlinux/amazonlinux:latest",
      "entryPoint": [
        "sh",
        "-c"
      ],
      "command": [
        "ls -la /mount/efs"
      ],
      "mountPoints": [
```

```
        {
            "sourceVolume": "myEfsVolume",
            "containerPath": "/mount/efs",
            "readOnly": true
        }
    ],
    "volumes": [
        {
            "name": "myEfsVolume",
            "efsVolumeConfiguration": {
                "fileSystemId": "fs-1234",
                "rootDirectory": "/path/to/my/data",
                "transitEncryption": "ENABLED",
                "transitEncryptionPort": integer,
                "authorizationConfig": {
                    "accessPointId": "fsap-1234",
                    "iam": "ENABLED"
                }
            }
        }
    ]
}
```

## efsVolumeConfiguration

Type: Object

Required: No

This parameter is specified when using Amazon EFS volumes.

### fileSystemId

Type: String

Required: Yes

The Amazon EFS file system ID to use.

### rootDirectory

Type: String

Required: No

The directory within the Amazon EFS file system to mount as the root directory inside the host. If this parameter is omitted, the root of the Amazon EFS volume is used. Specifying `/` has the same effect as omitting this parameter.

 **Important**

If an EFS access point is specified in the `authorizationConfig`, the root directory parameter must either be omitted or set to `/`, which enforces the path set on the EFS access point.

`transitEncryption`

Type: String

Valid values: ENABLED | DISABLED

Required: No

Specifies whether to enable encryption for Amazon EFS data in transit between the Amazon ECS host and the Amazon EFS server. If Amazon EFS IAM authorization is used, transit encryption must be enabled. If this parameter is omitted, the default value of DISABLED is used. For more information, see [Encrypting Data in Transit](#) in the *Amazon Elastic File System User Guide*.

`transitEncryptionPort`

Type: Integer

Required: No

The port to use when sending encrypted data between the Amazon ECS host and the Amazon EFS server. If you don't specify a transit encryption port, it uses the port selection strategy that the Amazon EFS mount helper uses. For more information, see [EFS Mount Helper](#) in the *Amazon Elastic File System User Guide*.

`authorizationConfig`

Type: Object

Required: No

The authorization configuration details for the Amazon EFS file system.

`accessPointId`

Type: String

Required: No

The access point ID to use. If an access point is specified, the root directory value in the `efsVolumeConfiguration` must either be omitted or set to `/`, which enforces the path set on the EFS access point. If an access point is used, transit encryption must be enabled in the `EFSVolumeConfiguration`. For more information, see [Working with Amazon EFS Access Points](#) in the *Amazon Elastic File System User Guide*.

`iam`

Type: String

Valid values: ENABLED | DISABLED

Required: No

Specifies whether to use the Amazon ECS task IAM role defined in a task definition when mounting the Amazon EFS file system. If enabled, transit encryption must be enabled in the `EFSVolumeConfiguration`. If this parameter is omitted, the default value of DISABLED is used. For more information, see [IAM Roles for Tasks](#).

## Configuring Amazon EFS file systems for Amazon ECS using the console

Learn how to use Amazon Elastic File System (Amazon EFS) file systems with Amazon ECS.

### Step 1: Create an Amazon ECS cluster

Use the following steps to create an Amazon ECS cluster.

#### To create a new cluster (Amazon ECS console)

Before you begin, assign the appropriate IAM permission. For more information, see [the section called "Amazon ECS cluster examples"](#).

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, for **Cluster name**, enter `EFS-tutorial` for the cluster name.
6. (Optional) To change the VPC and subnets where your tasks and services launch, under **Networking**, perform any of the following operations:
  - To remove a subnet, under **Subnets**, choose **X** for each subnet that you want to remove.
  - To change to a VPC other than the **default** VPC, under **VPC**, choose an existing **VPC**, and then under **Subnets**, select each subnet.
7. To add Amazon EC2 instances to your cluster, expand **Infrastructure**, and then select **Amazon EC2 instances**. Next, configure the Auto Scaling group which acts as the capacity provider:
  - To create a Auto Scaling group, from **Auto Scaling group (ASG)**, select **Create new group**, and then provide the following details about the group:
    - For **Operating system/Architecture**, choose Amazon Linux 2.
    - For **EC2 instance type**, choose `t2.micro`.
  - For **SSH key pair**, choose the pair that proves your identity when you connect to the instance.
  - For **Capacity**, enter 1.
8. Choose **Create**.

## Step 2: Create a security group for Amazon EC2 instances and the Amazon EFS file system

In this step, you create a security group for your Amazon EC2 instances that allows inbound network traffic on port 80 and your Amazon EFS file system that allows inbound access from your container instances.

Create a security group for your Amazon EC2 instances with the following options:

- **Security group name** - a unique name for your security group.
- **VPC** - the VPC that you identified earlier for your cluster.
- **Inbound rule**

- **Type** - HTTP
- **Source** - 0.0.0.0/0.

Create a security group for your Amazon EFS file system with the following options:

- **Security group name** - a unique name for your security group. For example, EFS-access-for-sg-*dc025fa2*.
- **VPC** - the VPC that you identified earlier for your cluster.
- **Inbound rule**
  - **Type** - NFS
  - **Source** - **Custom** with the ID of the security group you created for your instances.

For information about how to create a security group, see [Create a security group for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide*.

### Step 3: Create an Amazon EFS file system

In this step, you create an Amazon EFS file system.

**To create an Amazon EFS file system for Amazon ECS tasks.**

1. Open the Amazon Elastic File System console at <https://console.aws.amazon.com/efs/>.
2. Choose **Create file system**.
3. Enter a name for your file system and then choose the VPC that your container instances are hosted in. By default, each subnet in the specified VPC receives a mount target that uses the default security group for that VPC. Then, choose **Customize**.

#### **Note**

This tutorial assumes that your Amazon EFS file system, Amazon ECS cluster, container instances, and tasks are in the same VPC. For more information about mounting a file system from a different VPC, see [Walkthrough: Mount a file system from a different VPC](#) in the *Amazon EFS User Guide*.

4. On the **File system settings** page, configure optional settings and then under **Performance settings**, choose the **Bursting** throughput mode for your file system. After you have configured settings, select **Next**.

- a. (Optional) Add tags for your file system. For example, you could specify a unique name for the file system by entering that name in the **Value** column next to the **Name** key.
  - b. (Optional) Enable lifecycle management to save money on infrequently accessed storage. For more information, see [EFS Lifecycle Management](#) in the *Amazon Elastic File System User Guide*.
  - c. (Optional) Enable encryption. Select the check box to enable encryption of your Amazon EFS file system at rest.
5. On the **Network access** page, under **Mount targets**, replace the existing security group configuration for every availability zone with the security group you created for the file system in [Step 2: Create a security group for Amazon EC2 instances and the Amazon EFS file system](#) and then choose **Next**.
  6. You do not need to configure **File system policy** for this tutorial, so you can skip the section by choosing **Next**.
  7. Review your file system options and choose **Create** to complete the process.
  8. From the **File systems** screen, record the **File system ID**. In the next step, you will reference this value in your Amazon ECS task definition.

#### Step 4: Add content to the Amazon EFS file system

In this step, you mount the Amazon EFS file system to an Amazon EC2 instance and add content to it. This is for testing purposes in this tutorial, to illustrate the persistent nature of the data. When using this feature you would normally have your application or another method of writing data to your Amazon EFS file system.

#### To create an Amazon EC2 instance and mount the Amazon EFS file system

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Launch Instance**.
3. Under **Application and OS Images (Amazon Machine Image)**, select the **Amazon Linux 2 AMI (HVM)**.
4. Under **Instance type**, keep the default instance type, `t2.micro`.
5. Under **Key pair (login)**, select a key pair for SSH access to the instance.
6. Under **Network settings**, select the VPC that you specified for your Amazon EFS file system and Amazon ECS cluster. Select a subnet and the instance security group created in [Step 2:](#)

[Create a security group for Amazon EC2 instances and the Amazon EFS file system](#). Configure the instance's security group. Ensure that **Auto-assign public IP** is enabled.

7. Under **Configure storage**, choose the **Edit** button for file systems and then choose **EFS**. Select the file system you created in [Step 3: Create an Amazon EFS file system](#). You can optionally change the mount point or leave the default value.

### Important

You must select a subnet before you can add a file system to the instance.

8. Clear the **Automatically create and attach security groups**. Leave the other check box selected. Choose **Add shared file system**.
9. Under **Advanced Details**, ensure that the user data script is populated automatically with the Amazon EFS file system mounting steps.
10. Under **Summary**, ensure the **Number of instances** is **1**. Choose **Launch instance**.
11. On the **Launch an instance** page, choose **View all instances** to see the status of your instances. Initially, the **Instance state** status is PENDING. After the state changes to RUNNING and the instance passes all status checks, the instance is ready for use.

Now, you connect to the Amazon EC2 instance and add content to the Amazon EFS file system.

### To connect to the Amazon EC2 instance and add content to the Amazon EFS file system

1. SSH to the Amazon EC2 instance you created. For more information, see [Connect to your Linux instance using SSH](#) in the *Amazon EC2 User Guide*.
2. From the terminal window, run the **df -T** command to verify that the Amazon EFS file system is mounted. In the following output, we have highlighted the Amazon EFS file system mount.

```
$ df -T
```

| Filesystem  | Type     | 1K-blocks        | Used    | Available        | Use% | Mounted on   |
|-------------|----------|------------------|---------|------------------|------|--------------|
| devtmpfs    | devtmpfs | 485468           | 0       | 485468           | 0%   | /dev         |
| tmpfs       | tmpfs    | 503480           | 0       | 503480           | 0%   | /dev/shm     |
| tmpfs       | tmpfs    | 503480           | 424     | 503056           | 1%   | /run         |
| tmpfs       | tmpfs    | 503480           | 0       | 503480           | 0%   | /sys/fs/     |
| cgroup      |          |                  |         |                  |      |              |
| /dev/xvda1  | xfs      | 8376300          | 1310952 | 7065348          | 16%  | /            |
| 127.0.0.1:/ | nfs4     | 9007199254739968 | 0       | 9007199254739968 | 0%   | /mnt/efs/fs1 |

|       |       |        |   |        |                       |
|-------|-------|--------|---|--------|-----------------------|
| tmpfs | tmpfs | 100700 | 0 | 100700 | 0% /run/<br>user/1000 |
|-------|-------|--------|---|--------|-----------------------|

3. Navigate to the directory that the Amazon EFS file system is mounted at. In the preceding example, that is `/mnt/efs/fs1`.
4. Create a file named `index.html` with the following content:

```
<html>
  <body>
    <h1>It Works!</h1>
    <p>You are using an Amazon EFS file system for persistent container
storage.</p>
  </body>
</html>
```

## Step 5: Create a task definition

The following task definition creates a data volume named `efs-html`. The `nginx` container mounts the host data volume at the NGINX root, `/usr/share/nginx/html`.

### To create a new task definition using the Amazon ECS console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task definitions**.
3. Choose **Create new task definition**, **Create new task definition with JSON**.
4. In the JSON editor box, copy and paste the following JSON text, replacing the `fileSystemId` with the ID of your Amazon EFS file system.

```
{
  "containerDefinitions": [
    {
      "memory": 128,
      "portMappings": [
        {
          "hostPort": 80,
          "containerPort": 80,
          "protocol": "tcp"
        }
      ],
      "essential": true,
```

```
        "mountPoints": [
            {
                "containerPath": "/usr/share/nginx/html",
                "sourceVolume": "efs-html"
            }
        ],
        "name": "nginx",
        "image": "public.ecr.aws/docker/library/nginx:latest"
    }
],
"volumes": [
    {
        "name": "efs-html",
        "efsVolumeConfiguration": {
            "fileSystemId": "fs-1324abcd",
            "transitEncryption": "ENABLED"
        }
    }
],
"family": "efs-tutorial",
"executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole"
}
```

#### Note

The Amazon ECS task execution IAM role does not require any specific Amazon EFS-related permissions to mount an Amazon EFS file system. By default, if no Amazon EFS resource-based policy exists, access is granted to all principals (\*) at file system creation.

The Amazon ECS task role is only required if "EFS IAM authorization" is enabled in the Amazon ECS task definition. When enabled, the task role identity must be allowed access to the Amazon EFS file system in the Amazon EFS resource-based policy, and anonymous access should be disabled.

#### 5. Choose **Create**.

### Step 6: Run a task and view the results

Now that your Amazon EFS file system is created and there is web content for the NGINX container to serve, you can run a task using the task definition that you created. The NGINX web server

serves your simple HTML page. If you update the content in your Amazon EFS file system, those changes are propagated to any containers that have also mounted that file system.

The task runs in the subnet that you defined for the cluster.

### To run a task and view the results using the console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, select the cluster to run the standalone task in.

Determine the resource from where you launch the service.

| To start a service from | Steps                                                                                                                                                                                                                  |  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Clusters                | <ol style="list-style-type: none"><li>a. On the <b>Clusters</b> page, select the cluster to create the service in.</li><li>b. From the <b>Tasks</b> tab, choose <b>Run new task</b>.</li></ol>                         |  |
| Launch type             | <ol style="list-style-type: none"><li>a. On the <b>Task</b> page, choose the task definition.</li><li>b. If there is more than one revision, select the revision.</li><li>c. Choose <b>Create, Run task</b>.</li></ol> |  |

3. (Optional) Choose how your scheduled task is distributed across your cluster infrastructure. Expand **Compute configuration**, and then do the following:

| Distribution method | Steps                                                                                                                                                                      |  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Launch type         | <ol style="list-style-type: none"><li>a. In the <b>Compute options</b> section, select <b>Launch type</b>.</li><li>b. For <b>Launch type</b>, choose <b>EC2</b>.</li></ol> |  |

4. For **Application type**, choose **Task**.
5. For **Task definition**, choose the `efs-tutorial` task definition that you created earlier.
6. For **Desired tasks**, enter 1.
7. Choose **Create**.
8. On the **Cluster** page, choose **Infrastructure**.
9. Under **Container Instances**, choose the container instance to connect to.
10. On the **Container Instance** page, under **Networking**, record the **Public IP** for your instance.
11. Open a browser and enter the public IP address. You should see the following message:

```
It works!  
You are using an Amazon EFS file system for persistent container storage.
```

#### **Note**

If you do not see the message, make sure that the security group for your container instance allows inbound network traffic on port 80 and the security group for your file system allows inbound access from the container instance.

## Use FSx for Windows File Server volumes with Amazon ECS

FSx for Windows File Server provides fully managed Windows file servers, that are backed by a Windows file system. When using FSx for Windows File Server together with ECS, you can provision your Windows tasks with persistent, distributed, shared, static file storage. For more information, see [What Is FSx for Windows File Server?](#).

#### **Note**

EC2 instances that use the Amazon ECS-Optimized Windows Server 2016 Full AMI do not support FSx for Windows File Server ECS task volumes.

You can't use FSx for Windows File Server volumes in a Windows containers on Fargate configuration. Instead, you can [modify containers to mount them on startup](#).

You can use FSx for Windows File Server to deploy Windows workloads that require access to shared external storage, highly-available Regional storage, or high-throughput storage. You can

mount one or more FSx for Windows File Server file system volumes to an Amazon ECS container that runs on an Amazon ECS Windows instance. You can share FSx for Windows File Server file system volumes between multiple Amazon ECS containers within a single Amazon ECS task.

To enable the use of FSx for Windows File Server with ECS, include the FSx for Windows File Server file system ID and the related information in a task definition. This is in the following example task definition JSON snippet. Before you create and run a task definition, you need the following.

- An ECS Windows EC2 instance that's joined to a valid domain. It can be hosted by an [AWS Directory Service for Microsoft Active Directory](#), on-premises Active Directory or self-hosted Active Directory on Amazon EC2.
- An AWS Secrets Manager secret or Systems Manager parameter that contains the credentials that are used to join the Active Directory domain and attach the FSx for Windows File Server file system. The credential values are the name and password credentials that you entered when creating the Active Directory.

For a related tutorial, see [Learn how to configure FSx for Windows File Server file systems for Amazon ECS](#).

## Considerations

Consider the following when using FSx for Windows File Server volumes:

- FSx for Windows File Server volumes are natively supported with Amazon ECS on Windows Amazon EC2 instances — Amazon ECS automatically manages the mount through task definition configuration.

On Linux Amazon EC2 instances, Amazon ECS can't automatically mount FSx for Windows File Server volumes through task definitions. However, you can manually mount an FSx for Windows File Server file share on a Linux EC2 instance at the host level and then bind-mount that path into your Amazon ECS containers. For more information, see [Mounting Amazon FSx file shares from Linux](#).

### Important

This is a self-managed configuration. For guidance on mounting and maintaining FSx for Windows File Server file shares on Linux, refer to the [FSx for Windows File Server documentation](#).

**⚠ Important**

When using a manually mounted FSx for Windows File Server share on Linux EC2 instances, Amazon ECS and FSx for Windows File Server operate independently — Amazon ECS does not monitor the Amazon FSx mount, and FSx for Windows File Server does not track Amazon ECS task placement or lifecycle events. You are responsible for ensuring network reachability between your Amazon ECS container instances and the Amazon FSx file system, implementing mount health checks, and handling reconnection logic to tolerate failover events.

- FSx for Windows File Server with Amazon ECS doesn't support AWS Fargate.
- FSx for Windows File Server with Amazon ECS isn't supported on Amazon ECS Managed Instances.
- FSx for Windows File Server with Amazon ECS with `awsvpc` network mode requires version `1.54.0` or later of the container agent.
- The maximum number of drive letters that can be used for an Amazon ECS task is 23. Each task with an FSx for Windows File Server volume gets a drive letter assigned to it.
- By default, task resource cleanup time is three hours after the task ended. Even if no tasks use it, a file mapping that's created by a task persists for three hours. You can configure the default cleanup time by using the Amazon ECS environment variable `ECS_ENGINE_TASK_CLEANUP_WAIT_DURATION`. For more information, see [Amazon ECS container agent configuration](#).
- Tasks typically only run in the same VPC as the FSx for Windows File Server file system. However, it's possible to have cross-VPC support if there's an established network connectivity between the Amazon ECS cluster VPC and the FSx for Windows File Server file-system through VPC peering.
- You control access to an FSx for Windows File Server file system at the network level by configuring the VPC security groups. Only tasks that are hosted on EC2 instances joined to the Active Directory domain with correctly configured Active Directory security groups can access the FSx for Windows File Server file-share. If the security groups are misconfigured, Amazon ECS fails to launch the task with the following error message: `unable to mount file system fs-id.`
- FSx for Windows File Server is integrated with AWS Identity and Access Management (IAM) to control the actions that your IAM users and groups can take on specific FSx for Windows

File Server resources. With client authorization, customers can define IAM roles that allow or deny access to specific FSx for Windows File Server file systems, optionally require read-only access, and optionally allow or disallow root access to the file system from the client. For more information, see [Security](#) in the Amazon FSx Windows User Guide.

## Best practices for using FSx for Windows File Server with Amazon ECS

Make note of the following best practice recommendations when you use FSx for Windows File Server with Amazon ECS.

### Security and access controls for FSx for Windows File Server

FSx for Windows File Server offers the following access control features that you can use to ensure that the data stored in an FSx for Windows File Server file system is secure and accessible only from applications that need it.

### Data encryption for FSx for Windows File Server volumes

FSx for Windows File Server supports two forms of encryption for file systems. They are encryption of data in transit and encryption at rest. Encryption of data in transit is supported on file shares that are mapped on a container instance that supports SMB protocol 3.0 or newer. Encryption of data at rest is automatically enabled when creating an Amazon FSx file system. Amazon FSx automatically encrypts data in transit using SMB encryption as you access your file system without the need for you to modify your applications. For more information, see [Data encryption in Amazon FSx](#) in the *Amazon FSx for Windows File Server User Guide*.

### Use Windows ACLs for folder level access control

The Windows Amazon EC2 instance access Amazon FSx file shares using Active Directory credentials. It uses standard Windows access control lists (ACLs) for fine-grained file-level and folder-level access control. You can create multiple credentials, each one for a specific folder within the share which maps to a specific task.

In the following example, the task has access to the folder App01 using a credential saved in Secrets Manager. Its Amazon Resource Name (ARN) is 1234.

```
"rootDirectory": "\\path\\to\\my\\data\\App01",  
"credentialsParameter": "arn-1234",  
"domain": "corp.fullyqualified.com",
```

In another example, a task has access to the folder App02 using a credential saved in the Secrets Manager. Its ARN is 6789.

```
"rootDirectory": "\\path\\to\\my\\data\\App02",
"credentialsParameter": "arn-6789",
"domain": "corp.fullyqualified.com",
```

## Specify an FSx for Windows File Server file system in an Amazon ECS task definition

To use FSx for Windows File Server file system volumes for your containers, specify the volume and mount point configurations in your task definition. The following task definition JSON snippet shows the syntax for the volumes and mountPoints objects for a container.

```
{
  "containerDefinitions": [
    {
      "entryPoint": [
        "powershell",
        "-Command"
      ],
      "portMappings": [],
      "command": ["New-Item -Path C:\\fsx-windows-dir\\index.html -ItemType file -Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>It Works!</h2> <p>You are using Amazon FSx for Windows File Server file system for persistent container storage.</p>' -Force"],
      "cpu": 512,
      "memory": 256,
      "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
      "essential": false,
      "name": "container1",
      "mountPoints": [
        {
          "sourceVolume": "fsx-windows-dir",
          "containerPath": "C:\\fsx-windows-dir",
          "readOnly": false
        }
      ]
    },
    {
      "entryPoint": [
```

```

        "powershell",
        "-Command"
    ],
    "portMappings": [
        {
            "hostPort": 443,
            "protocol": "tcp",
            "containerPort": 80
        }
    ],
    "command": ["Remove-Item -Recurse C:\\\\inetpub\\\\wwwroot\\\\* -Force; Start-Sleep -Seconds 120; Move-Item -Path C:\\\\fsx-windows-dir\\\\index.html -Destination C:\\\\inetpub\\\\wwwroot\\\\index.html -Force; C:\\\\ServiceMonitor.exe w3svc"],
    "mountPoints": [
        {
            "sourceVolume": "fsx-windows-dir",
            "containerPath": "C:\\\\fsx-windows-dir",
            "readOnly": false
        }
    ],
    "cpu": 512,
    "memory": 256,
    "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
    "essential": true,
    "name": "container2"
}
],
"family": "fsx-windows",
"executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole",
"volumes": [
    {
        "name": "fsx-windows-dir",
        "fsxWindowsFileServerVolumeConfiguration": {
            "fileSystemId": "fs-0eeb5730b2EXAMPLE",
            "authorizationConfig": {
                "domain": "example.com",
                "credentialsParameter": "arn:arn-1234"
            },
            "rootDirectory": "share"
        }
    }
]

```

```
}
```

## FSxWindowsFileServerVolumeConfiguration

Type: Object

Required: No

This parameter is specified when you're using [FSx for Windows File Server](#) file system for task storage.

`fileSystemId`

Type: String

Required: Yes

The FSx for Windows File Server file system ID to use.

`rootDirectory`

Type: String

Required: Yes

The directory within the FSx for Windows File Server file system to mount as the root directory inside the host.

`authorizationConfig`

`credentialsParameter`

Type: String

Required: Yes

The authorization credential options:

- Amazon Resource Name (ARN) of an [Secrets Manager](#) secret.
- Amazon Resource Name (ARN) of an [Systems Manager](#) parameter.

`domain`

Type: String

Required: Yes

A fully qualified domain name that's hosted by an [AWS Directory Service for Microsoft Active Directory](#) (AWS Managed Microsoft AD) directory or a self-hosted EC2 Active Directory.

## Methods for storing FSx for Windows File Server volume credentials

There are two different methods of storing credentials for use with the credentials parameter.

- **AWS Secrets Manager secret**

This credential can be created in the AWS Secrets Manager console by using the *Other type of secret* category. You add a row for each key/value pair, username/admin and password/*password*.

- **Systems Manager parameter**

This credential can be created in the Systems Manager parameter console by entering text in the form that's in the following example code snippet.

```
{
  "username": "admin",
  "password": "password"
}
```

The credentialsParameter in the task definition

FSxWindowsFileServerVolumeConfiguration parameter holds either the secret ARN or the Systems Manager parameter ARN. For more information, see [What is AWS Secrets Manager](#) in the *Secrets Manager User Guide* and [Systems Manager Parameter Store](#) from the *Systems Manager User Guide*.

## Learn how to configure FSx for Windows File Server file systems for Amazon ECS

Learn how to launch an Amazon ECS-Optimized Windows instance that hosts an FSx for Windows File Server file system and containers that can access the file system. To do this, you first create an Directory Service AWS Managed Microsoft Active Directory. Then, you create an FSx for Windows File Server File Server file system and cluster with an Amazon EC2 instance and a task definition. You configure the task definition for your containers to use the FSx for Windows File Server file system. Finally, you test the file system.

It takes 20 to 45 minutes each time you launch or delete either the Active Directory or the FSx for Windows File Server file system. Be prepared to reserve at least 90 minutes to complete the tutorial or complete the tutorial over a few sessions.

## Prerequisites for the tutorial

- An administrative user. See [Set up to use Amazon ECS](#).
- (Optional) A PEM key pair for connecting to your EC2 Windows instance through RDP access. For information about how to create key pairs, see [Amazon EC2 key pairs and Amazon EC2 instances](#) in the *Amazon EC2 User Guide*.
- A VPC with at least one public and one private subnet, and one security group. You can use your default VPC. You don't need a NAT gateway or device. Directory Service doesn't support Network Address Translation (NAT) with Active Directory. For this to work, the Active Directory, FSx for Windows File Server file system, ECS Cluster, and EC2 instance must be located within your VPC. For more information regarding VPCs and Active Directories, see [Create a VPC](#) and [Prerequisites for creating an AWS Managed Microsoft AD](#).
- The IAM `ecsInstanceRole` and `ecsTaskExecutionRole` permissions are associated with your account. These service-linked roles allow services to make API calls and access containers, secrets, directories, and file servers on your behalf.

## Step 1: Create IAM access roles

### Create a cluster with the AWS Management Console.

1. See [Amazon ECS container instance IAM role](#) to check whether you have an `ecsInstanceRole` and to see how you can create one if you don't have one.
2. We recommend that role policies are customized for minimum permissions in an actual production environment. For the purpose of working through this tutorial, verify that the following AWS managed policy is attached to your `ecsInstanceRole`. Attach the policy if it is not already attached.
  - `AmazonEC2ContainerServiceforEC2Role`
  - `AmazonSSMManagedInstanceCore`
  - `AmazonSSMDirectoryServiceAccess`

To attach AWS managed policies.

- a. Open the [IAM console](#).
  - b. In the navigation pane, choose **Roles**.
  - c. Choose an **AWS managed role**.
  - d. Choose **Permissions, Attach policies**.
  - e. To narrow the available policies to attach, use **Filter**.
  - f. Select the appropriate policy and choose **Attach policy**.
3. See [Amazon ECS task execution IAM role](#) to check whether you have an `ecsTaskExecutionRole` and to see how you can create one if you don't have one.

We recommend that role policies are customized for minimum permissions in an actual production environment. For the purpose of working through this tutorial, verify that the following AWS managed policies are attached to your `ecsTaskExecutionRole`. Attach the policies if they are not already attached. Use the procedure given in the preceding section to attach the AWS managed policies.

- `SecretsManagerReadWrite`
- `AmazonFSxReadOnlyAccess`
- `AmazonSSMReadOnlyAccess`
- `AmazonECSTaskExecutionRolePolicy`

## Step 2: Create Windows Active Directory (AD)

1. Follow the steps described in [Creating your AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*. Use the VPC you have designated for this tutorial. On Step 3 of *Creating your AWS Managed Microsoft AD*, save the user name and admin password for use in a following step. Also, note the fully qualified directory DNS name for future steps. You can complete the following step while the Active Directory is being created.
2. Create an AWS Secrets Manager secret to use in the following steps. For more information, see [Get started with Secrets Manager](#) in the *AWS Secrets Manager User Guide*.
  - a. Open the [Secrets Manager console](#).
  - b. Click **Store a new secret**.
  - c. Select **Other type of secrets**.

- d. For **Secret key/value**, in the first row, create a key **username** with value **admin**. Click on **+ Add row**.
- e. In the new row, create a key **password**. For value, type in the password you entered in Step 3 of *Create Your AWS Managed AD Directory*.
- f. Click on the **Next** button.
- g. Provide a secret name and description. Click **Next**.
- h. Click **Next**. Click **Store**.
- i. From the list of **Secrets** page, click on the secret you have just created.
- j. Save the ARN of the new secret for use in the following steps.
- k. You can proceed to the next step while your Active Directory is being created.

### Step 3: Verify and update your security group

In this step, you verify and update the rules for the security group that you're using. For this, you can use the default security group that was created for your VPC.

#### Verify and update security group.

You need to create or edit your security group to send data from and to the ports, which are described in [Amazon VPC Security Groups](#) in the *FSx for Windows File Server User Guide*. You can do this by creating the security group inbound rule shown in the first row of the following table of inbound rules. This rule allows inbound traffic from network interfaces (and their associated instances) that are assigned to the security group. All of the cloud resources you create are within the same VPC and attached to the same security group. Therefore, this rule allows traffic to be sent to and from the FSx for Windows File Server file system, Active Directory, and ECS instance as required. The other inbound rules allow traffic to serve the website and RDP access for connecting to your ECS instance.

The following table shows which security group inbound rules are required for this tutorial.

| Type        | Protocol | Port range | Source                  |
|-------------|----------|------------|-------------------------|
| All traffic | All      | All        | <i>sg-securitygroup</i> |

| Type  | Protocol | Port range | Source                 |
|-------|----------|------------|------------------------|
| HTTPS | TCP      | 443        | 0.0.0.0/0              |
| RDP   | TCP      | 3389       | your laptop IP address |

The following table shows which security group outbound rules are required for this tutorial.

| Type        | Protocol | Port range | Destination |
|-------------|----------|------------|-------------|
| All traffic | All      | All        | 0.0.0.0/0   |

1. Open the [EC2 console](#) and select **Security Groups** from the left-hand menu.
2. From the list of security groups now displayed, select check the check-box to the left of the security group that you are using for this tutorial.

Your security group details are displayed.

3. Edit the inbound and outbound rules by selecting the **Inbound rules** or **Outbound rules** tabs and choosing the **Edit inbound rules** or **Edit outbound rules** buttons. Edit the rules to match those displayed in the preceding tables. After you create your EC2 instance later on in this tutorial, edit the inbound rule RDP source with the public IP address of your EC2 instance as described in [Connect to your Windows instance using RDP](#) from the *Amazon EC2 User Guide*.

#### Step 4: Create an FSx for Windows File Server file system

After your security group is verified and updated and your Active Directory is created and is in the active status, create the FSx for Windows File Server file system in the same VPC as your Active Directory. Use the following steps to create an FSx for Windows File Server file system for your Windows tasks.

##### Create your first file system.

1. Open the [Amazon FSx console](#).

2. On the dashboard, choose **Create file system** to start the file system creation wizard.
3. On the **Select file system type** page, choose **FSx for Windows File Server**, and then choose **Next**. The **Create file system** page appears.
4. In the **File system details** section, provide a name for your file system. Naming your file systems makes it easier to find and manage your them. You can use up to 256 Unicode characters. Allowed characters are letters, numbers, spaces, and the special characters plus sign (+), minus sign (-), equal sign (=), period (.), underscore (\_), colon (:), and forward slash (/).
5. For **Deployment type** choose **Single-AZ** to deploy a file system that is deployed in a single Availability Zone. *Single-AZ 2* is the latest generation of single Availability Zone file systems, and it supports SSD and HDD storage.
6. For **Storage type**, choose **HDD**.
7. For **Storage capacity**, enter the minimum storage capacity.
8. Keep **Throughput capacity** at its default setting.
9. In the **Network & security** section, choose the same Amazon VPC that you chose for your Directory Service directory.
10. For **VPC Security Groups**, choose the security group that you verified in *Step 3: Verify and update your security group*.
11. For **Windows authentication**, choose **AWS Managed Microsoft Active Directory**, and then choose your Directory Service directory from the list.
12. For **Encryption**, keep the default **Encryption key** setting of **aws/fsx (default)**.
13. Keep the default settings for **Maintenance preferences**.
14. Click on the **Next** button.
15. Review the file system configuration shown on the **Create file system** page. For your reference, note which file system settings you can modify after file system is created. Choose **Create file system**.
16. Note the file system ID. You will need to use it in a later step.

You can go on to the next steps to create a cluster and EC2 instance while the FSx for Windows File Server file system is being created.

## Step 5: Create an Amazon ECS cluster

### Create a cluster using the Amazon ECS console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, for **Cluster name**, enter **windows-fsx-cluster**.
6. Expand **Infrastructure**, clear AWS Fargate (serverless) and then select **Amazon EC2 instances**.
  - To create a Auto Scaling group, from **Auto Scaling group (ASG)**, select **Create new group**, and then provide the following details about the group:
    - For **Operating system/Architecture**, choose **Windows Server 2019 Core**.
    - For **EC2 instance type**, choose t2.medium or t2.micro.
7. Choose **Create**.

## Step 6: Create an Amazon ECS optimized Amazon EC2 instance

Create an Amazon ECS Windows container instance.

### To create an Amazon ECS instance

1. Use the `aws ssm get-parameters` command to retrieve the AMI name for the Region that hosts your VPC. For more information, see [Retrieving Amazon ECS-Optimized AMI metadata](#).
2. Use the Amazon EC2 console to launch the instance.
  - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
  - b. From the navigation bar, select the Region to use.
  - c. From the **EC2 Dashboard**, choose **Launch instance**.
  - d. For **Name**, enter a unique name.
  - e. For **Application and OS Images (Amazon Machine Image)**, in the **search** field, enter the AMI name that you retrieved.
  - f. For **Instance type**, choose t2.medium or t2.micro.
  - g. For **Key pair (login)**, choose a key pair. If you don't specify a key pair, you

- h. Under **Network settings**, for **VPC** and **Subnet**, choose your VPC and a public subnet.
- i. Under **Network settings**, for **Security group**, choose an existing security group, or create a new one. Ensure that the security group you choose has the inbound and outbound rules defined in [Prerequisites for the tutorial](#)
- j. Under **Network settings**, for **Auto-assign Public IP**, select **Enable**.
- k. Expand **Advanced details**, and then for **Domain join directory**, select the ID of the Active Directory that you created. This option domain joins your AD when the EC2 instance is launched.
- l. Under **Advanced details**, for **IAM instance profile**, choose **ecsInstanceRole**.
- m. Configure your Amazon ECS container instance with the following user data. Under **Advanced Details**, paste the following script into the **User data** field, replacing *cluster\_name* with the name of your cluster.

```
<powershell>
Initialize-ECSAgent -Cluster windows-fsx-cluster -EnableTaskIAMRole
</powershell>
```

- n. When you are ready, select the acknowledgment field, and then choose **Launch Instances**.
  - o. A confirmation page lets you know that your instance is launching. Choose **View Instances** to close the confirmation page and return to the console.
3. Open the console at <https://console.aws.amazon.com/ecs/v2>.
  4. In the navigation pane, choose **Clusters**, and then choose **windows-fsx-cluster**.
  5. Choose the **Infrastructure** tab and verify that your instance has been registered in the **windows-fsx-cluster** cluster.

## Step 7: Register a Windows task definition

Before you can run Windows containers in your Amazon ECS cluster, you must register a task definition. The following task definition example displays a simple web page. The task launches two containers that have access to the FSx file system. The first container writes an HTML file to the file system. The second container downloads the HTML file from the file system and serves the webpage.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task definitions**.

3. Choose **Create new task definition**, **Create new task definition with JSON**.
4. In the JSON editor box, replace the values for your task execution role and the details about your FSx file system and then choose **Save**.

```
{
  "containerDefinitions": [
    {
      "entryPoint": [
        "powershell",
        "-Command"
      ],
      "portMappings": [],
      "command": ["New-Item -Path C:\\fsx-windows-dir\\index.html -ItemType
file -Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body
{margin-top: 40px; background-color: #333;} </style> </head><body> <div
style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>It
Works!</h2> <p>You are using Amazon FSx for Windows File Server file system for
persistent container storage.</p>' -Force"],
      "cpu": 512,
      "memory": 256,
      "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-
ltsc2019",
      "essential": false,
      "name": "container1",
      "mountPoints": [
        {
          "sourceVolume": "fsx-windows-dir",
          "containerPath": "C:\\fsx-windows-dir",
          "readOnly": false
        }
      ]
    },
    {
      "entryPoint": [
        "powershell",
        "-Command"
      ],
      "portMappings": [
        {
          "hostPort": 443,
          "protocol": "tcp",
          "containerPort": 80
        }
      ]
    }
  ]
}
```

```

    ],
    "command": ["Remove-Item -Recurse C:\\inetpub\\wwwroot\\* -Force;
Start-Sleep -Seconds 120; Move-Item -Path C:\\fsx-windows-dir\\index.html -
Destination C:\\inetpub\\wwwroot\\index.html -Force; C:\\ServiceMonitor.exe
w3svc"],
    "mountPoints": [
        {
            "sourceVolume": "fsx-windows-dir",
            "containerPath": "C:\\fsx-windows-dir",
            "readOnly": false
        }
    ],
    "cpu": 512,
    "memory": 256,
    "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-
ltsc2019",
    "essential": true,
    "name": "container2"
  }
],
"family": "fsx-windows",
"executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole",
"volumes": [
  {
    "name": "fsx-windows-dir",
    "fsxWindowsFileServerVolumeConfiguration": {
      "fileSystemId": "fs-0eeb5730b2EXAMPLE",
      "authorizationConfig": {
        "domain": "example.com",
        "credentialsParameter": "arn:arn-1234"
      },
    },
    "rootDirectory": "share"
  }
]
}

```

## Step 8: Run a task and view the results

Before running the task, verify that the status of your FSx for Windows File Server file system is **Available**. After it is available, you can run a task using the task definition that you created. The

task starts out by creating containers that shuffle an HTML file between them using the file system. After the shuffle, a web server serves the simple HTML page.

 **Note**

You might not be able to connect to the website from within a VPN.

**Run a task and view the results with the Amazon ECS console.**

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**, and then choose **windows-fsx-cluster**.
3. Choose the **Tasks** tab, and then choose **Run new task**.
4. For **Launch Type**, choose **EC2**.
5. Under Deployment configuration, for **Task Definition**, choose the **fsx-windows**, and then choose **Create**.
6. When your task status is **RUNNING**, choose the task ID.
7. Under **Containers**, when the container1 status is **STOPPED**, select container2 to view the container's details.
8. Under **Container details for container2**, select **Network bindings** and then click on the external IP address that is associated with the container. Your browser will open and display the following message.

```
Amazon ECS Sample App
It Works!
You are using Amazon FSx for Windows File Server file system for persistent
container storage.
```

 **Note**

It may take a few minutes for the message to be displayed. If you don't see this message after a few minutes, check that you aren't running in a VPN and make sure that the security group for your container instance allows inbound network HTTP traffic on port 443.

## Step 9: Clean up

### Note

It takes 20 to 45 minutes to delete the FSx for Windows File Server file system or the AD. You must wait until the FSx for Windows File Server file system delete operations are complete before starting the AD delete operations.

### Delete FSx for Windows File Server file system.

1. Open the [Amazon FSx console](#)
2. Choose the radio button to the left of the FSx for Windows File Server file system that you just created.
3. Choose **Actions**.
4. Select **Delete file system**.

### Delete AD.

1. Open the [Directory Service console](#).
2. Choose the radio button to the left of the AD you just created.
3. Choose **Actions**.
4. Select **Delete directory**.

### Delete the cluster.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**, and then choose **windows-fsx-cluster**.
3. Choose **Delete cluster**.
4. Enter the phrase and then choose **Delete**.

### Terminate EC2 instance.

1. Open the [Amazon EC2 console](#).
2. From the left-hand menu, select **Instances**.

3. Check the box to the left of the EC2 instance you created.
4. Click the **Instance state, Terminate instance**.

### Delete secret.

1. Open the [Secrets Manager console](#).
2. Select the secret you created for this walk through.
3. Click **Actions**.
4. Select **Delete secret**.

## Configuring S3 Files for Amazon ECS

S3 Files is a shared file system that connects any AWS compute resource directly with your data in Amazon S3. It provides fast, direct access to all of your S3 data as files with full file system semantics and low-latency performance, without your data ever leaving S3. You can read, write, and organize data using file and directory operations, while S3 Files keeps your file system and S3 bucket synchronized automatically. With Amazon ECS, you can define S3 file systems as volumes in your task definitions, giving your containers direct file system access to data stored in S3 buckets. To learn more about Amazon S3 Files and its capabilities, see the [Amazon S3 User Guide](#).

### Availability

S3 Files support in Amazon ECS is available for the following launch types at General Availability:

- **Fargate** — Fully supported.
- **Amazon ECS Managed Instances** — Fully supported.
- **Amazon EC2** — Fully supported.

### Considerations

- S3 file system uses a dedicated `s3filesVolumeConfiguration` parameter in the task definition.
- S3 file system requires a full Amazon Resource Name (ARN) to identify the file system. The ARN format is:

```
arn:{partition}:s3files:{region}:{account-id}:file-system/fs-xxxxx
```

- Transit encryption is mandatory for S3 file system volumes and is automatically enforced. There is no option to disable it.
- Task IAM Role is mandatory for S3 file system volumes and is automatically enforced. There is no option to disable it.

## Prerequisites

Before configuring S3 file system volumes in your Amazon ECS task definitions, ensure the following prerequisites are met:

- **An S3 file system and mount target** — You must have an S3 file system created and associated with an S3 bucket. For instructions on creating an S3 file system, see the [Amazon S3 Files User Guide](#).
- **A Task IAM Role** — Your task definition must include a Task IAM Role with the following permissions:
  - Permissions to connect to and interact with S3 file systems from your application code (running in the container).
  - Permissions to read S3 objects from your application code (running in the container).
- **VPC and security group configuration** — Your S3 file system must be accessible from the VPC and subnets where your Amazon ECS tasks run.
- **(Optional) S3 Files access points** — If you want to enforce application-specific access controls, create an S3 Files access point and provide the ARN in the task definition.

For more information, refer to [prerequisites for S3 Files](#).

## Specify an Amazon S3 Files volume in your Amazon ECS task definition

You can configure S3 Files volumes in your Amazon ECS task definitions using the Amazon ECS console, the AWS CLI, or the AWS API.

### Using the Amazon ECS console

1. Open the Amazon ECS console at <https://console.aws.amazon.com/ecs/>.
2. In the navigation pane, choose **Task definitions**.
3. Choose **Create new task definition** or select an existing task definition and create a new revision.

4. In the **Infrastructure** section, ensure you have a Task IAM Role configured with the required permissions.
5. In the **Storage** section, choose **Add volume**.
6. For **Volume type**, select **S3 Files**.
7. For **File system ARN**, enter the full ARN of your S3 file system. The ARN format is:

```
arn:{partition}:s3files:{region}:{account-id}:file-system/fs-xxxxx
```

8. (Optional) For **Root directory**, enter the path within the file system to mount as the root. If not specified, the root of the file system (/) is used.
9. (Optional) For **Transit encryption port**, enter the port number for sending encrypted data between the Amazon ECS host and the S3 file system. If you don't specify a transit encryption port, it uses the port selection strategy that the Amazon EFS mount helper uses.
10. (Optional) For **Access point ARN**, select the S3 Files access point to use from the dropdown list.
11. In the **Container mount points** section, select the container and specify the local mount path in your container where the volume should be mounted inside the container.
12. Choose **Create** to create the task definition.

## Using the AWS CLI

To specify an S3 Files volume in a task definition using the AWS CLI, use the `register-task-definition` command with the `s3filesVolumeConfiguration` parameter in the volume definition.

The following is an example task definition JSON snippet that defines an S3 Files volume and mounts it to a container:

```
{
  "family": "s3files-task-example",
  "taskRoleArn": "arn:aws:iam::123456789012:role/ecsTaskRole",
  "containerDefinitions": [
    {
      "name": "my-container",
      "image": "my-image:latest",
      "essential": true,
      "mountPoints": [
```

```

        {
            "containerPath": "/mnt/s3data",
            "sourceVolume": "my-s3files-volume"
        }
    ]
},
"volumes": [
    {
        "name": "my-s3files-volume",
        "s3filesVolumeConfiguration": {
            "fileSystemArn": "arn:aws:s3files:us-east-1:123456789012:file-
system/fs-0123456789abcdef0",
            "rootDirectory": "/",
            "transitEncryptionPort": 2999
        }
    }
]
}

```

Register the task definition:

```
aws ecs register-task-definition --cli-input-json file://s3files-task-def.json
```

To use an access point, include the `accessPointArn` parameter:

```

{
    "name": "my-s3files-volume",
    "s3filesVolumeConfiguration": {
        "fileSystemArn": "arn:aws:s3files:us-east-1:123456789012:file-
system/fs-0123456789abcdef0",
        "rootDirectory": "/",
        "transitEncryptionPort": 2999,
        "accessPointArn": "arn:aws:s3files:us-east-1:123456789012:file-
system/fs-0123456789abcdef0/access-point/fsap-0123456789abcdef0"
    }
}

```

### S3 Files volume configuration parameters

The following table describes the parameters available in the `s3filesVolumeConfiguration` object:

## fileSystemArn

Type: String

Required: Yes

The full ARN of the S3 file system to mount. Format:

arn:*{partition}*:s3files:*{region}*:*{account-id}*:file-system/*fs-xxxxx*

## rootDirectory

Type: String

Required: No

The directory within the S3 file system to mount as the root of the volume. Defaults to / if not specified.

## transitEncryptionPort

Type: Integer

Required: No

The port to use for sending encrypted data between the Amazon ECS host and the S3 file system. Transit encryption itself is always enabled and cannot be disabled.

## accessPointArn

Type: String

Required: No

The full ARN of the S3 Files access point to use. Access points provide application-specific entry points into the file system with enforced user identity and root directory settings.

## Use Docker volumes with Amazon ECS

When using Docker volumes, the built-in `local` driver or a third-party volume driver can be used. Docker volumes are managed by Docker and a directory is created in `/var/lib/docker/volumes` on the container instance that contains the volume data.

To use Docker volumes, specify a `dockerVolumeConfiguration` in your task definition. For more information, see [Volumes](#) in the Docker documentation.

Some common use cases for Docker volumes are the following:

- To provide persistent data volumes for use with containers
- To share a defined data volume at different locations on different containers on the same container instance
- To define an empty, nonpersistent data volume and mount it on multiple containers within the same task
- To provide a data volume to your task that's managed by a third-party driver

### Considerations for using Docker volumes

Consider the following when using Docker volumes:

- Docker volumes are only supported when using the EC2 launch type or external instances.
- Windows containers only support the use of the `local` driver.
- If a third-party driver is used, make sure it's installed and active on the container instance before the container agent is started. If the third-party driver isn't active before the agent is started, you can restart the container agent using one of the following commands:
  - For the Amazon ECS-optimized Amazon Linux 2 AMI:

```
sudo systemctl restart ecs
```

- For the Amazon ECS-optimized Amazon Linux AMI:

```
sudo stop ecs && sudo start ecs
```

For information about how to specify a Docker volume in a task definition, see [Specify a Docker volume in an Amazon ECS task definition](#).

### Specify a Docker volume in an Amazon ECS task definition

Before your containers can use data volumes, you must specify the volume and mount point configurations in your task definition. This section describes the volume configuration for a

container. For tasks that use a Docker volume, specify a `dockerVolumeConfiguration`. For tasks that use a bind mount host volume, specify a `host` and optional `sourcePath`.

The following task definition JSON shows the syntax for the `volumes` and `mountPoints` objects for a container.

```
{
  "containerDefinitions": [
    {
      "mountPoints": [
        {
          "sourceVolume": "string",
          "containerPath": "/path/to/mount_volume",
          "readOnly": boolean
        }
      ]
    }
  ],
  "volumes": [
    {
      "name": "string",
      "dockerVolumeConfiguration": {
        "scope": "string",
        "autoprovision": boolean,
        "driver": "string",
        "driverOpts": {
          "key": "value"
        },
        "labels": {
          "key": "value"
        }
      }
    }
  ]
}
```

name

Type: String

Required: No

The name of the volume. Up to 255 letters (uppercase and lowercase), numbers, hyphens (-), and underscores (\_) are allowed. This name is referenced in the `sourceVolume` parameter of the container definition `mountPoints` object.

#### `dockerVolumeConfiguration`

Type: [DockerVolumeConfiguration](#) Object

Required: No

This parameter is specified when using Docker volumes. Docker volumes are supported only when running tasks on EC2 instances. Windows containers support only the use of the `local` driver. To use bind mounts, specify a host instead.

#### `scope`

Type: String

Valid Values: `task` | `shared`

Required: No

The scope for the Docker volume, which determines its lifecycle. Docker volumes that are scoped to a task are automatically provisioned when the task starts and destroyed when the task stops. Docker volumes that are scoped as `shared` persist after the task stops.

#### `autoprovision`

Type: Boolean

Default value: `false`

Required: No

If this value is `true`, the Docker volume is created if it doesn't already exist. This field is used only if the scope is `shared`. If the scope is `task`, then this parameter must be omitted.

#### `driver`

Type: String

Required: No

The Docker volume driver to use. The driver value must match the driver name provided by Docker because this name is used for task placement. If the driver was installed by using the

Docker plugin CLI, use `docker plugin ls` to retrieve the driver name from your container instance. If the driver was installed by using another method, use Docker plugin discovery to retrieve the driver name.

#### `driverOpts`

Type: String

Required: No

A map of Docker driver-specific options to pass through. This parameter maps to `DriverOpts` in the Create a volume section of Docker.

#### `labels`

Type: String

Required: No

Custom metadata to add to your Docker volume.

#### `mountPoints`

Type: Object array

Required: No

The mount points for the data volumes in your container. This parameter maps to `Volumes` in the create-container Docker API and the `--volume` option to `docker run`.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`. Windows containers cannot mount directories on a different drive, and mount points cannot be used across drives. You must specify mount points to attach an Amazon EBS volume directly to an Amazon ECS task.

#### `sourceVolume`

Type: String

Required: Yes, when `mountPoints` are used

The name of the volume to mount.

#### `containerPath`

Type: String

Required: Yes, when `mountPoints` are used

The path in the container where the volume will be mounted.

`readOnly`

Type: Boolean

Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

For tasks that run on EC2 instances running the Windows operating system, leave the value as the default of `false`.

## Docker volume examples for Amazon ECS

The following examples show how to provide ephemeral storage for a container and how to provide a shared volume for multiple containers, and how to provide NFS persistent storage for a container.

### To provide ephemeral storage for a container using a Docker volume

In this example, a container uses an empty data volume that is disposed of after the task is finished. One example use case is that you might have a container that needs to access some scratch file storage location during a task. This task can be achieved using a Docker volume.

1. In the task definition `volumes` section, define a data volume with name and `DockerVolumeConfiguration` values. In this example, we specify the scope as `task` so the volume is deleted after the task stops and use the built-in `local` driver.

```
"volumes": [  
  {  
    "name": "scratch",  
    "dockerVolumeConfiguration" : {  
      "scope": "task",  
      "driver": "local",  
      "labels": {  
        "scratch": "space"  
      }  
    }  
  }  
]
```

```
    }  
  ]  
}
```

2. In the `containerDefinitions` section, define a container with `mountPoints` values that reference the name of the defined volume and the `containerPath` value to mount the volume at on the container.

```
"containerDefinitions": [  
  {  
    "name": "container-1",  
    "mountPoints": [  
      {  
        "sourceVolume": "scratch",  
        "containerPath": "/var/scratch"  
      }  
    ]  
  }  
]
```

## To provide persistent storage for multiple containers using a Docker volume

In this example, you want a shared volume for multiple containers to use and you want it to persist after any single task that use it stopped. The built-in `local` driver is being used. This is so the volume is still tied to the lifecycle of the container instance.

1. In the task definition `volumes` section, define a data volume with name and `DockerVolumeConfiguration` values. In this example, specify a shared scope so the volume persists, set `autoprovision` to `true`. This is so that the volume is created for use. Then, also use the built-in `local` driver.

```
"volumes": [  
  {  
    "name": "database",  
    "dockerVolumeConfiguration" : {  
      "scope": "shared",  
      "autoprovision": true,  
      "driver": "local",  
      "labels": {  
        "database": "database_name"  
      }  
    }  
  }  
]
```

```
    }  
  ]  
}
```

2. In the `containerDefinitions` section, define a container with `mountPoints` values that reference the name of the defined volume and the `containerPath` value to mount the volume at on the container.

```
"containerDefinitions": [  
  {  
    "name": "container-1",  
    "mountPoints": [  
      {  
        "sourceVolume": "database",  
        "containerPath": "/var/database"  
      }  
    ],  
  },  
  {  
    "name": "container-2",  
    "mountPoints": [  
      {  
        "sourceVolume": "database",  
        "containerPath": "/var/database"  
      }  
    ],  
  }  
]
```

## To provide NFS persistent storage for a container using a Docker volume

In this example, a container uses an NFS data volume that is automatically mounted when the task starts and unmounted when the task stops. This uses the Docker built-in `local` driver. One example use case is that you might have a local NFS storage and need to access it from an ECS Anywhere task. This can be achieved using a Docker volume with NFS driver option.

1. In the task definition `volumes` section, define a data volume with `name` and `DockerVolumeConfiguration` values. In this example, specify a task scope so the volume is unmounted after the task stops. Use the `local` driver and configure the `driverOpts` with the `type`, `device`, and `o` options accordingly. Replace `NFS_SERVER` with the NFS server endpoint.

```
"volumes": [
  {
    "name": "NFS",
    "dockerVolumeConfiguration": {
      "scope": "task",
      "driver": "local",
      "driverOpts": {
        "type": "nfs",
        "device": "$NFS_SERVER:/mnt/nfs",
        "o": "addr=$NFS_SERVER"
      }
    }
  }
]
```

2. In the `containerDefinitions` section, define a container with `mountPoints` values that reference the name of the defined volume and the `containerPath` value to mount the volume on the container.

```
"containerDefinitions": [
  {
    "name": "container-1",
    "mountPoints": [
      {
        "sourceVolume": "NFS",
        "containerPath": "/var/nfsmount"
      }
    ]
  }
]
```

## Use bind mounts with Amazon ECS

With bind mounts, a file or directory on a host, such as an Amazon EC2 instance, is mounted into a container. Bind mounts are supported for tasks that are hosted on both Fargate and Amazon EC2 instances. Bind mounts are tied to the lifecycle of the container that uses them. After all of the containers that use a bind mount are stopped, such as when a task is stopped, the data is removed. For tasks that are hosted on Amazon EC2 instances, the data can be tied to the lifecycle of the host

Amazon EC2 instance by specifying a host and optional `sourcePath` value in your task definition. For more information, see [Bind mounts](#) in the Docker documentation.

The following are common use cases for bind mounts.

- To provide an empty data volume to mount in one or more containers.
- To mount a host data volume in one or more containers.
- To share a data volume from a source container with other containers in the same task.
- To expose a path and its contents from a Dockerfile to one or more containers.

## Considerations when using bind mounts

When using bind mounts, consider the following.

- By default, tasks that are hosted on AWS Fargate using platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows) receive a minimum of 20 GiB of ephemeral storage for bind mounts. You can increase the total amount of ephemeral storage up to a maximum of 200 GiB by specifying the `ephemeralStorage` parameter in your task definition.
- To expose files from a Dockerfile to a data volume when a task is run, the Amazon ECS data plane looks for a `VOLUME` directive. If the absolute path that's specified in the `VOLUME` directive is the same as the `containerPath` that's specified in the task definition, the data in the `VOLUME` directive path is copied to the data volume. In the following Dockerfile example, a file that's named `examplefile` in the `/var/log/exported` directory is written to the host and then mounted inside the container.

```
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
RUN mkdir -p /var/log/exported
RUN touch /var/log/exported/examplefile
VOLUME ["/var/log/exported"]
```

By default, the volume permissions are set to `0755` and the owner as `root`. You can customize these permissions in the Dockerfile. The following example defines the owner of the directory as `node`.

```
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
RUN yum install -y shadow-utils && yum clean all
RUN useradd node
RUN mkdir -p /var/log/exported && chown node:node /var/log/exported
```

```
RUN touch /var/log/exported/examplefile
USER node
VOLUME ["/var/log/exported"]
```

- For tasks that are hosted on Amazon EC2 instances, when a host and sourcePath value aren't specified, the Docker daemon manages the bind mount for you. When no containers reference this bind mount, the Amazon ECS container agent task cleanup service eventually deletes it. By default, this happens three hours after the container exits. However, you can configure this duration with the ECS\_ENGINE\_TASK\_CLEANUP\_WAIT\_DURATION agent variable. For more information, see [Amazon ECS container agent configuration](#). If you need this data to persist beyond the lifecycle of the container, specify a sourcePath value for the bind mount.
- For tasks that are hosted on Amazon ECS Managed Instances, portions of the root filesystem are read-only. Read/write bind mounts must use writable directories such as /var for persistent data or /tmp for temporary data. Attempting to create read/write bind mounts to other directories results in the task failing to launch with an error similar to the following:

```
error creating empty volume: error while creating volume path '/path': mkdir /path:
read-only file system
```

Read-only bind mounts (configured with "readOnly": true in the mountPoints parameter) can point to any accessible directory on the host.

To view a full list of writable paths, you can run a task on a Amazon ECS Managed Instance and use to inspect the instance's mount table. Create a task definition with the following settings to access the host filesystem:

```
{
  "pidMode": "host",
  "containerDefinitions": [{
    "privileged": true,
    ...
  }]
}
```

Then run the following commands from within the container:

```
# List writable mounts
cat /proc/1/root/proc/1/mounts | awk '$4 ~ /^rw,/ || $4 == "rw" {print $2}' | sort
```

```
# List read-only mounts
cat /proc/1/root/proc/1/mounts | awk '$4 ~ /^ro,/ || $4 == "ro" {print $2}' | sort
```

### Important

The `privileged` setting grants the container extended capabilities on the host, equivalent to root access. In this example, it is used to inspect the host's mount table for diagnostic purposes. For more information, see [Avoid running containers as privileged \(Amazon EC2\)](#).

For more information about running commands interactively in containers, see [Monitor Amazon ECS containers with ECS Exec](#).

## Specify a bind mount in an Amazon ECS task definition

For Amazon ECS tasks that are hosted on either Fargate or Amazon EC2 instances, the following task definition JSON snippet shows the syntax for the `volumes`, `mountPoints`, and `ephemeralStorage` objects for a task definition.

```
{
  "family": "",
  ...
  "containerDefinitions" : [
    {
      "mountPoints" : [
        {
          "containerPath" : "/path/to/mount_volume",
          "sourceVolume" : "string"
        }
      ],
      "name" : "string"
    }
  ],
  ...
  "volumes" : [
    {
      "name" : "string"
    }
  ],
  ...
}
```

```
"ephemeralStorage": {  
  "sizeInGiB": integer  
}  
}
```

For Amazon ECS tasks that are hosted on Amazon EC2 instances, you can use the optional `host` parameter and a `sourcePath` when specifying the task volume details. When it's specified, it ties the bind mount to the lifecycle of the task rather than the container.

```
"volumes" : [  
  {  
    "host" : {  
      "sourcePath" : "string"  
    },  
    "name" : "string"  
  }  
]
```

The following describes each task definition parameter in more detail.

#### name

Type: String

Required: No

The name of the volume. Up to 255 letters (uppercase and lowercase), numbers, hyphens (-), and underscores (\_) are allowed. This name is referenced in the `sourceVolume` parameter of the container definition `mountPoints` object.

#### host

Required: No

The `host` parameter is used to tie the lifecycle of the bind mount to the host Amazon EC2 instance, rather than the task, and where it is stored. If the `host` parameter is empty, then the Docker daemon assigns a host path for your data volume, but the data is not guaranteed to persist after the containers associated with it stop running.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`.

**Note**

The `sourcePath` parameter is supported only when using tasks that are hosted on Amazon EC2 instances or Amazon ECS Managed Instances.

**sourcePath**

Type: String

Required: No

When the `host` parameter is used, specify a `sourcePath` to declare the path on the host Amazon EC2 instance that is presented to the container. If this parameter is empty, then the Docker daemon assigns a host path for you. If the `host` parameter contains a `sourcePath` file location, then the data volume persists at the specified location on the host Amazon EC2 instance until you delete it manually. If the `sourcePath` value does not exist on the host Amazon EC2 instance, the Docker daemon creates it. If the location does exist, the contents of the source path folder are exported.

**mountPoints**

Type: Object array

Required: No

The mount points for the data volumes in your container. This parameter maps to `Volumes` in the create-container Docker API and the `--volume` option to `docker run`.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`. Windows containers cannot mount directories on a different drive, and mount points cannot be used across drives. You must specify mount points to attach an Amazon EBS volume directly to an Amazon ECS task.

**sourceVolume**

Type: String

Required: Yes, when `mountPoints` are used

The name of the volume to mount.

## containerPath

Type: String

Required: Yes, when mountPoints are used

The path in the container where the volume will be mounted.

## readOnly

Type: Boolean

Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

For tasks that run on EC2 instances running the Windows operating system, leave the value as the default of `false`.

## ephemeralStorage

Type: Object

Required: No

The amount of ephemeral storage to allocate for the task. This parameter is used to expand the total amount of ephemeral storage available, beyond the default amount, for tasks hosted on AWS Fargate using platform version `1.4.0` or later (Linux) or `1.0.0` or later (Windows).

You can use the Copilot CLI, CloudFormation, the AWS SDK or the CLI to specify ephemeral storage for a bind mount.

## Bind mount examples for Amazon ECS

The following examples cover the common use cases for using a bind mount for your containers.

### To allocate an increased amount of ephemeral storage space for a Fargate task

For Amazon ECS tasks that are hosted on Fargate using platform version `1.4.0` or later (Linux) or `1.0.0` (Windows), you can allocate more than the default amount of ephemeral storage for the containers in your task to use. This example can be incorporated into the other examples to allocate more ephemeral storage for your Fargate tasks.

- In the task definition, define an `ephemeralStorage` object. The `sizeInGiB` must be an integer between the values of 21 and 200 and is expressed in GiB.

```
"ephemeralStorage": {  
    "sizeInGiB": integer  
}
```

## To provide an empty data volume for one or more containers

In some cases, you want to provide the containers in a task some scratch space. For example, you might have two database containers that need to access the same scratch file storage location during a task. This can be achieved using a bind mount.

1. In the task definition `volumes` section, define a bind mount with the name `database_scratch`.

```
"volumes": [  
    {  
        "name": "database_scratch"  
    }  
]
```

2. In the `containerDefinitions` section, create the database container definitions. This is so that they mount the volume.

```
"containerDefinitions": [  
    {  
        "name": "database1",  
        "image": "my-repo/database",  
        "cpu": 100,  
        "memory": 100,  
        "essential": true,  
        "mountPoints": [  
            {  
                "sourceVolume": "database_scratch",  
                "containerPath": "/var/scratch"  
            }  
        ]  
    },  
    {  
        "name": "database2",
```

```
    "image": "my-repo/database",
    "cpu": 100,
    "memory": 100,
    "essential": true,
    "mountPoints": [
      {
        "sourceVolume": "database_scratch",
        "containerPath": "/var/scratch"
      }
    ]
  }
]
```

## To expose a path and its contents in a Dockerfile to a container

In this example, you have a Dockerfile that writes data that you want to mount inside a container. This example works for tasks that are hosted on Fargate or Amazon EC2 instances.

1. Create a Dockerfile. The following example uses the public Amazon Linux 2 container image and creates a file that's named `examplefile` in the `/var/log/exported` directory that we want to mount inside the container. The `VOLUME` directive should specify an absolute path.

```
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
RUN mkdir -p /var/log/exported
RUN touch /var/log/exported/examplefile
VOLUME ["/var/log/exported"]
```

By default, the volume permissions are set to `0755` and the owner as `root`. These permissions can be changed in the Dockerfile. In the following example, the owner of the `/var/log/exported` directory is set to `node`.

```
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
RUN yum install -y shadow-utils && yum clean all
RUN useradd node
RUN mkdir -p /var/log/exported && chown node:node /var/log/exported
USER node
RUN touch /var/log/exported/examplefile
VOLUME ["/var/log/exported"]
```

2. In the task definition volumes section, define a volume with the name `application_logs`.

```
"volumes": [  
  {  
    "name": "application_logs"  
  }  
]
```

3. In the `containerDefinitions` section, create the application container definitions. This is so they mount the storage. The `containerPath` value must match the absolute path that's specified in the `VOLUME` directive from the Dockerfile.

```
"containerDefinitions": [  
  {  
    "name": "application1",  
    "image": "my-repo/application",  
    "cpu": 100,  
    "memory": 100,  
    "essential": true,  
    "mountPoints": [  
      {  
        "sourceVolume": "application_logs",  
        "containerPath": "/var/log/exported"  
      }  
    ]  
  },  
  {  
    "name": "application2",  
    "image": "my-repo/application",  
    "cpu": 100,  
    "memory": 100,  
    "essential": true,  
    "mountPoints": [  
      {  
        "sourceVolume": "application_logs",  
        "containerPath": "/var/log/exported"  
      }  
    ]  
  }  
]
```

## To provide an empty data volume for a container that's tied to the lifecycle of the host Amazon EC2 instance

For tasks that are hosted on Amazon EC2 instances, you can use bind mounts and have the data tied to the lifecycle of the host Amazon EC2 instance. You can do this by using the `host` parameter and specifying a `sourcePath` value. Any files that exist at the `sourcePath` are presented to the containers at the `containerPath` value. Any files that are written to the `containerPath` value are written to the `sourcePath` value on the host Amazon EC2 instance.

### Important

Amazon ECS doesn't sync your storage across Amazon EC2 instances. Tasks that use persistent storage can be placed on any Amazon EC2 instance in your cluster that has available capacity. If your tasks require persistent storage after stopping and restarting, always specify the same Amazon EC2 instance at task launch time with the AWS CLI [start-task](#) command. You can also use Amazon EFS volumes for persistent storage. For more information, see [Use Amazon EFS volumes with Amazon ECS](#).

1. In the task definition `volumes` section, define a bind mount with `name` and `sourcePath` values. In the following example, the host Amazon EC2 instance contains data at `/ecs/webdata` that you want to mount inside the container.

```
"volumes": [  
  {  
    "name": "webdata",  
    "host": {  
      "sourcePath": "/ecs/webdata"  
    }  
  }  
]
```

2. In the `containerDefinitions` section, define a container with a `mountPoints` value that references the name of the bind mount and the `containerPath` value to mount the bind mount at on the container.

```
"containerDefinitions": [  
  {  
    "name": "web",  
    "image": "public.ecr.aws/docker/library/nginx:latest",
```

```
    "cpu": 99,
    "memory": 100,
    "portMappings": [
      {
        "containerPort": 80,
        "hostPort": 80
      }
    ],
    "essential": true,
    "mountPoints": [
      {
        "sourceVolume": "webdata",
        "containerPath": "/usr/share/nginx/html"
      }
    ]
  }
]
```

## To mount a defined volume on multiple containers at different locations

You can define a data volume in a task definition and mount that volume at different locations on different containers. For example, your host container has a website data folder at `/data/webroot`. You might want to mount that data volume as read-only on two different web servers that have different document roots.

1. In the task definition `volumes` section, define a data volume with the name `webroot` and the source path `/data/webroot`.

```
"volumes": [
  {
    "name": "webroot",
    "host": {
      "sourcePath": "/data/webroot"
    }
  }
]
```

2. In the `containerDefinitions` section, define a container for each web server with `mountPoints` values that associate the `webroot` volume with the `containerPath` value pointing to the document root for that container.

```
"containerDefinitions": [  
  {  
    "name": "web-server-1",  
    "image": "my-repo/ubuntu-apache",  
    "cpu": 100,  
    "memory": 100,  
    "portMappings": [  
      {  
        "containerPort": 80,  
        "hostPort": 80  
      }  
    ],  
    "essential": true,  
    "mountPoints": [  
      {  
        "sourceVolume": "webroot",  
        "containerPath": "/var/www/html",  
        "readOnly": true  
      }  
    ]  
  },  
  {  
    "name": "web-server-2",  
    "image": "my-repo/sles11-apache",  
    "cpu": 100,  
    "memory": 100,  
    "portMappings": [  
      {  
        "containerPort": 8080,  
        "hostPort": 8080  
      }  
    ],  
    "essential": true,  
    "mountPoints": [  
      {  
        "sourceVolume": "webroot",  
        "containerPath": "/srv/www/htdocs",  
        "readOnly": true  
      }  
    ]  
  }  
]
```

## To mount volumes from another container using `volumesFrom`

For tasks hosted on Amazon EC2 instances, you can define one or more volumes on a container, and then use the `volumesFrom` parameter in a different container definition within the same task to mount all of the volumes from the `sourceContainer` at their originally defined mount points. The `volumesFrom` parameter applies to volumes defined in the task definition, and those that are built into the image with a Dockerfile.

1. (Optional) To share a volume that is built into an image, use the `VOLUME` instruction in the Dockerfile. The following example Dockerfile uses an `httpd` image, and then adds a volume and mounts it at `dockerfile_volume` in the Apache document root. It is the folder used by the `httpd` web server.

```
FROM httpd
VOLUME ["/usr/local/apache2/htdocs/dockerfile_volume"]
```

You can build an image with this Dockerfile and push it to a repository, such as Docker Hub, and use it in your task definition. The example `my-repo/httpd_dockerfile_volume` image that's used in the following steps was built with the preceding Dockerfile.

2. Create a task definition that defines your other volumes and mount points for the containers. In this example `volumes` section, you create an empty volume called `empty`, which the Docker daemon manages. There's also a host volume defined that's called `host_etc`. It exports the `/etc` folder on the host container instance.

```
{
  "family": "test-volumes-from",
  "volumes": [
    {
      "name": "empty",
      "host": {}
    },
    {
      "name": "host_etc",
      "host": {
        "sourcePath": "/etc"
      }
    }
  ]
},
```

In the container definitions section, create a container that mounts the volumes defined earlier. In this example, the web container mounts the empty and host\_etc volumes. This is the container that uses the image built with a volume in the Dockerfile.

```
"containerDefinitions": [  
  {  
    "name": "web",  
    "image": "my-repo/httpd_dockerfile_volume",  
    "cpu": 100,  
    "memory": 500,  
    "portMappings": [  
      {  
        "containerPort": 80,  
        "hostPort": 80  
      }  
    ],  
    "mountPoints": [  
      {  
        "sourceVolume": "empty",  
        "containerPath": "/usr/local/apache2/htdocs/empty_volume"  
      },  
      {  
        "sourceVolume": "host_etc",  
        "containerPath": "/usr/local/apache2/htdocs/host_etc"  
      }  
    ],  
    "essential": true  
  },  
]
```

Create another container that uses `volumesFrom` to mount all of the volumes that are associated with the web container. All of the volumes on the web container are likewise mounted on the busybox container. This includes the volume that's specified in the Dockerfile that was used to build the `my-repo/httpd_dockerfile_volume` image.

```
{  
  "name": "busybox",  
  "image": "busybox",  
  "volumesFrom": [  
    {  
      "sourceContainer": "web"  
    }  
  ]  
}
```

```
    ],
    "cpu": 100,
    "memory": 500,
    "entryPoint": [
        "sh",
        "-c"
    ],
    "command": [
        "echo $(date) > /usr/local/apache2/htdocs/empty_volume/date && echo $(date) > /usr/local/apache2/htdocs/host_etc/date && echo $(date) > /usr/local/apache2/htdocs/dockerfile_volume/date"
    ],
    "essential": false
  }
]
```

When this task is run, the two containers mount the volumes, and the command in the busybox container writes the date and time to a file. This file is called `date` in each of the volume folders. The folders are then visible at the website displayed by the web container.

 **Note**

Because the busybox container runs a quick command and then exits, it must be set as `"essential": false` in the container definition. Otherwise, it stops the entire task when it exits.

## Managing container swap memory space on Amazon ECS

With Amazon ECS, you can control the usage of swap memory space on your Linux-based Amazon EC2 instances at the container level. Using a per-container swap configuration, each container within a task definition can have swap enabled or disabled. For those that have it enabled, the maximum amount of swap space that's used can be limited. For example, latency-critical containers can have swap disabled. In contrast, containers with high transient memory demands can have swap turned on to reduce the chances of out-of-memory errors when the container is under load.

The swap configuration for a container is managed by the following container definition parameters.

## maxSwap

The total amount of swap memory (in MiB) a container can use. This parameter is translated to the `--memory-swap` option to `docker run` where the value is the sum of the container memory plus the `maxSwap` value.

If a `maxSwap` value of `0` is specified, the container doesn't use swap. Accepted values are `0` or any positive integer. If the `maxSwap` parameter is omitted, the container uses the swap configuration for the container instance that it's running on. A `maxSwap` value must be set for the `swappiness` parameter to be used.

## swappiness

You can use this to tune a container's memory swappiness behavior. A `swappiness` value of `0` causes swapping to not occur unless required. A `swappiness` value of `100` causes pages to be swapped aggressively. Accepted values are whole numbers between `0` and `100`. If the `swappiness` parameter isn't specified, a default value of `60` is used. If a value isn't specified for `maxSwap`, this parameter is ignored. This parameter maps to the `--memory-swappiness` option to `docker run`.

In the following example, the JSON syntax is provided.

```
"containerDefinitions": [{  
    ...  
    "linuxParameters": {  
        "maxSwap": integer,  
        "swappiness": integer  
    },  
    ...  
}]
```

## Considerations

Consider the following when you use a per-container swap configuration.

- Swap space must be enabled and allocated on the Amazon EC2 instance hosting your tasks for the containers to use. By default, the Amazon ECS optimized AMIs do not have swap enabled. You must enable swap on the instance to use this feature. For more information, see [Instance Store Swap Volumes](#) in the *Amazon EC2 User Guide* or [How do I allocate memory to work as swap space in an Amazon EC2 instance?](#).

- The swap space container definition parameters are only supported for task definitions that specify EC2. These parameters are not supported for task definitions intended only for Amazon ECS on Fargate use.
- This feature is only supported for Linux containers. Windows containers are not supported currently.
- If the `maxSwap` and `swappiness` container definition parameters are omitted from a task definition, each container has a default swappiness value of 60. Moreover, the total swap usage is limited to two times the memory of the container.
- If you're using tasks on Amazon Linux 2023 the `swappiness` parameter isn't supported.

## Amazon ECS task definition differences for Amazon ECS Managed Instances

In order to use Amazon ECS Managed Instances, you must configure your task definition to use the Amazon ECS Managed Instances launch type. There are additional considerations when using Amazon ECS Managed Instances.

### Task definition parameters

Tasks that use Amazon ECS Managed Instances support most of the Amazon ECS task definition parameters that are available. However, some parameters have specific behaviors or limitations when used with Amazon ECS Managed Instances tasks.

The following task definition parameters are not valid in Amazon ECS Managed Instances tasks:

- `disableNetworking`
- `dnsSearchDomains`
- `dnsServers`
- `dockerSecurityOptions`
- `dockerVolumeConfiguration`
- `ephemeralStorage`
- `extraHosts`
- `fsxWindowsFileServerVolumeConfiguration`
- `hostname`

- `inferenceAccelerator`
- `ipcMode`
- `links`
- `maxSwap`
- `proxyConfiguration`
- `sharedMemorySize`
- `sourcepath` volumes
- `swappiness`
- `tmpfs`

The following task definition parameters are valid in Amazon ECS Managed Instances tasks, but have limitations that should be noted:

- `networkConfiguration` - Amazon ECS Managed Instances tasks use the `awsvpc` or `host` network mode.
- `placementConstraints` - The following constraint attributes are supported.
  - `ecs.subnet-id`
  - `ecs.availability-zone`
  - `ecs.instance-type`
  - `ecs.cpu-architecture`
- `requiresCompatibilities` - Must include `MANAGED_INSTANCES` to ensure the task definition is compatible with Amazon ECS Managed Instances.
- `resourceRequirement` - `InferenceAccelerator` is not supported.
- `operatingSystemFamily` - Amazon ECS Managed Instances use `LINUX`.
- `volumes` - When using bind mounts with a `sourcePath`, the path must point to a writable directory on the host. Portions of the Amazon ECS Managed Instance filesystem are read-only. Writable directories include `/var` and `/tmp`. For more information, see [Use bind mounts with Amazon ECS](#).
- `firelensConfiguration` - Configures the FireLens log router. The `s3` configuration file type isn't supported; use the `file` type. For more information, see [Example Amazon ECS task definition: Route logs to FireLens](#).

To ensure that your task definition validates for use with Amazon ECS Managed Instances, you can specify the following when you register the task definition:

- In the AWS Management Console, for the **Requires Compatibilities** field, specify `MANAGED_INSTANCES`.
- In the AWS CLI, specify the `--requires-compatibilities` option.
- In the Amazon ECS API, specify the `requiresCompatibilities` flag.

## Amazon ECS task definition differences for Fargate

In order to use Fargate, you must configure your task definition to use the Fargate launch type. There are additional considerations when using Fargate.

### Task definition parameters

Tasks that use Fargate don't support all of the Amazon ECS task definition parameters that are available. Some parameters aren't supported at all, and others behave differently for Fargate tasks.

The following task definition parameters are not valid in Fargate tasks:

- `disableNetworking`
- `dnsSearchDomains`
- `dnsServers`
- `dockerSecurityOptions`
- `extraHosts`
- `gpu`
- `ipcMode`
- `links`
- `placementConstraints`
- `privileged`
- `maxSwap`
- `swappiness`

The following task definition parameters are valid in Fargate tasks, but have limitations that should be noted:

- `linuxParameters` – When specifying Linux-specific options that are applied to the container, for capabilities the only capability you can add is `CAP_SYS_PTRACE`. The `devices`, `sharedMemorySize`, and `tmpfs` parameters are not supported. For more information, see [Linux parameters](#).
- `volumes` – Fargate tasks only support bind mount host volumes, so the `dockerVolumeConfiguration` parameter is not supported. For more information, see [Volumes](#).
- `cpu` - For Windows containers on AWS Fargate, the value cannot be less than 1 vCPU.
- `networkConfiguration` - Fargate tasks always use the `awsvpc` network mode.

To ensure that your task definition validates for use with Fargate, you can specify the following when you register the task definition:

- In the AWS Management Console, for the **Requires Compatibilities** field, specify `FARGATE`.
- In the AWS CLI, specify the `--requires-compatibilities` option.
- In the Amazon ECS API, specify the `requiresCompatibilities` flag.

## Operating Systems and architectures

When you configure a task and container definition for AWS Fargate, you must specify the Operating System that the container runs. The following Operating Systems are supported for AWS Fargate:

- Amazon Linux 2

### Note

Linux containers use only the kernel and kernel configuration from the host Operating System. For example, the kernel configuration includes the `sysctl` system controls. A Linux container image can be made from a base image that contains the files and programs from any Linux distribution. If the CPU architecture matches, you can run containers from any Linux container image on any Operating System.

- Windows Server 2019 Full
- Windows Server 2019 Core
- Windows Server 2022 Full

- Windows Server 2022 Core

When you run Windows containers on AWS Fargate, you must have the X86\_64 CPU architecture.

When you run Linux containers on AWS Fargate, you can use the X86\_64 CPU architecture, or the ARM64 architecture for your ARM-based applications. For more information, see [the section called “Task definitions for 64-bit ARM workloads”](#).

## Task CPU and memory

Amazon ECS task definitions for AWS Fargate require that you specify CPU and memory at the task level. Most use cases are satisfied by only specifying these resources at the task level. The following table shows the valid combinations of task-level CPU and memory. You can specify memory values in the task definition as a string in MiB or GB. For example, you can specify a memory value either as 3072 in MiB or 3 GB in GB. You can specify CPU values in the JSON file as a string in CPU units or virtual CPUs (vCPUs). For example, you can specify a CPU value either as 1024 in CPU units or 1 vCPU in vCPUs.

| CPU value      | Memory value                               | Operating systems supported for AWS Fargate |
|----------------|--------------------------------------------|---------------------------------------------|
| 256 (.25 vCPU) | 512 MiB, 1 GB, 2 GB                        | Linux                                       |
| 512 (.5 vCPU)  | 1 GB, 2 GB, 3 GB, 4 GB                     | Linux                                       |
| 1024 (1 vCPU)  | 2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB   | Linux, Windows                              |
| 2048 (2 vCPU)  | Between 4 GB and 16 GB in 1 GB increments  | Linux, Windows                              |
| 4096 (4 vCPU)  | Between 8 GB and 30 GB in 1 GB increments  | Linux, Windows                              |
| 8192 (8 vCPU)  | Between 16 GB and 60 GB in 4 GB increments | Linux                                       |

| CPU value                                                                                                                                                                               | Memory value                                | Operating systems supported for AWS Fargate |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|---------------------------------------------|
| <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div>   |                                             |                                             |
| 16384 (16 vCPU)                                                                                                                                                                         | Between 32 GB and 120 GB in 8 GB increments | Linux                                       |
| <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div>   |                                             |                                             |
| 32768 (32 vCPU)                                                                                                                                                                         | 60 GB, 120 GB, 244 GB                       | Linux                                       |
| <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div> |                                             |                                             |

## Task networking

Amazon ECS tasks for AWS Fargate require the awsvpc network mode, which provides each task with an elastic network interface. When you run a task or create a service with this network mode, you must specify one or more subnets to attach the network interface and one or more security groups to apply to the network interface.

If you are using public subnets, decide whether to provide a public IP address for the network interface. For a Fargate task in a public subnet to pull container images, a public IP address needs to be assigned to the task's elastic network interface, with a route to the internet or a NAT gateway that can route requests to the internet. For a Fargate task in a private subnet to pull container

images, you need a NAT gateway in the subnet to route requests to the internet. When you host your container images in Amazon ECR, you can configure Amazon ECR to use an interface VPC endpoint. In this case, the task's private IPv4 address is used for the image pull. For more information about Amazon ECR interface endpoints, see [Amazon ECR interface VPC endpoints \(AWS PrivateLink\)](#) in the *Amazon Elastic Container Registry User Guide*.

The following is an example of the `networkConfiguration` section for a Fargate service:

```
"networkConfiguration": {
  "awsvpcConfiguration": {
    "assignPublicIp": "ENABLED",
    "securityGroups": [ "sg-12345678" ],
    "subnets": [ "subnet-12345678" ]
  }
}
```

## Task resource limits

Amazon ECS task definitions for Linux containers on AWS Fargate support the `ulimits` parameter to define the resource limits to set for a container.

Amazon ECS task definitions for Windows on AWS Fargate do not support the `ulimits` parameter to define the resource limits to set for a container.

Amazon ECS tasks hosted on Fargate use the default resource limit values set by the operating system with the exception of the `nofile` resource limit parameter. The `nofile` resource limit sets a restriction on the number of open files that a container can use. On Fargate, the default `nofile` soft limit is 65535 and hard limit is 65535. You can set the values of both limits up to 1048576.

The following is an example task definition snippet that shows how to define a custom `nofile` limit that has been doubled:

```
"ulimits": [
  {
    "name": "nofile",
    "softLimit": 2048,
    "hardLimit": 8192
  }
]
```

For more information on the other resource limits that can be adjusted, see [Resource limits](#).

## Logging

### Event logging

Amazon ECS logs the actions that it takes to EventBridge. You can use Amazon ECS events for EventBridge to receive near real-time notifications regarding the current state of your Amazon ECS clusters, services, and tasks. Additionally, you can automate actions to respond to these events. For more information, see [Automate responses to Amazon ECS errors using EventBridge](#).

### Task lifecycle logging

Tasks that run on Fargate publish timestamps to track the task through the states of the task lifecycle. You can see the timestamps in the task details in the AWS Management Console and by describing the task in the AWS CLI and SDKs. For example, you can use the timestamps to evaluate how much time the task spent downloading the container images and decide if you should optimize the container image size, or use Seekable OCI indexes. For more information about container image practices, see [Best practices for Amazon ECS container images](#).

### Application logging

Amazon ECS task definitions for AWS Fargate support the `awslogs`, `splunk`, and `awsfirelens` log drivers for the log configuration.

The `awslogs` log driver configures your Fargate tasks to send log information to Amazon CloudWatch Logs. The following shows a snippet of a task definition where the `awslogs` log driver is configured:

```
"logConfiguration": {
  "logDriver": "awslogs",
  "options": {
    "awslogs-group" : "/ecs/fargate-task-definition",
    "awslogs-region": "us-east-1",
    "awslogs-stream-prefix": "ecs"
  }
}
```

For more information about using the `awslogs` log driver in a task definition to send your container logs to CloudWatch Logs, see [Send Amazon ECS logs to CloudWatch](#).

For more information about the `awsfirelens` log driver in a task definition, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

For more information about using the `sp1unk` log driver in a task definition, see [sp1unk log driver](#).

## Task storage

For Amazon ECS tasks hosted on Fargate, the following storage types are supported:

- Amazon EBS volumes provide cost-effective, durable, high-performance block storage for data-intensive containerized workloads. For more information, see [Use Amazon EBS volumes with Amazon ECS](#).
- Amazon EFS volumes for persistent storage. For more information, see [Use Amazon EFS volumes with Amazon ECS](#).
- Bind mounts for ephemeral storage. For more information, see [Use bind mounts with Amazon ECS](#).

## Lazy loading container images using Seekable OCI (SOCI)

Amazon ECS tasks on Fargate that use Linux platform version `1.4.0` can use Seekable OCI (SOCI) to help start tasks faster. With SOCI, containers only spend a few seconds on the image pull before they can start, providing time for environment setup and application instantiation while the image is downloaded in the background. This is called *lazy loading*. When Fargate starts an Amazon ECS task, Fargate automatically detects if a SOCI index exists for an image in the task and starts the container without waiting for the entire image to be downloaded.

For containers that run without SOCI indexes, container images are downloaded completely before the container is started. This behavior is the same on all other platform versions of Fargate and on the Amazon ECS-optimized AMI on Amazon EC2 instances.

Seekable OCI (SOCI) is an open source technology developed by AWS that can launch containers faster by lazily loading the container image. SOCI works by creating an index (SOCI Index) of the files within an existing container image. This index helps to launch containers faster, providing the capability to extract an individual file from a container image before downloading the entire image. The SOCI index must be stored as an artifact in the same repository as the image within the container registry. You should only use SOCI indices from trusted sources, as the index is the authoritative source for the contents of the image. For more information, see [Introducing Seekable OCI for lazy loading container images](#).

Customers looking to use SOCI will only be able to use the SOCI index manifest v2. Existing customers that have previously used SOCI on Fargate can continue to use the SOCI Index Manifest

v1, however we strongly advise those customers migrate to SOCI Index Manifest v2. The SOCI Index Manifest v2 creates an explicit relationship between container images and their SOCI indexes to ensure consistent deployments.

## Considerations

If you want Fargate to use a SOCI index to lazily load container images in a task, consider the following:

- Only tasks that run on Linux platform version 1.4.0 can use SOCI indexes. Tasks that run Windows containers on Fargate aren't supported.
- Tasks that run on X86\_64 or ARM64 CPU architecture are supported.
- Container images in the task definition must be stored in a compatible image registry. The following lists the compatible registries:
  - Amazon ECR private registries.
- Only container images that use gzip compression, or are not compressed are supported. Container images that use zstd compression aren't supported.
- For SOCI Index Manifest v2, generating a SOCI index manifest modifies the container image manifest as we add an annotation for the SOCI index. This results in a new container image digest. The contents of the container images filesystem layers do not change.
- For SOCI Index Manifest v2, when the container image has already been stored in the container image repository, after a SOCI index has been generated, you need to repush the container image. Re-pushing a container image will not increase storage costs by duplicating the filesystem layers, it only uploads a new manifest file.
- We recommend that you try lazy loading with container images greater than 250 MiB compressed in size. You are less likely to see a reduction in the time to load smaller images.
- Because lazy loading can change how long your tasks take to start, you might need to change various timeouts like the health check grace period for Elastic Load Balancing.
- If you want to prevent a container image from being lazy loaded, the container image will need to be repushed without a SOCI index attached.

## Creating a Seekable OCI index

For a container image to be lazy loaded it needs a SOCI index (a metadata file) created and stored in the container image repository along side the container image. To create and push a SOCI index you can use the open source [soci-snapshotter CLI tool](#) on GitHub. Or, you can deploy the

CloudFormation AWS SOCI Index Builder. This is a serverless solution that automatically creates and pushes a SOCI index when a container image is pushed to Amazon ECR. For more information about the solution and the installation steps, see [CloudFormation AWS SOCI Index Builder](#) on GitHub. The CloudFormation AWS SOCI Index Builder is a way to automate getting started with SOCI, while the open source `soci` tool has more flexibility around index generation and the ability to integrate index generation in your continuous integration and continuous delivery (CI/CD) pipelines.

#### Note

For the SOCI index to be created for an image, the image must exist in the containerd image store on the computer running `soci-snapshotter`. If the image is in the Docker image store, the image can't be found.

## Verifying that a task used lazy loading

To verify that a task was lazily loaded using SOCI, check the task metadata endpoint from inside the task. When you query the task metadata endpoint version 4, there is a `Snapshotter` field in the default path for the container that you are querying from. Additionally, there are `Snapshotter` fields for each container in the `/task` path. The default value for this field is `overlayfs`, and this field is set to `soci` if SOCI is used. To verify that a container image has a SOCI Index Manifest v2 attached you can retrieve the Image Index from Amazon ECR using the AWS CLI.

```
IMAGE_REPOSITORY=r
IMAGE_TAG=latest

aws ecr batch-get-image \
  --repository-name=$IMAGE_REPOSITORY \
  --image-ids imageTag=$IMAGE_TAG \
  --query 'images[0].imageManifest' --output text | jq -r '.manifests[] |
select(.artifactType=="application/vnd.amazon.soci.index.v2+json")'
```

To verify that a container image has a SOCI Index Manifest v1 attached you can use the OCI Referrers API.

```
ACCOUNT_ID=111222333444
AWS_REGION=us-east-1
IMAGE_REPOSITORY=nginx-demo
IMAGE_TAG=latest
IMAGE_DIGEST=$(aws ecr describe-images --repository-name $IMAGE_REPOSITORY --image-ids
  imageTag=$IMAGE_TAG --query 'imageDetails[0].imageDigest' --output text)
ECR_PASSWORD=$(aws ecr get-login-password)

curl \
  --silent \
  --user AWS:$ECR_PASSWORD \
  https://$ACCOUNT_ID.dkr.ecr.$AWS_REGION.amazonaws.com/v2/$IMAGE_REPOSITORY/
  referriers/$IMAGE_DIGEST?artifactType=application%2Fvnd.amazon.soci.index.v1%2Bjson | jq
  -r '.'
```

## Amazon ECS task definition differences for EC2 instances running Windows

Tasks that run on EC2 Windows instances don't support all of the Amazon ECS task definition parameters that are available. Some parameters aren't supported at all, and others behave differently.

The following task definition parameters aren't supported for Amazon EC2 Windows task definitions:

- containerDefinitions
  - disableNetworking
  - dnsServers
  - dnsSearchDomains
  - extraHosts
  - links
  - linuxParameters
  - privileged
  - readonlyRootFilesystem
  - user
  - ulimits
- volumes

- `dockerVolumeConfiguration`
- `cpu`

We recommend specifying container-level CPU for Windows containers.

- `memory`

We recommend specifying container-level memory for Windows containers.

- `proxyConfiguration`
- `ipcMode`
- `pidMode`
- `taskRoleArn`

The IAM roles for tasks on EC2 Windows instances features requires additional configuration, but much of this configuration is similar to configuring IAM roles for tasks on Linux container instances. For more information see [the section called “Amazon EC2 Windows instance additional configuration”](#).

## Creating an Amazon ECS task definition using the console

You create a task definition so that you can define the application that you run as a task or service.

When you create a task definition for the external launch type, you need to create the task definition using JSON editor and set the `requiresCompatibilities` parameter to `EXTERNAL`.

You can create a task definition by using the console experience, or by specifying a JSON file. You can have Amazon Q provide recommendations when you use the JSON editor. For more information, see [Using Amazon Q Developer to provide task definition recommendations in the Amazon ECS console](#)

### JSON validation

The Amazon ECS console JSON editor validates the following in the JSON file:

- The file is a valid JSON file.
- The file doesn't contain any extraneous keys.
- The file contains the `familyName` parameter.
- There is at least one entry under `containerDefinitions`.

## CloudFormation stacks

The following behavior applies to task definitions that were created in the new Amazon ECS console before January 12, 2023.

When you create a task definition, the Amazon ECS console automatically creates a CloudFormation stack that has a name that begins with `ECS-Console-V2-TaskDefinition-`. If you used the AWS CLI or an AWS SDK to deregister the task definition, then you must manually delete the task definition stack. For more information, see [Deleting a stack](#) in the *CloudFormation User Guide*.

Task definitions created after January 12, 2023, do not have a CloudFormation stack automatically created for them.

## Procedure

Amazon ECS console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task definitions**.
3. On the **Create new task definition** menu, choose **Create new task definition**.
4. For **Task definition family**, specify a unique name for the task definition.
5. For **Launch type**, choose the application environment. The console default is **AWS Fargate** (which is serverless). Amazon ECS uses this value to perform validation to ensure that the task definition parameters are valid for the infrastructure type.
6. For **Operating system/Architecture**, choose the operating system and CPU architecture for the task.

To run your task on a 64-bit ARM architecture, choose **Linux/ARM64**. For more information, see [the section called “Runtime platform”](#).

To run your **AWS Fargate** tasks on Windows containers, choose a supported Windows operating system. For more information, see [the section called “Operating Systems and architectures”](#).

7. For **Task size**, choose the CPU and memory values to reserve for the task. The CPU value is specified as vCPUs and memory is specified as GB.

For tasks hosted on Fargate, the following table shows the valid CPU and memory combinations.

| CPU value                                                                                                                                                                               | Memory value                                | Operating systems supported for AWS Fargate |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|---------------------------------------------|
| 256 (.25 vCPU)                                                                                                                                                                          | 512 MiB, 1 GB, 2 GB                         | Linux                                       |
| 512 (.5 vCPU)                                                                                                                                                                           | 1 GB, 2 GB, 3 GB, 4 GB                      | Linux                                       |
| 1024 (1 vCPU)                                                                                                                                                                           | 2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB    | Linux, Windows                              |
| 2048 (2 vCPU)                                                                                                                                                                           | Between 4 GB and 16 GB in 1 GB increments   | Linux, Windows                              |
| 4096 (4 vCPU)                                                                                                                                                                           | Between 8 GB and 30 GB in 1 GB increments   | Linux, Windows                              |
| 8192 (8 vCPU)                                                                                                                                                                           | Between 16 GB and 60 GB in 4 GB increments  | Linux                                       |
| <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div> |                                             |                                             |
| 16384 (16 vCPU)                                                                                                                                                                         | Between 32 GB and 120 GB in 8 GB increments | Linux                                       |
| <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div> |                                             |                                             |

| CPU value       | Memory value          | Operating systems supported for AWS Fargate |
|-----------------|-----------------------|---------------------------------------------|
| 32768 (32 vCPU) | 60 GB, 120 GB, 244 GB | Linux                                       |

 **Note**  
 This option requires Linux platform 1.4.0 or later.

For tasks that use EC2 instances, or external instances, the supported task CPU values are between 128 CPU units (0.125 vCPUs) and 196608 CPU units (192 vCPUs).

To specify the memory value in GB, enter **GB** after the value. For example, to set the **Memory value** to 3GB, enter **3GB**.

#### Note

Task-level CPU and memory parameters are ignored for Windows containers.

8. For **Network mode**, choose the network mode to use. The default is **awsvpc** mode. For more information, see [Amazon ECS task networking](#).

If you choose **bridge**, under **Port mappings**, for **Host port**, enter the port number on the container instance to reserve for your container.

9. (Optional) Expand the **Task roles** section to configure the AWS Identity and Access Management (IAM) roles for the task:
  - a. For **Task role**, choose the IAM role to assign to the task. A task IAM role provides permissions for the containers in a task to call AWS API operations.
  - b. For **Task execution role**, choose the role.

For information about when to use a task execution role, see [the section called "Task execution IAM role"](#). If you don't need the role, choose **None**.

10. (Optional) Expand the **Task placement** section to add placement constraints. Task placement constraints allow you to filter the container instances used for the placement of your tasks using built-in or custom attributes.
11. (Optional) Expand the **Fault injection** section to enable fault injection. Fault injection lets you test how your application responds to certain impairment scenarios.
12. For each container to define in your task definition, complete the following steps.
  - a. For **Name**, enter a name for the container.
  - b. For **Image URI**, enter the image to use to start a container. Images in the Amazon ECR Public Gallery registry can be specified by using the Amazon ECR Public registry name only. For example, if `public.ecr.aws/ecs/amazon-ecs-agent:latest` is specified, the Amazon Linux container hosted on the Amazon ECR Public Gallery is used. For all other repositories, specify the repository by using either the `repository-url/image:tag` or `repository-url/image@digest` formats.
  - c. If your image is in a private registry outside of Amazon ECR, under **Private registry**, turn on **Private registry authentication**. Then, in **Secrets Manager ARN or name**, enter the Amazon Resource Name (ARN) of the secret.
  - d. For **Essential container**, if your task definition has two or more containers defined, you can specify whether the container should be considered essential. When a container is marked as **Essential**, if that container stops, then the task is stopped. Each task definition must contain at least one essential container.
  - e. A port mapping allows the container to access ports on the host to send or receive traffic. Under **Port mappings**, do one of the following:
    - When you use the **awsvpc** network mode, for **Container port** and **Protocol**, choose the port mapping to use for the container.
    - When you use the **bridge** network mode, for **Container port** and **Protocol**, choose the port mapping to use for the container.

Choose **Add more port mappings** to specify additional container port mappings.

- f. To give the container read-only access to its root file system, for **Read only root file system**, select **Read only**.
- g. (Optional) To define the container-level CPU, GPU, and memory limits that are different from task-level values, under **Resource allocation limits**, do the following:

- For **CPU**, enter the number of CPU units that the Amazon ECS container agent reserves for the container.
- For **GPU**, enter the number of GPU units for the container instance.

An Amazon EC2 instance with GPU support has 1 GPU unit for every GPU. For more information, see [the section called “Task definitions for GPU workloads”](#).

- For **Memory hard limit**, enter the amount of memory, in GB, to present to the container. If the container attempts to exceed the hard limit, the container stops.
- The Docker 20.10.0 or later daemon reserves a minimum of 6 mebibytes (MiB) of memory for a container, so don't specify fewer than 6 MiB of memory for your containers.

The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container, so don't specify fewer than 4 MiB of memory for your containers.

- For **Memory soft limit**, enter the soft limit (in GB) of memory to reserve for the container.

When system memory is under contention, Docker attempts to keep the container memory to this soft limit. If you don't specify task-level memory, you must specify a non-zero integer for one or both of **Memory hard limit** and **Memory soft limit**. If you specify both, **Memory hard limit** must be greater than **Memory soft limit**.

This feature is not supported on Windows containers.

- h. (Optional) Expand the **Environment variables** section to specify environment variables to inject into the container. You can specify environment variables either individually by using key-value pairs or in bulk by specifying an environment variable file that's hosted in an Amazon S3 bucket. For information about how to format an environment variable file, see [Pass an individual environment variable to an Amazon ECS container](#).

When you specify an environment variable for secret storage, for **Key**, enter the secret name. Then for **ValueFrom**, enter the full ARN of the Systems Manager Parameter Store secret or Secrets Manager secret

- i. (Optional) Select the **Use log collection** option to specify a log configuration. For each available log driver, there are log driver options to specify. The default option sends container logs to Amazon CloudWatch Logs. The other log driver options are

configured by using AWS FireLens. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

The following describes each container log destination in more detail.

- **Amazon CloudWatch** – Configure the task to send container logs to CloudWatch Logs. The default log driver options are provided, which create a CloudWatch log group on your behalf. To specify a different log group name, change the driver option values.
  - **Export logs to Splunk** – Configure the task to send container logs to the Splunk driver that sends the logs to a remote service. You must enter the URL to your Splunk web service. The Splunk token is specified as a secret option because it can be treated as sensitive data.
  - **Export logs to Amazon Data Firehose** – Configure the task to send container logs to Firehose. The default log driver options are provided, which sends log to an Firehose delivery stream. To specify a different delivery stream name, change the driver option values.
  - **Export logs to Amazon Kinesis Data Streams** – Configure the task to send container logs to Kinesis Data Streams. The default log driver options are provided, which send logs to a Kinesis Data Streams stream. To specify a different stream name, change the driver option values.
  - **Export logs to Amazon OpenSearch Service** – Configure the task to send container logs to an OpenSearch Service domain. The log driver options must be provided.
  - **Export logs to Amazon S3** – Configure the task to send container logs to an Amazon S3 bucket. The default log driver options are provided, but you must specify a valid Amazon S3 bucket name.
- j. (Optional) Configure additional container parameters.

| To configure this option                                                                                                                                                | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |  |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <p data-bbox="289 283 500 321"><b>Restart policy</b></p> <p data-bbox="289 363 657 493">These options define a restart policy to restart a container when it exits.</p> | <p data-bbox="706 252 1088 382">Expand <b>Restart policy</b>, and then configure the following items:</p> <ul data-bbox="706 430 1088 1818" style="list-style-type: none"><li data-bbox="706 430 1088 640">• To enable a restart policy for the container, turn on <b>Enable Restart policy</b>.</li><li data-bbox="706 682 1088 1291">• For <b>Ignored exit codes</b>, specify a comma-separated list of integer container exit codes. If the container exits with any of the specified exit codes, Amazon ECS will not try to restart the container. If nothing is specified, Amazon ECS will not ignore any exit codes.</li><li data-bbox="706 1333 1088 1818">• For <b>Attempt reset period</b>, specify an integer period of time, in seconds, that the container must run for before a restart can be attempted in the event of an exit. Amazon ECS can attempt to restart a container only</li></ul> |  |

- k. (Optional) Choose **Add more containers** to add additional containers to the task definition.
13. (Optional) The **Storage** section is used to expand the amount of ephemeral storage for tasks hosted on Fargate. You can also use this section to add a data volume configuration for the task.
  - To expand the available ephemeral storage beyond the default value of 20 gibibytes (GiB) for your Fargate tasks, for **Amount**, enter a value up to 200 GiB.

14. (Optional) To add a data volume configuration for the task definition, choose **Add volume**, and then follow these steps.
  - a. For **Volume name**, enter a name for the data volume. The data volume name is used when creating a container mount point.
  - b. For **Volume configuration**, select whether you want to configure your volume when creating the task definition or during deployment.

 **Note**

Volumes that can be configured when creating a task definition include Bind mount, Docker, Amazon EFS, and Amazon FSx for Windows File Server. Volumes that can be configured at deployment when running a task, or when creating or updating a service include Amazon EBS.

- c. For **Volume type**, select a volume type compatible with the configuration type that you selected, and then configure the volume type.

| Volume type | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |

15. To add a volume from another container, choose **Add volume from**, and then configure the following:

- For **Container**, choose the container.
- For **Source**, choose the container which has the volume you want to mount.
- For **Read only**, select whether the container has read-only access to the volume.

16. (Optional) To configure your application trace and metric collection settings by using the AWS Distro for OpenTelemetry integration, expand **Monitoring**, and then select **Use metric collection** to collect and send metrics for your tasks to either Amazon CloudWatch or Amazon Managed Service for Prometheus. When this option is selected, Amazon ECS creates an AWS Distro for OpenTelemetry container sidecar that is preconfigured to send the application metrics. For more information, see [Correlate Amazon ECS application performance using application metrics](#).
- a. When **Amazon CloudWatch** is selected, your custom application metrics are routed to CloudWatch as custom metrics. For more information, see [Exporting application metrics to Amazon CloudWatch](#).

 **Important**

When exporting application metrics to Amazon CloudWatch, your task definition requires a task IAM role with the required permissions. For more information, see [Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon CloudWatch](#).

- b. When you select **Amazon Managed Service for Prometheus (Prometheus libraries instrumentation)**, your task-level CPU, memory, network, and storage metrics and your custom application metrics are routed to Amazon Managed Service for Prometheus. For **Workspace remote write endpoint**, enter the remote write endpoint URL for your Prometheus workspace. For **Scraping target**, enter the host and port the AWS Distro for OpenTelemetry collector can use to scrape for metrics data. For more information, see [Exporting application metrics to Amazon Managed Service for Prometheus](#).

 **Important**

When exporting application metrics to Amazon Managed Service for Prometheus, your task definition requires a task IAM role with the required permissions. For more information, see [Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon Managed Service for Prometheus](#).

- c. When you select **Amazon Managed Service for Prometheus (OpenTelemetry instrumentation)**, your task-level CPU, memory, network, and storage metrics

and your custom application metrics are routed to Amazon Managed Service for Prometheus. For **Workspace remote write endpoint**, enter the remote write endpoint URL for your Prometheus workspace. For more information, see [Exporting application metrics to Amazon Managed Service for Prometheus](#).

 **Important**

When exporting application metrics to Amazon Managed Service for Prometheus, your task definition requires a task IAM role with the required permissions. For more information, see [Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon Managed Service for Prometheus](#).

17. (Optional) Expand the **Tags** section to add tags, as key-value pairs, to the task definition.
  - [Add a tag] Choose **Add tag**, and then do the following:
    - For **Key**, enter the key name.
    - For **Value**, enter the key value.
  - [Remove a tag] Next to the tag, choose **Remove tag**.
18. Choose **Create** to register the task definition.

#### Amazon ECS console JSON editor

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task definitions**.
3. On the **Create new task definition** menu, choose **Create new task definition with JSON**.
4. In the JSON editor box, edit your JSON file,

The JSON must pass the validation checks specified in [the section called "JSON validation"](#).

5. Choose **Create**.

# Using Amazon Q Developer to provide task definition recommendations in the Amazon ECS console

When you use the JSON editor in the Amazon ECS console to create a task definition, you can use Amazon Q Developer to provide AI-generated code suggestions for your task definitions.

You can use the inline chat capability to ask Amazon Q Developer to generate, explain, or refactor task definition JSON with a conversational interface. You can inject generated suggestions at any point in the task definition and accept or reject the changes proposed. Amazon ECS has also enhanced the existing inline suggestions feature to utilize Amazon Q Developer.

When you create a task definition using the JSON editor, you can have Amazon Q Developer provide recommendations to help you create a task definition more quickly. You can have property-based inline suggestions, or use the Amazon Q Developer suggestions to autocomplete whole blocks of sample code.

You can use this feature in Regions where Amazon Q Developer is supported. For more information, see [AWS Services by Regions](#).

## Prerequisites

The following are prerequisites:

- In addition to the console permissions, the user that creates the task definition in the console must have the `codewhisperer:GenerateRecommendations` permission for the recommendations and `q:SendMessage` to use inline chat. For more information, see [Permissions required for using Amazon Q Developer to provide recommendations in the console](#).

## Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task definitions**.
3. On the **Create new task definition** menu, choose **Create new task definition with JSON**.

The **Create task definition** page opens.

The console provides the following default template.

```
{
  "requiresCompatibilities": [
    "FARGATE"
  ],
  "family": "",
  "containerDefinitions": [
    {
      "name": "",
      "image": "",
      "essential": true
    }
  ],
  "volumes": [],
  "networkMode": "awsvpc",
  "memory": "3 GB",
  "cpu": "1 vCPU",
  "executionRoleArn": "arn:aws:iam::123456789012:role/ecsTaskExecutionRole"
}
```

4. In the Amazon Q inline suggestions pop-up, choose **Allow**.

If you dismiss the pop-up, you can enable Amazon Q under the gear icon.

5. In the JSON editor box, edit the JSON document.

To have Amazon Q create and populate the parameters, enter a comment with what you want to add. In the following example, the comment causes Amazon Q to generate the lines in bold.

```
{
  "requiresCompatibilities": [
    "FARGATE"
  ],
  "family": "",
  "containerDefinitions": [
    {
      "name": "",
      "image": "",
      "essential": true
    },
    // add an nginx container using an image from Public ECR, with port 80
    // open, and send logs to CloudWatch log group "myproxy"
    {
      "name": "nginx",
```

```
        "image": "public.ecr.aws/nginx/nginx:latest",
        "essential": true,
        "portMappings": [
            {
                "containerPort": 80,
                "hostPort": 80,
                "protocol": "tcp"
            }
        ],
        "logConfiguration": {
            "logDriver": "awslogs",
            "options": {
                "awslogs-group": "myproxy",
                "awslogs-region": "us-east-1",
                "awslogs-stream-prefix": "nginx"
            }
        }
    }
},
"volumes": [],
"networkMode": "awsvpc",
"memory": "3 GB",
"cpu": "1 vCPU",
"executionRoleArn": "arn:aws:iam::123456789012:role/ecsTaskExecutionRole"
}
```

6. To use the inline chat feature, you can highlight the lines, and then choose the star icon.

The Amazon Q Developer chat box displays.

Enter your request.

Amazon Q Developer generates, and then updates the JSON.

To accept the changes, choose **Accept All**

7. Choose **Create**.

## Updating an Amazon ECS task definition using the console

A *task definition revision* is a copy of the current task definition with the new parameter values replacing the existing ones. All parameters that you do not modify are in the new revision.

To update a task definition, create a task definition revision. If the task definition is used in a service, you must update that service to use the updated task definition.

When you create a revision, you can modify the following container properties and environment properties.

- Container image URI
- Port mappings
- Environment variables
- Infrastructure requirements
- Task size
- Container size
- Task role
- Task execution role
- Volumes and container mount points
- Private registry

You can have Amazon Q provide recommendations when you use the JSON editor. For more information, see [Using Amazon Q Developer to provide task definition recommendations in the Amazon ECS console](#)

## JSON validation

The Amazon ECS console JSON editor validates the following in the JSON file:

- The file is a valid JSON file
- The file does not contain any extraneous keys
- The file contains the `familyName` parameter
- There is at least one entry under `containerDefinitions`

## Procedure

Amazon ECS console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.

2. From the navigation bar, choose the Region that contains your task definition.
3. In the navigation pane, choose **Task definitions**.
4. Choose the task definition.
5. Select the task definition revision, and then choose **Create new revision, Create new revision**.
6. On the **Create new task definition revision** page, make changes. For example, to change the existing container definitions (such as the container image, memory limits, or port mappings), select the container, and then make the changes. You can update task definition compatibility to one of **AWS Fargate, Managed Instances, Amazon EC2 instances**.
7. Verify the information, and then choose **Update**.
8. If your task definition is used in a service, update your service with the updated task definition. For more information, see [Updating an Amazon ECS service](#).

#### Amazon ECS console JSON editor

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task definitions**.
3. Choose **Create new revision, Create new revision with JSON**.
4. In the JSON editor box, edit your JSON file,

The JSON must pass the validation checks specified in [the section called "JSON validation"](#).

5. Choose **Create**.

## Deregistering an Amazon ECS task definition revision using the console

You can deregister the task definition revision so that it no longer displays in your `ListTaskDefinition` API calls or in the console when you want to run a task or update a service.

When you deregister a task definition revision, it is immediately marked as `INACTIVE`. Existing tasks and services that reference an `INACTIVE` task definition revision continue to run without disruption. Existing services that reference an `INACTIVE` task definition revision can still scale up or down by modifying the service's desired count.

You can't use an INACTIVE task definition revision to run new tasks or create new services. You also can't update an existing service to reference an INACTIVE task definition revision (even though there may be up to a 10-minute window following deregistration where these restrictions have not yet taken effect).

### Note

When you deregister all revisions in a task family, the task definition family is moved to the INACTIVE list. Adding a new revision of an INACTIVE task definition moves the task definition family back to the ACTIVE list.

At this time, INACTIVE task definition revisions remain discoverable in your account indefinitely. However, this behavior is subject to change in the future. Therefore, you should not rely on INACTIVE task definition revisions persisting beyond the lifecycle of any associated tasks and services.

## CloudFormation stacks

The following behavior applies to task definitions that were created in the new Amazon ECS console before January 12, 2023.

When you create a task definition, the Amazon ECS console automatically creates a CloudFormation stack that has a name that begins with ECS-Console-V2-TaskDefinition-. If you used the AWS CLI or an AWS SDK to deregister the task definition, then you must manually delete the task definition stack. For more information, see [Deleting a stack](#) in the *CloudFormation User Guide*.

Task definitions created after January 12, 2023, do not have a CloudFormation stack automatically created for them.

## Procedure

### To deregister a new task definition (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, choose the region that contains your task definition.
3. In the navigation pane, choose **Task definitions**.

4. On the **Task definitions** page, choose the task definition family that contains one or more revisions that you want to deregister.
5. On the **task definition Name** page, select the revisions to delete, and then choose **Actions, Deregister**.
6. Verify the information in the **Deregister** window, and then choose **Deregister** to finish.

## Deleting an Amazon ECS task definition revision using the console

When no longer need a specific task definition revision in Amazon ECS, you can delete the task definition revision.

When you delete a task definition revision, it immediately transitions from the `INACTIVE` to `DELETE_IN_PROGRESS`. Existing tasks and services that reference a `DELETE_IN_PROGRESS` task definition revision continue to run without disruption.

You can't use a `DELETE_IN_PROGRESS` task definition revision to run new tasks or create new services. You also can't update an existing service to reference a `DELETE_IN_PROGRESS` task definition revision.

When you delete all `INACTIVE` task definition revisions, the task definition name is not displayed in the console and not returned in the API. If a task definition revision is in the `DELETE_IN_PROGRESS` state, the task definition name is displayed in the console and returned in the API. The task definition name is retained by Amazon ECS and the revision is incremented the next time you create a task definition with that name.

## Amazon ECS resources that can block a deletion

A task definition deletion request will not complete when there are any Amazon ECS resources that depend on the task definition revision. The following resources might prevent a task definition from being deleted:

- Amazon ECS standalone tasks - The task definition is required in order for the task to remain healthy.
- Amazon ECS service tasks - The task definition is required in order for the task to remain healthy.
- Amazon ECS service deployments and task sets - The task definition is required when a scaling event is initiated for an Amazon ECS deployment or task set.

If your task definition remains in the `DELETE_IN_PROGRESS` state, you can use the console, or the AWS CLI to identify, and then stop the resources which block the task definition deletion.

## Task definition deletion after the blocked resource is removed

The following rules apply after you remove the resources that block the task definition deletion:

- Amazon ECS tasks - The task definition deletion can take up to 1 hour to complete after the task is stopped.
- Amazon ECS service deployments and task sets - The task definition deletion can take up to 24 hours to complete after the deployment or task set is deleted.

## Procedure

### To delete task definitions (Amazon ECS console)

You must deregister a task definition revision before you delete it. For more information, see [the section called “Deregistering a task definition revision using the console”](#).

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, choose the region that contains your task definition.
3. In the navigation pane, choose **Task definitions**.
4. On the **Task definitions** page, choose the task definition family that contains one or more revisions that you want to delete.
5. On the **Task definition name** page, select the revisions to delete, and then choose **Actions**, **Delete**.

If **Delete** is unavailable, you must deregister the task definition.

6. Verify the information in the **Delete** confirmation box, and then choose **Delete** to finish.

## Amazon ECS task definition use cases

Learn more about how to write task definitions for various AWS services and features.

Depending on your workload, there are certain task definition parameters that need to be set. Also for EC2, you have to choose specific instances that are engineered for the workload.

## Amazon ECS task definitions for GPU workloads

Amazon ECS supports workloads that use GPUs, when you create clusters with container instances that support GPUs. Amazon EC2 GPU-based container instances that use the p2, p3, p4d, p5, g3, g4, g5, g6, g6e, and g6f instance types provide access to NVIDIA GPUs. For more information, see [Linux Accelerated Computing Instances](#) in the *Amazon EC2 Instance Types guide*.

Amazon ECS provides a GPU-optimized AMI that comes with pre-configured NVIDIA kernel drivers and a Docker GPU runtime. For more information, see [Amazon ECS-optimized Linux AMIs](#).

You can designate a number of GPUs in your task definition for task placement consideration at a container level. Amazon ECS schedules to available container instances that support GPUs and pin physical GPUs to proper containers for optimal performance.

The following Amazon EC2 GPU-based instance types are supported. For more information, see [Amazon EC2 P2 Instances](#), [Amazon EC2 P3 Instances](#), [Amazon EC2 P4d Instances](#), [Amazon EC2 P5 Instances](#), [Amazon EC2 G3 Instances](#), [Amazon EC2 G4 Instances](#), [Amazon EC2 G5 Instances](#), [Amazon EC2 G6 Instances](#), [Amazon EC2 G6e Instances](#), and [Amazon EC2 G6f Instances](#).

| Instance type | GPUs | GPU memory (GiB) | vCPUs | Memory (GiB) |
|---------------|------|------------------|-------|--------------|
| p3.2xlarge    | 1    | 16               | 8     | 61           |
| p3.8xlarge    | 4    | 64               | 32    | 244          |

| Instance type | GPUs | GPU memory (GiB) | vCPUs | Memory (GiB) |
|---------------|------|------------------|-------|--------------|
| p3.16xlarge   | 8    | 128              | 64    | 488          |
| p3dn.24xlarge | 8    | 256              | 96    | 768          |
| p4d.24xlarge  | 8    | 320              | 96    | 1152         |
| p5.48xlarge   | 8    | 640              | 192   | 2048         |
| g3s.xlarge    | 1    | 8                | 4     | 30.5         |
| g3.4xlarge    | 1    | 8                | 16    | 122          |
| g3.8xlarge    | 2    | 16               | 32    | 244          |
| g3.16xlarge   | 4    | 32               | 64    | 488          |
| g4dn.xlarge   | 1    | 16               | 4     | 16           |
| g4dn.2xlarge  | 1    | 16               | 8     | 32           |
| g4dn.4xlarge  | 1    | 16               | 16    | 64           |
| g4dn.8xlarge  | 1    | 16               | 32    | 128          |
| g4dn.12xlarge | 4    | 64               | 48    | 192          |
| g4dn.16xlarge | 1    | 16               | 64    | 256          |
| g5.xlarge     | 1    | 24               | 4     | 16           |
| g5.2xlarge    | 1    | 24               | 8     | 32           |
| g5.4xlarge    | 1    | 24               | 16    | 64           |
| g5.8xlarge    | 1    | 24               | 32    | 128          |
| g5.16xlarge   | 1    | 24               | 64    | 256          |
| g5.12xlarge   | 4    | 96               | 48    | 192          |

| Instance type | GPUs | GPU memory (GiB) | vCPUs | Memory (GiB) |
|---------------|------|------------------|-------|--------------|
| g5.24xlarge   | 4    | 96               | 96    | 384          |
| g5.48xlarge   | 8    | 192              | 192   | 768          |
| g6.xlarge     | 1    | 24               | 4     | 16           |
| g6.2xlarge    | 1    | 24               | 8     | 32           |
| g6.4xlarge    | 1    | 24               | 16    | 64           |
| g6.8xlarge    | 1    | 24               | 32    | 128          |
| g6.16.xlarge  | 1    | 24               | 64    | 256          |
| g6.12xlarge   | 4    | 96               | 48    | 192          |
| g6.24xlarge   | 4    | 96               | 96    | 384          |
| g6.48xlarge   | 8    | 192              | 192   | 768          |
| g6.metal      | 8    | 192              | 192   | 768          |
| gr6.4xlarge   | 1    | 24               | 16    | 128          |
| g6e.xlarge    | 1    | 48               | 4     | 32           |
| g6e.2xlarge   | 1    | 48               | 8     | 64           |
| g6e.4xlarge   | 1    | 48               | 16    | 128          |
| g6e.8xlarge   | 1    | 48               | 32    | 256          |
| g6e16.xlarge  | 1    | 48               | 64    | 512          |
| g6e12.xlarge  | 4    | 192              | 48    | 384          |
| g6e24.xlarge  | 4    | 192              | 96    | 768          |
| g6e48.xlarge  | 8    | 384              | 192   | 1536         |

| Instance type | GPUs        | GPU memory (GiB) | vCPUs | Memory (GiB) |
|---------------|-------------|------------------|-------|--------------|
| gr6.8xlarge   | 1           | 24               | 32    | 256          |
| g6f.large     | 1/8 (0.125) | 3                | 2     | 8            |
| g6f.xlarge    | 1/8 (0.125) | 3                | 4     | 16           |
| g6f.2xlarge   | 1/4 (0.25)  | 6                | 8     | 32           |
| g6f.4xlarge   | 1/2 (0.5)   | 12               | 16    | 64           |
| gr6f.4xlarge  | 1/2 (0.5)   | 12               | 16    | 128          |

You can retrieve the Amazon Machine Image (AMI) ID for Amazon ECS-optimized AMIs by querying the AWS Systems Manager Parameter Store API. Using this parameter, you don't need to manually look up Amazon ECS-optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see [GetParameter](#). The user that you use must have the `ssm:GetParameter` IAM permission to retrieve the Amazon ECS-optimized AMI metadata.

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/gpu/
recommended --region us-east-1
```

## Use GPUs with Amazon ECS Managed Instances

Amazon ECS Managed Instances supports GPU-accelerated computing for workloads such as machine learning, high-performance computing, and video processing through the following Amazon EC2 instance types. For more information about instance types supported by Amazon ECS Managed Instances, see [Amazon ECS Managed Instances instance types](#).

The following is a subset of GPU-based instance types supported on Amazon ECS Managed Instances:

- **g4dn:** Powered by NVIDIA T4 GPUs, suitable for machine learning inference, computer vision, and graphics-intensive applications.
- **g5:** Powered by NVIDIA A10G GPUs, offering higher performance for graphics-intensive applications and machine learning workloads.

- p3: Powered by NVIDIA V100 GPUs, designed for high-performance computing and deep learning training.
- p4d: Powered by NVIDIA A100 GPUs, offering the highest performance for machine learning training and high-performance computing.
- g6f: Powered by NVIDIA L4 GPUs (fractional), providing hardware-partitioned GPU slices (1/8, 1/4, or 1/2 of an NVIDIA L4 GPU) with dedicated GPU memory and compute.

When you use GPU-enabled instance types with Amazon ECS Managed Instances, the NVIDIA drivers and CUDA toolkit are pre-installed on the instance, making it easier to run GPU-accelerated workloads.

You can also share a single GPU across multiple containers. For more information about GPU sharing, see [Share GPUs on Amazon ECS](#).

### GPU-enabled instance selection

To select GPU-enabled instance types for your Amazon ECS Managed Instances workloads, use the `instanceRequirements` object in the launch template of the capacity provider. The following snippet shows the attributes that can be used for selecting GPU-enabled instances.

```
{
  "instanceRequirements": {
    "acceleratorTypes": "gpu",
    "acceleratorCount": 1,
    "acceleratorManufacturers": ["nvidia"]
  }
}
```

The following snippet shows the attributes that can be used to specify GPU-enabled instance types in the launch template.

```
{
  "instanceRequirements": {
    "allowedInstanceTypes": ["g4dn.xlarge", "p4de.24xlarge"]
  }
}
```

## GPU-enabled container images

To use GPUs in your containers, you need to use container images that contain the necessary GPU libraries and tools. NVIDIA provides several pre-built container images that you can use as a base for your GPU workloads, including the following:

- `nvidia:cuda`: Base images with the CUDA toolkit for GPU computing.
- `tensorflow/tensorflow:latest-gpu`: TensorFlow with GPU support.
- `pytorch/pytorch:latest-cuda`: PyTorch with GPU support.

For an example task definition for Amazon ECS on Amazon ECS Managed Instances that involves the use of GPUs, see [Specifying GPUs in an Amazon ECS task definition](#).

## Considerations

### Note

The support for g2 instance family type has been deprecated.

The p2 instance family type is only supported on versions earlier than 20230912 of the Amazon ECS GPU-optimized AMI. If you need to continue to use p2 instances, see [What to do if you need a P2 instance](#).

In-place updates of the NVIDIA/CUDA drivers on both these instance family types will cause potential GPU workload failures.

We recommend that you consider the following before you begin working with GPUs on Amazon ECS.

- Your clusters can contain a mix of GPU and non-GPU container instances.
- You can run GPU workloads on external instances. When registering an external instance with your cluster, ensure the `--enable-gpu` flag is included on the installation script. For more information, see [Registering an external instance to an Amazon ECS cluster](#).
- You must set `ECS_ENABLE_GPU_SUPPORT` to `true` in your agent configuration file. For more information, see [the section called "Container agent configuration"](#).
- When running a task or creating a service, you can use instance type attributes when you configure task placement constraints to determine the container instances the task is to be

launched on. By doing this, you can more effectively use your resources. For more information, see [How Amazon ECS places tasks on container instances](#).

The following example launches a task on a `g4dn.xlarge` container instance in your default cluster.

```
aws ecs run-task --cluster default --task-definition ecs-gpu-task-def \
    --placement-constraints type=memberOf,expression="attribute:ecs.instance-type ==
    g4dn.xlarge" --region us-east-2
```

- For each container that has a GPU resource requirement that's specified in the container definition, Amazon ECS sets the container runtime to be the NVIDIA container runtime.
- The NVIDIA container runtime requires some environment variables to be set in the container to function properly. For a list of these environment variables, see [Specialized Configurations with Docker](#). Amazon ECS sets the `NVIDIA_VISIBLE_DEVICES` environment variable value to be a list of the GPU device IDs that Amazon ECS assigns to the container. For the other required environment variables, Amazon ECS doesn't set them. So, make sure that your container image sets them or they're set in the container definition.
- The p5 instance type family is supported on version 20230929 and later of the Amazon ECS GPU-optimized AMI.
- The g4 instance type family is supported on version 20230913 and later of the Amazon ECS GPU-optimized AMI. For more information, see [Amazon ECS-optimized Linux AMIs](#). It's not supported in the Create Cluster workflow in the Amazon ECS console. To use these instance types, you must either use the Amazon EC2 console, AWS CLI, or API and manually register the instances to your cluster.
- The p4d.24xlarge instance type only works with CUDA 11 or later.
- The Amazon ECS GPU-optimized AMI has IPv6 enabled, which causes issues when using yum. This can be resolved by configuring yum to use IPv4 with the following command.

```
echo "ip_resolve=4" >> /etc/yum.conf
```

- When you build a container image that doesn't use the NVIDIA/CUDA base images, you must set the `NVIDIA_DRIVER_CAPABILITIES` container runtime variable to one of the following values:
  - `utility,compute`
  - `all`

For information about how to set the variable, see [Controlling the NVIDIA Container Runtime](#) on the NVIDIA website.

- GPUs are not supported on Windows containers.

## Launch a GPU container instance for Amazon ECS

To use a GPU instance on Amazon ECS on Amazon EC2, you need to create a launch template, a user data file, and launch the instance.

You can then run a task that uses a task definition configured for GPU.

### Use a launch template

You can create a launch template.

- Create a launch template that uses the Amazon ECS-optimized GPU AMI ID For the AMI. For information about how to create a launch template, see [Create a new launch template using parameters you define](#) in the *Amazon EC2 User Guide*.

Use the AMI ID from the previous step for the **Amazon Machine image**. For information about how to specify the AMI ID with the Systems Manager parameter, see [Specify a Systems Manager parameter in a launch template](#) in the *Amazon EC2 User Guide*.

Add the following to the **User data** in the launch template. Replace *cluster-name* with the name of your cluster.

```
#!/bin/bash
echo ECS_CLUSTER=cluster-name >> /etc/ecs/ecs.config;
echo ECS_ENABLE_GPU_SUPPORT=true >> /etc/ecs/ecs.config
```

### Use the AWS CLI

You can use the AWS CLI to launch the container instance.

1. Create a file that's called `userdata.toml`. This file is used for the instance user data. Replace *cluster-name* with the name of your cluster.

```
#!/bin/bash
echo ECS_CLUSTER=cluster-name >> /etc/ecs/ecs.config;
```

```
echo ECS_ENABLE_GPU_SUPPORT=true >> /etc/ecs/ecs.config
```

2. Run the following command to get the GPU AMI ID. You use this in the following step.

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/gpu/  
recommended --region us-east-1
```

3. Run the following command to launch the GPU instance. Remember to replace the following parameters:

- Replace *subnet* with the ID of the private or public subnet that your instance will launch in.
- Replace *gpu\_ami* with the AMI ID from the previous step.
- Replace *t3.large* with the instance type that you want to use.
- Replace *region* with the Region code.

```
aws ec2 run-instances --key-name ecs-gpu-example \  
  --subnet-id subnet \  
  --image-id gpu_ami \  
  --instance-type t3.large \  
  --region region \  
  --tag-specifications 'ResourceType=instance,Tags=[{Key=GPU,Value=example}]' \  
  --user-data file:///userdata.toml \  
  --iam-instance-profile Name=ecsInstanceRole
```

4. Run the following command to verify that the container instance is registered to the cluster. When you run this command, remember to replace the following parameters:

- Replace *cluster* with your cluster name.
- Replace *region* with your Region code.

```
aws ecs list-container-instances --cluster cluster-name --region region
```

## Specifying GPUs in an Amazon ECS task definition

To use the GPUs on a container instance and the Docker GPU runtime, make sure that you designate the number of GPUs your container requires in the task definition. You can specify an integer value, a decimal value for fractional GPUs, or ALL. When you specify ALL, all GPUs on

the container instance are allocated to the container. When you specify a decimal value such as 0.25, Amazon ECS places the task on a fractional GPU instance that provides the requested GPU capacity. As containers that support GPUs are placed, the Amazon ECS container agent pins the desired number of physical GPUs to the appropriate container. The number of GPUs reserved for all containers in a task cannot exceed the number of available GPUs on the container instance the task is launched on. For more information, see [Creating an Amazon ECS task definition using the console](#).

To share a single physical GPU across multiple workloads instead of allocating a whole or fractional GPU to each container, see [Share GPUs on Amazon ECS](#).

**⚠ Important**

If your GPU requirements aren't specified in the task definition, the task uses the default Docker runtime.

The following shows the JSON format for the GPU requirements in a task definition:

```
{
  "containerDefinitions": [
    {
      ...
      "resourceRequirements" : [
        {
          "type" : "GPU",
          "value" : "2"
        }
      ],
    },
    ...
  ]
}
```

You can also specify ALL as the value instead of a number to allocate all GPUs on the container instance to the container.

The following example demonstrates the syntax for a Docker container that specifies a GPU requirement. This container uses two GPUs, runs the `nvidia-smi` utility, and then exits.

```
{
```

```

"containerDefinitions": [
  {
    "memory": 80,
    "essential": true,
    "name": "gpu",
    "image": "nvidia/cuda:11.0.3-base",
    "resourceRequirements": [
      {
        "type": "GPU",
        "value": "2"
      }
    ],
    "command": [
      "sh",
      "-c",
      "nvidia-smi"
    ],
    "cpu": 100
  }
],
"family": "example-ecs-gpu"
}

```

The following example task definition shows a TensorFlow container that prints the number of available GPUs. The task runs on Amazon ECS Managed Instances, requires one GPU, and uses a `g4dn.xlarge` instance.

```

{
  "family": "tensorflow-gpu",
  "networkMode": "awsvpc",
  "executionRoleArn": "arn:aws:iam::account-id:role/ecsTaskExecutionRole",
  "containerDefinitions": [
    {
      "name": "tensorflow",
      "image": "tensorflow/tensorflow:latest-gpu",
      "essential": true,
      "command": [
        "python",
        "-c",
        "import tensorflow as tf; print('Num GPUs Available: ',
len(tf.config.list_physical_devices('GPU')))"
      ],
      "resourceRequirements": [

```

```
{
  {
    "type": "GPU",
    "value": "1"
  }
],
"logConfiguration": {
  "logDriver": "awslogs",
  "options": {
    "awslogs-group": "/ecs/tensorflow-gpu",
    "awslogs-region": "region",
    "awslogs-stream-prefix": "ecs"
  }
}
},
"requiresCompatibilities": [
  "MANAGED_INSTANCES"
],
"cpu": "4096",
"memory": "8192",
}
```

## Specifying fractional GPUs

Amazon ECS supports fractional GPU scheduling with Amazon EC2 G6f instances. G6f instances provide hardware-partitioned fractions of an NVIDIA L4 GPU, where each instance exposes a fixed GPU slice (1/8, 1/4, or 1/2) with dedicated GPU memory and compute. To use a fractional GPU, specify a decimal value in your container definition's `resourceRequirements`:

```
"resourceRequirements": [
  {
    "type": "GPU",
    "value": "0.25"
  }
]
```

The supported fractional values and their corresponding G6f instance types are:

| GPU value | GPU fraction | GPU memory | Instance types        |
|-----------|--------------|------------|-----------------------|
| 0.125     | 1/8 GPU      | 3 GB       | g6f.large, g6f.xlarge |

| GPU value | GPU fraction | GPU memory | Instance types            |
|-----------|--------------|------------|---------------------------|
| 0.25      | 1/4 GPU      | 6 GB       | g6f.2xlarge               |
| 0.5       | 1/2 GPU      | 12 GB      | g6f.4xlarge, gr6f.4xlarge |

The following example task definition runs a lightweight inference container on a fractional GPU with 1/4 of an NVIDIA L4 GPU (6 GB GPU memory):

```
{
  "family": "fractional-gpu-inference",
  "networkMode": "awsvpc",
  "executionRoleArn": "arn:aws:iam::account-id:role/ecsTaskExecutionRole",
  "containerDefinitions": [
    {
      "name": "inference",
      "image": "nvidia/cuda:12.0.0-base-ubuntu22.04",
      "essential": true,
      "command": ["nvidia-smi"],
      "resourceRequirements": [
        {
          "type": "GPU",
          "value": "0.25"
        }
      ],
      "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
          "awslogs-group": "/ecs/fractional-gpu-inference",
          "awslogs-region": "region",
          "awslogs-stream-prefix": "ecs"
        }
      }
    }
  ],
  "requiresCompatibilities": [
    "MANAGED_INSTANCES"
  ],
  "cpu": "2048",
  "memory": "4096"
}
```

```
}
```

## Fractional GPU considerations

- Only one container per task can request a fractional GPU value. If a container specifies a fractional GPU, no other container in that task definition can have a GPU resource requirement.
- Integer values (1, 2, etc.) are treated as full GPU requests and only place on instances with full GPU capacity. Decimal values (0.125, 0.25, 0.5) are treated as fractional GPU requests and place on instances with the corresponding fractional GPU partition.
- You can include both fractional GPU instances (G6f) and full GPU instances (such as g5 or g6) in the same capacity provider. Amazon ECS routes tasks to the correct instance type based on the declared GPU value. You do not need separate capacity providers per GPU family.
- You can use fractional GPU scheduling with Amazon ECS Managed Instances and Amazon ECS on Amazon EC2. Fargate and Amazon ECS Anywhere do not support fractional GPU scheduling.
- For full GPU workloads, continue using integer values as before: "value": "1".

## Share GPUs on Amazon ECS

Many GPU workloads, such as inference and small model serving, use only a fraction of a GPU's compute and memory. Without sharing, the rest of that capacity sits idle. With Amazon ECS, you can share a single physical NVIDIA GPU across multiple containers so that you can pack more workloads onto the same hardware and reduce GPU waste.

With Amazon ECS, you can use NVIDIA Multi-Process Service (MPS) for GPU sharing. MPS is an NVIDIA CUDA feature that runs multiple processes concurrently on the same GPU, which improves GPU utilization and reduces context-switching overhead. MPS provides memory and compute partitioning, so each container gets a configurable memory limit and an optional compute ceiling.

Amazon ECS manages MPS for you. It starts the MPS daemon on GPU instances, places containers onto GPUs based on available memory, and enforces per-container limits.

MPS provides software-level sharing rather than hardware-level partitioning. For more information about MPS, see [Multi-Process Service](#) in the NVIDIA documentation.

Amazon ECS supports GPU sharing with MPS on Amazon ECS Managed Instances and Amazon ECS on Amazon EC2.

## When to use GPU sharing

GPU sharing with MPS is well suited for:

- Inference workloads, embedding generation, and small model serving that don't fully utilize a GPU
- Multi-model serving where multiple models can share a single GPU
- Development and testing environments
- Running multiple lightweight GPU workloads on the same hardware to reduce cost

GPU sharing is not recommended for:

- Large model training that needs the full GPU memory
- Workloads that are sensitive to GPU faults from neighboring containers, because MPS is software-level sharing and all containers on a GPU share the same CUDA context
- Workloads that require hardware-level isolation between processes

## How GPU sharing works

You configure GPU sharing in the container definition of a task definition. In each container's `resourceRequirements`, you provide a `sharingStrategy` with a GPU memory value instead of specifying an integer in `value` for a dedicated GPU.

When Amazon ECS places a task that uses GPU sharing, it adds up the GPU memory requested by all GPU containers in the task and looks for a GPU with enough free memory. All GPU containers within a single task are placed on the same physical GPU. If the task requests 4,000 MiB across two containers, Amazon ECS finds a single GPU with at least 4,000 MiB of remaining memory and places both containers there.

Multiple tasks can also share the same physical GPU. As long as a GPU has enough remaining memory, Amazon ECS can place additional tasks on it, even if those tasks come from different services. A task that shares a GPU and a task that uses a dedicated GPU can run on the same instance, on different GPUs.

On Amazon ECS Managed Instances, Amazon ECS monitors the health of GPUs and the MPS daemon on each instance. If Amazon ECS detects a GPU hardware failure or an MPS daemon failure, it drains the instance and replaces it. For more information about GPU auto repair, see [GPU auto repair for Amazon ECS managed instances](#).

## Configure GPU sharing

To share a GPU, add a `sharingStrategy` object to the `resourceRequirements` of each GPU container in your task definition. The `sharingStrategy` object contains an `nvidiaMps` object with the following fields. For more information about `resourceRequirements`, see [Resource requirements](#).

### `memory`

Required: Yes

The GPU memory limit for the container, in MiB. This value is a hard ceiling on the GPU memory that the container can use. The value must be greater than 0.

To find the total GPU memory available on an instance, use the `DescribeContainerInstances` API (the `totalMemoryInMiB` field) or check the GPU specifications for your instance type.

### `maxComputePercent`

Required: No

The maximum percentage of GPU compute that the container can use, as an integer from 1 to 100. This sets a ceiling on the container's GPU compute usage, not a reservation. When a container is idle, its unused compute is available to other containers on the same GPU, up to each of their own `maxComputePercent` values. If you don't specify this parameter, the container can use up to 100 percent.

Amazon ECS places tasks based on GPU memory only, so it doesn't account for compute when making placement decisions.

You can set the sharing strategy in the Amazon ECS console task-definition editor, or with JSON, the AWS CLI, or the API.

Amazon ECS sets the following reserved environment variables in each container that shares a GPU. Don't set these variables in your container definition.

- `CUDA_MPS_PINNED_DEVICE_MEM_LIMIT` for the memory limit
- `CUDA_MPS_ACTIVE_THREAD_PERCENTAGE` for the compute ceiling

The following example task definition runs two inference containers that share one GPU with MPS, along with one non-GPU sidecar container. Each GPU container requests a different amount of GPU memory and compute.

In the following example, replace *account-id* with your AWS account ID.

```
{
  "family": "mps-inference",
  "networkMode": "awsvpc",
  "executionRoleArn": "arn:aws:iam::account-id:role/ecsTaskExecutionRole",
  "containerDefinitions": [
    {
      "name": "model-a",
      "image": "nvidia/cuda:12.0.0-base-ubuntu22.04",
      "essential": true,
      "resourceRequirements": [
        {
          "type": "GPU",
          "sharingStrategy": {
            "nvidiaMps": {
              "memory": 12288,
              "maxComputePercent": 50
            }
          }
        }
      ]
    },
    {
      "name": "model-b",
      "image": "nvidia/cuda:12.0.0-base-ubuntu22.04",
      "essential": true,
      "resourceRequirements": [
        {
          "type": "GPU",
          "sharingStrategy": {
            "nvidiaMps": {
              "memory": 8192,
              "maxComputePercent": 25
            }
          }
        }
      ]
    }
  ],
}
```

```
{
  "name": "log-router",
  "image": "public.ecr.aws/aws-observability/aws-for-fluent-bit:stable",
  "essential": false
},
"requiresCompatibilities": [
  "MANAGED_INSTANCES"
],
"cpu": "4096",
"memory": "8192"
}
```

## Validation rules

Amazon ECS applies the following rules to GPU sharing configurations:

- A GPU resource requirement uses either `value` (a dedicated GPU) or `sharingStrategy` (a shared GPU), but not both. When you specify `sharingStrategy`, you must omit `value`.
- All GPU containers in a task must use the same sharing strategy. If any container uses `sharingStrategy`, no other container in that task can request a dedicated GPU with `value`.
- The `memory` value is required and must be greater than 0.
- The `maxComputePercent` value is optional. If you specify it, the value must be an integer from 1 to 100.
- For Amazon ECS Managed Instances, the task's `requiresCompatibilities` must include `MANAGED_INSTANCES`. For Amazon ECS on Amazon EC2, use the EC2 launch type.
- GPU sharing is not supported for task definitions that require `EXTERNAL` compatibility (Amazon ECS Anywhere).
- You can't specify `sharingStrategy` in a container override. Container overrides in the `RunTask` and `StartTask` requests don't support GPU sharing configuration, so define `sharingStrategy` in the task definition instead. Services run the task definition as registered and aren't affected.

## Set up GPU sharing by launch type

With Amazon ECS Managed Instances, Amazon ECS selects and manages the GPU instances for you. You don't need any setup beyond the task definition.

With Amazon ECS on Amazon EC2, launch a supported NVIDIA GPU instance with the Amazon ECS AL2023 GPU-optimized AMI. GPU sharing with MPS on Amazon ECS on Amazon EC2 requires Amazon ECS container agent version 1.107.0 or later and the Amazon ECS AL2023 GPU-optimized AMI version 20261019 or later. After the instance registers with your cluster, the task-definition configuration is the same as for Amazon ECS Managed Instances.

## Considerations

- GPU sharing with MPS is supported on the G4dn, G5, G6, G6e, G7, G7e, P3, P4d, P5, P5e, P5en, and P6-B200 instance families. GPU sharing is not supported on AWS Fargate, Amazon ECS Express Mode, or Amazon ECS managed daemon tasks.
- GPU sharing with MPS on Amazon ECS on Amazon EC2 requires Amazon ECS container agent version 1.107.0 or later and the Amazon ECS AL2023 GPU-optimized AMI version 20261019 or later.
- Run a single GPU process per container when you use NVIDIA MPS for GPU sharing. For applications that require multiple GPU processes, configure the GPU memory requirement based on the combined peak memory usage of all processes. Use application-level controls to keep total consumption within the configured value. Amazon ECS uses this value to determine container placement on shared GPUs. As a result, multi-process applications can consume more GPU memory than configured, which can cause memory contention.
- If one container triggers a fatal GPU error, such as an illegal memory access from a faulty GPU kernel, the containers sharing that physical GPU could be affected. Containers on other GPUs on the same instance aren't affected.
- The `maxComputePercent` value is a ceiling, not a guaranteed reservation. When a container is idle, its unused compute is available to other containers on the same GPU, up to each of their own `maxComputePercent` values.
- GPU sharing is not supported for task definitions that require EXTERNAL compatibility (Amazon ECS Anywhere).
- Tasks from different services that use the same capacity provider can be placed on the same GPU. To prevent tasks from different services from sharing a GPU, use separate capacity providers or separate clusters for those services.
- For GPUs shared with MPS, Amazon ECS doesn't emit the following per-task and per-container GPU metrics:
  - The `TaskGPUUtilization` and `ContainerGPUUtilization` metrics.
  - The `TaskGPUMemoryUtilization` and `ContainerGPUMemoryUtilization` metrics.

- The `TaskGPUMemoryTotal` and `ContainerGPUMemoryTotal` metrics.
- The `TaskGPUMemoryUsed` and `ContainerGPUMemoryUsed` metrics.
- The following per-task and per-container GPU metrics remain available for GPUs shared with MPS:
  - The `TaskGPUPowerDraw` and `ContainerGPUPowerDraw` metrics.
  - The `TaskGPUTemperature` and `ContainerGPUTemperature` metrics.
  - The `TaskGPURestartAppXidCount` and `ContainerGPURestartAppXidCount` metrics.
- Instance-level GPU metrics remain available, including `InstanceGPUUsageTotal` and `InstanceGPULimit`.

## Monitor GPU sharing

You can confirm that a GPU is shared and track GPU usage with the Amazon ECS API and Amazon CloudWatch metrics.

### Confirm a GPU is shared

To confirm that a GPU is shared, call the `DescribeContainerInstances` API. The response includes the `gpuDevices` field with the sharing mode, container count, and remaining memory for each GPU. The following is an example response.

```
{
  "containerInstances": [
    {
      "ec2InstanceId": "i-0c74b75400ab4228d",
      "runningTasksCount": 1,
      "gpuDevices": [
        {
          "gpuId": "GPU-70d3bdaf-8635-81e0-8e44-446248a92c83",
          "sharingMode": "NVIDIA_MPS",
          "totalMemoryInMiB": 22587,
          "remainingMemoryInMiB": 16587,
          "containerCount": 2
        }
      ]
    }
  ]
}
```

## View per-task configuration

To view the sharing configuration for each task, call the `DescribeTasks` API. Each container's `gpuSharingStrategy` shows its memory and compute limits, and containers that share a GPU list the same value in `gpuIds`. The following is an example response.

```
{
  "tasks": [
    {
      "lastStatus": "RUNNING",
      "launchType": "MANAGED_INSTANCES",
      "containers": [
        {
          "name": "mps-a",
          "gpuIds": ["GPU-70d3bdaf-8635-81e0-8e44-446248a92c83"],
          "gpuSharingStrategy": { "nvidiaMps": { "memory": 4000, "maxComputePercent":
50 } }
        },
        {
          "name": "mps-b",
          "gpuIds": ["GPU-70d3bdaf-8635-81e0-8e44-446248a92c83"],
          "gpuSharingStrategy": { "nvidiaMps": { "memory": 2000, "maxComputePercent":
50 } }
        }
      ]
    }
  ]
}
```

## Track GPU usage

- **Higher task density:** With GPU sharing, more tasks run on the same instance. Use the `RunningTaskCount` metric to compare task counts per service before and after you enable sharing. For per-instance task density, use the `instance_number_of_running_tasks` metric, which CloudWatch Container Insights collects for each EC2 instance when you deploy the CloudWatch agent to collect EC2 instance-level metrics.
- **Fewer GPUs for the same workload:** The `InstanceGPUUsageTotal` metric in CloudWatch Container Insights shows how many physical GPUs are in use. With MPS, the same workload uses fewer GPUs.
- **Instance GPU headroom:** Compare `InstanceGPUUsageTotal` with `InstanceGPULimit` to see how full an instance is. With MPS, more tasks fit before an instance runs out of GPUs.

## Share GPUs manually on Amazon ECS on Amazon EC2

To share GPUs manually on Amazon ECS on Amazon EC2, you set up and manage GPU sharing yourself. Use the managed approach instead, in which Amazon ECS sets up and manages the sharing for you. For more information about the managed approach, see [Share GPUs on Amazon ECS](#).

When you want to share GPUs, you need to configure the following.

1. Remove GPU resource requirements from your task definitions so that Amazon ECS does not reserve any GPUs that should be shared.
2. Add the following user data to your instances when you want to share GPUs. This will make nvidia the default Docker container runtime on the container instance so that all Amazon ECS containers can use the GPUs. For more information see [Run commands when you launch an EC2 instance with user data input](#) in the *Amazon EC2 User Guide*.

```
const userData = ec2.UserData.forLinux();
userData.addCommands(
  'sudo rm /etc/sysconfig/docker',
  'echo DAEMON_MAXFILES=1048576 | sudo tee -a /etc/sysconfig/docker',
  'echo OPTIONS="--default-ulimit nofile=32768:65536 --default-runtime nvidia" |'
  'sudo tee -a /etc/sysconfig/docker',
  'echo DAEMON_PIDFILE_TIMEOUT=10 | sudo tee -a /etc/sysconfig/docker',
  'sudo systemctl restart docker',
);
```

3. Set the NVIDIA\_VISIBLE\_DEVICES environment variable on your container. You can do this by specifying the environment variable in your task definition. For information on the valid values, see [GPU Enumeration](#) on the NVIDIA documentation site.

## What to do if you need a P2 instance

If you need to use P2 instance, you can use one of the following options to continue using the instances.

You must modify the instance user data for both options. For more information see [Run commands when you launch an EC2 instance with user data input](#) in the *Amazon EC2 User Guide*.

## Use the last supported GPU-optimized AMI

You can use the 20230906 version of the GPU-optimized AMI, and add the following to the instance user data.

Replace cluster-name with the name of your cluster.

```
#!/bin/bash
echo "exclude=*nvidia* *cuda*" >> /etc/yum.conf
echo "ECS_CLUSTER=cluster-name" >> /etc/ecs/ecs.config
```

## Use the latest GPU-optimized AMI, and update the user data

You can add the following to the instance user data. This uninstalls the Nvidia 535/Cuda12.2 drivers, and then installs the Nvidia 470/Cuda11.4 drivers and fixes the version.

```
#!/bin/bash
yum remove -y cuda-toolkit* nvidia-driver-latest-dkms*
tmpfile=$(mktemp)
cat >$tmpfile <<EOF
[amzn2-nvidia]
name=Amazon Linux 2 Nvidia repository
mirrorlist=\$awsproto://\$amazonlinux.\$awsregion.\$awsdomain/\$releasever/amzn2-
nvidia/latest/\$basearch/mirror.list
priority=20
gpgcheck=1
gpgkey=https://developer.download.nvidia.com/compute/cuda/repos/rhel7/
x86_64/7fa2af80.pub
enabled=1
exclude=libglvnd-*
EOF

mv $tmpfile /etc/yum.repos.d/amzn2-nvidia-tmp.repo
yum install -y system-release-nvidia cuda-toolkit-11-4 nvidia-driver-latest-
dkms-470.182.03
yum install -y libnvidia-container-1.4.0 libnvidia-container-tools-1.4.0 nvidia-
container-runtime-hook-1.4.0 docker-runtime-nvidia-1

echo "exclude=*nvidia* *cuda*" >> /etc/yum.conf
nvidia-smi
```

## Create your own P2 compatible GPU-optimized AMI

You can create your own custom Amazon ECS GPU-optimized AMI that is compatible with P2 instances, and then launch P2 instances using the AMI.

1. Run the following command to clone the `amazon-ecs-ami` repo.

```
git clone https://github.com/aws/amazon-ecs-ami
```

2. Set the required Amazon ECS agent and source Amazon Linux AMI versions in `release.auto.pkvars.hcl` or `overrides.auto.pkvars.hcl`.
3. Run the following command to build a private P2 compatible EC2 AMI.

Replace `region` with the Region with the instance Region.

```
REGION=region make al2keplergpu
```

4. Use the AMI with the following instance user data to connect to the Amazon ECS cluster.

Replace `cluster-name` with the name of your cluster.

```
#!/bin/bash
echo "ECS_CLUSTER=cluster-name" >> /etc/ecs/ecs.config
```

## Amazon ECS task definitions for video transcoding workloads

To use video transcoding workloads on Amazon ECS, register [Amazon EC2 VT1](#) instances. After you registered these instances, you can run live and pre-rendered video transcoding workloads as tasks on Amazon ECS. Amazon EC2 VT1 instances use Xilinx U30 media transcoding cards to accelerate live and pre-rendered video transcoding workloads.

### Note

For instructions on how to run video transcoding workloads in containers other than Amazon ECS, see the [Xilinx documentation](#).

## Considerations

Before you begin deploying VT1 on Amazon ECS, consider the following:

- Your clusters can contain a mix of VT1 and non-VT1 instances.
- You need a Linux application that uses Xilinx U30 media transcoding cards with accelerated AVC (H.264) and HEVC (H.265) codecs.

**⚠ Important**

Applications that use other codecs might not have improved performance on VT1 instances.

- Only one transcoding task can run on a U30 card. Each card has two devices that are associated with it. You can run as many transcoding tasks as there are cards for each of your VT1 instance.
- When creating a service or running a standalone task, you can use instance type attributes when configuring task placement constraints. This ensures that the task is launched on the container instance that you specify. Doing so helps ensure that you use your resources effectively and that your tasks for video transcoding workloads are on your VT1 instances. For more information, see [How Amazon ECS places tasks on container instances](#).

In the following example, a task is run on a `vt1.3xlarge` instance on your default cluster.

```
aws ecs run-task \
  --cluster default \
  --task-definition vt1-3xlarge-ffmpeg-processor \
  --placement-constraints type=memberOf,expression="attribute:ecs.instance-type == vt1.3xlarge"
```

- You configure a container to use the specific U30 card available on the host container instance. You can do this by using the `linuxParameters` parameter and specifying the device details. For more information, see [Task definition requirements](#).

## Using a VT1 AMI

You have two options for running an AMI on Amazon EC2 for Amazon ECS container instances. The first option is to use the Xilinx official AMI on the AWS Marketplace. The second option is to build your own AMI from the sample repository.

- [Xilinx offers AMIs on the AWS Marketplace](#).
- Amazon ECS provides a sample repository that you can use to build an AMI for video transcoding workloads. This AMI comes with Xilinx U30 drivers. You can find the repository that contains Packer scripts on [GitHub](#). For more information about Packer, see the [Packer documentation](#).

## Task definition requirements

To run video transcoding containers on Amazon ECS, your task definition must contain a video transcoding application that uses the accelerated H.264/AVC and H.265/HEVC codecs. You can build a container image by following the steps on the [Xilinx GitHub](#).

The task definition must be specific to the instance type. The instance types are 3xlarge, 6xlarge, and 24xlarge. You must configure a container to use specific Xilinx U30 devices that are available on the host container instance. You can do so using the `linuxParameters` parameter. The following table details the cards and device SoCs that are specific to each instance type.

| Instance Type | vCPUs | RAM (GiB) | U30 accelerator cards | Addressable XCU30 SoC devices | Device Paths                                                                                                                   |
|---------------|-------|-----------|-----------------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| vt1.3xlarge   | 12    | 24        | 1                     | 2                             | /dev/dri/<br>renderD12<br>8 ,/dev/<br>dri/<br>renderD12<br>9                                                                   |
| vt1.6xlarge   | 24    | 48        | 2                     | 4                             | /dev/dri/<br>renderD12<br>8 ,/dev/<br>dri/<br>renderD12<br>9 ,/dev/<br>dri/<br>renderD13<br>0 ,/dev/<br>dri/<br>renderD13<br>1 |
| vt1.24xlarge  | 96    | 182       | 8                     | 16                            | /dev/dri/<br>renderD12<br>8 ,/dev/                                                                                             |

| Instance Type | vCPUs | RAM (GiB) | U30 accelerator cards | Addressable XCU30 SoC devices | Device Paths                                                                                                                                                                                                                                                                                                                                                |
|---------------|-------|-----------|-----------------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |       |           |                       |                               | dri/<br>renderD12<br>9 ,/dev/<br>dri/<br>renderD13<br>0 ,/dev/<br>dri/<br>renderD13<br>1 ,/dev/<br>dri/<br>renderD13<br>2 ,/dev/<br>dri/<br>renderD13<br>3 ,/dev/<br>dri/<br>renderD13<br>4 ,/dev/<br>dri/<br>renderD13<br>5 ,/dev/<br>dri/<br>renderD13<br>6 ,/dev/<br>dri/<br>renderD13<br>7 ,/dev/<br>dri/<br>renderD13<br>8 ,/dev/<br>dri/<br>renderD13 |

| Instance Type | vCPUs | RAM (GiB) | U30 accelerator cards | Addressable XCU30 SoC devices | Device Paths                                                                          |
|---------------|-------|-----------|-----------------------|-------------------------------|---------------------------------------------------------------------------------------|
|               |       |           |                       |                               | 9 ,/dev/dri/renderD140 ,/dev/dri/renderD141 ,/dev/dri/renderD142 ,/dev/dri/renderD143 |

### Important

If the task definition lists devices that the EC2 instance doesn't have, the task fails to run. When the task fails, the following error message appears in the `stoppedReason`: `CannotStartContainerError: Error response from daemon: error gathering device information while adding custom device "/dev/dri/renderD130": no such file or directory.`

## Specifying video transcoding in an Amazon ECS task definition

In the following example, the syntax that's used for a task definition of a Linux container on Amazon EC2 is provided. This task definition is for container images that are built following the procedure that's provided in the [Xilinx documentation](#). If you use this example, replace `image` with your own image, and copy your video files into the instance in the `/home/ec2-user` directory.

## vt1.3xlarge

1. Create a text file that's named `vt1-3xlarge-ffmpeg-linux.json` with the following content.

```
{
  "family": "vt1-3xlarge-ffmpeg-processor",
  "requiresCompatibilities": ["EC2"],
  "placementConstraints": [
    {
      "type": "memberOf",
      "expression": "attribute:ecs.os-type == linux"
    },
    {
      "type": "memberOf",
      "expression": "attribute:ecs.instance-type == vt1.3xlarge"
    }
  ],
  "containerDefinitions": [
    {
      "entryPoint": [
        "/bin/bash",
        "-c"
      ],
      "command": ["/video/ecs_ffmpeg_wrapper.sh"],
      "linuxParameters": {
        "devices": [
          {
            "containerPath": "/dev/dri/renderD128",
            "hostPath": "/dev/dri/renderD128",
            "permissions": [
              "read",
              "write"
            ]
          },
          {
            "containerPath": "/dev/dri/renderD129",
            "hostPath": "/dev/dri/renderD129",
            "permissions": [
              "read",
              "write"
            ]
          }
        ]
      }
    }
  ]
}
```

```

        ]
      },
      "mountPoints": [
        {
          "containerPath": "/video",
          "sourceVolume": "video_file"
        }
      ],
      "cpu": 0,
      "memory": 12000,
      "image": "0123456789012.dkr.ecr.us-west-2.amazonaws.com/aws/xilinx-
xffmpeg",
      "essential": true,
      "name": "xilinx-ffmpeg"
    }
  ],
  "volumes": [
    {
      "name": "video_file",
      "host": {"sourcePath": "/home/ec2-user"}
    }
  ]
}

```

## 2. Register the task definition.

```
aws ecs register-task-definition --family vt1-3xlarge-ffmpeg-processor --cli-
input-json file://vt1-3xlarge-ffmpeg-linux.json --region us-east-1
```

## vt1.6xlarge

1. Create a text file that's named `vt1-6xlarge-ffmpeg-linux.json` with the following content.

```

{
  "family": "vt1-6xlarge-ffmpeg-processor",
  "requiresCompatibilities": ["EC2"],
  "placementConstraints": [
    {
      "type": "memberOf",
      "expression": "attribute:ecs.os-type == linux"
    }
  ],

```

```

    {
      "type": "memberOf",
      "expression": "attribute:ecs.instance-type == vt1.6xlarge"
    }
  ],
  "containerDefinitions": [
    {
      "entryPoint": [
        "/bin/bash",
        "-c"
      ],
      "command": ["/video/ecs_ffmpeg_wrapper.sh"],
      "linuxParameters": {
        "devices": [
          {
            "containerPath": "/dev/dri/renderD128",
            "hostPath": "/dev/dri/renderD128",
            "permissions": [
              "read",
              "write"
            ]
          },
          {
            "containerPath": "/dev/dri/renderD129",
            "hostPath": "/dev/dri/renderD129",
            "permissions": [
              "read",
              "write"
            ]
          },
          {
            "containerPath": "/dev/dri/renderD130",
            "hostPath": "/dev/dri/renderD130",
            "permissions": [
              "read",
              "write"
            ]
          },
          {
            "containerPath": "/dev/dri/renderD131",
            "hostPath": "/dev/dri/renderD131",
            "permissions": [
              "read",
              "write"
            ]
          }
        ]
      }
    }
  ]
}
```

```

        ]
      }
    ]
  },
  "mountPoints": [
    {
      "containerPath": "/video",
      "sourceVolume": "video_file"
    }
  ],
  "cpu": 0,
  "memory": 12000,
  "image": "0123456789012.dkr.ecr.us-west-2.amazonaws.com/aws/xilinx-
xffmpeg",
  "essential": true,
  "name": "xilinx-xffmpeg"
}
],
"volumes": [
  {
    "name": "video_file",
    "host": {"sourcePath": "/home/ec2-user"}
  }
]
}

```

## 2. Register the task definition.

```
aws ecs register-task-definition --family vt1-6xlarge-xffmpeg-processor --cli-
input-json file://vt1-6xlarge-xffmpeg-linux.json --region us-east-1
```

## vt1.24xlarge

1. Create a text file that's named `vt1-24xlarge-ffmpeg-linux.json` with the following content.

```

{
  "family": "vt1-24xlarge-xffmpeg-processor",
  "requiresCompatibilities": ["EC2"],
  "placementConstraints": [
    {
      "type": "memberOf",

```

```

        "expression": "attribute:ecs.os-type == linux"
    },
    {
        "type": "memberOf",
        "expression": "attribute:ecs.instance-type == vt1.24xlarge"
    }
],
"containerDefinitions": [
    {
        "entryPoint": [
            "/bin/bash",
            "-c"
        ],
        "command": ["/video/ecs_ffmpeg_wrapper.sh"],
        "linuxParameters": {
            "devices": [
                {
                    "containerPath": "/dev/dri/renderD128",
                    "hostPath": "/dev/dri/renderD128",
                    "permissions": [
                        "read",
                        "write"
                    ]
                },
                {
                    "containerPath": "/dev/dri/renderD129",
                    "hostPath": "/dev/dri/renderD129",
                    "permissions": [
                        "read",
                        "write"
                    ]
                },
                {
                    "containerPath": "/dev/dri/renderD130",
                    "hostPath": "/dev/dri/renderD130",
                    "permissions": [
                        "read",
                        "write"
                    ]
                },
                {
                    "containerPath": "/dev/dri/renderD131",
                    "hostPath": "/dev/dri/renderD131",
                    "permissions": [

```

```
        "read",
        "write"
    ]
},
{
    "containerPath": "/dev/dri/renderD132",
    "hostPath": "/dev/dri/renderD132",
    "permissions": [
        "read",
        "write"
    ]
},
{
    "containerPath": "/dev/dri/renderD133",
    "hostPath": "/dev/dri/renderD133",
    "permissions": [
        "read",
        "write"
    ]
},
{
    "containerPath": "/dev/dri/renderD134",
    "hostPath": "/dev/dri/renderD134",
    "permissions": [
        "read",
        "write"
    ]
},
{
    "containerPath": "/dev/dri/renderD135",
    "hostPath": "/dev/dri/renderD135",
    "permissions": [
        "read",
        "write"
    ]
},
{
    "containerPath": "/dev/dri/renderD136",
    "hostPath": "/dev/dri/renderD136",
    "permissions": [
        "read",
        "write"
    ]
},
},
```

```
{
  "containerPath": "/dev/dri/renderD137",
  "hostPath": "/dev/dri/renderD137",
  "permissions": [
    "read",
    "write"
  ]
},
{
  "containerPath": "/dev/dri/renderD138",
  "hostPath": "/dev/dri/renderD138",
  "permissions": [
    "read",
    "write"
  ]
},
{
  "containerPath": "/dev/dri/renderD139",
  "hostPath": "/dev/dri/renderD139",
  "permissions": [
    "read",
    "write"
  ]
},
{
  "containerPath": "/dev/dri/renderD140",
  "hostPath": "/dev/dri/renderD140",
  "permissions": [
    "read",
    "write"
  ]
},
{
  "containerPath": "/dev/dri/renderD141",
  "hostPath": "/dev/dri/renderD141",
  "permissions": [
    "read",
    "write"
  ]
},
{
  "containerPath": "/dev/dri/renderD142",
  "hostPath": "/dev/dri/renderD142",
  "permissions": [
```

```

        "read",
        "write"
    ]
},
{
    "containerPath": "/dev/dri/renderD143",
    "hostPath": "/dev/dri/renderD143",
    "permissions": [
        "read",
        "write"
    ]
}
],
},
"mountPoints": [
    {
        "containerPath": "/video",
        "sourceVolume": "video_file"
    }
],
"cpu": 0,
"memory": 12000,
"image": "0123456789012.dkr.ecr.us-west-2.amazonaws.com/aws/xilinx-
xffmpeg",
    "essential": true,
    "name": "xilinx-ffmpeg"
}
],
"volumes": [
    {
        "name": "video_file",
        "host": {"sourcePath": "/home/ec2-user"}
    }
]
}

```

## 2. Register the task definition.

```
aws ecs register-task-definition --family vt1-24xlarge-ffmpeg-processor --cli-
input-json file://vt1-24xlarge-ffmpeg-linux.json --region us-east-1
```

# Amazon ECS task definitions for AWS Neuron machine learning workloads

You can use [Amazon EC2 Trn1](#), [Amazon EC2 Trn2](#), [Amazon EC2 Inf1](#) (Inf1 is only supported on EC2 launch type), and [Amazon EC2 Inf2](#) instances with your clusters for machine learning workloads.

Amazon EC2 Trn1 and Trn2 instances are powered by [AWS Trainium](#) chips. These instances provide high performance and low cost training for machine learning in the cloud. You can train a machine learning inference model using a machine learning framework with AWS Neuron on a Trn1 or Trn2 instance. Then, you can run the model on an Inf1 instance (Inf1 is only supported on EC2 launch type), or an Inf2 instance to use the acceleration of the AWS Inferentia chips.

The Amazon EC2 Inf1 instances and Inf2 instances are powered by [AWS Inferentia](#) chips. They provide high performance and lowest cost inference in the cloud.

Machine learning models are deployed to containers using [AWS Neuron](#), which is a specialized Software Developer Kit (SDK). The SDK consists of a compiler, runtime, and profiling tools that optimize the machine learning performance of AWS machine learning chips. AWS Neuron supports popular machine learning frameworks such as TensorFlow, PyTorch, and Apache MXNet.

## Considerations

Before you begin deploying Neuron on Amazon ECS, consider the following:

- Depending on the launch type, your clusters can contain a mix of Trn1, Trn2, Inf1, Inf2, and other instances.
- You need a Linux application in a container that uses a machine learning framework that supports AWS Neuron.

### Important

Applications that use other frameworks might not have improved performance on Trn1, Trn2, Inf1, and Inf2 instances.

- Amazon ECS supports two approaches for configuring Neuron device access:
  - **Managed Neuron device allocation** – Use the `resourceRequirements` parameter with type `NeuronDevice` in your container definition. Amazon ECS automatically discovers and assigns Neuron devices to your containers. Available on Managed Instances only. For more information, see [Managed Neuron device allocation](#).

- **Manual Neuron device specification** – Use the `linuxParameters.devices` parameter to explicitly specify Neuron device paths. Available on both EC2 launch type and Managed Instances. For more information, see [Manual Neuron device specification](#).

### Important

Use only one approach consistently to avoid conflicts.

## Managed Neuron device allocation

With Managed Instances, you can use the `resourceRequirements` parameter in your container definition to request Neuron devices. Amazon ECS automatically discovers Neuron devices on the instance, assigns them to your task, and configures the container with access to all Neuron devices on the instance. Because the task requires exclusive access to all devices, only one Neuron task runs per instance.

### Note

Inf1 instances are only supported on the EC2 launch type. To use Inf1 instances, see [Manual Neuron device specification](#).

## Neuron instance selection

To select Neuron-enabled instance types for your Managed Instances workloads, use the `instanceRequirements` object in the launch template of the capacity provider. You can use the following attributes to select Neuron-enabled instances:

- `acceleratorManufacturers` – Use `amazon-web-services` to select instances with AWS accelerators (includes Inferentia and Trainium).
- `acceleratorNames` – Use `inferentia2`, `trainium`, or `trainium2` to select specific accelerator chips.
- `allowedInstanceTypes` – Use `inf*` and `trn*` to select Neuron instance types by name.

The following example uses `allowedInstanceTypes`:

```
{
```

```
"instanceRequirements": {
  "allowedInstanceTypes": ["inf*", "trn*"]
}
```

## Task definition

To request Neuron devices in your task definition, add a `resourceRequirements` entry with type `NeuronDevice` and value `ALL`. This gives the container exclusive access to all Neuron devices on the instance.

The following constraints apply:

- At most one container definition can specify `NeuronDevice` in `resourceRequirements`.
- You can't combine `resourceRequirements` with type `NeuronDevice` and `linuxParameters.devices` for Neuron devices in the same task definition.

After your task starts, you can verify the Neuron device assignment by calling the `DescribeTasks` API operation. The response includes a `neuronDeviceIds` field on each container that shows the IDs of the assigned Neuron devices. You can also call the `DescribeContainerInstances` API operation to view `NEURON_DEVICES` in the `registeredResources` and `remainingResources` fields for the container instance.

For an example task definition, see [Example Neuron task definitions](#).

## Manual Neuron device specification

With this approach, you manually specify AWS Trainium or AWS Inferentia device paths in your task definition using the `linuxParameters.devices` parameter. This approach works on both the EC2 launch type and Managed Instances.

Only one inference or inference-training task can run on each [AWS Trainium](#) or [AWS Inferentia](#) chip. You can run as many tasks as there are chips on the instance by assigning different devices to each task.

For the EC2 launch type, you can use instance type attributes when you configure task placement constraints to ensure that the task is launched on the instance type you specify. For more information, see [How Amazon ECS places tasks on container instances](#).

## Task definition requirements

The task definition must be specific to a single instance type. You must configure a container to use specific AWS Trainium or AWS Inferentia devices that are available on the host container instance. You can do so using the `linuxParameters` parameter. The following table details the chips that are specific to each instance type.

| Instance Type | vCPUs | RAM (GiB) | AWS ML accelerator chips | Device Paths                                                                                                                                                                                                                                        |
|---------------|-------|-----------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| trn1.2xlarge  | 8     | 32        | 1                        | /dev/neuron0                                                                                                                                                                                                                                        |
| trn1.32xlarge | 128   | 512       | 16                       | /dev/neuron0 , /dev/neuron1 , /dev/neuron2 , /dev/neuron3 , /dev/neuron4 , /dev/neuron5 , /dev/neuron6 , /dev/neuron7 , /dev/neuron8 , /dev/neuron9 , /dev/neuron10 , /dev/neuron11 , /dev/neuron12 , /dev/neuron13 , /dev/neuron14 , /dev/neuron15 |

| Instance Type | vCPUs | RAM (GiB) | AWS ML accelerator chips | Device Paths                                                                                                                                                                                                                                        |
|---------------|-------|-----------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| trn2.48xlarge | 192   | 2048      | 16                       | /dev/neuron0 , /dev/neuron1 , /dev/neuron2 , /dev/neuron3 , /dev/neuron4 , /dev/neuron5 , /dev/neuron6 , /dev/neuron7 , /dev/neuron8 , /dev/neuron9 , /dev/neuron10 , /dev/neuron11 , /dev/neuron12 , /dev/neuron13 , /dev/neuron14 , /dev/neuron15 |
| inf1.xlarge   | 4     | 8         | 1                        | /dev/neuron0                                                                                                                                                                                                                                        |
| inf1.2xlarge  | 8     | 16        | 1                        | /dev/neuron0                                                                                                                                                                                                                                        |

| Instance Type | vCPUs | RAM (GiB) | AWS ML accelerator chips | Device Paths                                                                                                                                                                                                                                        |
|---------------|-------|-----------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| inf1.6xlarge  | 24    | 48        | 4                        | /dev/neuron0 , /dev/neuron1 , /dev/neuron2 , /dev/neuron3                                                                                                                                                                                           |
| inf1.24xlarge | 96    | 192       | 16                       | /dev/neuron0 , /dev/neuron1 , /dev/neuron2 , /dev/neuron3 , /dev/neuron4 , /dev/neuron5 , /dev/neuron6 , /dev/neuron7 , /dev/neuron8 , /dev/neuron9 , /dev/neuron10 , /dev/neuron11 , /dev/neuron12 , /dev/neuron13 , /dev/neuron14 , /dev/neuron15 |

| Instance Type | vCPUs | RAM (GiB) | AWS ML accelerator chips | Device Paths                                                                                                                                                                        |
|---------------|-------|-----------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| inf2.xlarge   | 4     | 16        | 1                        | /dev/neuron0                                                                                                                                                                        |
| inf2.8xlarge  | 32    | 128       | 1                        | /dev/neuron0                                                                                                                                                                        |
| inf2.24xlarge | 96    | 384       | 6                        | /dev/neuron0 , /dev/neuron1 , /dev/neuron2 , /dev/neuron3 , /dev/neuron4 , /dev/neuron5                                                                                             |
| inf2.48xlarge | 192   | 768       | 12                       | /dev/neuron0 , /dev/neuron1 , /dev/neuron2 , /dev/neuron3 , /dev/neuron4 , /dev/neuron5 , /dev/neuron6 , /dev/neuron7 , /dev/neuron8 , /dev/neuron9 , /dev/neuron10 , /dev/neuron11 |

For an example task definition, see [Example Neuron task definitions](#).

## Managed Instances

Managed Instances automatically use an AMI that includes the Neuron driver. No additional AMI configuration is required.

### EC2 launch type

Amazon ECS provides an Amazon ECS optimized AMI that's based on Amazon Linux 2023 for AWS Trainium and AWS Inferentia workloads. It comes with the AWS Neuron drivers and runtime for Docker. This AMI makes running machine learning inference workloads easier on Amazon ECS.

We recommend using the Amazon ECS-optimized Amazon Linux 2023 (Neuron) AMI when launching your Amazon EC2 Trn1, Inf1, and Inf2 instances.

You can retrieve the current Amazon ECS-optimized Amazon Linux 2023 (Neuron) AMI using the AWS CLI with the following command.

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/neuron/
recommended
```

## Example Neuron task definitions

### Managed device allocation example

The following example shows a task definition that requests all Neuron devices on the instance using the `resourceRequirements` parameter. This approach is only available on Managed Instances.

```
{
  "family": "ecs-neuron",
  "requiresCompatibilities": ["MANAGED_INSTANCES"],
  "networkMode": "awsvpc",
  "cpu": "8192",
  "memory": "16384",
  "executionRoleArn": "${YOUR_EXECUTION_ROLE}",
  "containerDefinitions": [
    {
      "name": "neuron-inference",
      "image": "763104351884.dkr.ecr.us-east-1.amazonaws.com/huggingface-vllm-
inference-neuronx:0.11.0-optimum0.4.5-neuronx-py310-sdk2.26.1-ubuntu22.04",
      "essential": true,
```

```

        "command": [
            "--model", "${YOUR_HUGGING_FACE_MODEL_ID}",
            "--port", "8080",
            "--tensor-parallel-size", "2",
            "--allow-non-cached-model"
        ],
        "portMappings": [
            {
                "containerPort": 8080,
                "protocol": "tcp"
            }
        ],
        "resourceRequirements": [
            {
                "type": "NeuronDevice",
                "value": "ALL"
            }
        ]
    }
}

```

In this example, the container image includes a vLLM inference server optimized for AWS Neuron. The image's entrypoint downloads a model from HuggingFace, compiles it for Neuron, and starts an OpenAI-compatible API server on port 8080. Replace `${YOUR_HUGGING_FACE_MODEL_ID}` with your HuggingFace model ID.

### Manual device specification example

The following example shows a Linux task definition for `inf1.xlarge` using the EC2 launch type with `linuxParameters.devices` to specify Neuron device paths.

```

{
    "family": "ecs-neuron",
    "requiresCompatibilities": ["EC2"],
    "placementConstraints": [
        {
            "type": "memberOf",
            "expression": "attribute:ecs.os-type == linux"
        },
        {
            "type": "memberOf",
            "expression": "attribute:ecs.instance-type == inf1.xlarge"
        }
    ]
}

```

```

    }
  ],
  "executionRoleArn": "${YOUR_EXECUTION_ROLE}",
  "containerDefinitions": [
    {
      "entryPoint": [
        "/usr/local/bin/entrypoint.sh",
        "--port=8500",
        "--rest_api_port=9000",
        "--model_name=resnet50_neuron",
        "--model_base_path=s3://amzn-s3-demo-bucket/resnet50_neuron"
      ],
      "portMappings": [
        {
          "hostPort": 8500,
          "protocol": "tcp",
          "containerPort": 8500
        },
        {
          "hostPort": 8501,
          "protocol": "tcp",
          "containerPort": 8501
        },
        {
          "hostPort": 0,
          "protocol": "tcp",
          "containerPort": 80
        }
      ],
      "linuxParameters": {
        "devices": [
          {
            "containerPath": "/dev/neuron0",
            "hostPath": "/dev/neuron0",
            "permissions": [
              "read",
              "write"
            ]
          }
        ],
        "capabilities": {
          "add": [
            "IPC_LOCK"
          ]
        }
      }
    }
  ]
}

```

```

        }
    },
    "cpu": 0,
    "memoryReservation": 1000,
    "image": "763104351884.dkr.ecr.us-east-1.amazonaws.com/tensorflow-
inference-neuron:1.15.4-neuron-py37-ubuntu18.04",
    "essential": true,
    "name": "resnet50"
}
]
}

```

## Amazon ECS task definitions for deep learning instances

To use deep learning workloads on Amazon ECS, register [Amazon EC2 DL1](#) instances to your clusters. Amazon EC2 DL1 instances are powered by Gaudi accelerators from Habana Labs (an Intel company). Use the Habana SynapseAI SDK to connect to the Habana Gaudi accelerators. The SDK supports the popular machine learning frameworks, TensorFlow and PyTorch.

### Considerations

Before you begin deploying DL1 on Amazon ECS, consider the following:

- Your clusters can contain a mix of DL1 and non-DL1 instances.
- When creating a service or running a standalone task, you can use instance type attributes specifically when you configure task placement constraints to ensure that your task is launched on the container instance that you specify. Doing so ensures that your resources are used effectively and that your tasks for deep learning workloads are on your DL1 instances. For more information, see [How Amazon ECS places tasks on container instances](#).

The following example runs a task on a `dl1.24xlarge` instance on your default cluster.

```

aws ecs run-task \
    --cluster default \
    --task-definition ecs-dl1-task-def \
    --placement-constraints type=memberOf,expression="attribute:ecs.instance-type ==
dl1.24xlarge"

```

## Using a DL1 AMI

You have three options for running an AMI on Amazon EC2 DL1 instances for Amazon ECS:

- AWS Marketplace AMIs that are provided by Habana [here](#).
- Habana Deep Learning AMIs that are provided by Amazon Web Services. Because it's not included, you need to install the Amazon ECS container agent separately.
- Use Packer to build a custom AMI that's provided by the [GitHub repo](#). For more information, see [the Packer documentation](#).

## Specifying deep learning in an Amazon ECS task definition

To run Habana Gaudi accelerated deep learning containers on Amazon ECS, your task definition must contain the container definition for a pre-built container that serves the deep learning model for TensorFlow or PyTorch using Habana SynapseAI that's provided by AWS Deep Learning Containers.

The following container image has TensorFlow 2.7.0 and Ubuntu 20.04. A complete list of pre-built Deep Learning Containers that's optimized for the Habana Gaudi accelerators is maintained on GitHub. For more information, see [Habana Training Containers](#).

```
763104351884.dkr.ecr.us-east-1.amazonaws.com/tensorflow-training-habana:2.7.0-hpu-py38-synapseai1.2.0-ubuntu20.04
```

The following is an example task definition for Linux containers on Amazon EC2, displaying the syntax to use. This example uses an image containing the Habana Labs System Management Interface Tool (HL-SMI) found here: `vault.habana.ai/gaudi-docker/1.1.0/ubuntu20.04/habanalabs/tensorflow-installer-tf-cpu-2.6.0:1.1.0-614`

```
{
  "family": "dl-test",
  "requiresCompatibilities": ["EC2"],
  "placementConstraints": [
    {
      "type": "memberOf",
      "expression": "attribute:ecs.os-type == linux"
    },
    {
      "type": "memberOf",
```

```

        "expression": "attribute:ecs.instance-type == dl1.24xlarge"
    }
],
"networkMode": "host",
"cpu": "10240",
"memory": "1024",
"containerDefinitions": [
    {
        "entryPoint": [
            "sh",
            "-c"
        ],
        "command": ["hl-smi"],
        "cpu": 8192,
        "environment": [
            {
                "name": "HABANA_VISIBLE_DEVICES",
                "value": "all"
            }
        ],
        "image": "vault.habana.ai/gaudi-docker/1.1.0/ubuntu20.04/habanalabs/
tensorflow-installer-tf-cpu-2.6.0:1.1.0-614",
        "essential": true,
        "name": "tensorflow-installer-tf-hpu"
    }
]
}

```

## Amazon ECS task definitions for 64-bit ARM workloads

Amazon ECS supports using 64-bit ARM applications. You can run your applications on the platform that's powered by [AWS Graviton Processors](#). It's suitable for a wide variety of workloads. This includes workloads such as application servers, micro-services, high-performance computing, CPU-based machine learning inference, video encoding, electronic design automation, gaming, open-source databases, and in-memory caches.

### Considerations

Before you begin deploying task definitions that use the 64-bit ARM architecture, consider the following:

- The applications can use the Fargate or EC2s.

- The applications can only use the Linux operating system.
- For the Fargate type, the applications must use Fargate platform version 1.4.0 or later.
- The applications can use Fluent Bit or CloudWatch for monitoring.
- For the Fargate, the following AWS Regions do not support 64-bit ARM workloads:
  - US East (N. Virginia), the use1-az3 Availability Zone
- For the EC2, see the following to verify that the Region that you're in supports the instance type you want to use:
  - [Amazon EC2 M6g Instances](#)
  - [Amazon EC2 T4g Instances](#)
  - [Amazon EC2 C6g Instances](#)
  - [Amazon EC2 R6gd Instances](#)
  - [Amazon EC2 X2gd Instances](#)

You can also use the Amazon EC2 `describe-instance-type-offerings` command with a filter to view the instance offering for your Region.

```
aws ec2 describe-instance-type-offerings --filters Name=instance-  
type,Values=instance-type --region region
```

The following example checks for the M6 instance type availability in the US East (N. Virginia) (us-east-1) Region.

```
aws ec2 describe-instance-type-offerings --filters "Name=instance-type,Values=m6*" --  
region us-east-1
```

For more information, see [describe-instance-type-offerings](#) in the *Amazon EC2 Command Line Reference*.

## Specifying the ARM architecture in an Amazon ECS task definition

To use the ARM architecture, specify ARM64 for the `cpuArchitecture` task definition parameter.

In the following example, the ARM architecture is specified in a task definition. It's in JSON format.

```
{  
  "runtimePlatform": {
```

```
    "operatingSystemFamily": "LINUX",
    "cpuArchitecture": "ARM64"
  },
  ...
}
```

In the following example, a task definition for the ARM architecture displays "hello world."

```
{
  "family": "arm64-testapp",
  "networkMode": "awsvpc",
  "containerDefinitions": [
    {
      "name": "arm-container",
      "image": "public.ecr.aws/docker/library/busybox:latest",
      "cpu": 100,
      "memory": 100,
      "essential": true,
      "command": [ "echo hello world" ],
      "entryPoint": [ "sh", "-c" ]
    }
  ],
  "requiresCompatibilities": [ "EC2" ],
  "cpu": "256",
  "memory": "512",
  "runtimePlatform": {
    "operatingSystemFamily": "LINUX",
    "cpuArchitecture": "ARM64"
  },
  "executionRoleArn": "arn:aws:iam::123456789012:role/ecsTaskExecutionRole"
}
```

## Send Amazon ECS logs to CloudWatch

You can configure the containers in your tasks to send log information to CloudWatch Logs. If you're using Fargate for your tasks, you can view the logs from your containers. If you're using EC2, you can view different logs from your containers in one convenient location, and it prevents your container logs from taking up disk space on your container instances.

**Note**

The type of information that is logged by the containers in your task depends mostly on their ENTRYPOINT command. By default, the logs that are captured show the command output that you typically might see in an interactive terminal if you ran the container locally, which are the STDOUT and STDERR I/O streams. The awslogs log driver simply passes these logs from Docker to CloudWatch Logs. For more information about how Docker processes logs, including alternative ways to capture different file data or streams, see [View logs for a container or service](#) in the Docker documentation.

To send system logs from your Amazon ECS container instances to CloudWatch Logs, see [Monitoring Log Files](#) and [CloudWatch Logs quotas](#) in the *Amazon CloudWatch Logs User Guide*.

## Fargate

If you're using Fargate for your tasks, you need to add the required logConfiguration parameters to your task definition to turn on the awslogs log driver. For more information, see [Example Amazon ECS task definition: Route logs to CloudWatch](#).

For Windows container on Fargate, perform one of the following options when any of your task definition parameters have special characters such as, & \ < > ^ |:

- Add an escape (\) with double quotes around the entire parameter string

**Example**

```
"awslogs-multiline-pattern": "\"^[|DEBUG|INFO|WARNING|ERROR\"",
```

- Add an escape (^) character around each special character

**Example**

```
"awslogs-multiline-pattern": "^[^|DEBUG^|INFO^|WARNING^|ERROR",
```

## EC2

If you're using EC2 for your tasks and want to turn on the awslogs log driver, your Amazon ECS container instances require at least version 1.9.0 of the container agent. For information about

how to check your agent version and updating to the latest version, see [Updating the Amazon ECS container agent](#).

**Note**

You must use either an Amazon ECS-optimized AMI or a custom AMI with at least version 1.9.0-1 of the `ecs-init` package. When using a custom AMI, you must specify that the `awslogs` logging driver is available on the Amazon EC2 instance when you start the agent by using the following environment variable in your **docker run** statement or environment variable file.

```
ECS_AVAILABLE_LOGGING_DRIVERS=["json-file","awslogs"]
```

Your Amazon ECS container instances also require `logs:CreateLogStream` and `logs:PutLogEvents` permission on the IAM role that you can launch your container instances with. If you created your Amazon ECS container instance role before `awslogs` log driver support was enabled in Amazon ECS, you might need to add this permission. The `ecsTaskExecutionRole` is used when it's assigned to the task and likely contains the correct permissions. For information about the task execution role, see [Amazon ECS task execution IAM role](#). If your container instances use the managed IAM policy for container instances, your container instances likely have the correct permissions. For information about the managed IAM policy for container instances, see [Amazon ECS container instance IAM role](#).

## Example Amazon ECS task definition: Route logs to CloudWatch

Before your containers can send logs to CloudWatch, you must specify the `awslogs` log driver for containers in your task definition. For more information about the log parameters, see [Storage and logging](#).

The task definition JSON that follows has a `logConfiguration` object specified for each container. One is for the WordPress container that sends logs to a log group called `awslogs-wordpress`. The other is for a MySQL container that sends logs to a log group that's called `awslogs-mysql`. Both containers use the `awslogs-example` log stream prefix.

```
{
  "containerDefinitions": [
    {
      "name": "wordpress",
```

```

    "links": [
      "mysql"
    ],
    "image": "public.ecr.aws/docker/library/wordpress:latest",
    "essential": true,
    "portMappings": [
      {
        "containerPort": 80,
        "hostPort": 80
      }
    ],
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
        "awslogs-create-group": "true",
        "awslogs-group": "awslogs-wordpress",
        "awslogs-region": "us-west-2",
        "awslogs-stream-prefix": "awslogs-example"
      }
    },
    "memory": 500,
    "cpu": 10
  },
  {
    "environment": [
      {
        "name": "MYSQL_ROOT_PASSWORD",
        "value": "password"
      }
    ],
    "name": "mysql",
    "image": "public.ecr.aws/docker/library/mysql:latest",
    "cpu": 10,
    "memory": 500,
    "essential": true,
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
        "awslogs-create-group": "true",
        "awslogs-group": "awslogs-mysql",
        "awslogs-region": "us-west-2",
        "awslogs-stream-prefix": "awslogs-example",
        "mode": "non-blocking",
        "max-buffer-size": "25m"
      }
    }
  }

```

```
    }  
  }  
},  
  "family": "awslogs-example"  
}
```

## Next steps

- You can optionally set a retention policy for the log group by using the CloudWatch AWS CLI or API. For more information, see [put-retention-policy](#) in the *AWS Command Line Interface Reference*.
- After you have registered a task definition with the `awslogs` log driver in a container definition log configuration, you can run a task or create a service with that task definition to start sending logs to CloudWatch Logs. For more information, see [Running an application as an Amazon ECS task](#) and [Creating an Amazon ECS rolling update deployment](#).

## Send Amazon ECS logs to an AWS service or AWS Partner

You can use FireLens for Amazon ECS to use task definition parameters to route logs to an AWS service or AWS Partner Network (APN) destination for log storage and analytics. The AWS Partner Network is a global community of partners that leverages programs, expertise, and resources to build, market, and sell customer offerings. For more information see [AWS Partner](#). FireLens works with [Fluentd](#) and [Fluent Bit](#). We provide the AWS for Fluent Bit image or you can use your own Fluentd or Fluent Bit image.

By default, Amazon ECS configures the container dependency so that the Firelens container starts before any container that uses it. The Firelens container also stops after all containers that use it stop.

To use this feature, you must create an IAM role for your tasks that provides the permissions necessary to use any AWS services that the tasks require. For example, if a container is routing logs to Firehose, the task requires permission to call the `firehose:PutRecordBatch` API. For more information, see [Adding and Removing IAM Identity Permissions](#) in the *IAM User Guide*.

Your task might also require the Amazon ECS task execution role under the following conditions. For more information, see [Amazon ECS task execution IAM role](#).

- If your task is hosted on Fargate and you are pulling container images from Amazon ECR or referencing sensitive data from AWS Secrets Manager in your log configuration, then you must include the task execution IAM role.
- When you use a custom configuration file that's hosted in Amazon S3, your task execution IAM role must include the `s3:GetObject` permission.

Consider the following when using FireLens for Amazon ECS:

- We recommend that you add `my_service_` to the log container name so that you can easily distinguish container names in the console.
- Amazon ECS adds a start container order dependency between the application containers and the FireLens container by default. When you specify a container order between the application containers and the FireLens container, then the default start container order is overridden.
- FireLens for Amazon ECS is supported for tasks that are hosted on both AWS Fargate on Linux and Amazon EC2 on Linux. Windows containers don't support FireLens.

For information about how to configure centralized logging for Windows containers, see [Centralized logging for Windows containers on Amazon ECS using Fluent Bit](#).

- You can use CloudFormation templates to configure FireLens for Amazon ECS. For more information, see [AWS::ECS::TaskDefinition FirelensConfiguration](#) in the *AWS CloudFormation User Guide*
- FireLens listens on port 24224, so to ensure that the FireLens log router isn't reachable outside of the task, you must not allow inbound traffic on port 24224 in the security group your task uses. For tasks that use the `awsvpc` network mode, this is the security group associated with the task. For tasks using the `host` network mode, this is the security group that's associated with the Amazon EC2 instance hosting the task. For tasks that use the `bridge` network mode, don't create any port mappings that use port 24224.
- For tasks that use the `bridge` network mode, the container with the FireLens configuration must start before any application containers that rely on it start. To control the start order of your containers, use dependency conditions in your task definition. For more information, see [Container dependency](#).

**Note**

If you use dependency condition parameters in container definitions with a FireLens configuration, ensure that each container has a `START` or `HEALTHY` condition requirement.

- By default, FireLens adds the cluster and task definition name and the Amazon Resource Name (ARN) of the cluster as metadata keys to your `stdout/stderr` container logs. The following is an example of the metadata format.

```
"ecs_cluster": "cluster-name",  
"ecs_task_arn": "arn:aws:ecs:region:111122223333:task/cluster-  
name/f2ad7dba413f45ddb4EXAMPLE",  
"ecs_task_definition": "task-def-name:revision",
```

If you do not want the metadata in your logs, set `enable-ecs-log-metadata` to `false` in the `firelensConfiguration` section of the task definition.

```
"firelensConfiguration":{  
  "type":"fluentbit",  
  "options":{  
    "enable-ecs-log-metadata":"false",  
    "config-file-type":"file",  
    "config-file-value":"/extra.conf"  
  }  
}
```

You can configure the FireLens container to run as a non-root user. Consider the following:

- To configure the FireLens container to run as a non-root user, you must specify the user in one of the following formats:
  - `uid`
  - `uid:gid`
  - `uid:group`

For more information about specifying a user in a container definition, see [ContainerDefinition](#) in the *Amazon Elastic Container Service API Reference*.

The FireLens container receives application logs over a UNIX socket. The Amazon ECS agent uses the `uid` to assign ownership of the socket directory to the FireLens container.

- Configuring the FireLens container to run as a non-root user is supported on Amazon ECS Agent version 1.96.0 and later, and Amazon ECS-optimized AMI version v20250716 and later.
- When you specify a user for the FireLens container, the `uid` must be unique and not used for other processes belonging to other containers in the task or the container instance.

For information about how to use multiple configuration files with Amazon ECS, including files that you host or files in Amazon S3, see [Init process for Fluent Bit on ECS, multi-config support](#).

For information about example configurations, see [Example Amazon ECS task definition: Route logs to FireLens](#).

For more information about configuring logs for high throughput, see [Configuring Amazon ECS logs for high throughput](#).

## Configuring Amazon ECS logs for high throughput

For high log throughput scenarios, we recommend using the `awsfirelens` log driver with FireLens and Fluent Bit. Fluent Bit is a lightweight log processor that's efficient with resources and can handle millions of log records. However, achieving optimal performance at scale requires tuning its configuration.

This section covers advanced Fluent Bit optimization techniques for handling high log throughput while maintaining system stability and ensuring no data loss.

For information about how to use custom configuration files with FireLens, see [Use a custom configuration file](#). For additional examples, see [Amazon ECS FireLens examples](#) on GitHub.

### Note

Some configuration options in this section, such as `workers` and `threaded`, require AWS for Fluent Bit version 3 or later. For information about available versions, see [AWS for Fluent Bit releases](#).

## Understanding chunks

Fluent Bit processes data in units called *chunks*. When an INPUT plugin receives data, the engine creates a chunk that gets stored in memory or on the filesystem before being sent to OUTPUT destinations.

Buffering behavior depends on the `storage.type` setting in your INPUT sections. By default, Fluent Bit uses memory buffering. For high-throughput or production scenarios, filesystem buffering provides better resilience.

For more information, see [Chunks](#) in the Fluent Bit documentation and [What is a Chunk?](#) in the AWS for Fluent Bit examples repository.

### Memory buffering (default)

By default, Fluent Bit uses memory buffering (`storage.type memory`). You can limit memory usage per INPUT plugin using the `Mem_Buf_Limit` parameter.

The following example shows a memory-buffered input configuration:

```
[INPUT]
  Name          tcp
  Tag           ApplicationLogs
  Port          5170
  storage.type  memory
  Mem_Buf_Limit 5MB
```

#### Important

When `Mem_Buf_Limit` is exceeded for a plugin, Fluent Bit pauses the input and new records are lost. This can cause backpressure and slow down your application. The following warning appears in the Fluent Bit logs:

```
[input] tcp.1 paused (mem buf overlimit)
```

Memory buffering is suitable for simple use cases with low to moderate log throughput. For high-throughput or production scenarios where data loss is a concern, use filesystem buffering instead.

For more information, see [Buffering and Memory](#) in the Fluent Bit documentation and [Memory Buffering Only](#) in the AWS for Fluent Bit examples repository.

## Filesystem buffering

For high-throughput scenarios, we recommend using filesystem buffering. For more information about how Fluent Bit manages buffering and storage, see [Buffering and Storage](#) in the Fluent Bit documentation.

Filesystem buffering provides the following advantages:

- **Larger buffer capacity** – Disk space is typically more abundant than memory.
- **Persistence** – Buffered data survives Fluent Bit restarts.
- **Graceful degradation** – During output failures, data accumulates on disk rather than causing memory exhaustion.

To enable filesystem buffering, provide a custom Fluent Bit configuration file. The following example shows the recommended configuration:

```
[SERVICE]
  # Flush logs every 1 second
  Flush 1
  # Wait 120 seconds during shutdown to flush remaining logs
  Grace 120
  # Directory for filesystem buffering
  storage.path /var/log/flb-storage/
  # Limit chunks stored 'up' in memory (reduce for memory-constrained environments)
  storage.max_chunks_up 32
  # Flush backlog chunks to destinations during shutdown (prevents log loss)
  storage.backlog.flush_on_shutdown On

[INPUT]
  Name forward
  unix_path /var/run/fluent.sock
  # Run input in separate thread to prevent blocking
  threaded true
  # Enable filesystem buffering for persistence
  storage.type filesystem

[OUTPUT]
  Name cloudwatch_logs
  Match *
  region us-west-2
  log_group_name /aws/ecs/my-app
```

```
log_stream_name $(ecs_task_id)
# Use multiple workers for parallel processing
workers 2
# Retry failed flushes up to 15 times
retry_limit 15
# Maximum disk space for buffered data for this output
storage.total_limit_size 10G
```

Key configuration parameters:

`storage.path`

The directory where Fluent Bit stores buffered chunks on disk.

`storage.backlog.flush_on_shutdown`

When enabled, Fluent Bit attempts to flush all backlog filesystem chunks to their destinations during shutdown. This helps ensure data delivery before Fluent Bit stops, but may increase shutdown time.

`storage.max_chunks_up`

The number of chunks that remain in memory. The default is 128 chunks, which can consume 500 MB+ of memory because each chunk can use up to 4–5 MB. In memory-constrained environments, lower this value. For example, if you have 50 MB available for buffering, set this to 8–10 chunks.

`storage.type filesystem`

Enables filesystem storage for the input plugin. Despite the name, Fluent Bit uses `mmap` to map chunks to both memory and disk, providing persistence without sacrificing performance.

`storage.total_limit_size`

The maximum disk space for buffered data for a specific OUTPUT plugin. When this limit is reached, the oldest records for that output are dropped. For more information about sizing, see [Understanding storage.total\\_limit\\_size](#).

`threaded true`

Runs the input in its own thread, separate from Fluent Bit's main event loop. This prevents slow inputs from blocking the entire pipeline.

For more information, see [Filesystem Buffering](#) in the Fluent Bit documentation and [Filesystem and Memory Buffering](#) in the AWS for Fluent Bit examples repository.

## Understanding `storage.total_limit_size`

The `storage.total_limit_size` parameter on each OUTPUT plugin controls the maximum disk space for buffered data for that output. When this limit is reached, the oldest records for that output are dropped to make room for new data. When disk space is completely exhausted, Fluent Bit fails to queue records and they are lost.

Use the following formula to calculate the appropriate `storage.total_limit_size` based on your log rate and desired recovery window:

If log rate is in KB/s, convert to MB/s first:

$$\text{log\_rate (MB/s)} = \text{log\_rate (KB/s)} / 1000$$
$$\text{storage.total\_limit\_size (GB)} = \text{log\_rate (MB/s)} \times \text{duration (hours)} \times 3600 \text{ (seconds/hour)} / 1000 \text{ (MB to GB)}$$

The following table shows example calculations for common log rates and recovery windows:

| Log Rate  | 1 hour | 6 hours | 12 hours | 24 hours |
|-----------|--------|---------|----------|----------|
| 0.25 MB/s | 0.9 GB | 5.4 GB  | 10.8 GB  | 21.6 GB  |
| 0.5 MB/s  | 1.8 GB | 10.8 GB | 21.6 GB  | 43.2 GB  |
| 1 MB/s    | 3.6 GB | 21.6 GB | 43.2 GB  | 86.4 GB  |
| 5 MB/s    | 18 GB  | 108 GB  | 216 GB   | 432 GB   |
| 10 MB/s   | 36 GB  | 216 GB  | 432 GB   | 864 GB   |

To observe peak throughput and choose appropriate buffer sizes, use the [measure-throughput FireLens sample](#).

Use the formula, example calculations, and benchmarking to choose a suitable `storage.total_limit_size` that provides runway for best-effort recovery during an outage.

## Amazon ECS task storage requirements

Sum all `storage.total_limit_size` values across OUTPUT sections and add buffer for overhead. This total determines the storage space needed in your Amazon ECS task definition. For example, 3 outputs × 10 GB each = 30 GB + buffer (5–10 GB) = 35–40 GB total required. If the total exceeds available storage, Fluent Bit may fail to queue records and they will be lost.

The following storage options are available:

### Bind mounts (ephemeral storage)

- For AWS Fargate, the default is 20 GB of ephemeral storage (max 200 GB). Configure using `ephemeralStorage` in the task definition. For more information, see [EphemeralStorage](#) in the *AWS CloudFormation User Guide*.
- For EC2, the default is 30 GB when using the Amazon ECS-optimized AMI (shared between the OS and Docker). Increase by changing the root volume size.

### Amazon EBS volumes

- Provides highly available, durable, high-performance block storage.
- Requires volume configuration and `mountPoint` in the task definition pointing to `storage.path` (default: `/var/log/flb-storage/`).
- For more information, see [Defer volume configuration to launch time in an Amazon ECS task definition](#).

### Amazon EFS volumes

- Provides simple, scalable file storage.
- Requires volume configuration and `mountPoint` in the task definition pointing to `storage.path` (default: `/var/log/flb-storage/`).
- For more information, see [Specify an Amazon EFS file system in an Amazon ECS task definition](#).

For more information about data volumes, see [Storage options for Amazon ECS tasks](#).

## Optimize output configuration

Network issues, service outages, and destination throttling can prevent logs from being delivered. Proper output configuration ensures resilience without data loss.

When an output flush fails, Fluent Bit can retry the operation. The following parameters control retry behavior:

## `retry_limit`

The maximum number of retries after the initial attempt before dropping records. The default is 1. For example, `retry_limit 3` means 4 total attempts (1 initial + 3 retries). For production environments, we recommend 15 or higher, which covers several minutes of outage with exponential backoff.

Set to `no_limits` or `False` for infinite retries:

- With memory buffering, infinite retries cause the input plugin to pause when memory limits are reached.
- With filesystem buffering, the oldest records are dropped when `storage.total_limit_size` is reached.

### **Important**

After exhausting all retry attempts (1 initial + `retry_limit` retries), records are dropped. AWS plugins with `auto_retry_requests true` (default) provide an additional retry layer before Fluent Bit's retry mechanism. For more information, see [Configure retries](#) in the Fluent Bit documentation.

For example, `retry_limit 3` with default settings (`scheduler.base 5`, `scheduler.cap 2000`, `net.connect_timeout 10s`) provides approximately 70 seconds of scheduler wait time (10s + 20s + 40s), 40 seconds of network connect timeouts (4 attempts × 10s), plus AWS plugin retries — totaling approximately 2–10 minutes depending on network conditions and OS TCP timeouts.

## `scheduler.base`

The base seconds between retries (default: 5). We recommend 10 seconds.

## `scheduler.cap`

The maximum seconds between retries (default: 2000). We recommend 60 seconds.

Wait time between retries uses exponential backoff with jitter:

```
wait_time = random(base, min(base * 2^retry_number, cap))
```

For example, with `scheduler.base 10` and `scheduler.cap 60`:

- First retry: random wait between 10–20 seconds
- Second retry: random wait between 10–40 seconds
- Third retry and later: random wait between 10–60 seconds (capped)

For more information, see [Configure wait time for retry](#) and [Networking](#) in the Fluent Bit documentation.

## workers

The number of threads for parallel output processing. Multiple workers allow concurrent flushes, improving throughput when processing many chunks.

## auto\_retry\_requests

An AWS plugin-specific setting that provides an additional retry layer before Fluent Bit's built-in retry mechanism. The default is `true`. When enabled, the AWS output plugin retries failed requests internally before the request is considered a failed flush and subject to the `retry_limit` configuration.

The `Grace` parameter in the `[SERVICE]` section sets the time Fluent Bit waits during shutdown to flush buffered data. The `Grace` period must be coordinated with the container's `stopTimeout`. Ensure that `stopTimeout` exceeds the `Grace` period to allow Fluent Bit to complete flushing before receiving `SIGKILL`. For example, if `Grace` is 120 seconds, set `stopTimeout` to 150 seconds.

The following example shows a complete Fluent Bit configuration with all recommended settings for high-throughput scenarios:

```
[SERVICE]
  # Flush logs every 1 second
  Flush 1
  # Wait 120 seconds during shutdown to flush remaining logs
  Grace 120
  # Directory for filesystem buffering
  storage.path /var/log/flb-storage/
  # Limit chunks stored 'up' in memory (reduce for memory-constrained environments)
  storage.max_chunks_up 32
```

```
# Flush backlog chunks to destinations during shutdown (prevents log loss)
storage.backlog.flush_on_shutdown On
# Minimum seconds between retries
scheduler.base          10
# Maximum seconds between retries (exponential backoff cap)
scheduler.cap           60
```

#### [INPUT]

```
Name forward
unix_path /var/run/fluent.sock
# Run input in separate thread to prevent blocking
threaded true
# Enable filesystem buffering for persistence
storage.type filesystem
```

#### [OUTPUT]

```
Name cloudwatch_logs
Match *
region us-west-2
log_group_name /aws/ecs/my-app
log_stream_name $(ecs_task_id)
# Use multiple workers for parallel processing
workers 2
# Retry failed flushes up to 15 times
retry_limit 15
# Maximum disk space for buffered data for this output
storage.total_limit_size 10G
```

## Understanding data loss scenarios

Records can be lost during extended outages or issues with output destinations. The configuration recommendations in this guide are best-effort approaches to minimize data loss, but cannot guarantee zero loss during prolonged failures. Understanding these scenarios helps you configure Fluent Bit to maximize resilience.

Records can be lost in two ways: oldest records are dropped when storage fills up, or newest records are rejected when the system cannot accept more data.

### Oldest records dropped

The oldest buffered records are dropped when retry attempts are exhausted or when `storage.total_limit_size` fills up and needs to make room for new data.

## Retry limit exceeded

Occurs after AWS plugin retries (if `auto_retry_requests true`) plus 1 initial Fluent Bit attempt plus `retry_limit` retries. To mitigate, set `retry_limit no_limits` per OUTPUT plugin for infinite retries:

```
[OUTPUT]
  Name          cloudwatch_logs
  Match         ApplicationLogs
  retry_limit    no_limits
  auto_retry_requests true
```

### Important

Infinite retries prevent dropping records due to retry exhaustion, but may cause `storage.total_limit_size` to fill up.

## Storage limit reached (filesystem buffering)

Occurs when the output destination is unavailable longer than your configured `storage.total_limit_size` can buffer. For example, a 10 GB buffer at 1 MB/s log rate provides approximately 2.7 hours of buffering. To mitigate, increase `storage.total_limit_size` per OUTPUT plugin and provision adequate Amazon ECS task storage:

```
[OUTPUT]
  Name          cloudwatch_logs
  Match         ApplicationLogs
  storage.total_limit_size 10G
```

## Newest records rejected

The newest records are dropped when disk space is exhausted or when input is paused due to `Mem_Buf_Limit`.

## Disk space exhausted (filesystem buffering)

Occurs when disk space is completely exhausted. Fluent Bit fails to queue new records and they are lost. To mitigate, sum all `storage.total_limit_size` values and provision adequate Amazon ECS task storage. For more information, see [Amazon ECS task storage requirements](#).

## Memory limit reached (memory buffering)

Occurs when the output destination is unavailable and the memory buffer fills. Paused input plugins stop accepting new records. To mitigate, use `storage.type filesystem` for better resilience, or increase `Mem_Buf_Limit`.

## Best practices to minimize data loss

Consider the following best practices to minimize data loss:

- **Use filesystem buffering** – Set `storage.type filesystem` for better resilience during outages.
- **Size storage appropriately** – Calculate `storage.total_limit_size` based on log rate and desired recovery window.
- **Provision adequate disk** – Ensure the Amazon ECS task has sufficient ephemeral storage, Amazon EBS, or Amazon EFS.
- **Configure retry behavior** – Balance between `retry_limit` (drops records after exhausting retries) and `no_limits` (retries indefinitely but may fill storage).

## Use multi-destination logging for reliability

Sending logs to multiple destinations eliminates single points of failure. For example, if CloudWatch Logs experiences an outage, logs still reach Amazon S3.

Multi-destination logging provides the following benefits. The Amazon S3 output plugin also supports compression options such as gzip and Parquet format, which can reduce storage costs. For more information, see [S3 compression](#) in the Fluent Bit documentation.

Multi-destination logging can provide the following benefits:

- **Redundancy** – If one destination fails, logs still reach the other.
- **Recovery** – Reconstruct gaps in one system from the other.
- **Durability** – Archive logs in Amazon S3 for long-term retention.

- **Cost optimization** – Keep recent logs in a fast query service like CloudWatch Logs with shorter retention, while archiving all logs to lower-cost Amazon S3 storage for long-term retention.

The following Fluent Bit configuration sends logs to both CloudWatch Logs and Amazon S3:

```
[OUTPUT]
  Name cloudwatch_logs
  Match *
  region us-west-2
  log_group_name /aws/ecs/my-app
  log_stream_name $(ecs_task_id)
  workers 2
  retry_limit 15

[OUTPUT]
  Name s3
  Match *
  bucket my-logs-bucket
  region us-west-2
  total_file_size 100M
  s3_key_format /fluent-bit-logs/$(ecs_task_id)/%Y%m%d/%H/%M/$UUID
  upload_timeout 10m
  # Maximum disk space for buffered data for this output
  storage.total_limit_size 5G
```

Both outputs use the same `Match *` pattern, so all records are sent to both destinations independently. During an outage of one destination, logs continue flowing to the other while failed flushes accumulate in the filesystem buffer for later retry.

## Use file-based logging with the tail input plugin

For high-throughput scenarios where log loss is a critical concern, you can use an alternative approach: have your application write logs to files on disk, and configure Fluent Bit to read them using the `tail` input plugin. This approach bypasses the Docker logging driver layer entirely.

File-based logging with the tail plugin provides the following benefits:

- **Offset tracking** – The tail plugin can store file offsets in a database file (using the DB option), providing durability across Fluent Bit restarts. This helps prevent log loss during container restarts.

- **Input-level buffering** – You can configure memory buffer limits directly on the input plugin using `Mem_Buf_Limit`, providing more granular control over memory usage.
- **Avoids Docker overhead** – Logs go directly from file to Fluent Bit without passing through Docker's log buffers.

To use this approach, your application must write logs to files instead of `stdout`. Both the application container and the Fluent Bit container mount a shared volume where the log files are stored.

The following example shows a tail input configuration with best practices:

```
[INPUT]
  Name tail
  # File path or glob pattern to tail
  Path /var/log/app.log
  # Database file for storing file offsets (enables resuming after restart)
  DB /var/log/flb_tail.db
  # when true, controls that only fluent-bit will access the database (improves
  performance)
  DB.locking true
  # Skip long lines instead of skipping the entire file
  Skip_Long_Lines On
  # How often (in seconds) to check for new files matching the glob pattern
  Refresh_Interval 10
  # Extra seconds to monitor a file after rotation to account for pending flush
  Rotate_Wait 30
  # Maximum size of the buffer for a single line
  Buffer_Max_Size 10MB
  # Initial allocation size for reading file data
  Buffer_Chunk_Size 1MB
  # Maximum memory buffer size (tail pauses when full)
  Mem_Buf_Limit 75MB
```

When using the tail input plugin, consider the following:

- Implement log rotation for your application logs to prevent disk exhaustion. Monitor the underlying volume metrics to gauge performance.
- Consider settings like `Ignore_Older`, `Read_from_Head`, and multiline parsers based on your log format.

For more information, see [Tail](#) in the Fluent Bit documentation. For best practices, see [Tail config with best practices](#) in the AWS for Fluent Bit troubleshooting guide.

## Log directly to FireLens

When the `awsfirelens` log driver is specified in a task definition, the Amazon ECS container agent injects the following environment variables into the container:

`FLUENT_HOST`

The IP address that's assigned to the FireLens container.

### Note

If you're using EC2 with the bridge network mode, the `FLUENT_HOST` environment variable in your application container can become inaccurate after a restart of the FireLens log router container (the container with the `firelensConfiguration` object in its container definition). This is because `FLUENT_HOST` is a dynamic IP address and can change after a restart. Logging directly from the application container to the `FLUENT_HOST` IP address can start failing after the address changes. For more information about restarting individual containers, see [Restart individual containers in Amazon ECS tasks with container restart policies](#).

`FLUENT_PORT`

The port that the Fluent Forward protocol is listening on.

You can use these environment variables to log directly to the Fluent Bit log router from your application code using the Fluent Forward protocol, instead of writing to `stdout`. This approach bypasses the Docker logging driver layer, which provides the following benefits:

- **Lower latency** – Logs go directly to Fluent Bit without passing through Docker's logging infrastructure.
- **Structured logging** – Send structured log data natively without JSON encoding overhead.
- **Better control** – Your application can implement its own buffering and error handling logic.

The following Fluent logger libraries support the Fluent Forward protocol and can be used to send logs directly to Fluent Bit:

- **Go** – [fluent-logger-golang](#)
- **Python** – [fluent-logger-python](#)
- **Java** – [fluent-logger-java](#)
- **Node.js** – [fluent-logger-node](#)
- **Ruby** – [fluent-logger-ruby](#)

## Configure the Docker buffer limit

When you create a task definition, you can specify the number of log lines that are buffered in memory by specifying the value in `log-driver-buffer-limit`. This controls the buffer between Docker and Fluent Bit. For more information, see [Fluentd logging driver](#) in the Docker documentation.

Use this option when there's high throughput, because Docker might run out of buffer memory and discard buffer messages so it can add new messages.

Consider the following when using this option:

- This option is supported on EC2 and Fargate type with platform version 1.4.0 or later.
- The option is only valid when `logDriver` is set to `awsfirelens`.
- The default buffer limit is 1048576 log lines.
- The buffer limit must be greater than or equal to 0 and less than 536870912 log lines.
- The maximum amount of memory used for this buffer is the product of the size of each log line and the size of the buffer. For example, if the application's log lines are on average 2 KiB, a buffer limit of 4096 would use at most 8 MiB. The total amount of memory allocated at the task level should be greater than the amount of memory that's allocated for all the containers in addition to the log driver memory buffer.

The following task definition shows how to configure `log-driver-buffer-limit`:

```
{
  "containerDefinitions": [
    {
```

```

        "name": "my_service_log_router",
        "image": "public.ecr.aws/aws-observability/aws-for-fluent-bit:3",
        "cpu": 0,
        "memoryReservation": 51,
        "essential": true,
        "firelensConfiguration": {
            "type": "fluentbit"
        }
    },
    {
        "essential": true,
        "image": "public.ecr.aws/docker/library/httpd:latest",
        "name": "app",
        "logConfiguration": {
            "logDriver": "awsfirelens",
            "options": {
                "Name": "firehose",
                "region": "us-west-2",
                "delivery_stream": "my-stream",
                "log-driver-buffer-limit": "52428800"
            }
        },
        "dependsOn": [
            {
                "containerName": "my_service_log_router",
                "condition": "START"
            }
        ],
        "memoryReservation": 100
    }
]
}

```

## AWS for Fluent Bit image repositories for Amazon ECS

AWS provides a Fluent Bit image with plugins for both CloudWatch Logs and Firehose. We recommend using Fluent Bit as your log router because it has a lower resource utilization rate than Fluentd. For more information, see [CloudWatch Logs for Fluent Bit](#) and [Amazon Kinesis Firehose for Fluent Bit](#).

The **AWS for Fluent Bit** image is available on Amazon ECR on both the Amazon ECR Public Gallery and in an Amazon ECR repository for high availability.

## Amazon ECR Public Gallery

The AWS for Fluent Bit image is available on the Amazon ECR Public Gallery. This is the recommended location to download the AWS for Fluent Bit image because it's a public repository and available to be used from all AWS Regions. For more information, see [aws-for-fluent-bit](#) on the Amazon ECR Public Gallery.

### Linux

The AWS for Fluent Bit image in the Amazon ECR Public Gallery supports the Amazon Linux operating system with the ARM64 or x86-64 architecture.

You can pull the AWS for Fluent Bit image from the Amazon ECR Public Gallery by specifying the repository URL with the desired image tag. The available image tags can be found on the **Image tags** tab on the Amazon ECR Public Gallery.

The following shows the syntax to use for the Docker CLI.

```
docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:tag
```

For example, you can pull the latest image in the "3.x" family of AWS for Fluent Bit releases using this Docker CLI command.

```
docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:3
```

#### Note

Unauthenticated pulls are allowed, but have a lower rate limit than authenticated pulls. To authenticate using your AWS account before pulling, use the following command.

```
aws ecr-public get-login-password --region us-east-1 | docker login --username  
AWS --password-stdin public.ecr.aws
```

## AWS for Fluent Bit 3.0.0

In addition to the existing AWS for Fluent Bit versions 2.x, AWS for Fluent Bit supports a new major version 3.x. The new major version includes upgrading images from Amazon Linux 2 to

Amazon Linux 2023 and Fluent Bit version 1.9.10 to 4.1.1. For more information, see the [AWS for Fluent Bit repository](#) on GitHub.

The following examples demonstrate updated tags for AWS for Fluent Bit 3.x images:

You can use multi-architecture tags for the AWS for Fluent Bit image.

```
docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:3
```

## Windows

The AWS for Fluent Bit image in the Amazon ECR Public Gallery supports the AMD64 architecture with the following operating systems:

- Windows Server 2022 Full
- Windows Server 2022 Core
- Windows Server 2019 Full
- Windows Server 2019 Core

Windows containers that are on AWS Fargate don't support FireLens.

You can pull the AWS for Fluent Bit image from the Amazon ECR Public Gallery by specifying the repository URL with the desired image tag. The available image tags can be found on the **Image tags** tab on the Amazon ECR Public Gallery.

The following shows the syntax to use for the Docker CLI.

```
docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:tag
```

For example, you can pull the newest stable AWS for Fluent Bit image using this Docker CLI command.

```
docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:windowsservercore-stable
```

### Note

Unauthenticated pulls are allowed, but have a lower rate limit than authenticated pulls. To authenticate using your AWS account before pulling, use the following command.

```
aws ecr-public get-login-password --region us-east-1 | docker login --username  
AWS --password-stdin public.ecr.aws
```

## Amazon ECR

The AWS for Fluent Bit image is available on Amazon ECR for high availability. The following commands can be used to retrieve image URIs and establish image availability in a given AWS Region.

### Linux

The latest stable AWS for Fluent Bit image URI can be retrieved using the following command.

```
aws ssm get-parameters \  
  --names /aws/service/aws-for-fluent-bit/stable \  
  --region us-east-1
```

All versions of the AWS for Fluent Bit image can be listed using the following command to query the Systems Manager Parameter Store parameter.

```
aws ssm get-parameters-by-path \  
  --path /aws/service/aws-for-fluent-bit \  
  --region us-east-1
```

The newest stable AWS for Fluent Bit image can be referenced in an CloudFormation template by referencing the Systems Manager parameter store name. The following is an example:

```
Parameters:  
  FireLensImage:  
    Description: Fluent Bit image for the FireLens Container  
    Type: AWS::SSM::Parameter::Value<String>  
    Default: /aws/service/aws-for-fluent-bit/stable
```

#### Note

If the command fails or there is no output, the image isn't available in the AWS Region in which the command is called.

## Windows

The latest stable AWS for Fluent Bit image URI can be retrieved using the following command.

```
aws ssm get-parameters \
  --names /aws/service/aws-for-fluent-bit/windowsservercore-stable \
  --region us-east-1
```

All versions of the AWS for Fluent Bit image can be listed using the following command to query the Systems Manager Parameter Store parameter.

```
aws ssm get-parameters-by-path \
  --path /aws/service/aws-for-fluent-bit/windowsservercore \
  --region us-east-1
```

The latest stable AWS for Fluent Bit image can be referenced in an CloudFormation template by referencing the Systems Manager parameter store name. The following is an example:

```
Parameters:
  FireLensImage:
    Description: Fluent Bit image for the FireLens Container
    Type: AWS::SSM::Parameter::Value<String>
    Default: /aws/service/aws-for-fluent-bit/windowsservercore-stable
```

## Example Amazon ECS task definition: Route logs to FireLens

To use custom log routing with FireLens, you must specify the following in your task definition:

- A log router container that contains a FireLens configuration. We recommend that the container be marked as `essential`.
- One or more application containers that contain a log configuration specifying the `awsfirelens` log driver.
- A task IAM role Amazon Resource Name (ARN) that contains the permissions needed for the task to route the logs.

When creating a new task definition using the AWS Management Console, there is a FireLens integration section that makes it easy to add a log router container. For more information, see [Creating an Amazon ECS task definition using the console](#).

Amazon ECS converts the log configuration and generates the Fluentd or Fluent Bit output configuration. The output configuration is mounted in the log routing container at `/fluent-bit/etc/fluent-bit.conf` for Fluent Bit and `/fluentd/etc/fluent.conf` for Fluentd.

### Important

FireLens listens on port 24224. Therefore, to ensure that the FireLens log router isn't reachable outside of the task, you must not allow ingress traffic on port 24224 in the security group your task uses. For tasks that use the `awsvpc` network mode, this is the security group that's associated with the task. For tasks that use the `host` network mode, this is the security group that's associated with the Amazon EC2 instance hosting the task. For tasks that use the `bridge` network mode, don't create any port mappings that use port 24224.

By default, Amazon ECS adds additional fields in your log entries that help identify the source of the logs.

- `ecs_cluster` – The name of the cluster that the task is part of.
- `ecs_task_arn` – The full Amazon Resource Name (ARN) of the task that the container is part of.
- `ecs_task_definition` – The task definition name and revision that the task is using.
- `ec2_instance_id` – The Amazon EC2 instance ID that the container is hosted on. This field is only valid for tasks using the EC2 launch type.

You can set the `enable-ecs-log-metadata` to `false` if you do not want the metadata.

The following task definition example defines a log router container that uses Fluent Bit to route its logs to CloudWatch Logs. It also defines an application container that uses a log configuration to route logs to Amazon Data Firehose and sets the memory that's used to buffer events to the 2 MiB.

### Note

For more example task definitions, see [Amazon ECS FireLens examples](#) on GitHub.

```
{
```

```

"family": "firelens-example-firehose",
"taskRoleArn": "arn:aws:iam::123456789012:role/ecs_task_iam_role",
"containerDefinitions": [
  {
    "name": "log_router",
    "image": "public.ecr.aws/aws-observability/aws-for-fluent-bit:3",
    "cpu": 0,
    "memoryReservation": 51,
    "portMappings": [],
    "essential": true,
    "environment": [],
    "mountPoints": [],
    "volumesFrom": [],
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
        "awslogs-group": "/ecs/ecs-aws-firelens-sidecar-container",
        "mode": "non-blocking",
        "awslogs-create-group": "true",
        "max-buffer-size": "25m",
        "awslogs-region": "us-east-1",
        "awslogs-stream-prefix": "firelens"
      },
      "secretOptions": []
    },
    "systemControls": [],
    "firelensConfiguration": {
      "type": "fluentbit"
    }
  },
  {
    "essential": true,
    "image": "public.ecr.aws/docker/library/httpd:latest",
    "name": "app",
    "logConfiguration": {
      "logDriver": "awsfirelens",
      "options": {
        "Name": "firehose",
        "region": "us-west-2",
        "delivery_stream": "my-stream",
        "log-driver-buffer-limit": "1048576"
      }
    },
    "memoryReservation": 100
  }
]

```

```
    }  
  ]  
}
```

The key-value pairs specified as options in the `logConfiguration` object are used to generate the Fluentd or Fluent Bit output configuration. The following is a code example from a Fluent Bit output definition.

```
[OUTPUT]  
  Name      firehose  
  Match     app-firelens*  
  region    us-west-2  
  delivery_stream my-stream
```

### Note

FireLens manages the match configuration. You do not specify the match configuration in your task definition.

## Use a custom configuration file

You can specify a custom configuration file. The configuration file format is the native format for the log router that you're using. For more information, see [Fluentd Config File Syntax](#) and [YAML Configuration](#).

In your custom configuration file, for tasks using the `bridge` or `awsvpc` network mode, don't set a Fluentd or Fluent Bit forward input over TCP because FireLens adds it to the input configuration.

Your FireLens configuration must contain the following options to specify a custom configuration file:

`config-file-type`

The source location of the custom configuration file. The available options are `s3` or `file`.

### Note

Tasks that are hosted on AWS Fargate or Amazon ECS Managed Instances only support the `file` configuration file type. You can still use configuration files hosted in Amazon

S3 with these launch types. To do this, use the AWS for Fluent Bit init container. For more information, see [Init process for Fluent Bit on ECS, multi-config support](#) on GitHub.

## config-file-value

The source for the custom configuration file. If the `s3` config file type is used, the config file value is the full ARN of the Amazon S3 bucket and file. If the `file` config file type is used, the config file value is the full path of the configuration file that exists either in the container image or on a volume that's mounted in the container.

### Important

When using a custom configuration file, you must specify a different path than the one FireLens uses. Amazon ECS reserves the `/fluent-bit/etc/fluent-bit.conf` filepath for Fluent Bit and `/fluentd/etc/fluent.conf` for Fluentd.

The following example shows the syntax required when specifying a custom configuration.

### Important

To specify a custom configuration file that's hosted in Amazon S3, ensure you have created a task execution IAM role with the proper permissions.

The following shows the syntax required when specifying a custom configuration.

```
{
  "containerDefinitions": [
    {
      "essential": true,
      "image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:3",
      "name": "log_router",
      "firelensConfiguration": {
        "type": "fluentbit",
        "options": {
          "config-file-type": "s3 | file",

```

```
    "config-file-value": "arn:aws:s3:::amzn-s3-demo-bucket/fluents.conf"
  | filepath"
    }
  }
}
]
```

### Note

Tasks that are hosted on AWS Fargate or Amazon ECS Managed Instances only support the file configuration file type. You can still use configuration files hosted in Amazon S3 with these launch types. To do this, use the AWS for Fluent Bit init container. For more information, see [Init process for Fluent Bit on ECS, multi-config support](#) on GitHub.

## Using non-AWS container images in Amazon ECS

Use private registry to store your credentials in AWS Secrets Manager, and then reference them in your task definition. This provides a way to reference container images that exist in private registries outside of AWS that require authentication in your task definitions. This feature is supported by tasks hosted on Fargate, Amazon EC2 instances, and external instances using Amazon ECS Anywhere.

### Important

If your task definition references an image that's stored in Amazon ECR, this topic doesn't apply. For more information, see [Using Amazon ECR Images with Amazon ECS](#) in the *Amazon Elastic Container Registry User Guide*.

For tasks hosted on Amazon EC2 instances, this feature requires version 1.19.0 or later of the container agent. However, we recommend using the latest container agent version. For information about how to check your agent version and update to the latest version, see [Updating the Amazon ECS container agent](#).

For tasks hosted on Fargate, this feature requires platform version 1.2.0 or later. For information, see [Fargate platform versions for Amazon ECS](#).

Within your container definition, specify the `repositoryCredentials` object with the details of the secret that you created. The referenced secret can be from a different AWS Region or a different account than the task using it.

 **Note**

When using the Amazon ECS API, AWS CLI, or AWS SDK, if the secret exists in the same AWS Region as the task that you're launching then you can use either the full ARN or name of the secret. If the secret exists in a different account, the full ARN of the secret must be specified. When using the AWS Management Console, the full ARN of the secret must be specified always.

The following is a snippet of a task definition that shows the required parameters:

Substitute the following parameters:

- *private-repo* with the private repository host name
- *private-image* with the image name
- *arn:aws:secretsmanager:region:aws\_account\_id:secret:secret\_name* with the secret Amazon Resource Name (ARN)

```
"containerDefinitions": [  
  {  
    "image": "private-repo/private-image",  
    "repositoryCredentials": {  
      "credentialsParameter":  
        "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name"  
    }  
  }  
]
```

 **Note**

Another method of enabling private registry authentication uses Amazon ECS container agent environment variables to authenticate to private registries. This method is

only supported for tasks hosted on Amazon EC2 instances. For more information, see [Configuring Amazon ECS container instances for private Docker images](#).

## To use private registry

1. The task definition must have a task execution role. This allows the container agent to pull the container image. For more information, see [Amazon ECS task execution IAM role](#).

Private registry authentication allows your Amazon ECS tasks to pull container images from private registries outside of AWS (such as Docker Hub, Quay.io, or your own private registry) that require authentication credentials. This feature uses Secrets Manager to securely store your registry credentials, which are then referenced in your task definition using the `repositoryCredentials` parameter.

For more information about configuring private registry authentication, see [Using non-AWS container images in Amazon ECS](#).

To provide access to the secrets that contain your private registry credentials, add the following permissions as an inline policy to the task execution role. For more information, see [Adding and Removing IAM Policies](#).

- `secretsmanager:GetSecretValue`—Required to retrieve the private registry credentials from Secrets Manager.
- `kms:Decrypt`—Required only if your secret uses a custom KMS key and not the default key. The Amazon Resource Name (ARN) for your custom key must be added as a resource.

The following is an example inline policy that adds the permissions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt",
        "secretsmanager:GetSecretValue"
      ]
    }
  ]
}
```

```
    ],
    "Resource": [
        "arn:aws:secretsmanager:us-
east-1:111122223333:secret:secret_name",
        "arn:aws:kms:us-east-1:111122223333:key/key_id"
    ]
}
]
```

2. Use AWS Secrets Manager to create a secret for your private registry credentials. For information about how to create a secret, see [Create an AWS Secrets Manager secret](#) in the *AWS Secrets Manager User Guide*.

Enter your private registry credentials using the following format:

```
{
  "username" : "privateRegistryUsername",
  "password" : "privateRegistryPassword"
}
```

3. Register a task definition. For more information, see [the section called "Creating a task definition using the console"](#).

## Restart individual containers in Amazon ECS tasks with container restart policies

You can enable a restart policy for each essential and non-essential container defined in your task definition, to overcome transient failures faster and maintain task availability. When you enable a restart policy for a container, Amazon ECS can restart the container if it exits, without needing to replace the task.

Restart policies are not enabled for containers by default. When you enable a restart policy for a container, you can specify exit codes that the container will not be restarted on. These can be exit codes that indicate success, like exit code 0, that don't require a restart. You can also specify how long a container must run successfully before a restart can be attempted. For more information about these parameters, see [Restart policy](#). For an example task definition that specifies these values, see [Specifying a container restart policy in an Amazon ECS task definition](#).

You can use the Amazon ECS task metadata endpoint or CloudWatch Container Insights to monitor the number of times a container has restarted. For more information about the task metadata endpoint, see [Amazon ECS task metadata endpoint version 4](#) and [Amazon ECS task metadata endpoint version 4 for tasks on Fargate](#). For more information about Container Insights metrics for Amazon ECS, see [Amazon ECS Container Insights metrics](#) in the *Amazon CloudWatch User Guide*.

Container restart policies are supported by tasks hosted on Fargate, Amazon EC2 instances, and external instances using Amazon ECS Anywhere.

## Considerations

Consider the following before enabling a restart policy for your container:

- Restart policies aren't supported for Windows containers on Fargate.
- For tasks hosted on Amazon EC2 instances, this feature requires version 1.86.0 or later of the container agent. However, we recommend using the latest container agent version. For information about how to check your agent version and update to the latest version, see [Updating the Amazon ECS container agent](#).
- If you're using EC2 with the bridge network mode, the `FLUENT_HOST` environment variable in your application container can become inaccurate after a restart of the FireLens log router container (the container with the `firelensConfiguration` object in its container definition). This is because `FLUENT_HOST` is a dynamic IP address and can change after a restart. Logging directly from the application container to the `FLUENT_HOST` IP address can start failing after the address changes. For more information about `FLUENT_HOST`, see [Configuring Amazon ECS logs for high throughput](#).
- The Amazon ECS agent handles the container restart policies. If for some unexpected reason the Amazon ECS agent fails or is no longer running, the container won't be restarted.
- The restart attempt period defined in your policy determines the period of time (in seconds) that the container must run for before Amazon ECS restarts a container.

## Specifying a container restart policy in an Amazon ECS task definition

To specify a restart policy for a container in a task definition, within the container definition, specify the `restartPolicy` object. For more information about the `restartPolicy` object, see [Restart policy](#).

The following is a task definition using the Linux containers on Fargate that sets up a web server. The container definition includes the `restartPolicy` object, with `enabled` set to `true` to enable

a restart policy for the container. The container must run for 180 seconds before it can be restarted and will not be restarted if it exits with the exit code 0, which indicates success.

```
{
  "containerDefinitions": [
    {
      "command": [
        "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample App</title>
<style>body {margin-top: 40px; background-color: #333;} </style> </head><body>
<div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1>
<h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon
ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-
foreground\""]
      ],
      "entryPoint": ["sh", "-c"],
      "essential": true,
      "image": "public.ecr.aws/docker/library/httpd:2.4",
      "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
          "awslogs-group": "/ecs/fargate-task-definition",
          "awslogs-region": "us-east-1",
          "awslogs-stream-prefix": "ecs"
        }
      },
      "name": "sample-fargate-app",
      "portMappings": [
        {
          "containerPort": 80,
          "hostPort": 80,
          "protocol": "tcp"
        }
      ],
      "restartPolicy": {
        "enabled": true,
        "ignoredExitCodes": [0],
        "restartAttemptPeriod": 180
      }
    }
  ],
  "cpu": "256",
  "executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
  "family": "fargate-task-definition",
```

```
"memory": "512",
"networkMode": "awsvpc",
"runtimePlatform": {
  "operatingSystemFamily": "LINUX"
},
"requiresCompatibilities": ["FARGATE"]
}
```

After you have registered a task definition with the `restartPolicy` object in a container definition, you can run a task or create a service with that task definition. For more information, see [Running an application as an Amazon ECS task](#) and [Creating an Amazon ECS rolling update deployment](#).

## Pass sensitive data to an Amazon ECS container

You can safely pass sensitive data, such as credentials to a database, into your container.

Secrets, such as API keys and database credentials, are frequently used by applications to gain access other systems. They often consist of a username and password, a certificate, or API key. Access to these secrets should be restricted to specific IAM principals that are using IAM and injected into containers at runtime.

Secrets can be seamlessly injected into containers from AWS Secrets Manager and Amazon EC2 Systems Manager Parameter Store. These secrets can be referenced in your task as any of the following.

1. They're referenced as environment variables that use the `secrets` container definition parameter.
2. They're referenced as `secretOptions` if your logging platform requires authentication. For more information, see [logging configuration options](#).
3. They're referenced as secrets pulled by images that use the `repositoryCredentials` container definition parameter if the registry where the container is being pulled from requires authentication. Use this method when pulling images from Amazon ECR Public Gallery. For more information, see [Private registry authentication for tasks](#).

We recommend that you do the following when setting up secrets management.

## Use AWS Secrets Manager or AWS Systems Manager Parameter Store for storing secret materials

You should securely store API keys, database credentials, and other secret materials in Secrets Manager or as an encrypted parameter in Systems Manager Parameter Store. These services are similar because they're both managed key-value stores that use AWS KMS to encrypt sensitive data. Secrets Manager, however, also includes the ability to automatically rotate secrets, generate random secrets, and share secrets across accounts. To utilize these features, use Secrets Manager. Otherwise, use encrypted parameters in Systems Manager Parameter Store.

### Important

If your secret changes, you must force a new deployment or launch a new task to retrieve the latest secret value. For more information, see the following topics:

- Tasks - Stop the task, and then start it. For more information, see [Stopping an Amazon ECS task](#) and [Running an application as an Amazon ECS task](#).
- Service - Update the service and use the force new deployment option. For more information, see [Updating an Amazon ECS service](#).

## Retrieve data from an encrypted Amazon S3 bucket

You should store secrets in an encrypted Amazon S3 bucket and use task roles to restrict access to those secrets. This prevents the values of environment variables from inadvertently leaking in logs and getting revealed when running `docker inspect`. When you do this, your application must be written to read the secret from the Amazon S3 bucket. For instructions, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

## Mount the secret to a volume using a sidecar container

Because there's an elevated risk of data leakage with environment variables, you should run a sidecar container that reads your secrets from AWS Secrets Manager and write them to a shared volume. This container can run and exit before the application container by using [Amazon ECS container ordering](#). When you do this, the application container subsequently mounts the volume where the secret was written. Like the Amazon S3 bucket method, your application must be written to read the secret from the shared volume. Because the volume is scoped to the task, the volume is automatically deleted after the task stops. For an example, see the [task-def.json](#) project.

On Amazon EC2, the volume that the secret is written to can be encrypted with a AWS KMS customer managed key. On AWS Fargate, volume storage is automatically encrypted using a service managed key.

## Pass an individual environment variable to an Amazon ECS container

### Important

We recommend storing your sensitive data in either AWS Secrets Manager secrets or AWS Systems Manager Parameter Store parameters. For more information, see [Pass sensitive data to an Amazon ECS container](#).

Environment variables specified in the task definition are readable by all users and roles that are allowed the DescribeTaskDefinition action for the task definition.

You can pass environment variables to your containers in the following ways:

- Individually using the `environment` container definition parameter. This maps to the `--env` option to [docker container run](#).
- In bulk, using the `environmentFiles` container definition parameter to list one or more files that contain the environment variables. The file must be hosted in Amazon S3. This maps to the `--env-file` option to [docker run](#).

The following is a snippet of a task definition showing how to specify individual environment variables.

```
{
  "family": "",
  "containerDefinitions": [
    {
      "name": "",
      "image": "",
      ...
      "environment": [
        {
          "name": "variable",
          "value": "value"
        }
      ],
    },
  ],
}
```

```
    ...  
  }  
],  
  ...  
}
```

## Pass environment variables to an Amazon ECS container

### Important

We recommend storing your sensitive data in either AWS Secrets Manager secrets or AWS Systems Manager Parameter Store parameters. For more information, see [Pass sensitive data to an Amazon ECS container](#).

Environment variable files are objects in Amazon S3 and all Amazon S3 security considerations apply.

You can't use the `environmentFiles` parameter on Windows containers and Windows containers on Fargate.

You can create an environment variable file and store it in Amazon S3 to pass environment variables to your container.

By specifying environment variables in a file, you can bulk inject environment variables. Within your container definition, specify the `environmentFiles` object with a list of Amazon S3 buckets containing your environment variable files.

Amazon ECS doesn't enforce a size limit on the environment variables, but a large environment variables file might fill up the disk space. Each task that uses an environment variables file causes a copy of the file to be downloaded to disk. Amazon ECS removes the file as part of the task cleanup.

For information about the supported environment variables, see [Advanced container definition parameters- Environment](#).

Consider the following when specifying an environment variable file in a container definition.

- For Amazon ECS tasks on Amazon EC2, your container instances require that the container agent is version `1.39.0` or later to use this feature. For information about how to check your agent version and update to the latest version, see [Updating the Amazon ECS container agent](#).
- For Amazon ECS tasks on AWS Fargate, your tasks must use platform version `1.4.0` or later (Linux) to use this feature. For more information, see [Fargate platform versions for Amazon ECS](#).

Verify that the variable is supported for the operating system platform. For more information, see [the section called “Container definitions”](#) and [the section called “Other task definition parameters”](#).

- The file must use the `.env` file extension and UTF-8 encoding.
- The task execution role is required to use this feature with the additional permissions for Amazon S3. This allows the container agent to pull the environment variable file from Amazon S3. For more information, see [Amazon ECS task execution IAM role](#).
- There is a limit of 10 files per task definition.
- Each line in an environment file must contain an environment variable in `VARIABLE=VALUE` format. Spaces or quotation marks **are** included as part of the values for Amazon ECS files. Lines beginning with `#` are treated as comments and are ignored. For more information about the environment variable file syntax, see [Set environment variables \(-e, --env, --env-file\)](#) in the Docker documentation.

The following is the appropriate syntax.

```
#This is a comment and will be ignored
VARIABLE=VALUE
ENVIRONMENT=PRODUCTION
```

- If there are environment variables specified using the `environment` parameter in a container definition, they take precedence over the variables contained within an environment file.
- If multiple environment files are specified and they contain the same variable, they're processed in order of entry. This means that the first value of the variable is used and subsequent values of duplicate variables are ignored. We recommend that you use unique variable names.
- If an environment file is specified as a container override, it's used. Moreover, any other environment files that are specified in the container definition is ignored.
- The following rules apply to the Fargate:
  - The file is handled similar to a native Docker `env-file`.
  - Container definitions that reference environment variables that are blank and stored in Amazon S3 do not appear in the container.
  - There is no support for shell escape handling.
  - The container entry point interprets the `VARIABLE` values.

## Example

The following is a snippet of a task definition showing how to specify an environment variable file.

```
{
  "family": "",
  "containerDefinitions": [
    {
      "name": "",
      "image": "",
      ...
      "environmentFiles": [
        {
          "value": "arn:aws:s3:::amzn-s3-demo-
bucket/envfile_object_name.env",
          "type": "s3"
        }
      ],
      ...
    }
  ],
  ...
}
```

## Pass Secrets Manager secrets programmatically in Amazon ECS

Instead of hardcoding sensitive information in plain text in your application, you can use Secrets Manager to store the sensitive data.

We recommend this method of retrieving sensitive data because if the Secrets Manager secret is subsequently updated, the application automatically retrieves the latest version of the secret.

Create a secret in Secrets Manager. After you create a Secrets Manager secret, update your application code to retrieve the secret.

Review the following considerations before securing sensitive data in Secrets Manager.

- Only secrets that store text data, which are secrets created with the `SecretString` parameter of the [CreateSecret](#) API, are supported. Secrets that store binary data, which are secrets created with the `SecretBinary` parameter of the [CreateSecret](#) API are not supported.

- Use interface VPC endpoints to enhance security controls. You must create the interface VPC endpoints for Secrets Manager. For information about the VPC endpoint, see [Create VPC endpoints](#) in the *AWS Secrets Manager User Guide*.
- The VPC your task uses must use DNS resolution.
- Your task definition must use a task role with the additional permissions for Secrets Manager. For more information, see [Amazon ECS task IAM role](#).

## Create the Secrets Manager secret

You can use the Secrets Manager console to create a secret for your sensitive data. For information about how to create secrets, see [Create an AWS Secrets Manager secret](#) in the *AWS Secrets Manager User Guide*.

## Update your application to programmatically retrieve Secrets Manager secrets

You can retrieve secrets with a call to the Secrets Manager APIs directly from your application. For information, see [Retrieve secrets from AWS Secrets Manager](#) in the *AWS Secrets Manager User Guide*.

To retrieve the sensitive data stored in the AWS Secrets Manager, see [Code examples for AWS Secrets Manager using AWS SDKs](#) in the *AWS SDK Code Examples Code Library*.

## Pass Systems Manager Parameter Store secrets programmatically in Amazon ECS

Systems Manager Parameter Store provides secure storage and management of secrets. You can store data such as passwords, database strings, EC2 instance IDs and AMI IDs, and license codes as parameter values, instead of hardcoding this information in your application. You can store values as plain text or encrypted data.

We recommend this method of retrieving sensitive data because if the Systems Manager Parameter Store parameter is subsequently updated, the application automatically retrieves the latest version.

Review the following considerations before securing sensitive data in Systems Manager Parameter Store.

- Only secrets that store text data are supported. Secrets that store binary data are not supported.
- Use interface VPC endpoints to enhance security controls.
- The VPC your task uses must use DNS resolution.

- For tasks that use EC2, you must use the Amazon ECS agent configuration variable `ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE=true` to use this feature. You can add it to the `/etc/ecs/ecs.config` file during container instance creation or you can add it to an existing instance and then restart the ECS agent. For more information, see [Amazon ECS container agent configuration](#).
- Your task definition must use a task role with the additional permissions for Systems Manager Parameter Store. For more information, see [Amazon ECS task IAM role](#).

## Create the parameter

You can use the Systems Manager console to create a Systems Manager Parameter Store parameter for your sensitive data. For more information, see [Create a Systems Manager parameter \(console\)](#) or [Create a Systems Manager parameter \(AWS CLI\)](#) in the *AWS Systems Manager User Guide*.

## Update your application to programmatically retrieve Systems Manager Parameter Store secrets

To retrieve the sensitive data stored in the Systems Manager Parameter Store parameter, see [Code examples for Systems Manager using AWS SDKs](#) in the *AWS SDK Code Examples Code Library*.

## Pass Secrets Manager secrets through Amazon ECS environment variables

When you inject a secret as an environment variable, you can specify the full contents of a secret, a specific JSON key within a secret. This helps you control the sensitive data exposed to your container. For more information about secret versioning, see [What's in a Secrets Manager secret?](#) in the *AWS Secrets Manager User Guide*.

The following should be considered when using an environment variable to inject a Secrets Manager secret into a container.

- Sensitive data is injected into your container when the container is initially started. If the secret is subsequently updated or rotated, the container will not receive the updated value automatically. You must either launch a new task or if your task is part of a service you can update the service and use the **Force new deployment** option to force the service to launch a fresh task.
- Applications that run on the container and container logs and debugging tools have access to the environment variables.
- For Amazon ECS tasks on AWS Fargate, consider the following:

- To inject the full content of a secret as an environment variable or in a log configuration, you must use platform version 1.3.0 or later. For information, see [Fargate platform versions for Amazon ECS](#).
- To inject a specific JSON key or version of a secret as an environment variable or in a log configuration, you must use platform version 1.4.0 or later (Linux) or 1.0.0 (Windows). For information, see [Fargate platform versions for Amazon ECS](#).
- For Amazon ECS tasks on EC2, the following should be considered:
  - To inject a secret using a specific JSON key or version of a secret, your container instance must have version 1.37.0 or later of the container agent. However, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see [Updating the Amazon ECS container agent](#).

To inject the full contents of a secret as an environment variable or to inject a secret in a log configuration, your container instance must have version 1.22.0 or later of the container agent.

- Use interface VPC endpoints to enhance security controls and connect to Secrets Manager through a private subnet. You must create the interface VPC endpoints for Secrets Manager. For information about the VPC endpoint, see [Create VPC endpoints](#) in the *AWS Secrets Manager User Guide*. For more information about using Secrets Manager and Amazon VPC, see [How to connect to Secrets Manager service within a Amazon VPC](#).
- For Windows tasks that are configured to use the awslogs logging driver, you must also set the ECS\_ENABLE\_AWSLOGS\_EXECUTIONROLE\_OVERRIDE environment variable on your container instance. Use the following syntax:

```
<powershell>
[Environment]::SetEnvironmentVariable("ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE",
    $TRUE, "Machine")
Initialize-ECSAgent -Cluster <cluster name> -EnableTaskIAMRole -LoggingDrivers
    ["json-file","awslogs"]'
</powershell>
```

- Your task definition must use a task execution role with the additional permissions for Secrets Manager. For more information, see [Amazon ECS task execution IAM role](#).

## Create the AWS Secrets Manager secret

You can use the Secrets Manager console to create a secret for your sensitive data. For more information, see [Create an AWS Secrets Manager secret](#) in the *AWS Secrets Manager User Guide*.

## Add the environment variable to the container definition

Within your container definition, you can specify the following:

- The `secrets` object containing the name of the environment variable to set in the container
- The Amazon Resource Name (ARN) of the Secrets Manager secret
- Additional parameters that contain the sensitive data to present to the container

The following example shows the full syntax that must be specified for the Secrets Manager secret.

```
arn:aws:secretsmanager:region:aws_account_id:secret:secret-name:json-key:version-stage:version-id
```

The following section describes the additional parameters. These parameters are optional, but if you do not use them, you must include the colons `:` to use the default values. Examples are provided below for more context.

### `json-key`

Specifies the name of the key in a key-value pair with the value that you want to set as the environment variable value. Only values in JSON format are supported. If you do not specify a JSON key, then the full contents of the secret is used.

### `version-stage`

Specifies the staging label of the version of a secret that you want to use. If a version staging label is specified, you cannot specify a version ID. If no version stage is specified, the default behavior is to retrieve the secret with the `AWSCURRENT` staging label.

Staging labels are used to keep track of different versions of a secret when they are either updated or rotated. Each version of a secret has one or more staging labels and an ID.

### `version-id`

Specifies the unique identifier of the version of a secret that you want to use. If a version ID is specified, you cannot specify a version staging label. If no version ID is specified, the default behavior is to retrieve the secret with the `AWSCURRENT` staging label.

Version IDs are used to keep track of different versions of a secret when they are either updated or rotated. Each version of a secret has an ID. For more information, see [Key Terms and Concepts for AWS Secrets Manager](#) in the *AWS Secrets Manager User Guide*.

## Example container definitions

The following examples show ways in which you can reference Secrets Manager secrets in your container definitions.

### Example referencing a full secret

The following is a snippet of a task definition showing the format when referencing the full text of a Secrets Manager secret.

```
{
  "containerDefinitions": [{
    "secrets": [{
      "name": "environment_variable_name",
      "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name-AbCdEf"
    }]
  }]
}
```

To access the value of this secret from within the container you would need to call the `$environment_variable_name`.

### Example referencing full secrets

The following is a snippet of a task definition showing the format when referencing the full text of multiple Secrets Manager secrets.

```
{
  "containerDefinitions": [{
    "secrets": [
      {
        "name": "environment_variable_name1",
        "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name-AbCdEf"
      },
      {
        "name": "environment_variable_name2",
```

```

        "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name-abcdef"
      },
      {
        "name": "environment_variable_name3",
        "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name-ABCDEF"
      }
    ]
  }]
}
```

To access the value of this secret from within the container you would need to call the `$environment_variable_name1`, `$environment_variable_name2`, and `$environment_variable_name3`.

### Example referencing a specific key within a secret

The following shows an example output from a [get-secret-value](#) command that displays the contents of a secret along with the version staging label and version ID associated with it.

```

{
  "ARN": "arn:aws:secretsmanager:region:aws_account_id:secret:appauthexample-AbCdEf",
  "Name": "appauthexample",
  "VersionId": "871d9eca-18aa-46a9-8785-981ddEXAMPLE",
  "SecretString": "{\"username1\":\":password1\",\"username2\":\":password2\",\"username3\":\":password3\"}",
  "VersionStages": [
    "AWSCURRENT"
  ],
  "CreateDate": 1581968848.921
}
```

Reference a specific key from the previous output in a container definition by specifying the key name at the end of the ARN.

```

{
  "containerDefinitions": [{
    "secrets": [{
      "name": "environment_variable_name",
      "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:appauthexample-AbCdEf:username1:"
    }
  ]
}
```

```
    }]
  }]
}
```

## Example referencing a specific secret version

The following shows an example output from a [describe-secret](#) command that displays the unencrypted contents of a secret along with the metadata for all versions of the secret.

```
{
  "ARN": "arn:aws:secretsmanager:region:aws_account_id:secret:appauthexample-AbCdEf",
  "Name": "appauthexample",
  "Description": "Example of a secret containing application authorization data.",
  "RotationEnabled": false,
  "LastChangedDate": 1581968848.926,
  "LastAccessedDate": 1581897600.0,
  "Tags": [],
  "VersionIdsToStages": {
    "871d9eca-18aa-46a9-8785-981ddEXAMPLE": [
      "AWSCURRENT"
    ],
    "9d4cb84b-ad69-40c0-a0ab-cead3EXAMPLE": [
      "AWSPREVIOUS"
    ]
  }
}
```

Reference a specific version staging label from the previous output in a container definition by specifying the key name at the end of the ARN.

```
{
  "containerDefinitions": [{
    "secrets": [{
      "name": "environment_variable_name",
      "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:appauthexample-AbCdEf::AWSPREVIOUS:"
    }]
  }]
}
```

Reference a specific version ID from the previous output in a container definition by specifying the key name at the end of the ARN.

```
{
  "containerDefinitions": [{
    "secrets": [{
      "name": "environment_variable_name",
      "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:appauthexample-AbCdEf::9d4cb84b-ad69-40c0-a0ab-cead3EXAMPLE"
    }]
  }]
}
```

### Example referencing a specific key and version staging label of a secret

The following shows how to reference both a specific key within a secret and a specific version staging label.

```
{
  "containerDefinitions": [{
    "secrets": [{
      "name": "environment_variable_name",
      "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:appauthexample-AbCdEf:username1:AWSPREVIOUS:"
    }]
  }]
}
```

To specify a specific key and version ID, use the following syntax.

```
{
  "containerDefinitions": [{
    "secrets": [{
      "name": "environment_variable_name",
      "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:appauthexample-AbCdEf:username1::9d4cb84b-ad69-40c0-a0ab-cead3EXAMPLE"
    }]
  }]
}
```

For information about how to create a task definition with the secret specified in an environment variable, see [Creating an Amazon ECS task definition using the console](#).

## Pass Systems Manager parameters through Amazon ECS environment variables

Amazon ECS allows you to inject sensitive data into your containers by storing your sensitive data in AWS Systems Manager Parameter Store parameters and then referencing them in your container definition.

Consider the following when using an environment variable to inject a Systems Manager secret into a container.

- Sensitive data is injected into your container when the container is initially started. If the secret is subsequently updated or rotated, the container will not receive the updated value automatically. You must either launch a new task or if your task is part of a service you can update the service and use the **Force new deployment** option to force the service to launch a fresh task.
- For Amazon ECS tasks on AWS Fargate, the following should be considered:
  - To inject the full content of a secret as an environment variable or in a log configuration, you must use platform version 1.3.0 or later. For information, see [Fargate platform versions for Amazon ECS](#).
  - To inject a specific JSON key or version of a secret as an environment variable or in a log configuration, you must use platform version 1.4.0 or later (Linux) or 1.0.0 (Windows). For information, see [Fargate platform versions for Amazon ECS](#).
- For Amazon ECS tasks on EC2, the following should be considered:
  - To inject a secret using a specific JSON key or version of a secret, your container instance must have version 1.37.0 or later of the container agent. However, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see [Updating the Amazon ECS container agent](#).

To inject the full contents of a secret as an environment variable or to inject a secret in a log configuration, your container instance must have version 1.22.0 or later of the container agent.

- Use interface VPC endpoints to enhance security controls. You must create the interface VPC endpoints for Systems Manager. For information about the VPC endpoint, see [Improve the security of EC2 instances by using VPC endpoints for Systems Manager](#) in the *AWS Systems Manager User Guide*.
- Your task definition must use a task execution role with the additional permissions for Systems Manager Parameter Store. For more information, see [Amazon ECS task execution IAM role](#).

- For Windows tasks that are configured to use the awslogs logging driver, you must also set the ECS\_ENABLE\_AWSLOGS\_EXECUTIONROLE\_OVERRIDE environment variable on your container instance. Use the following syntax:

```
<powershell>
[Environment]::SetEnvironmentVariable("ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE",
$TRUE, "Machine")
Initialize-ECSAgent -Cluster <cluster name> -EnableTaskIAMRole -LoggingDrivers
'["json-file","awslogs"]'
</powershell>
```

## Create the Systems Manager parameter

You can use the Systems Manager console to create a Systems Manager Parameter Store parameter for your sensitive data. For more information, see [Create a Systems Manager parameter \(console\)](#) or [Create a Systems Manager parameter \(AWS CLI\)](#) in the *AWS Systems Manager User Guide*.

## Add the environment variable to the container definition

Within your container definition in the task definition, specify secrets with the name of the environment variable to set in the container and the full ARN of the Systems Manager Parameter Store parameter containing the sensitive data to present to the container. For more information, see [secrets](#).

The following is a snippet of a task definition showing the format when referencing a Systems Manager Parameter Store parameter. If the Systems Manager Parameter Store parameter exists in the same Region as the task you are launching, then you can use either the full ARN or name of the parameter. If the parameter exists in a different Region, then specify the full ARN.

```
{
  "containerDefinitions": [{
    "secrets": [{
      "name": "environment_variable_name",
      "valueFrom": "arn:aws:ssm:region:aws_account_id:parameter/parameter_name"
    }]
  }]
}
```

For information about how to create a task definition with the secret specified in an environment variable, see [Creating an Amazon ECS task definition using the console](#).

## Update your application to programmatically retrieve Systems Manager Parameter Store secrets

To retrieve the sensitive data stored in the Systems Manager Parameter Store parameter, see [Code examples for Systems Manager using AWS SDKs](#) in the *AWS SDK Code Examples Code Library*.

## Pass secrets for Amazon ECS logging configuration

You can use the `secretOptions` parameter in `logConfiguration` to pass sensitive data used for logging.

You can store the secret in Secrets Manager or Systems Manager.

### Use Secrets Manager

Within your container definition, when specifying a `logConfiguration` you can specify `secretOptions` with the name of the log driver option to set in the container and the full ARN of the Secrets Manager secret containing the sensitive data to present to the container. For more information about creating secrets, see [Create an AWS Secrets Manager](#).

The following is a snippet of a task definition showing the format when referencing an Secrets Manager secret.

```
{
  "containerDefinitions": [{
    "logConfiguration": [{
      "logDriver": "splunk",
      "options": {
        "splunk-url": "https://your_splunk_instance:8088"
      },
      "secretOptions": [{
        "name": "splunk-token",
        "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name-AbCdEf"
      }]
    }]
  }]
}
```

## Add the environment variable to the container definition

Within your container definition, specify `secrets` with the name of the environment variable to set in the container and the full ARN of the Systems Manager Parameter Store parameter containing the sensitive data to present to the container. For more information, see [secrets](#).

The following is a snippet of a task definition showing the format when referencing a Systems Manager Parameter Store parameter. If the Systems Manager Parameter Store parameter exists in the same Region as the task you are launching, then you can use either the full ARN or name of the parameter. If the parameter exists in a different Region, then specify the full ARN.

```
{
  "containerDefinitions": [{
    "secrets": [{
      "name": "environment_variable_name",
      "valueFrom": "arn:aws:ssm:region:aws_account_id:parameter/parameter_name"
    }]
  }]
}
```

For information about how to create a task definition with the secret specified in an environment variable, see [Creating an Amazon ECS task definition using the console](#).

## Use Systems Manager

You can inject sensitive data in a log configuration. Within your container definition, when specifying a `logConfiguration` you can specify `secretOptions` with the name of the log driver option to set in the container and the full ARN of the Systems Manager Parameter Store parameter containing the sensitive data to present to the container.

### Important

If the Systems Manager Parameter Store parameter exists in the same Region as the task you are launching, then you can use either the full ARN or name of the parameter. If the parameter exists in a different Region, then specify the full ARN.

The following is a snippet of a task definition showing the format when referencing a Systems Manager Parameter Store parameter.

```
{
```

```
"containerDefinitions": [{
  "logConfiguration": [{
    "logDriver": "fluentd",
    "options": {
      "tag": "fluentd demo"
    },
    "secretOptions": [{
      "name": "fluentd-address",
      "valueFrom": "arn:aws:ssm:region:aws_account_id:parameter:/parameter_name"
    }]
  }]
}]
}
```

## Specifying sensitive data using Secrets Manager secrets in Amazon ECS

Amazon ECS allows you to inject sensitive data into your containers by storing your sensitive data in AWS Secrets Manager secrets and then referencing them in your container definition. For more information, see [Pass sensitive data to an Amazon ECS container](#).

Learn how to create an Secrets Manager secret, reference the secret in an Amazon ECS task definition, and then verify it worked by querying the environment variable inside a container showing the contents of the secret.

### Prerequisites

This tutorial assumes that the following prerequisites have been completed:

- The steps in [Set up to use Amazon ECS](#) have been completed.
- Your user has the required IAM permissions to create the Secrets Manager and Amazon ECS resources.

### Step 1: Create an Secrets Manager secret

You can use the Secrets Manager console to create a secret for your sensitive data. In this tutorial we will be creating a basic secret for storing a username and password to reference later in a container. For more information, see [Create an AWS Secrets Manager secret](#) in the *AWS Secrets Manager User Guide*.

The **key/value pairs to be stored in this secret** is the environment variable value in your container at the end of the tutorial.

Save the **Secret ARN** to reference in your task execution IAM policy and task definition in later steps.

## Step 2: Add the secrets permissions to the task execution role

In order for Amazon ECS to retrieve the sensitive data from your Secrets Manager secret, you must have the secrets permissions for the task execution role. For more information, see [Secrets Manager or Systems Manager permissions](#).

## Step 3: Create a task definition

You can use the Amazon ECS console to create a task definition that references a Secrets Manager secret.

### To create a task definition that specifies a secret

Use the IAM console to update your task execution role with the required permissions.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task definitions**.
3. Choose **Create new task definition**, **Create new task definition with JSON**.
4. In the JSON editor box, enter the following task definition JSON text, ensuring that you specify the full ARN of the Secrets Manager secret you created in step 1 and the task execution role you updated in step 2. Choose **Save**.

```
5. {
    "executionRoleArn": "arn:aws:iam::aws_account_id:role/ecsTaskExecutionRole",
    "containerDefinitions": [
      {
        "entryPoint": [
          "sh",
          "-c"
        ],
        "portMappings": [
          {
            "hostPort": 80,
            "protocol": "tcp",
            "containerPort": 80
          }
        ],
        "command": [
```

```

        "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample
App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </
head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</
h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in
Amazon ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html &&
httpd-foreground\""
    ],
    "cpu": 10,
    "secrets": [
        {
            "valueFrom":
"arn:aws:secretsmanager:region:aws_account_id:secret:username_value",
            "name": "username_value"
        }
    ],
    "memory": 300,
    "image": "public.ecr.aws/docker/library/httpd:2.4",
    "essential": true,
    "name": "ecs-secrets-container"
  }
],
  "family": "ecs-secrets-tutorial"
}

```

## 6. Choose **Create**.

### Step 4: Create a cluster

You can use the Amazon ECS console to create a cluster containing a container instance to run the task on. If you have an existing cluster with at least one container instance registered to it with the available resources to run one instance of the task definition created for this tutorial you can skip to the next step.

For this tutorial we will be creating a cluster with one `t2.micro` container instance using the Amazon ECS-optimized Amazon Linux 2 AMI.

For information about how to create a cluster for EC2, see [the section called “Creating a cluster for Amazon EC2 workloads”](#).

### Step 5: Run a task

You can use the Amazon ECS console to run a task using the task definition you created. For this tutorial we will be running a task using EC2, using the cluster we created in the previous step.

For information about how to run a task, see [the section called “Running an application as a task”](#).

## Step 6: Verify

You can verify all of the steps were completed successfully and the environment variable was created properly in your container using the following steps.

### To verify that the environment variable was created

1. Find the public IP or DNS address for your container instance.
  - a. Open the console at <https://console.aws.amazon.com/ecs/v2>.
  - b. In the navigation pane, choose **Clusters**, and then choose the cluster you created.
  - c. Choose **Infrastructure**, and then choose the container instance.
  - d. Record the **Public IP** or **Public DNS** for your instance.
2. If you are using a macOS or Linux computer, connect to your instance with the following command, substituting the path to your private key and the public address for your instance:

```
$ ssh -i /path/to/my-key-pair.pem ec2-user@ec2-198-51-100-1.compute-1.amazonaws.com
```

For more information about using a Windows computer, see [Connect to your Linux instance using PuTTY](#) in the *Amazon EC2 User Guide*.

#### Important

For more information about any issues while connecting to your instance, see [Troubleshooting Connecting to Your Instance](#) in the *Amazon EC2 User Guide*.

3. List the containers running on the instance. Note the container ID for `ecs-secrets-tutorial` container.

```
docker ps
```

4. Connect to the `ecs-secrets-tutorial` container using the container ID from the output of the previous step.

```
docker exec -it container_ID /bin/bash
```

5. Use the `echo` command to print the value of the environment variable.

```
echo $username_value
```

If the tutorial was successful, you should see the following output:

```
password_value
```

 **Note**

Alternatively, you can list all environment variables in your container using the `env` (or `printenv`) command.

## Step 7: Clean up

When you are finished with this tutorial, you should clean up the associated resources to avoid incurring charges for unused resources.

### To clean up the resources

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster.
4. Choose **Delete Cluster**.
5. In the confirmation box, enter **delete *cluster name***, and then choose **Delete**.
6. Open the IAM console at <https://console.aws.amazon.com/iam/>.
7. In the navigation pane, choose **Roles**.
8. Search the list of roles for `ecsTaskExecutionRole` and select it.
9. Choose **Permissions**, then choose the **X** next to **ECSSecretsTutorial**. Choose **Remove**.
10. Open the Secrets Manager console at <https://console.aws.amazon.com/secretsmanager/>.
11. Select the **username\_value** secret you created and choose **Actions, Delete secret**.

# Amazon ECS task definition parameters for Amazon ECS Managed Instances

Task definitions are split into separate parts: the task family, the AWS Identity and Access Management (IAM) task role, the network mode, container definitions, volumes, and capacity. The family and container definitions are required in a task definition. In contrast, task role, network mode, volumes, and capacity are optional.

You can use these parameters in a JSON file to configure your task definition.

The following are more detailed descriptions for each task definition parameter for Amazon ECS Managed Instances.

## Family

family

Type: String

Required: Yes

When you register a task definition, you give it a family, which is similar to a name for multiple versions of the task definition, specified with a revision number. The first task definition that's registered into a particular family is given a revision of 1, and any task definitions registered after that are given a sequential revision number.

## Capacity

When you register a task definition, you can specify the capacity that Amazon ECS should validate the task definition against. If the task definition doesn't validate against the compatibilities specified, a client exception is returned. For more information, see [Amazon ECS launch types](#).

The following parameter is allowed in a task definition.

requiresCompatibilities

Type: String array

Required: No

Valid Values: MANAGED\_INSTANCES

The capacity to validate the task definition against. This initiates a check to ensure that all of the parameters that are used in the task definition meet the requirements for Amazon ECS Managed Instances.

## Task role

`taskRoleArn`

Type: String

Required: No

When you register a task definition, you can provide a task role for an IAM role that allows the containers in the task permission to call the AWS APIs that are specified in its associated policies on your behalf. For more information, see [Amazon ECS task IAM role](#).

## Task execution role

`executionRoleArn`

Type: String

Required: Conditional

The Amazon Resource Name (ARN) of the task execution role that grants the Amazon ECS container agent permission to make AWS API calls on your behalf. For more information, see [Amazon ECS task execution IAM role](#).

### Note

The task execution IAM role is required depending on the requirements of your task. The role is required for private ECR image pulls and using the `awslogs` log driver.

## Network mode

`networkMode`

Type: String

Required: No

Default: awsvpc

The networking mode to use for the containers in the task. For Amazon ECS tasks that are hosted on Amazon ECS Managed Instances, the valid values are awsvpc and host. If no network mode is specified, the default network mode is awsvpc.

If the network mode is host, the task bypasses network isolation and containers use the host's network stack directly.

 **Important**

When running tasks that use the host network mode, do not run containers using the root user (UID 0) for better security. As a security best practice, always use a non-root user.

If the network mode is awsvpc, the task is allocated an elastic network interface, and you must specify a `NetworkConfiguration` when you create a service or run a task with the task definition. For more information, see [Amazon ECS task networking for Amazon ECS Managed Instances](#).

The host and awsvpc network modes offer the highest networking performance for containers because they use the Amazon EC2 network stack. With the host and awsvpc network modes, exposed container ports are mapped directly to the corresponding host port (for the host network mode) or the attached elastic network interface port (for the awsvpc network mode). Because of this, you can't use dynamic host port mappings.

## Runtime platform

`operatingSystemFamily`

Type: String

Required: No

Default: LINUX

When you register a task definition, you specify the operating system family.

The valid value for this field is LINUX.

All task definitions that are used in a service must have the same value for this parameter.

When a task definition is part of a service, this value must match the service platformFamily value.

## cpuArchitecture

Type: String

Required: Conditional

When you register a task definition, you specify the CPU architecture. The valid values are X86\_64 and ARM64.

If you don't specify a value, Amazon ECS attempts to place tasks on the available CPU architecture based on the capacity provider configuration. To ensure that tasks are placed on a specific CPU architecture, specify a value for cpuArchitecture in the task definition.

All task definitions that are used in a service must have the same value for this parameter.

For more information about ARM64, see [the section called “Task definitions for 64-bit ARM workloads”](#).

## Task size

When you register a task definition, you can specify the total CPU and memory used for the task. This is separate from the cpu and memory values at the container definition level. For tasks that are hosted on Amazon EC2 instances, these fields are optional.

### Note

Task-level CPU and memory parameters are ignored for Windows containers. We recommend specifying container-level resources for Windows containers.

## cpu

Type: String

**Required: Conditional**

The hard limit of CPU units to present for the task. You can specify CPU values in the JSON file as a string in CPU units or virtual CPUs (vCPUs). For example, you can specify a CPU value either as 1024 in CPU units or 1 vCPU in vCPUs. When the task definition is registered, a vCPU value is converted to an integer indicating the CPU units.

This field is optional. If your cluster doesn't have any registered container instances with the requested CPU units available, the task fails. Supported values are between 0.125 vCPUs and 10 vCPUs.

**memory**

Type: String

**Required: Conditional**

The hard limit of memory to present to the task. You can specify memory values in the task definition as a string in mebibytes (MiB) or gigabytes (GB). For example, you can specify a memory value either as 3072 in MiB or 3 GB in GB. When the task definition is registered, a GB value is converted to an integer indicating the MiB.

This field is optional and any value can be used. If a task-level memory value is specified, then the container-level memory value is optional. If your cluster doesn't have any registered container instances with the requested memory available, the task fails. You can maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type. For more information, see [Reserving Amazon ECS Linux container instance memory](#).

## Other task definition parameters

The following task definition parameters can be used when registering task definitions in the Amazon ECS console by using the **Configure via JSON** option. For more information, see [Creating an Amazon ECS task definition using the console](#).

**Topics**

- [Ephemeral storage](#)
- [IPC mode](#)

- [PID mode](#)
- [Proxy configuration](#)
- [Tags](#)
- [Elastic Inference accelerator \(deprecated\)](#)
- [Placement constraints](#)
- [Volumes](#)

## Ephemeral storage

`ephemeralStorage`

### Note

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: [EphemeralStorage](#) object

Required: No

The amount of ephemeral storage (in GB) to allocate for the task. This parameter is used to expand the total amount of ephemeral storage available, beyond the default amount, for tasks that are hosted on AWS Fargate. For more information, see [the section called “Bind mounts”](#).

## IPC mode

`ipcMode`

Type: String

Required: No

The IPC resource namespace to use for the containers in the task. The valid values are `host`, `task`, or `none`. If `host` is specified, then all the containers that are within the tasks that specified the `host` IPC mode on the same container instance share the same IPC resources with the host Amazon EC2 instance. If `task` is specified, all the containers that are within the specified task share the same IPC resources. If `none` is specified, then IPC resources within the containers of a task are private and not shared with other containers in a task or on the

container instance. If no value is specified, then the IPC resource namespace sharing depends on the container runtime configuration.

## PID mode

pidMode

Type: String

Required: No

The process namespace to use for the containers in the task. The valid values are `host` or `task`. If `host` is specified, then all the containers that are within the tasks that specified the `host` PID mode on the same container instance share the same process namespace with the host Amazon EC2 instance. If `task` is specified, all the containers that are within the specified task share the same process namespace. If no value is specified, the default is a private namespace.

If the `host` PID mode is used, there's a heightened risk of undesired process namespace exposure.

## Proxy configuration

proxyConfiguration

### Note

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: [ProxyConfiguration](#) object

Required: No

The configuration details for the App Mesh proxy.

## Tags

The metadata that you apply to a task definition to help you categorize and organize them. Each tag consists of a key and an optional value. You define both of them.

The following basic restrictions apply to tags:

- Maximum number of tags per resource - 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length - 128 Unicode characters in UTF-8
- Maximum value length - 256 Unicode characters in UTF-8
- If your tagging schema is used across multiple services and resources, remember that other services may have restrictions on allowed characters. Generally allowed characters are: letters, numbers, and spaces representable in UTF-8, and the following characters: + - = . \_ : / @.
- Tag keys and values are case-sensitive.
- Don't use `aws:`, `AWS:`, or any upper or lowercase combination of such as a prefix for either keys or values as it is reserved for AWS use. You can't edit or delete tag keys or values with this prefix. Tags with this prefix do not count against your tags per resource limit.

key

Type: String

Required: No

One part of a key-value pair that make up a tag. A key is a general label that acts like a category for more specific tag values.

value

Type: String

Required: No

The optional part of a key-value pair that make up a tag. A value acts as a descriptor within a tag category (key).

## Elastic Inference accelerator (deprecated)

### Note

Amazon Elastic Inference (EI) is no longer available to customers.

## inferenceAccelerator

### Note

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: [InferenceAccelerator](#) object

Required: No

The Elastic Inference accelerators to use for the containers in the task.

## Placement constraints

### placementConstraints

Type: Array of [TaskDefinitionPlacementConstraint](#) objects

Required: No

An array of placement constraint objects to use for the task. You can specify a maximum of 10 constraints per task (this limit includes constraints in the task definition and those specified at runtime).

Amazon ECS supports the `distinctInstance` and `memberOf` placement constraints for tasks running on Amazon ECS Managed Instances. The following attributes are supported for tasks that use the `memberOf` placement constraint:

- `ecs.subnet-id`
- `ecs.availability-zone`
- `ecs.cpu-architecture`
- `ecs.instance-type`

For more information about placement constraints, see [Define which container instances Amazon ECS uses for tasks](#).

## Volumes

When you register a task definition, you can optionally specify a list of volumes for your tasks. This allows you to use data volumes in your tasks.

For more information about volume types and other parameters, see [the section called “Storage options for tasks”](#).

name

Type: String

Required: Yes

The name of the volume. Up to 255 letters (uppercase and lowercase), numbers, and hyphens are allowed. This name is referenced in the `sourceVolume` parameter of container definition `mountPoints`.

host

Type: [HostVolumeProperties](#) object

Required: No

This parameter is specified when you're using bind mount host volumes. The contents of the `host` parameter determine whether your bind mount host volume persists on the host container instance and where it's stored. If the `host` parameter is empty, then the system assigns a host path for your data volume. However, the data isn't guaranteed to persist after the containers that are associated with it stop running.

sourcePath

Type: String

Required: No

When the `host` parameter is used, specify a `sourcePath` to declare the path on the host instance that is presented to the container. If this parameter is empty, then the system assigns a host path for you. If the `host` parameter contains a `sourcePath` file location, then the data volume persists at the specified location on the host instance until you delete it manually. If the `sourcePath` value does not exist on the host instance, the system creates it. If the location does exist, the contents of the source path folder are exported.

On Amazon ECS Managed Instances, portions of the host filesystem are read-only. The `sourcePath` must point to a writable directory such as `/var` or `/tmp`. For more information, see [Use bind mounts with Amazon ECS](#).

#### `dockerVolumeConfiguration`

 **Note**

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: [DockerVolumeConfiguration](#) object

Required: No

This parameter is specified when you're using Docker volumes.

#### `efsVolumeConfiguration`

Type: [EFSVolumeConfiguration](#) object

Required: No

This parameter is specified when you're using an Amazon EFS file system for task storage.

#### `fsxWindowsFileServerVolumeConfiguration`

 **Note**

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: [FSxWindowsFileServerVolumeConfiguration](#) object

Required: No

This parameter is specified when you're using Amazon FSx for Windows File Server file system for task storage.

#### `configuredAtLaunch`

Type: Boolean

Required: No

Indicates whether the volume should be configured at launch time. This is used to create Amazon EBS volumes for standalone tasks or tasks created as part of a service. Each task definition revision may only have one volume configured at launch in the volume configuration.

## Container definitions

When you register a task definition, you must specify a list of container definitions that are passed to the Docker daemon on a container instance. The following parameters are allowed in a container definition.

### Topics

- [Name](#)
- [Image](#)
- [Memory](#)
- [CPU](#)
- [Port mappings](#)
- [Private Repository Credentials](#)
- [Essential](#)
- [Entry point](#)
- [Command](#)
- [Working directory](#)
- [Advanced container definition parameters](#)
- [Linux parameters](#)

### Name

name

Type: String

Required: Yes

The name of a container. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed. If you're linking multiple containers in a task definition, the name

of one container can be entered in the links of another container. This is to connect the containers.

## Image

image

Type: String

Required: Yes

The image used to start a container. This string is passed directly to the Docker daemon. By default, images in the Docker Hub registry are available. You can also specify other repositories with either *repository-url/image:tag* or *repository-url/image@digest*. Up to 255 letters (uppercase and lowercase), numbers, hyphens, underscores, colons, periods, forward slashes, and number signs are allowed. This parameter maps to Image in the docker create-container command and the IMAGE parameter of the Docker run command.

- When a new task starts, the Amazon ECS container agent pulls the latest version of the specified image and tag for the container to use. However, subsequent updates to a repository image aren't propagated to already running tasks.
- When you don't specify a tag or digest in the image path in the task definition, the Amazon ECS container agent uses the latest tag to pull the specified image.
- Subsequent updates to a repository image aren't propagated to already running tasks.
- Images in private registries are supported. For more information, see [Using non-AWS container images in Amazon ECS](#).
- Images in Amazon ECR repositories can be specified by using either the full registry/repository:tag or registry/repository@digest naming convention (for example, *aws\_account\_id.dkr.ecr.region.amazonaws.com/my-web-app:latest* or *aws\_account\_id.dkr.ecr.region.amazonaws.com/my-web-app@sha256:94afd1f2e64d908bc90dbca0035a5b567EXAMPLE*).
- Images in official repositories on Docker Hub use a single name (for example, ubuntu or mongo).
- Images in other repositories on Docker Hub are qualified with an organization name (for example, amazon/amazon-ecs-agent).
- Images in other online repositories are qualified further by a domain name (for example, quay.io/assemblyline/ubuntu).

## versionConsistency

Type: String

Valid values: enabled|disabled

Required: No

Specifies whether Amazon ECS will resolve the container image tag provided in the container definition to an image digest. By default, this behavior is enabled. If you set the value for a container as disabled, Amazon ECS will not resolve the container image tag to a digest and will use the original image URI specified in the container definition for deployment. For more information about container image resolution, see [Container image resolution](#).

## Memory

### memory

Type: Integer

Required: No

The amount (in MiB) of memory to present to the container. If your container attempts to exceed the memory specified here, the container is killed. The total amount of memory reserved for all containers within a task must be lower than the task memory value, if one is specified. This parameter maps to Memory in the docker create-container command and the --memory option to docker run.

The Docker 20.10.0 or later daemon reserves a minimum of 6 MiB of memory for a container. So, don't specify less than 6 MiB of memory for your containers.

The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container. So, don't specify less than 4 MiB of memory for your containers.

#### Note

If you're trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see [Reserving Amazon ECS Linux container instance memory](#).

## memoryReservation

Type: Integer

Required: No

The soft limit (in MiB) of memory to reserve for the container. When system memory is under contention, Docker attempts to keep the container memory to this soft limit. However, your container can use more memory when needed. The container can use up to the hard limit that's specified with the `memory` parameter (if applicable) or all of the available memory on the container instance, whichever comes first. This parameter maps to `MemoryReservation` in the `docker create-container` command and the `--memory-reservation` option to `docker run`.

If a task-level memory value isn't specified, you must specify a non-zero integer for one or both of `memory` or `memoryReservation` in a container definition. If you specify both, `memory` must be greater than `memoryReservation`. If you specify `memoryReservation`, then that value is subtracted from the available memory resources for the container instance that the container is placed on. Otherwise, the value of `memory` is used.

For example, suppose that your container normally uses 128 MiB of memory, but occasionally bursts to 256 MiB of memory for short periods of time. You can set a `memoryReservation` of 128 MiB, and a `memory` hard limit of 300 MiB. This configuration allows the container to only reserve 128 MiB of memory from the remaining resources on the container instance. At the same time, this configuration also allows the container to use more memory resources when needed.

The Docker 20.10.0 or later daemon reserves a minimum of 6 MiB of memory for a container. So, don't specify less than 6 MiB of memory for your containers.

The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container. So, don't specify less than 4 MiB of memory for your containers.

### Note

If you're trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see [Reserving Amazon ECS Linux container instance memory](#).

## CPU

cpu

Type: Integer

Required: No

The number of cpu units reserved for the container. This parameter maps to CpuShares in the docker create-container command and the `--cpu-shares` option to docker run.

This field is optional for tasks using EC2 capacity providers, and the only requirement is that the total amount of CPU reserved for all containers within a task be lower than the task-level cpu value.

### Note

You can determine the number of CPU units that are available per EC2 instance type by multiplying the vCPUs listed for that instance type on the [Amazon EC2 Instances](#) detail page by 1,024.

Linux containers share unallocated CPU units with other containers on the container instance with the same ratio as their allocated amount. For example, if you run a single-container task on a single-core instance type with 512 CPU units specified for that container, and that's the only task running on the container instance, that container could use the full 1,024 CPU units at any given time. However, if you launched another copy of the same task on that container instance, each task is guaranteed a minimum of 512 CPU units when needed. Moreover, each container could float to higher CPU usage if the other container was not using it. If both tasks were 100% active all of the time, they would be limited to 512 CPU units.

On Linux container instances, the Docker daemon on the container instance uses the CPU value to calculate the relative CPU share ratios for running containers. For more information, see [CPU share constraint](#) in the Docker documentation. The minimum valid CPU share value that the Linux kernel allows is 2. However, the CPU parameter isn't required, and you can use CPU values below 2 in your container definitions. For CPU values below 2 (including null), the behavior varies based on your Amazon ECS container agent version:

- **Agent versions less than or equal to 1.1.0:** Null and zero CPU values are passed to Docker as 0, which Docker then converts to 1,024 CPU shares. CPU values of 1 are passed to Docker as 1, which the Linux kernel converts to two CPU shares.
- **Agent versions greater than or equal to 1.2.0:** Null, zero, and CPU values of 1 are passed to Docker as 2.

On Windows container instances, the CPU limit is enforced as an absolute limit, or a quota. Windows containers only have access to the specified amount of CPU that's described in the task definition. A null or zero CPU value is passed to Docker as 0, which Windows interprets as 1% of one CPU.

## Port mappings

portMappings

Type: Object array

Required: No

Port mappings expose your container's network ports to the outside world. This allows clients to access your application. It's also used for inter-container communication within the same task.

For task definitions that use the `awsvpc` network mode, only specify the `containerPort`. The `hostPort` is always ignored, and the container port is automatically mapped to a random high-numbered port on the host.

Most fields of this parameter (including `containerPort`, `hostPort`, `protocol`) map to `PortBindings` in the `docker create-container` command and the `--publish` option to `docker run`. If the network mode of a task definition is set to `host`, host ports must either be undefined or match the container port in the port mapping.

### Note

After a task reaches the `RUNNING` status, manual and automatic host and container port assignments are visible in the following locations:

- Console: The **Network Bindings** section of a container description for a selected task.
- AWS CLI: The `networkBindings` section of the **describe-tasks** command output.
- API: The `DescribeTasks` response.

- **Metadata:** The task metadata endpoint.

## appProtocol

Type: String

Required: No

The application protocol that's used for the port mapping. This parameter only applies to Service Connect. We recommend that you set this parameter to be consistent with the protocol that your application uses. If you set this parameter, Amazon ECS adds protocol-specific connection handling to the service connect proxy. If you set this parameter, Amazon ECS adds protocol-specific telemetry in the Amazon ECS console and CloudWatch.

If you don't set a value for this parameter, then TCP is used. However, Amazon ECS doesn't add protocol-specific telemetry for TCP.

For more information, see [the section called "Service Connect"](#).

Valid protocol values: "HTTP" | "HTTP2" | "GRPC"

## containerPort

Type: Integer

Required: Yes, when portMappings are used

The port number on the container that's bound to the user-specified or automatically assigned host port.

For tasks that use the awsvpc network mode, you use containerPort to specify the exposed ports.

## containerPortRange

Type: String

Required: No

The port number range on the container that's bound to the dynamically mapped host port range.

You can only set this parameter by using the `register-task-definition` API. The option is available in the `portMappings` parameter. For more information, see [register-task-definition](#) in the *AWS Command Line Interface Reference*.

The following rules apply when you specify a `containerPortRange`:

- You must use the `awsvpc` network mode.
- The container instance must have at least version 1.67.0 of the container agent and at least version 1.67.0-1 of the `ecs-init` package.
- You can specify a maximum of 100 port ranges for each container.
- You don't specify a `hostPortRange`. The value of the `hostPortRange` is set as follows:
  - For containers in a task with the `awsvpc` network mode, the `hostPort` is set to the same value as the `containerPort`. This is a static mapping strategy.
- The `containerPortRange` valid values are between 1 and 65535.
- A port can only be included in one port mapping for each container.
- You can't specify overlapping port ranges.
- The first port in the range must be less than last port in the range.
- Docker recommends that you turn off the Docker-proxy in the Docker daemon config file when you have a large number of ports.

For more information, see [Issue #11185](#) on GitHub.

For information about how to turn off the docker-proxy in the Docker daemon config file, see [Docker daemon](#) in the *Amazon ECS Developer Guide*.

You can call [DescribeTasks](#) to view the `hostPortRange`, which are the host ports that are bound to the container ports.

The port ranges aren't included in the Amazon ECS task events, which are sent to EventBridge. For more information, see [the section called "Automate responses to Amazon ECS errors using EventBridge"](#).

## `hostPortRange`

Type: String

Required: No

The port number range on the host that's used with the network binding. This is assigned by Docker and delivered by the Amazon ECS agent.

## hostPort

Type: Integer

Required: No

The port number on the container instance to reserve for your container.

The hostPort can either be kept blank or be the same value as containerPort.

The default ephemeral port range Docker version 1.6.0 and later is listed on the instance under `/proc/sys/net/ipv4/ip_local_port_range`. If this kernel parameter is unavailable, the default ephemeral port range from 49153–65535 is used. Don't attempt to specify a host port in the ephemeral port range. This is because these are reserved for automatic assignment. In general, ports under 32768 are outside of the ephemeral port range.

The default reserved ports are 22 for SSH, the Docker ports 2375 and 2376, and the Amazon ECS container agent ports 51678–51680. Any host port that was previously user-specified for a running task is also reserved while the task is running. After a task stops, the host port is released. The current reserved ports are displayed in the `remainingResources` of **describe-container-instances** output. A container instance might have up to 100 reserved ports at a time, including the default reserved ports. Automatically assigned ports don't count toward the 100 reserved ports quota.

## name

Type: String

Required: No, required for Service Connect and VPC Lattice to be configured in a service

The name that's used for the port mapping. This parameter only applies to Service Connect and VPC Lattice. This parameter is the name that you use in the Service Connect and VPC Lattice configuration of a service.

For more information, see [Use Service Connect to connect Amazon ECS services with short names](#).

In the following example, both of the required fields for Service Connect and VPC Lattice are used.

```
"portMappings": [  
  {  
    "name": string,  
    "containerPort": integer  
  }  
]
```

## protocol

Type: String

Required: No

The protocol that's used for the port mapping. Valid values are `tcp` and `udp`. The default is `tcp`.

### Important

Only `tcp` is supported for Service Connect. Remember that `tcp` is implied if this field isn't set.

If you're specifying a host port, use the following syntax.

```
"portMappings": [  
  {  
    "containerPort": integer,  
    "hostPort": integer  
  }  
  ...  
]
```

If you want an automatically assigned host port, use the following syntax.

```
"portMappings": [  
  {  
    "containerPort": integer  
  }  
  ...  
]
```

## Private Repository Credentials

repositoryCredentials

Type: [RepositoryCredentials](#) object

Required: No

The repository credentials for private registry authentication.

For more information, see [Using non-AWS container images in Amazon ECS](#).

credentialsParameter

Type: String

Required: Yes, when repositoryCredentials are used

The Amazon Resource Name (ARN) of the secret containing the private repository credentials.

For more information, see [Using non-AWS container images in Amazon ECS](#).

### Note

When you use the Amazon ECS API, AWS CLI, or AWS SDKs, if the secret exists in the same Region as the task that you're launching then you can use either the full ARN or the name of the secret. When you use the AWS Management Console, you must specify the full ARN of the secret.

The following is a snippet of a task definition that shows the required parameters:

```
"containerDefinitions": [  
  {  
    "image": "private-repo/private-image",  
    "repositoryCredentials": {  
      "credentialsParameter":  
        "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name"  
    }  
  }  
]
```

```
]
```

## Essential

`essential`

Type: Boolean

Required: No

If the `essential` parameter of a container is marked as `true`, and that container fails or stops for any reason, all other containers that are part of the task are stopped. If the `essential` parameter of a container is marked as `false`, its failure doesn't affect the rest of the containers in a task. If this parameter is omitted, a container is assumed to be essential.

All tasks must have at least one essential container. If you have an application that's composed of multiple containers, group containers that are used for a common purpose into components, and separate the different components into multiple task definitions. For more information, see [the section called “Architect your application”](#).

## Entry point

`entryPoint`

Type: String array

Required: No

The entry point that's passed to the container. This parameter maps to `Entrypoint` in the `docker create-container` command and the `--entrypoint` option to `docker run`.

```
"entryPoint": ["string", ...]
```

## Command

`command`

Type: String array

Required: No

The command that's passed to the container. This parameter maps to `Cmd` in the `docker create-container` command and the `COMMAND` parameter to `docker run`. If there are multiple arguments, each argument is a separated string in the array.

```
"command": ["string", ...]
```

## Working directory

`workingDirectory`

Type: String

Required: No

The working directory to run commands inside the container in. This parameter maps to `WorkingDir` in the `docker create-container` command and the `--workdir` option to `docker run`.

## Advanced container definition parameters

The following advanced container definition parameters provide extended capabilities to the `Docker run` command that's used to launch containers on your Amazon ECS container instances.

### Topics

- [Restart policy](#)
- [Health check](#)
- [Environment](#)
- [Security](#)
- [Network settings](#)
- [Storage and logging](#)
- [Resource requirements](#)
- [Container timeouts](#)
- [Container dependency](#)

- [System controls](#)
- [Interactive](#)
- [Pseudo terminal](#)

## Restart policy

### `restartPolicy`

The container restart policy and associated configuration parameters. When you set up a restart policy for a container, Amazon ECS can restart the container without needing to replace the task. For more information, see [Restart individual containers in Amazon ECS tasks with container restart policies](#).

#### `enabled`

Type: Boolean

Required: Yes

Specifies whether a restart policy is enabled for the container.

#### `ignoredExitCodes`

Type: Integer array

Required: No

A list of exit codes that Amazon ECS will ignore and not attempt a restart on. You can specify a maximum of 50 container exit codes. By default, Amazon ECS does not ignore any exit codes.

#### `restartAttemptPeriod`

Type: Integer

Required: No

A period of time (in seconds) that the container must run for before a restart can be attempted. A container can be restarted only once every `restartAttemptPeriod` seconds. If a container isn't able to run for this time period and exits early, it will not be restarted. You can set a minimum `restartAttemptPeriod` of 60 seconds and a maximum

restartAttemptPeriod of 1800 seconds. By default, a container must run for 300 seconds before it can be restarted.

## Health check

### healthCheck

The container health check command and the associated configuration parameters for the container. For more information, see [Determine Amazon ECS task health using container health checks](#).

#### command

A string array that represents the command that the container runs to determine if it's healthy. The string array can start with `CMD` to run the command arguments directly, or `CMD-SHELL` to run the command with the container's default shell. If neither is specified, `CMD` is used.

When registering a task definition in the AWS Management Console, use a comma separated list of commands. These commands are converted to a string after the task definition is created. An example input for a health check is the following.

```
CMD-SHELL, curl -f http://localhost/ || exit 1
```

When registering a task definition using the AWS Management Console JSON panel, the AWS CLI, or the APIs, enclose the list of commands in brackets. An example input for a health check is the following.

```
[ "CMD-SHELL", "curl -f http://localhost/ || exit 1" ]
```

An exit code of 0, with no `stderr` output, indicates success, and a non-zero exit code indicates failure.

#### interval

The period of time (in seconds) between each health check. You can specify between 5 and 300 seconds. The default value is 30 seconds.

#### timeout

The period of time (in seconds) to wait for a health check to succeed before it's considered a failure. You can specify between 2 and 60 seconds. The default value is 5 seconds.

## retries

The number of times to retry a failed health check before the container is considered unhealthy. You can specify between 1 and 10 retries. The default value is three retries.

## startPeriod

The optional grace period to provide containers time to bootstrap in before failed health checks count towards the maximum number of retries. You can specify a value between 0 and 300 seconds. By default, `startPeriod` is disabled.

If a health check succeeds within the `startPeriod`, then the container is considered healthy and any subsequent failures count toward the maximum number of retries.

## Environment

### cpu

Type: Integer

Required: No

The number of `cpu` units the Amazon ECS container agent reserves for the container. On Linux, this parameter maps to `CpuShares` in the [Create a container](#) section.

This field is optional for tasks that run on Amazon ECS Managed Instances. The total amount of CPU reserved for all the containers that are within a task must be lower than the task-level `cpu` value.

Linux containers share unallocated CPU units with other containers on the container instance with the same ratio as their allocated amount. For example, assume that you run a single-container task on a single-core instance type with 512 CPU units specified for that container. Moreover, that task is the only task running on the container instance. In this example, the container can use the full 1,024 CPU unit share at any given time. However, assume then that you launched another copy of the same task on that container instance. Each task is guaranteed a minimum of 512 CPU units when needed. Similarly, if the other container isn't using the remaining CPU, each container can float to higher CPU usage. However, if both tasks were 100% active all of the time, they are limited to 512 CPU units.

On Linux container instances, the Docker daemon on the container instance uses the CPU value to calculate the relative CPU share ratios for running containers. The minimum valid CPU share

value that the Linux kernel allows is 2, and the maximum valid CPU share value that the Linux kernel allows is 262144. However, the CPU parameter isn't required, and you can use CPU values below two and above 262144 in your container definitions. For CPU values below two (including null) and above 262144, the behavior varies based on your Amazon ECS container agent version:

For more examples, see [How Amazon ECS manages CPU and memory resources](#).

## gpu

Type: [ResourceRequirement](#) object

Required: No

The number of physical GPUs that the Amazon ECS container agent reserves for the container. You can specify an integer value, a decimal value for fractional GPUs, or ALL. When you specify ALL, all GPUs on the container instance are allocated to the container. When you specify a decimal value (such as 0.125, 0.25, or 0.5), Amazon ECS places the task on a fractional GPU instance (G6f) that provides the requested GPU capacity. The number of GPUs reserved for all containers in a task must not exceed the number of available GPUs on the container instance the task is launched on. For more information, see [Amazon ECS task definitions for GPU workloads](#).

## Neuron device

Type: [ResourceRequirement](#) object

Required: No

The Neuron devices that the Amazon ECS container agent reserves for the container. The only supported value is ALL, which gives the container exclusive access to all Neuron devices on the instance. For more information, see [Amazon ECS task definitions for AWS Neuron machine learning workloads](#).

## Elastic Inference accelerator

### Note

This parameter isn't supported for containers that are hosted on Amazon ECS Managed Instances.

Type: [ResourceRequirement](#) object

Required: No

For the `InferenceAccelerator` type, the value matches the `deviceName` for an `InferenceAccelerator` specified in a task definition. For more information, see [the section called “Elastic Inference accelerator name \(deprecated\)”](#).

## `essential`

Type: Boolean

Required: No

Suppose that the `essential` parameter of a container is marked as `true`, and that container fails or stops for any reason. Then, all other containers that are part of the task are stopped. If the `essential` parameter of a container is marked as `false`, then its failure doesn't affect the rest of the containers in a task. If this parameter is omitted, a container is assumed to be `essential`.

All tasks must have at least one essential container. Suppose that you have an application that's composed of multiple containers. Then, group containers that are used for a common purpose into components, and separate the different components into multiple task definitions. For more information, see [Architect your application for Amazon ECS](#).

```
"essential": true|false
```

## `entryPoint`

### Important

Early versions of the Amazon ECS container agent don't properly handle `entryPoint` parameters. If you have problems using `entryPoint`, update your container agent or enter your commands and arguments as command array items instead.

Type: String array

Required: No

The entry point that's passed to the container.

```
"entryPoint": ["string", ...]
```

## command

Type: String array

Required: No

The command that's passed to the container. This parameter maps to `Cmd` in the `create-container` command and the `COMMAND` parameter to `docker run`. If there are multiple arguments, make sure that each argument is a separated string in the array.

```
"command": ["string", ...]
```

## workingDirectory

Type: String

Required: No

The working directory to run commands inside the container in. This parameter maps to `WorkingDir` in the [Create a container](#) section of the [Docker Remote API](#) and the `--workdir` option to [docker run](#).

```
"workingDirectory": "string"
```

## environmentFiles

Type: Object array

Required: No

A list of files containing the environment variables to pass to a container. This parameter maps to the `--env-file` option to the `Docker run` command.

You can specify up to 10 environment files. The file must have a `.env` file extension. Each line in an environment file contains an environment variable in `VARIABLE=VALUE` format. Lines that start with `#` are treated as comments and are ignored.

If there are individual environment variables specified in the container definition, they take precedence over the variables contained within an environment file. If multiple environment files are specified that contain the same variable, they're processed from the top down. We recommend that you use unique variable names. For more information, see [Pass an individual environment variable to an Amazon ECS container](#).

value

Type: String

Required: Yes

The Amazon Resource Name (ARN) of the Amazon S3 object containing the environment variable file.

type

Type: String

Required: Yes

The file type to use. The only supported value is s3.

environment

Type: Object array

Required: No

The environment variables to pass to a container. This parameter maps to Env in the docker create-container command and the --env option to the docker run command.

 **Important**

We do not recommend using plaintext environment variables for sensitive information, such as credential data.

name

Type: String

Required: Yes, when environment is used

The name of the environment variable.

value

Type: String

Required: Yes, when environment is used

The value of the environment variable.

```
"environment" : [  
  { "name" : "string", "value" : "string" },  
  { "name" : "string", "value" : "string" }  
]
```

## secrets

Type: Object array

Required: No

An object that represents the secret to expose to your container. For more information, see [Pass sensitive data to an Amazon ECS container](#).

name

Type: String

Required: Yes

The value to set as the environment variable on the container.

valueFrom

Type: String

Required: Yes

The secret to expose to the container. The supported values are either the full Amazon Resource Name (ARN) of the AWS Secrets Manager secret or the full ARN of the parameter in the AWS Systems Manager Parameter Store.

### Note

If the Systems Manager Parameter Store parameter or Secrets Manager parameter exists in the same AWS Region as the task that you're launching, you can use either the full ARN or name of the secret. If the parameter exists in a different Region, then the full ARN must be specified.

```
"secrets": [  
  {  
    "name": "string",  
    "valueFrom": "string"  
  },  
  {  
    "name": "string",  
    "valueFrom": "string"  
  }  
]
```

```
{
  "name": "environment_variable_name",
  "valueFrom": "arn:aws:ssm:region:aws_account_id:parameter/parameter_name"
}
```

## Security

### privileged

Type: Boolean

Required: No

When this parameter is `true`, the container is given elevated privileges on the host container instance (similar to the `root` user). This parameter maps to `Privileged` in the `docker create-container` command and the `--privileged` option to `docker run`.

### user

Type: String

Required: No

The user to use inside the container. This parameter maps to `User` in the `docker create-container` command and the `--user` option to `docker run`.

#### Important

When running tasks using the host network mode, don't run containers using the root user (UID 0). We recommend using a non-root user for better security.

You can specify the user using the following formats. If specifying a UID or GID, you must specify it as a positive integer.

- `user`
- `user:group`
- `uid`
- `uid:gid`

- `user:gid`
- `uid:group`

`readonlyRootFilesystem`

Type: Boolean

Required: No

When this parameter is `true`, the container is given a read-only root filesystem. This parameter maps to `ReadonlyRootfs` in the `docker create-container` command and the `--read-only` option to `docker run`.

`dockerSecurityOptions`

 **Note**

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: String array

Required: No

A list of strings to provide custom labels for SELinux and AppArmor multi-level security systems. This field isn't valid for containers in tasks using Fargate.

`ulimits`

Type: Array of [Ulimit](#) objects

Required: No

A list of `ulimits` to set in the container. If a `ulimit` value is specified in a task definition, it overrides the default values set by Docker. This parameter maps to `Ulimits` in the `docker create-container` command and the `--ulimit` option to `docker run`. Valid naming values are displayed in the [Ulimit](#) data type.

Amazon ECS tasks that are hosted on Fargate use the default resource limit values set by the operating system with the exception of the `nofile` resource limit parameter which Fargate overrides. The `nofile` resource limit sets a restriction on the number of open files that a container can use. The default `nofile` soft limit is 1024 and the default hard limit is 65535.

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance. To check the Docker Remote API version on your container instance, log in to your container instance and run the following command: `sudo docker version --format '{{.Server.APIVersion}}'`

## `dockerLabels`

Type: String to string map

Required: No

A key/value map of labels to add to the container. This parameter maps to `Labels` in the `docker create-container` command and the `--label` option to `docker run`.

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

```
"dockerLabels": {"string": "string"
  ...}
```

## Network settings

### `disableNetworking`

#### Note

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: Boolean

Required: No

When this parameter is true, networking is off within the container.

The default is false.

```
"disableNetworking": true|false
```

## links

### **Note**

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: String array

Required: No

The `link` parameter allows containers to communicate with each other without the need for port mappings. This parameter is only supported if the network mode of a task definition is set to `bridge`. The `name:internalName` construct is analogous to `name:alias` in Docker links. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed..

### **Important**

Containers that are colocated on the same container instance might communicate with each other without requiring links or host port mappings. The network isolation on a container instance is controlled by security groups and VPC settings.

```
"links": ["name:internalName", ...]
```

## hostname

### **Note**

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: String

Required: No

The hostname to use for your container. This parameter maps to `Hostname` in the `docker create-container` and the `--hostname` option to `docker run`.

```
"hostname": "string"
```

## dnsServers

### Note

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: String array

Required: No

A list of DNS servers that are presented to the container.

```
"dnsServers": ["string", ...]
```

## extraHosts

### Note

This parameter isn't supported for tasks that use the awsvpc network mode.

Type: Object array

Required: No

A list of hostnames and IP address mappings to append to the `/etc/hosts` file on the container.

This parameter maps to `ExtraHosts` in the `docker create-container` command and the `--add-host` option to `docker run`.

```
"extraHosts": [  
  {  
    "hostname": "string",  
    "ipAddress": "string"  
  },  
  ...  
]
```

## hostname

Type: String

Required: Yes, when `extraHosts` are used

The hostname to use in the `/etc/hosts` entry.

## ipAddress

Type: String

Required: Yes, when `extraHosts` are used

The IP address to use in the `/etc/hosts` entry.

## Storage and logging

### readonlyRootFilesystem

Type: Boolean

Required: No

When this parameter is true, the container is given read-only access to its root file system. This parameter maps to `ReadonlyRootfs` in the `docker create-container` command the `--read-only` option to `docker run`.

The default is false.

```
"readonlyRootFilesystem": true|false
```

### mountPoints

Type: Object array

Required: No

The mount points for the data volumes in your container. This parameter maps to `Volumes` in the `create-container Docker API` and the `--volume` option to `docker run`.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`. Windows containers cannot mount directories on a different drive, and mount points cannot be

used across drives. You must specify mount points to attach an Amazon EBS volume directly to an Amazon ECS task.

`sourceVolume`

Type: String

Required: Yes, when `mountPoints` are used

The name of the volume to mount.

`containerPath`

Type: String

Required: Yes, when `mountPoints` are used

The path in the container where the volume will be mounted.

`readOnly`

Type: Boolean

Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

For tasks that run on EC2 instances running the Windows operating system, leave the value as the default of `false`.

`volumesFrom`

Type: Object array

Required: No

Data volumes to mount from another container. This parameter maps to `VolumesFrom` in the `docker create-container` command and the `--volumes-from` option to `docker run`.

`sourceContainer`

Type: String

Required: Yes, when `volumesFrom` is used

The name of the container to mount volumes from.

## readOnly

Type: Boolean

Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

```
"volumesFrom": [  
  {  
    "sourceContainer": "string",  
    "readOnly": true|false  
  }  
]
```

## logConfiguration

Type: [LogConfiguration](#) Object

Required: No

The log configuration specification for the container.

For example task definitions that use a log configuration, see [Example Amazon ECS task definitions](#).

This parameter maps to `LogConfig` in the `docker create-container` command and the `--log-driver` option to `docker run`. By default, containers use the same logging driver that the Docker daemon uses. However, the container might use a different logging driver than the Docker daemon by specifying a log driver with this parameter in the container definition. To use a different logging driver for a container, the log system must be configured properly on the container instance (or on a different log server for remote logging options).

Consider the following when specifying a log configuration for your containers:

- Amazon ECS supports a subset of the logging drivers that are available to the Docker daemon.
- This parameter requires version 1.18 or later of the Docker Remote API on your container instance.

```
"logConfiguration": {
```

```
    "logDriver": "awslogs","splunk", "awsfirelens",
    "options": {"string": "string"
        ...},
    "secretOptions": [{
        "name": "string",
        "valueFrom": "string"
    }]
}
```

## logDriver

Type: String

Valid values: "awslogs","splunk","awsfirelens"

Required: Yes, when logConfiguration is used

The log driver to use for the container. By default, the valid values that are listed earlier are log drivers that the Amazon ECS container agent can communicate with.

The supported log drivers are awslogs, splunk, and awsfirelens.

For more information about how to use the awslogs log driver in task definitions to send your container logs to CloudWatch Logs, see [Send Amazon ECS logs to CloudWatch](#).

For more information about using the awsfirelens log driver, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

### Note

If you have a custom driver that isn't listed, you can fork the Amazon ECS container agent project that's [available on GitHub](#) and customize it to work with that driver. We encourage you to submit pull requests for changes that you want to have included. However, we don't currently support running modified copies of this software.

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

## options

Type: String to string map

Required: No

The key/value map of configuration options to send to the log driver.

The options you can specify depend on the log driver. Some of the options you can specify when you use the `awslogs` router to route logs to Amazon CloudWatch include the following:

`awslogs-create-group`

Required: No

Specify whether you want the log group to be created automatically. If this option isn't specified, it defaults to `false`.

 **Note**

Your IAM policy must include the `logs:CreateLogGroup` permission before you attempt to use `awslogs-create-group`.

`awslogs-region`

Required: Yes

Specify the AWS Region that the `awslogs` log driver is to send your Docker logs to. You can choose to send all of your logs from clusters in different Regions to a single region in CloudWatch Logs. This is so that they're all visible in one location. Otherwise, you can separate them by Region for more granularity. Make sure that the specified log group exists in the Region that you specify with this option.

`awslogs-group`

Required: Yes

Make sure to specify a log group that the `awslogs` log driver sends its log streams to.

`awslogs-stream-prefix`

Required: Yes

Use the `awslogs-stream-prefix` option to associate a log stream with the specified prefix, the container name, and the ID of the Amazon ECS task that the container belongs

to. If you specify a prefix with this option, then the log stream takes the following format.

```
prefix-name/container-name/ecs-task-id
```

If you don't specify a prefix with this option, then the log stream is named after the container ID that's assigned by the Docker daemon on the container instance. Because it's difficult to trace logs back to the container that sent them with just the Docker container ID (which is only available on the container instance), we recommend that you specify a prefix with this option.

For Amazon ECS services, you can use the service name as the prefix. Doing so, you can trace log streams to the service that the container belongs to, the name of the container that sent them, and the ID of the task that the container belongs to.

You must specify a stream-prefix for your logs to have your logs appear in the Log pane when using the Amazon ECS console.

`awslogs-datetime-format`

Required: No

This option defines a multiline start pattern in Python `strftime` format. A log message consists of a line that matches the pattern and any following lines that don't match the pattern. The matched line is the delimiter between log messages.

One example of a use case for using this format is for parsing output such as a stack dump, which might otherwise be logged in multiple entries. The correct pattern allows it to be captured in a single entry.

For more information, see [awslogs-datetime-format](#).

You cannot configure both the `awslogs-datetime-format` and `awslogs-multiline-pattern` options.

 **Note**

Multiline logging performs regular expression parsing and matching of all log messages. This might have a negative impact on logging performance.

## awslogs-multiline-pattern

Required: No

This option defines a multiline start pattern that uses a regular expression. A log message consists of a line that matches the pattern and any following lines that don't match the pattern. The matched line is the delimiter between log messages.

For more information, see [awslogs-multiline-pattern](#).

This option is ignored if `awslogs-datetime-format` is also configured.

You cannot configure both the `awslogs-datetime-format` and `awslogs-multiline-pattern` options.

### Note

Multiline logging performs regular expression parsing and matching of all log messages. This might have a negative impact on logging performance.

## mode

Required: No

Valid values: `non-blocking` | `blocking`

This option defines the delivery mode of log messages from the container to the `awslogs` log driver. The delivery mode you choose affects application availability when the flow of logs from the container is interrupted.

If you use the `blocking` mode and the flow of logs to CloudWatch is interrupted, calls from container code to write to the `stdout` and `stderr` streams will block. The logging thread of the application will block as a result. This may cause the application to become unresponsive and lead to container healthcheck failure.

If you use the `non-blocking` mode, the container's logs are instead stored in an in-memory intermediate buffer configured with the `max-buffer-size` option. This prevents the application from becoming unresponsive when logs cannot be sent to CloudWatch. We recommend using this mode if you want to ensure service availability and are okay with some log loss. For more information, see [Preventing log loss with non-blocking mode in the awslogs container log driver](#).

## `max-buffer-size`

Required: No

Default value: 1m

When non-blocking mode is used, the `max-buffer-size` log option controls the size of the buffer that's used for intermediate message storage. Make sure to specify an adequate buffer size based on your application. When the buffer fills up, further logs cannot be stored. Logs that cannot be stored are lost.

To route logs using the `splunk` log router, you need to specify a `splunk-token` and a `splunk-url`.

When you use the `awsfirelens` log router to route logs to an AWS service or AWS Partner Network destination for log storage and analytics, you can set the `log-driver-buffer-limit` option to limit the number of events that are buffered in memory, before being sent to the log router container. It can help to resolve potential log loss issue because high throughput might result in memory running out for the buffer inside of Docker. For more information, see [the section called “Configuring logs for high throughput”](#).

Other options you can specify when using `awsfirelens` to route logs depend on the destination. When you export logs to Amazon Data Firehose, you can specify the AWS Region with `region` and a name for the log stream with `delivery_stream`.

When you export logs to Amazon Kinesis Data Streams, you can specify an AWS Region with `region` and a data stream name with `stream`.

When you export logs to Amazon OpenSearch Service, you can specify options like `Name`, `Host` (OpenSearch Service endpoint without protocol), `Port`, `Index`, `Type`, `Aws_auth`, `Aws_region`, `Suppress_Type_Name`, and `tls`.

When you export logs to Amazon S3, you can specify the bucket using the `bucket` option. You can also specify `region`, `total_file_size`, `upload_timeout`, and `use_put_object` as options.

This parameter requires version 1.19 of the Docker Remote API or greater on your container instance.

## `secretOptions`

Type: Object array

Required: No

An object that represents the secret to pass to the log configuration. Secrets that are used in log configuration can include an authentication token, certificate, or encryption key. For more information, see [Pass sensitive data to an Amazon ECS container](#).

name

Type: String

Required: Yes

The value to set as the environment variable on the container.

valueFrom

Type: String

Required: Yes

The secret to expose to the log configuration of the container.

```
"logConfiguration": {
  "logDriver": "splunk",
  "options": {
    "splunk-url": "https://cloud.splunk.com:8080",
    "splunk-token": "...",
    "tag": "...",
    ...
  },
  "secretOptions": [{
    "name": "splunk-token",
    "valueFrom": "/ecs/logconfig/splunkcred"
  }]
}
```

firelensConfiguration

Type: [FirelensConfiguration](#) Object

Required: No

The FireLens configuration for the container. This is used to specify and configure a log router for container logs. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

```
{
  "firelensConfiguration": {
    "type": "fluentd",
    "options": {
      "KeyName": ""
    }
  }
}
```

### options

Type: String to string map

Required: No

The key/value map of options to use when configuring the log router. This field is optional and can be used to specify a custom configuration file or to add additional metadata, such as the task, task definition, cluster, and container instance details to the log event. If specified, the syntax to use is "options":{"enable-ecs-log-metadata":"true|false","config-file-type":"file","config-file-value":"filepath"}. For more information, see [Example Amazon ECS task definition: Route logs to FireLens](#).

### type

Type: String

Required: Yes

The log router to use. The valid values are fluentd or fluentbit.

## Resource requirements

### resourceRequirements

Type: Array of [ResourceRequirement](#) objects

Required: No

The type and amount of each resource to assign to a container. The supported resources are GPUs and Neuron devices.

### type

Type: String

Required: Yes

The type of resource to assign to a container. The supported values are GPU and NeuronDevice.

value

Type: String

Required: Yes

The value for the specified resource type.

If the GPU type is used, the value is the number of physical GPUs the Amazon ECS container agent reserves for the container. You can specify an integer value for full GPUs, a decimal value (0.125, 0.25, or 0.5) for fractional GPUs on G6f instances, or ALL to allocate all GPUs on the container instance to the container. The number of GPUs reserved for all containers in a task cannot exceed the number of available GPUs on the container instance the task is launched on.

GPUs aren't available for tasks that are running on Fargate.

If the NeuronDevice type is used, the only supported value is ALL. When ALL is specified, the container gets exclusive access to all Neuron devices on the instance.

Neuron devices aren't available for tasks that are running on Fargate.

sharingStrategy

Type: SharingStrategy object

Required: No

The GPU sharing configuration for the container. Specify sharingStrategy to share a single physical GPU across multiple containers with NVIDIA Multi-Process Service (MPS). This object contains an nvidiaMps object with the following fields:

On a GPU resource requirement, value and sharingStrategy are mutually exclusive. When you specify sharingStrategy, you must omit value.

memory

Type: Integer

Required: Yes

The GPU memory limit for the container, in MiB. This value is a hard ceiling on the GPU memory that the container can use. The value must be greater than 0.

`maxComputePercent`

Type: Integer

Required: No

The maximum percentage of GPU compute that the container can use, as an integer from 1 to 100. This value is a ceiling, not a reservation. If you omit it, the container can use up to 100 percent.

## Container timeouts

`startTimeout`

Type: Integer

Required: No

Example values: 120

Time duration (in seconds) to wait before giving up on resolving dependencies for a container.

For example, you specify two containers in a task definition with `containerA` having a dependency on `containerB` reaching a `COMPLETE`, `SUCCESS`, or `HEALTHY` status. If a `startTimeout` value is specified for `containerB` and it doesn't reach the desired status within that time, then `containerA` doesn't start.

### Note

If a container doesn't meet a dependency constraint or times out before meeting the constraint, Amazon ECS doesn't progress dependent containers to their next state.

The maximum value is 600 seconds (10 minutes).

`stopTimeout`

Type: Integer

Required: No

Example values: 120

Time duration (in seconds) to wait before the container is forcefully killed if it doesn't exit normally on its own.

If the parameter isn't specified, then the default value of 30 seconds is used. The maximum value is 86400 seconds (24 hours).

## Container dependency

dependsOn

Type: Array of [ContainerDependency](#) objects

Required: No

The dependencies defined for container startup and shutdown. A container can contain multiple dependencies. When a dependency is defined for container startup, for container shutdown it is reversed. For an example, see [Container dependency](#).

### Note

If a container doesn't meet a dependency constraint or times out before meeting the constraint, Amazon ECS doesn't progress dependent containers to their next state.

This parameter requires that the task or service uses platform version 1.3.0 or later (Linux) or 1.0.0 (Windows).

```
"dependsOn": [  
  {  
    "containerName": "string",  
    "condition": "string"  
  }  
]
```

containerName

Type: String

Required: Yes

The container name that must meet the specified condition.

`condition`

Type: String

Required: Yes

The dependency condition of the container. The following are the available conditions and their behavior:

- **START** – This condition emulates the behavior of links and volumes today. The condition validates that a dependent container is started before permitting other containers to start.
- **COMPLETE** – This condition validates that a dependent container runs to completion (exits) before permitting other containers to start. This can be useful for non-essential containers that run a script and then exit. This condition can't be set on an essential container.
- **SUCCESS** – This condition is the same as **COMPLETE**, but it also requires that the container exits with a zero status. This condition can't be set on an essential container.
- **HEALTHY** – This condition validates that the dependent container passes its container health check before permitting other containers to start. This requires that the dependent container has health checks configured in the task definition. This condition is confirmed only at task startup.

## System controls

`systemControls`

Type: [SystemControl](#) object

Required: No

A list of namespace kernel parameters to set in the container. This parameter maps to `Sysctl`s in the `docker create-container` command and the `--sysctl` option to `docker run`. For example, you can configure `net.ipv4.tcp_keepalive_time` setting to maintain longer lived connections.

We don't recommend that you specify network-related `systemControls` parameters for multiple containers in a single task that also uses either the `awsvpc` or `host` network mode. Doing this has the following disadvantages:

- If you set `systemControls` for any container, it applies to all containers in the task. If you set different `systemControls` for multiple containers in a single task, the container that's started last determines which `systemControls` take effect.

If you're setting an IPC resource namespace to use for the containers in the task, the following conditions apply to your system controls. For more information, see [IPC mode](#).

- For tasks that use the host IPC mode, IPC namespace `systemControls` aren't supported.
- For tasks that use the task IPC mode, IPC namespace `systemControls` values apply to all containers within a task.

```
"systemControls": [  
  {  
    "namespace": "string",  
    "value": "string"  
  }  
]
```

#### namespace

Type: String

Required: No

The namespace kernel parameter to set a value for.

Valid IPC namespace values: "kernel.msgmax" | "kernel.msgmnb" | "kernel.msgmni" | "kernel.sem" | "kernel.shmall" | "kernel.shmmax" | "kernel.shmmni" | "kernel.shm\_rmid\_forced", and Sysctls that start with "fs.mqueue.\*"

Valid network namespace values: Sysctls that start with "net.\*". On Fargate, only namespaced Sysctls that exist within the container are accepted.

All of these values are supported by Fargate.

#### value

Type: String

Required: No

The value for the namespace kernel parameter that's specified in namespace.

## Interactive

### interactive

Type: Boolean

Required: No

When this parameter is `true`, you can deploy containerized applications that require `stdin` or a `tty` to be allocated. This parameter maps to `OpenStdin` in the `docker create-container` command and the `--interactive` option to `docker run`.

The default is `false`.

## Pseudo terminal

### pseudoTerminal

Type: Boolean

Required: No

When this parameter is `true`, a TTY is allocated. This parameter maps to `Tty` in the `docker create-container` command and the `--tty` option to `docker run`.

The default is `false`.

## Linux parameters

### linuxParameters

Type: [LinuxParameters](#) object

Required: No

Linux-specific modifications that are applied to the container, such as Linux kernel capabilities.  
`capabilities`

Type: [KernelCapabilities](#) object

Required: No

The Linux capabilities for the container that are added to or dropped from the default configuration provided by Docker.

#### devices

Type: Array of [Device](#) objects

Required: No

Any host devices to expose to the container. This parameter maps to `Devices` in the `docker create-container` command and the `--device` option to `docker run`.

#### initProcessEnabled

Type: Boolean

Required: No

Run an `init` process inside the container that forwards signals and reaps processes. This parameter maps to the `--init` option to `docker run`.

#### maxSwap

##### **Note**

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: Integer

Required: No

The total amount of swap memory (in MiB) a container can use. This parameter is translated to the `--memory-swap` option to `docker run` where the value is the sum of the container memory plus the `maxSwap` value.

#### swappiness

##### **Note**

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: Integer

Required: No

This allows you to tune a container's memory swappiness behavior. A swappiness value of 0 causes swapping not to happen unless absolutely necessary. A swappiness value of 100 causes pages to be swapped very aggressively. Valid values are whole numbers between 0 and 100. If the swappiness parameter isn't specified, a default value of 60 is used. If a value isn't specified for `maxSwap`, then this parameter is ignored. This parameter maps to the `--memory-swappiness` option to `docker run`.

`sharedMemorySize`

 **Note**

This parameter isn't supported for tasks running on Amazon ECS Managed Instances.

Type: Integer

Required: No

The size (in MiB) of the `/dev/shm` volume. This parameter maps to the `--shm-size` option to `docker run`.

`tmpfs`

Type: Array of [Tmpfs](#) objects

Required: No

The container path, mount options, and size (in MiB) of the `tmpfs` mount. This parameter maps to the `--tmpfs` option to `docker run`.

## Amazon ECS task definition parameters for Fargate

Task definitions are split into separate parts: the task family, the AWS Identity and Access Management (IAM) task role, the network mode, container definitions, volumes, and launch types. The family and container definitions are required in a task definition. In contrast, task role, network mode, volumes, and launch type are optional.

You can use these parameters in a JSON file to configure your task definition.

The following are more detailed descriptions for each task definition parameter for Fargate.

## Family

`family`

Type: String

Required: Yes

When you register a task definition, you give it a family, which is similar to a name for multiple versions of the task definition, specified with a revision number. The first task definition that's registered into a particular family is given a revision of 1, and any task definitions registered after that are given a sequential revision number.

## Capacity

When you register a task definition, you can specify the capacity that Amazon ECS should validate the task definition against. If the task definition doesn't validate against the compatibilities specified, a client exception is returned.

The following parameter is allowed in a task definition.

`requiresCompatibilities`

Type: String array

Required: No

Valid Values: FARGATE

The capacity to validate the task definition against. This initiates a check to ensure that all of the parameters that are used in the task definition meet the requirements of Fargate

## Task role

`taskRoleArn`

Type: String

Required: No

When you register a task definition, you can provide a task role for an IAM role that allows the containers in the task permission to call the AWS APIs that are specified in its associated policies on your behalf. For more information, see [Amazon ECS task IAM role](#).

## Task execution role

executionRoleArn

Type: String

Required: Conditional

The Amazon Resource Name (ARN) of the task execution role that grants the Amazon ECS container agent permission to make AWS API calls on your behalf.

### Note

The task execution IAM role is required depending on the requirements of your task. For more information, see [Amazon ECS task execution IAM role](#).

## Network mode

networkMode

Type: String

Required: Yes

The Docker networking mode to use for the containers in the task. For Amazon ECS tasks hosted on Fargate, the awsvpc network mode is required.

## Runtime platform

operatingSystemFamily

Type: String

Required: Conditional

Default: LINUX

This parameter is required for Amazon ECS tasks that are hosted on Fargate.

When you register a task definition, you specify the operating system family.

The valid values are LINUX, WINDOWS\_SERVER\_2025\_FULL, WINDOWS\_SERVER\_2025\_CORE, WINDOWS\_SERVER\_2022\_FULL, WINDOWS\_SERVER\_2022\_CORE, WINDOWS\_SERVER\_2019\_FULL, and WINDOWS\_SERVER\_2019\_CORE.

All task definitions that are used in a service must have the same value for this parameter.

When a task definition is part of a service, this value must match the service platformFamily value.

## cpuArchitecture

Type: String

Required: Conditional

Default: X86\_64

If the parameter is left as null, the default value is automatically assigned upon the initiation of a task hosted on Fargate.

When you register a task definition, you specify the CPU architecture. The valid values are X86\_64 and ARM64.

All task definitions that are used in a service must have the same value for this parameter.

When you have Linux tasks, you can set the value to ARM64. For more information, see [the section called “Task definitions for 64-bit ARM workloads”](#).

## Task size

When you register a task definition, you can specify the total CPU and memory used for the task. This is separate from the cpu and memory values at the container definition level. For tasks that are hosted on Fargate (both Linux and Windows), these fields are required and there are specific values for both cpu and memory that are supported.

The following parameter is allowed in a task definition:

cpu

Type: String

Required: Yes

 **Note**

Task-level CPU and memory parameters are required and used to determine the instance type and size that tasks run on. For Windows tasks, these values aren't enforced at runtime, because Windows doesn't have a native mechanism that can easily enforce collective resource limits on a group of containers. If you want to enforce resource limits, we recommend using the container-level resources for Windows containers.

The hard limit of CPU units to present for the task. You can specify CPU values in the JSON file as a string in CPU units or virtual CPUs (vCPUs). For example, you can specify a CPU value either as 1024 in CPU units or 1 vCPU in vCPUs. When the task definition is registered, a vCPU value is converted to an integer indicating the CPU units.

This field is required and you must use one of the following values, which determines your range of supported values for the memory parameter. The following table shows the valid combinations of task-level CPU and memory.

| CPU value      | Memory value                              | Operating systems supported for AWS Fargate |
|----------------|-------------------------------------------|---------------------------------------------|
| 256 (.25 vCPU) | 512 MiB, 1 GB, 2 GB                       | Linux                                       |
| 512 (.5 vCPU)  | 1 GB, 2 GB, 3 GB, 4 GB                    | Linux                                       |
| 1024 (1 vCPU)  | 2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB  | Linux, Windows                              |
| 2048 (2 vCPU)  | Between 4 GB and 16 GB in 1 GB increments | Linux, Windows                              |

| CPU value                                                                                                                                                                                              | Memory value                                | Operating systems supported for AWS Fargate |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|---------------------------------------------|
| 4096 (4 vCPU)                                                                                                                                                                                          | Between 8 GB and 30 GB in 1 GB increments   | Linux, Windows                              |
| 8192 (8 vCPU) <div><div><div><div><div><div></div></div></div><div><div><div><strong>Note</strong></div><div>This option requires Linux platform 1.4.0 or later.</div></div></div></div></div></div>   | Between 16 GB and 60 GB in 4 GB increments  | Linux                                       |
| 16384 (16 vCPU) <div><div><div><div><div><div></div></div></div><div><div><div><strong>Note</strong></div><div>This option requires Linux platform 1.4.0 or later.</div></div></div></div></div></div> | Between 32 GB and 120 GB in 8 GB increments | Linux                                       |
| 32768 (32 vCPU) <div><div><div><div><div><div></div></div></div><div><div><div><strong>Note</strong></div><div>This option requires Linux platform 1.4.0 or later.</div></div></div></div></div></div> | 60 GB, 120 GB, 244 GB                       | Linux                                       |

memory

Type: String

Required: Yes

**Note**

Task-level CPU and memory parameters are required and used to determine the instance type and size that tasks run on. For Windows tasks, these values aren't enforced at runtime, because Windows doesn't have a native mechanism that can easily enforce collective resource limits on a group of containers. If you want to enforce resource limits, we recommend using the container-level resources for Windows containers.

The hard limit of memory to present to the task. You can specify memory values in the task definition as a string in mebibytes (MiB) or gigabytes (GB). For example, you can specify a memory value either as 3072 in MiB or 3 GB in GB. When the task definition is registered, a GB value is converted to an integer indicating the MiB.

This field is required and you must use one of the following values, which determines your range of supported values for the `cpu` parameter:

| Memory value (in MiB, with approximate equivalent value in GB)                           | CPU value      | Operating systems supported for Fargate |
|------------------------------------------------------------------------------------------|----------------|-----------------------------------------|
| 512 (0.5 GB), 1024 (1 GB), 2048 (2 GB)                                                   | 256 (.25 vCPU) | Linux                                   |
| 1024 (1 GB), 2048 (2 GB), 3072 (3 GB), 4096 (4 GB)                                       | 512 (.5 vCPU)  | Linux                                   |
| 2048 (2 GB), 3072 (3 GB), 4096 (4GB), 5120 (5 GB), 6144 (6 GB), 7168 (7 GB), 8192 (8 GB) | 1024 (1 vCPU)  | Linux, Windows                          |
| Between 4096 (4 GB) and 16384 (16 GB) in increments of 1024 (1 GB)                       | 2048 (2 vCPU)  | Linux, Windows                          |

| Memory value (in MiB, with approximate equivalent value in GB)                                                                                                                                                                      | CPU value      | Operating systems supported for Fargate |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------------------------------|
| Between 8192 (8 GB) and 30720 (30 GB) in increments of 1024 (1 GB)                                                                                                                                                                  | 4096 (4 vCPU)  | Linux, Windows                          |
| Between 16 GB and 60 GB in 4 GB increments <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div>    | 8192 (8 vCPU)  | Linux                                   |
| Between 32 GB and 120 GB in 8 GB increments <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div> | 16384 (16vCPU) | Linux                                   |

## Container definitions

When you register a task definition, you must specify a list of container definitions that are passed to the Docker daemon on a container instance. The following parameters are allowed in a container definition.

### Topics

- [Standard container definition parameters](#)
- [Advanced container definition parameters](#)
- [Other container definition parameters](#)

## Standard container definition parameters

The following task definition parameters are either required or used in most container definitions.

### Topics

- [Name](#)
- [Image](#)
- [Memory](#)
- [Port mappings](#)
- [Private Repository Credentials](#)

### Name

name

Type: String

Required: Yes

The name of a container. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed. If you're linking multiple containers in a task definition, the name of one container can be entered in the `links` of another container. This is to connect the containers.

### Image

image

Type: String

Required: Yes

The image used to start a container. This string is passed directly to the Docker daemon. By default, images in the Docker Hub registry are available. You can also specify other repositories with either *repository-url/image:tag* or *repository-url/image@digest*. Up to 255 letters (uppercase and lowercase), numbers, hyphens, underscores, colons, periods, forward slashes, and number signs are allowed. This parameter maps to `Image` in the `docker create-container` command and the `IMAGE` parameter of the `Docker run` command.

- When a new task starts, the Amazon ECS container agent pulls the latest version of the specified image and tag for the container to use. However, subsequent updates to a repository image aren't propagated to already running tasks.
- When you don't specify a tag or digest in the image path in the task definition, the Amazon ECS container agent uses the latest tag to pull the specified image.
- Subsequent updates to a repository image aren't propagated to already running tasks.
- Images in private registries are supported. For more information, see [Using non-AWS container images in Amazon ECS](#).
- Images in Amazon ECR repositories can be specified by using either the full `registry/repository:tag` or `registry/repository@digest` naming convention (for example, `aws_account_id.dkr.ecr.region.amazonaws.com/my-web-app:latest` or `aws_account_id.dkr.ecr.region.amazonaws.com/my-web-app@sha256:94afd1f2e64d908bc90dbca0035a5b567EXAMPLE`).
- Images in official repositories on Docker Hub use a single name (for example, `ubuntu` or `mongo`).
- Images in other repositories on Docker Hub are qualified with an organization name (for example, `amazon/amazon-ecs-agent`).
- Images in other online repositories are qualified further by a domain name (for example, `quay.io/assemblyline/ubuntu`).

## versionConsistency

Type: String

Valid values: `enabled|disabled`

Required: No

Specifies whether Amazon ECS will resolve the container image tag provided in the container definition to an image digest. By default, this behavior is enabled. If you set the value for a container as `disabled`, Amazon ECS will not resolve the container image tag to a digest and will use the original image URI specified in the container definition for deployment. For more information about container image resolution, see [Container image resolution](#).

## Memory

memory

Type: Integer

Required: No

The amount (in MiB) of memory to present to the container. If your container attempts to exceed the memory specified here, the container is killed. The total amount of memory reserved for all containers within a task must be lower than the task memory value, if one is specified. This parameter maps to `Memory` in the `docker create-container` command and the `--memory` option to `docker run`.

The Docker 20.10.0 or later daemon reserves a minimum of 6 MiB of memory for a container. So, don't specify less than 6 MiB of memory for your containers.

The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container. So, don't specify less than 4 MiB of memory for your containers.

### Note

If you're trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see [Reserving Amazon ECS Linux container instance memory](#).

memoryReservation

Type: Integer

Required: No

The soft limit (in MiB) of memory to reserve for the container. When system memory is under contention, Docker attempts to keep the container memory to this soft limit. However, your container can use more memory when needed. The container can use up to the hard limit that's specified with the `memory` parameter (if applicable) or all of the available memory on the container instance, whichever comes first. This parameter maps to `MemoryReservation` in the `docker create-container` command and the `--memory-reservation` option to `docker run`.

If a task-level memory value isn't specified, you must specify a non-zero integer for one or both of `memory` or `memoryReservation` in a container definition. If you specify both, `memory` must be greater than `memoryReservation`. If you specify `memoryReservation`, then that value is subtracted from the available memory resources for the container instance that the container is placed on. Otherwise, the value of `memory` is used.

For example, suppose that your container normally uses 128 MiB of memory, but occasionally bursts to 256 MiB of memory for short periods of time. You can set a `memoryReservation` of 128 MiB, and a `memory` hard limit of 300 MiB. This configuration allows the container to only reserve 128 MiB of memory from the remaining resources on the container instance. At the same time, this configuration also allows the container to use more memory resources when needed.

 **Note**

This parameter isn't supported for Windows containers.

The Docker 20.10.0 or later daemon reserves a minimum of 6 MiB of memory for a container. So, don't specify less than 6 MiB of memory for your containers.

The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container. So, don't specify less than 4 MiB of memory for your containers.

 **Note**

If you're trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see [Reserving Amazon ECS Linux container instance memory](#).

## Port mappings

`portMappings`

Type: Object array

Required: No

Port mappings expose your container's network ports to the outside world. This allows clients to access your application. It's also used for inter-container communication within the same task.

For task definitions that use the `awsvpc` network mode, only specify the `containerPort`. The `hostPort` is always ignored, and the container port is automatically mapped to a random high-numbered port on the host.

Port mappings on Windows use the `NetNAT` gateway address rather than `localhost`. There's no loopback for port mappings on Windows, so you can't access a container's mapped port from the host itself.

Most fields of this parameter (including `containerPort`, `hostPort`, `protocol`) map to `PortBindings` in the `docker create-container` command and the `--publish` option to `docker run`. If the network mode of a task definition is set to `host`, host ports must either be undefined or match the container port in the port mapping.

#### Note

After a task reaches the `RUNNING` status, manual and automatic host and container port assignments are visible in the following locations:

- Console: The **Network Bindings** section of a container description for a selected task.
- AWS CLI: The `networkBindings` section of the **describe-tasks** command output.
- API: The `DescribeTasks` response.
- Metadata: The task metadata endpoint.

`appProtocol`

Type: String

Required: No

The application protocol that's used for the port mapping. This parameter only applies to Service Connect. We recommend that you set this parameter to be consistent with the protocol that your application uses. If you set this parameter, Amazon ECS adds protocol-specific connection handling to the service connect proxy. If you set this parameter, Amazon ECS adds protocol-specific telemetry in the Amazon ECS console and CloudWatch.

If you don't set a value for this parameter, then TCP is used. However, Amazon ECS doesn't add protocol-specific telemetry for TCP.

For more information, see [the section called "Service Connect"](#).

Valid protocol values: "http" | "http2" | "grpc"

#### `containerPort`

Type: Integer

Required: Yes, when `portMappings` are used

The port number on the container that's bound to the user-specified or automatically assigned host port.

For tasks that use the `awsvpc` network mode, you use `containerPort` to specify the exposed ports.

For Windows containers on Fargate, you can't use port 3150 for the `containerPort`. This is because it's reserved.

#### `containerPortRange`

Type: String

Required: No

The port number range on the container that's bound to the dynamically mapped host port range.

You can only set this parameter by using the `register-task-definition` API. The option is available in the `portMappings` parameter. For more information, see [register-task-definition](#) in the *AWS Command Line Interface Reference*.

The following rules apply when you specify a `containerPortRange`:

- You must use the `awsvpc` network mode.
- This parameter is available for both the Linux and Windows operating systems.
- The container instance must have at least version 1.67.0 of the container agent and at least version 1.67.0-1 of the `ecs-init` package.

- You can specify a maximum of 100 port ranges for each container.
- You don't specify a `hostPortRange`. The value of the `hostPortRange` is set as follows:
  - For containers in a task with the `awsvpc` network mode, the `hostPort` is set to the same value as the `containerPort`. This is a static mapping strategy.
- The `containerPortRange` valid values are between 1 and 65535.
- A port can only be included in one port mapping for each container.
- You can't specify overlapping port ranges.
- The first port in the range must be less than last port in the range.
- Docker recommends that you turn off the Docker-proxy in the Docker daemon config file when you have a large number of ports.

For more information, see [Issue #11185](#) on GitHub.

For information about how to turn off the docker-proxy in the Docker daemon config file, see [Docker daemon](#) in the *Amazon ECS Developer Guide*.

You can call [DescribeTasks](#) to view the `hostPortRange`, which are the host ports that are bound to the container ports.

The port ranges aren't included in the Amazon ECS task events, which are sent to EventBridge. For more information, see [the section called "Automate responses to Amazon ECS errors using EventBridge"](#).

## `hostPortRange`

Type: String

Required: No

The port number range on the host that's used with the network binding. This is assigned by Docker and delivered by the Amazon ECS agent.

## `hostPort`

Type: Integer

Required: No

The port number on the container instance to reserve for your container.

The `hostPort` can either be kept blank or be the same value as `containerPort`.

The default ephemeral port range Docker version 1.6.0 and later is listed on the instance under `/proc/sys/net/ipv4/ip_local_port_range`. If this kernel parameter is unavailable, the default ephemeral port range from 49153–65535 is used. Don't attempt to specify a host port in the ephemeral port range. This is because these are reserved for automatic assignment. In general, ports under 32768 are outside of the ephemeral port range.

The default reserved ports are 22 for SSH, the Docker ports 2375 and 2376, and the Amazon ECS container agent ports 51678–51680. Any host port that was previously user-specified for a running task is also reserved while the task is running. After a task stops, the host port is released. The current reserved ports are displayed in the `remainingResources` of **describe-container-instances** output. A container instance might have up to 100 reserved ports at a time, including the default reserved ports. Automatically assigned ports don't count toward the 100 reserved ports quota.

name

Type: String

Required: No, required for Service Connect and VPC Lattice to be configured in a service

The name that's used for the port mapping. This parameter only applies to Service Connect and VPC Lattice. This parameter is the name that you use in the Service Connect and VPC Lattice configuration of a service.

For more information, see [Use Service Connect to connect Amazon ECS services with short names](#).

In the following example, both of the required fields for Service Connect and VPC Lattice are used.

```
"portMappings": [  
  {  
    "name": string,  
    "containerPort": integer  
  }  
]
```

## protocol

Type: String

Required: No

The protocol that's used for the port mapping. Valid values are `tcp` and `udp` (case-sensitive). The default is `tcp`. Amazon Amazon ECS treats any other specified value as `tcp`.

### Important

Only `tcp` is supported for Service Connect. Remember that `tcp` is implied if this field isn't set.

If you're specifying a host port, use the following syntax.

```
"portMappings": [  
  {  
    "containerPort": integer,  
    "hostPort": integer  
  }  
  ...  
]
```

If you want an automatically assigned host port, use the following syntax.

```
"portMappings": [  
  {  
    "containerPort": integer  
  }  
  ...  
]
```

## Private Repository Credentials

### repositoryCredentials

Type: [RepositoryCredentials](#) object

Required: No

The repository credentials for private registry authentication.

For more information, see [Using non-AWS container images in Amazon ECS](#).

`credentialsParameter`

Type: String

Required: Yes, when `repositoryCredentials` are used

The Amazon Resource Name (ARN) of the secret containing the private repository credentials.

For more information, see [Using non-AWS container images in Amazon ECS](#).

 **Note**

When you use the Amazon ECS API, AWS CLI, or AWS SDKs, if the secret exists in the same Region as the task that you're launching then you can use either the full ARN or the name of the secret. When you use the AWS Management Console, you must specify the full ARN of the secret.

The following is a snippet of a task definition that shows the required parameters:

```
"containerDefinitions": [  
  {  
    "image": "private-repo/private-image",  
    "repositoryCredentials": {  
      "credentialsParameter":  
        "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name"  
    }  
  }  
]
```

## Advanced container definition parameters

The following advanced container definition parameters provide extended capabilities to the Docker run command that's used to launch containers on your Amazon ECS container instances.

## Topics

- [Restart policy](#)
- [Health check](#)
- [Environment](#)
- [Network settings](#)
- [Storage and logging](#)
- [Security](#)
- [Resource limits](#)
- [Docker labels](#)

## Restart policy

### `restartPolicy`

The container restart policy and associated configuration parameters. When you set up a restart policy for a container, Amazon ECS can restart the container without needing to replace the task. For more information, see [Restart individual containers in Amazon ECS tasks with container restart policies](#).

#### `enabled`

Type: Boolean

Required: Yes

Specifies whether a restart policy is enabled for the container.

#### `ignoredExitCodes`

Type: Integer array

Required: No

A list of exit codes that Amazon ECS will ignore and not attempt a restart on. You can specify a maximum of 50 container exit codes. By default, Amazon ECS does not ignore any exit codes.

#### `restartAttemptPeriod`

Type: Integer

Required: No

A period of time (in seconds) that the container must run for before a restart can be attempted. A container can be restarted only once every `restartAttemptPeriod` seconds. If a container isn't able to run for this time period and exits early, it will not be restarted. You can set a minimum `restartAttemptPeriod` of 60 seconds and a maximum `restartAttemptPeriod` of 1800 seconds. By default, a container must run for 300 seconds before it can be restarted.

## Health check

`healthCheck`

The container health check command and the associated configuration parameters for the container. For more information, see [Determine Amazon ECS task health using container health checks](#).

`command`

A string array that represents the command that the container runs to determine if it's healthy. The string array can start with `CMD` to run the command arguments directly, or `CMD-SHELL` to run the command with the container's default shell. If neither is specified, `CMD` is used.

When registering a task definition in the AWS Management Console, use a comma separated list of commands. These commands are converted to a string after the task definition is created. An example input for a health check is the following.

```
CMD-SHELL, curl -f http://localhost/ || exit 1
```

When registering a task definition using the AWS Management Console JSON panel, the AWS CLI, or the APIs, enclose the list of commands in brackets. An example input for a health check is the following.

```
[ "CMD-SHELL", "curl -f http://localhost/ || exit 1" ]
```

An exit code of 0, with no `stderr` output, indicates success, and a non-zero exit code indicates failure.

## interval

The period of time (in seconds) between each health check. You can specify between 5 and 300 seconds. The default value is 30 seconds.

## timeout

The period of time (in seconds) to wait for a health check to succeed before it's considered a failure. You can specify between 2 and 60 seconds. The default value is 5 seconds.

## retries

The number of times to retry a failed health check before the container is considered unhealthy. You can specify between 1 and 10 retries. The default value is three retries.

## startPeriod

The optional grace period to provide containers time to bootstrap in before failed health checks count towards the maximum number of retries. You can specify a value between 0 and 300 seconds. By default, `startPeriod` is disabled.

If a health check succeeds within the `startPeriod`, then the container is considered healthy and any subsequent failures count toward the maximum number of retries.

## Environment

### cpu

Type: Integer

Required: No

The number of `cpu` units the Amazon ECS container agent reserves for the container. On Linux, this parameter maps to `CpuShares` in the [Create a container](#) section.

This field is optional for tasks that use Fargate. The total amount of CPU reserved for all the containers that are within a task must be lower than the task-level `cpu` value.

Linux containers share unallocated CPU units with other containers on the container instance with the same ratio as their allocated amount. For example, assume that you run a single-container task on a single-core instance type with 512 CPU units specified for that container. Moreover, that task is the only task running on the container instance. In this example, the

container can use the full 1,024 CPU unit share at any given time. However, assume then that you launched another copy of the same task on that container instance. Each task is guaranteed a minimum of 512 CPU units when needed. Similarly, if the other container isn't using the remaining CPU, each container can float to higher CPU usage. However, if both tasks were 100% active all of the time, they are limited to 512 CPU units.

On Linux container instances, the Docker daemon on the container instance uses the CPU value to calculate the relative CPU share ratios for running containers. The minimum valid CPU share value that the Linux kernel allows is 2, and the maximum valid CPU share value that the Linux kernel allows is 262144. However, the CPU parameter isn't required, and you can use CPU values below two and above 262144 in your container definitions. For CPU values below two (including null) and above 262144, the behavior varies based on your Amazon ECS container agent version:

On Windows container instances, the CPU quota is enforced as an absolute quota. Windows containers only have access to the specified amount of CPU that's defined in the task definition. A null or zero CPU value is passed to Docker as 0. Windows then interprets this value as 1% of one CPU.

For more examples, see [How Amazon ECS manages CPU and memory resources](#).

## gpu

This parameter isn't supported for containers that are hosted on Fargate.

Type: [ResourceRequirement](#) object

Required: No

The number of physical GPUs that the Amazon ECS container agent reserves for the container. The number of GPUs reserved for all containers in a task must not exceed the number of available GPUs on the container instance the task is launched on. For more information, see [Amazon ECS task definitions for GPU workloads](#).

## Elastic Inference accelerator

This parameter isn't supported for containers that are hosted on Fargate.

Type: [ResourceRequirement](#) object

Required: No

For the `InferenceAccelerator` type, the value matches the `deviceName` for an `InferenceAccelerator` specified in a task definition. For more information, see [the section called “Elastic Inference accelerator name \(deprecated\)”](#).

## `essential`

Type: Boolean

Required: No

Suppose that the `essential` parameter of a container is marked as `true`, and that container fails or stops for any reason. Then, all other containers that are part of the task are stopped. If the `essential` parameter of a container is marked as `false`, then its failure doesn't affect the rest of the containers in a task. If this parameter is omitted, a container is assumed to be `essential`.

All tasks must have at least one essential container. Suppose that you have an application that's composed of multiple containers. Then, group containers that are used for a common purpose into components, and separate the different components into multiple task definitions. For more information, see [Architect your application for Amazon ECS](#).

```
"essential": true|false
```

## `entryPoint`

### Important

Early versions of the Amazon ECS container agent don't properly handle `entryPoint` parameters. If you have problems using `entryPoint`, update your container agent or enter your commands and arguments as `command array` items instead.

Type: String array

Required: No

The entry point that's passed to the container.

```
"entryPoint": ["string", ...]
```

## command

Type: String array

Required: No

The command that's passed to the container. This parameter maps to `Cmd` in the `create-container` command and the `COMMAND` parameter to `docker run`. If there are multiple arguments, make sure that each argument is a separated string in the array.

```
"command": ["string", ...]
```

## workingDirectory

Type: String

Required: No

The working directory to run commands inside the container in. This parameter maps to `WorkingDir` in the [Create a container](#) section of the [Docker Remote API](#) and the `--workdir` option to [docker run](#).

```
"workingDirectory": "string"
```

## environmentFiles

This isn't available for Windows containers on Fargate.

Type: Object array

Required: No

A list of files containing the environment variables to pass to a container. This parameter maps to the `--env-file` option to the `Docker run` command.

You can specify up to 10 environment files. The file must have a `.env` file extension. Each line in an environment file contains an environment variable in `VARIABLE=VALUE` format. Lines that start with `#` are treated as comments and are ignored.

If there are individual environment variables specified in the container definition, they take precedence over the variables contained within an environment file. If multiple environment files are specified that contain the same variable, they're processed from the top down. We

recommend that you use unique variable names. For more information, see [Pass an individual environment variable to an Amazon ECS container](#).

value

Type: String

Required: Yes

The Amazon Resource Name (ARN) of the Amazon S3 object containing the environment variable file.

type

Type: String

Required: Yes

The file type to use. The only supported value is s3.

environment

Type: Object array

Required: No

The environment variables to pass to a container. This parameter maps to Env in the docker create-container command and the --env option to the docker run command.

 **Important**

We do not recommend using plaintext environment variables for sensitive information, such as credential data.

name

Type: String

Required: Yes, when environment is used

The name of the environment variable.

value

Type: String

Required: Yes, when environment is used

The value of the environment variable.

```
"environment" : [  
  { "name" : "string", "value" : "string" },  
  { "name" : "string", "value" : "string" }  
]
```

## secrets

Type: Object array

Required: No

An object that represents the secret to expose to your container. For more information, see [Pass sensitive data to an Amazon ECS container](#).

name

Type: String

Required: Yes

The value to set as the environment variable on the container.

valueFrom

Type: String

Required: Yes

The secret to expose to the container. The supported values are either the full Amazon Resource Name (ARN) of the AWS Secrets Manager secret or the full ARN of the parameter in the AWS Systems Manager Parameter Store.

### Note

If the Systems Manager Parameter Store parameter or Secrets Manager parameter exists in the same AWS Region as the task that you're launching, you can use either the full ARN or name of the secret. If the parameter exists in a different Region, then the full ARN must be specified.

```
"secrets": [  
  {  
    "name": "environment_variable_name",  
    "valueFrom": "arn:aws:ssm:region:aws_account_id:parameter/parameter_name"  
  }  
]
```

## Network settings

### disableNetworking

This parameter is not supported for tasks running on Fargate.

Type: Boolean

Required: No

When this parameter is true, networking is off within the container.

The default is false.

```
"disableNetworking": true|false
```

### links

This parameter isn't supported for tasks using the awsvpc network mode.

Type: String array

Required: No

The link parameter allows containers to communicate with each other without the need for port mappings. This parameter is only supported if the network mode of a task definition is set to bridge. The `name:internalName` construct is analogous to `name:alias` in Docker links. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed..

#### Important

Containers that are collocated on the same container instance might communicate with each other without requiring links or host port mappings. The network isolation on a container instance is controlled by security groups and VPC settings.

```
"links": ["name:internalName", ...]
```

## hostname

Type: String

Required: No

The hostname to use for your container. This parameter maps to Hostname in the docker create-container and the --hostname option to docker run.

### Note

If you're using the awsvpc network mode, the hostname parameter isn't supported.

```
"hostname": "string"
```

## dnsServers

This is not supported for tasks running on Fargate.

Type: String array

Required: No

A list of DNS servers that are presented to the container.

```
"dnsServers": ["string", ...]
```

## extraHosts

This parameter isn't supported for tasks that use the awsvpc network mode.

Type: Object array

Required: No

A list of hostnames and IP address mappings to append to the /etc/hosts file on the container.

This parameter maps to `ExtraHosts` in the `docker create-container` command and the `--add-host` option to `docker run`.

```
"extraHosts": [  
  {  
    "hostname": "string",  
    "ipAddress": "string"  
  },  
  ...  
]
```

`hostname`

Type: String

Required: Yes, when `extraHosts` are used

The hostname to use in the `/etc/hosts` entry.

`ipAddress`

Type: String

Required: Yes, when `extraHosts` are used

The IP address to use in the `/etc/hosts` entry.

## Storage and logging

`readonlyRootFilesystem`

Type: Boolean

Required: No

When this parameter is true, the container is given read-only access to its root file system. This parameter maps to `ReadonlyRootfs` in the `docker create-container` command and the `--read-only` option to `docker run`.

### Note

This parameter is not supported for Windows containers.

The default is `false`.

```
"readonlyRootFilesystem": true|false
```

## mountPoints

Type: Object array

Required: No

The mount points for the data volumes in your container. This parameter maps to `Volumes` in the create-container Docker API and the `--volume` option to `docker run`.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`. Windows containers cannot mount directories on a different drive, and mount points cannot be used across drives. You must specify mount points to attach an Amazon EBS volume directly to an Amazon ECS task.

### sourceVolume

Type: String

Required: Yes, when `mountPoints` are used

The name of the volume to mount.

## containerPath

Type: String

Required: Yes, when `mountPoints` are used

The path in the container where the volume will be mounted.

## readOnly

Type: Boolean

Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

For tasks that run on EC2 instances running the Windows operating system, leave the value as the default of `false`.

## volumesFrom

Type: Object array

Required: No

Data volumes to mount from another container. This parameter maps to `VolumesFrom` in the `docker create-container` command and the `--volumes-from` option to `docker run`.

`sourceContainer`

Type: String

Required: Yes, when `volumesFrom` is used

The name of the container to mount volumes from.

`readOnly`

Type: Boolean

Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

```
"volumesFrom": [  
  {  
    "sourceContainer": "string",  
    "readOnly": true|false  
  }  
]
```

## logConfiguration

Type: [LogConfiguration](#) Object

Required: No

The log configuration specification for the container.

For example task definitions that use a log configuration, see [Example Amazon ECS task definitions](#).

This parameter maps to LogConfig in the docker create-container command and the `--log-driver` option to docker run. By default, containers use the same logging driver that the Docker daemon uses. However, the container might use a different logging driver than the Docker daemon by specifying a log driver with this parameter in the container definition. To use a different logging driver for a container, the log system must be configured properly on the container instance (or on a different log server for remote logging options).

Consider the following when specifying a log configuration for your containers:

- Amazon ECS supports a subset of the logging drivers that are available to the Docker daemon.
- This parameter requires version 1.18 or later of the Docker Remote API on your container instance.
- You must install any additional software outside of the task. For example, the Fluentd output aggregators or a remote host running Logstash to send Gelf logs to.

```
"logConfiguration": {
    "logDriver": "awslogs","fluentd","gelf","json-
file","journald","splunk","syslog","awsfirelens",
    "options": {"string": "string"
    ...},
    "secretOptions": [{
        "name": "string",
        "valueFrom": "string"
    }]
}
```

## logDriver

Type: String

Valid values: "awslogs", "fluentd", "gelf", "json-file", "journald", "splunk", "syslog", "awsfirelens"

Required: Yes, when logConfiguration is used

The log driver to use for the container. By default, the valid values that are listed earlier are log drivers that the Amazon ECS container agent can communicate with.

The supported log drivers are awslogs, splunk, and awsfirelens.

For more information about how to use the `awslogs` log driver in task definitions to send your container logs to CloudWatch Logs, see [Send Amazon ECS logs to CloudWatch](#).

For more information about using the `awsfirelens` log driver, see [Custom Log Routing](#).

 **Note**

If you have a custom driver that isn't listed, you can fork the Amazon ECS container agent project that's [available on GitHub](#) and customize it to work with that driver. We encourage you to submit pull requests for changes that you want to have included. However, we don't currently support running modified copies of this software.

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

## options

Type: String to string map

Required: No

The key/value map of configuration options to send to the log driver.

The options you can specify depend on the log driver. Some of the options you can specify when you use the `awslogs` router to route logs to Amazon CloudWatch include the following:

### `awslogs-create-group`

Required: No

Specify whether you want the log group to be created automatically. If this option isn't specified, it defaults to `false`.

 **Note**

Your IAM policy must include the `logs:CreateLogGroup` permission before you attempt to use `awslogs-create-group`.

## `awslogs-region`

Required: Yes

Specify the AWS Region that the `awslogs` log driver is to send your Docker logs to. You can choose to send all of your logs from clusters in different Regions to a single region in CloudWatch Logs. This is so that they're all visible in one location. Otherwise, you can separate them by Region for more granularity. Make sure that the specified log group exists in the Region that you specify with this option.

## `awslogs-group`

Required: Yes

Make sure to specify a log group that the `awslogs` log driver sends its log streams to.

## `awslogs-stream-prefix`

Required: Yes

Use the `awslogs-stream-prefix` option to associate a log stream with the specified prefix, the container name, and the ID of the Amazon ECS task that the container belongs to. If you specify a prefix with this option, then the log stream takes the following format.

```
prefix-name/container-name/ecs-task-id
```

If you don't specify a prefix with this option, then the log stream is named after the container ID that's assigned by the Docker daemon on the container instance. Because it's difficult to trace logs back to the container that sent them with just the Docker container ID (which is only available on the container instance), we recommend that you specify a prefix with this option.

For Amazon ECS services, you can use the service name as the prefix. Doing so, you can trace log streams to the service that the container belongs to, the name of the container that sent them, and the ID of the task that the container belongs to.

You must specify a stream-prefix for your logs to have your logs appear in the Log pane when using the Amazon ECS console.

## `awslogs-datetime-format`

Required: No

This option defines a multiline start pattern in Python `strftime` format. A log message consists of a line that matches the pattern and any following lines that don't match the pattern. The matched line is the delimiter between log messages.

One example of a use case for using this format is for parsing output such as a stack dump, which might otherwise be logged in multiple entries. The correct pattern allows it to be captured in a single entry.

For more information, see [awslogs-datetime-format](#).

You cannot configure both the `awslogs-datetime-format` and `awslogs-multiline-pattern` options.

 **Note**

Multiline logging performs regular expression parsing and matching of all log messages. This might have a negative impact on logging performance.

## `awslogs-multiline-pattern`

Required: No

This option defines a multiline start pattern that uses a regular expression. A log message consists of a line that matches the pattern and any following lines that don't match the pattern. The matched line is the delimiter between log messages.

For more information, see [awslogs-multiline-pattern](#).

This option is ignored if `awslogs-datetime-format` is also configured.

You cannot configure both the `awslogs-datetime-format` and `awslogs-multiline-pattern` options.

 **Note**

Multiline logging performs regular expression parsing and matching of all log messages. This might have a negative impact on logging performance.

The following options apply to all supported log drivers.

## mode

Required: No

Valid values: non-blocking | blocking

This option defines the delivery mode of log messages from the container to the log driver specified using `logDriver`. The delivery mode you choose affects application availability when the flow of logs from the container is interrupted.

If you use the `blocking` mode and the flow of logs is interrupted, calls from container code to write to the `stdout` and `stderr` streams will block. The logging thread of the application will block as a result. This may cause the application to become unresponsive and lead to container healthcheck failure.

If you use the `non-blocking` mode, the container's logs are instead stored in an in-memory intermediate buffer configured with the `max-buffer-size` option. This prevents the application from becoming unresponsive when logs cannot be sent. We recommend using this mode if you want to ensure service availability and are okay with some log loss. For more information, see [Preventing log loss with non-blocking mode in the awslogs container log driver](#).

You can set a default mode for all containers in a specific AWS Region by using the `defaultLogDriverMode` account setting. If you don't specify the mode option in the `logConfiguration` or configure the account setting, Amazon ECS will default to `non-blocking` mode. For more information about the account setting, see [Default log driver mode](#).

When `non-blocking` mode is used, the `max-buffer-size` log option controls the size of the buffer that's used for intermediate message storage. Make sure to specify an adequate buffer size based on your application. The total amount of memory allocated at the task level should be greater than the amount of memory that's allocated for all the containers in addition to the log driver memory buffer.

### Note

On June 25, 2025, Amazon ECS changed the default log driver mode from `blocking` to `non-blocking` to prioritize task availability over logging. To continue using the `blocking` mode after this change, do one of the following:

- Set the mode option in your container definition's logConfiguration as blocking.
- Set the defaultLogDriverMode account setting to blocking.

## max-buffer-size

Required: No

Default value: 10m

When non-blocking mode is used, the max-buffer-size log option controls the size of the buffer that's used for intermediate message storage. Make sure to specify an adequate buffer size based on your application. When the buffer fills up, further logs cannot be stored. Logs that cannot be stored are lost.

To route logs using the splunk log router, you need to specify a splunk-token and a splunk-url.

When you use the awsfirelens log router to route logs to an AWS service or AWS Partner Network destination for log storage and analytics, you can set the log-driver-buffer-limit option to limit the number of log lines that are buffered in memory, before being sent to the log router container. It can help to resolve potential log loss issue because high throughput might result in memory running out for the buffer inside of Docker. For more information, see [the section called “Configuring logs for high throughput”](#).

Other options you can specify when using awsfirelens to route logs depend on the destination. When you export logs to Amazon Data Firehose, you can specify the AWS Region with region and a name for the log stream with delivery\_stream.

When you export logs to Amazon Kinesis Data Streams, you can specify an AWS Region with region and a data stream name with stream.

When you export logs to Amazon OpenSearch Service, you can specify options like Name, Host (OpenSearch Service endpoint without protocol), Port, Index, Type, Aws\_auth, Aws\_region, Suppress\_Type\_Name, and tls.

When you export logs to Amazon S3, you can specify the bucket using the bucket option. You can also specify region, total\_file\_size, upload\_timeout, and use\_put\_object as options.

This parameter requires version 1.19 of the Docker Remote API or greater on your container instance.

### secretOptions

Type: Object array

Required: No

An object that represents the secret to pass to the log configuration. Secrets that are used in log configuration can include an authentication token, certificate, or encryption key. For more information, see [Pass sensitive data to an Amazon ECS container](#).

#### name

Type: String

Required: Yes

The value to set as the environment variable on the container.

#### valueFrom

Type: String

Required: Yes

The secret to expose to the log configuration of the container.

```
"logConfiguration": {
  "logDriver": "splunk",
  "options": {
    "splunk-url": "https://cloud.splunk.com:8080",
    "splunk-token": "...",
    "tag": "...",
    ...
  },
  "secretOptions": [{
    "name": "splunk-token",
    "valueFrom": "/ecs/logconfig/splunkcred"
  }]
}
```

### firelensConfiguration

Type: [FirelensConfiguration](#) Object

Required: No

The FireLens configuration for the container. This is used to specify and configure a log router for container logs. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

```
{
  "firelensConfiguration": {
    "type": "fluentd",
    "options": {
      "KeyName": ""
    }
  }
}
```

options

Type: String to string map

Required: No

The key/value map of options to use when configuring the log router. This field is optional and can be used to specify a custom configuration file or to add additional metadata, such as the task, task definition, cluster, and container instance details to the log event. If specified, the syntax to use is "options":{"enable-ecs-log-metadata":"true|false", "config-file-type":"s3|file", "config-file-value":"arn:aws:s3:::*amzn-s3-demo-bucket*/fluent.conf|filepath"}. For more information, see [Example Amazon ECS task definition: Route logs to FireLens](#).

type

Type: String

Required: Yes

The log router to use. The valid values are fluentd or fluentbit.

## Security

For more information about container security, see [Amazon ECS task and container security best practices](#).

## credentialSpecs

Type: String array

Required: No

A list of ARNs in SSM or Amazon S3 to a credential spec (CredSpec) file that configures the container for Active Directory authentication. We recommend that you use this parameter instead of the `dockerSecurityOptions`. The maximum number of ARNs is 1.

There are two formats for each ARN.

`credentialSpecDomainless:MyARN`

You use `credentialSpecDomainless:MyARN` to provide a CredSpec with an additional section for a secret in Secrets Manager. You provide the login credentials to the domain in the secret.

Each task that runs on any container instance can join different domains.

You can use this format without joining the container instance to a domain.

`credentialSpec:MyARN`

You use `credentialSpec:MyARN` to provide a CredSpec for a single domain.

You must join the container instance to the domain before you start any tasks that use this task definition.

In both formats, replace MyARN with the ARN in SSM or Amazon S3.

The `credspec` must provide a ARN in Secrets Manager for a secret containing the username, password, and the domain to connect to. For better security, the instance isn't joined to the domain for domainless authentication. Other applications on the instance can't use the domainless credentials. You can use this parameter to run tasks on the same instance, even if the tasks need to join different domains. For more information, see [Using gMSAs for Windows Containers](#) and [Using gMSAs for Linux Containers](#).

## user

Type: String

Required: No

The user to use inside the container. This parameter maps to `User` in the `docker create-container` command and the `--user` option to `docker run`.

 **Important**

When running tasks that use the host network mode, don't run containers using the root user (UID 0). As a security best practice, always use a non-root user.

You can specify the user using the following formats. If specifying a UID or GID, you must specify it as a positive integer.

- `user`
- `user:group`
- `uid`
- `uid:gid`
- `user:gid`
- `uid:group`

 **Note**

This parameter is not supported for Windows containers.

```
"user": "string"
```

## Resource limits

### `ulimits`

Type: Object array

Required: No

A list of `ulimit` values to define for a container. This value overwrites the default resource quota setting for the operating system. This parameter maps to `Ulimits` in the `docker create-container` command and the `--ulimit` option to `docker run`.

Amazon ECS tasks hosted on Fargate use the default resource limit values set by the operating system with the exception of the `nofile` resource limit parameter. The `nofile` resource limit sets a restriction on the number of open files that a container can use. On Fargate, the default `nofile` soft limit is 65535 and hard limit is 65535. You can set the values of both limits up to 1048576. For more information, see [Task resource limits](#).

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

 **Note**

This parameter is not supported for Windows containers.

```
"ulimits": [
  {
    "name":
"core"|"cpu"|"data"|"fsize"|"locks"|"memlock"|"msgqueue"|"nice"|"nofile"|"nproc"|"rss"|"rtpr
    "softLimit": integer,
    "hardLimit": integer
  }
  ...
]
```

name

Type: String

Valid values: "core" | "cpu" | "data" | "fsize" | "locks" | "memlock" | "msgqueue" | "nice" | "nofile" | "nproc" | "rss" | "rtprio" | "rttime" | "sigpending" | "stack"

Required: Yes, when `ulimits` are used

The type of the `ulimit`.

hardLimit

Type: Integer

Required: Yes, when `ulimits` are used

The hard limit for the `ulimit` type. The value can be specified in bytes, seconds, or as a count, depending on the type of the `ulimit`.

`softLimit`

Type: Integer

Required: Yes, when `ulimits` are used

The soft limit for the `ulimit` type. The value can be specified in bytes, seconds, or as a count, depending on the type of the `ulimit`.

## Docker labels

`dockerLabels`

Type: String to string map

Required: No

A key/value map of labels to add to the container. This parameter maps to `Labels` in the `docker create-container` command and the `--label` option to `docker run`.

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

```
"dockerLabels": {"string": "string"
  ...}
```

## Other container definition parameters

The following container definition parameters can be used when registering task definitions in the Amazon ECS console by using the **Configure via JSON** option. For more information, see [Creating an Amazon ECS task definition using the console](#).

### Topics

- [Linux parameters](#)
- [Container dependency](#)
- [Container timeouts](#)

- [System controls](#)
- [Interactive](#)
- [Pseudo terminal](#)

## Linux parameters

### linuxParameters

Type: [LinuxParameters](#) object

Required: No

Linux-specific options that are applied to the container, such as [KernelCapabilities](#).

#### Note

This parameter isn't supported for Windows containers.

```
"linuxParameters": {
  "capabilities": {
    "add": ["string", ...],
    "drop": ["string", ...]
  }
}
```

### capabilities

Type: [KernelCapabilities](#) object

Required: No

The Linux capabilities for the container that are dropped from the default configuration provided by Docker. For more information about these Linux capabilities, see the [capabilities\(7\)](#) Linux manual page.

#### add

Type: String array

Valid values: "SYS\_PTRACE"

Required: No

The Linux capabilities for the container to add to the default configuration that's provided by Docker. This parameter maps to CapAdd in the docker create-container command and the --cap-add option to docker run.

drop

Type: String array

Valid values: "ALL" | "AUDIT\_CONTROL" | "AUDIT\_WRITE" | "BLOCK\_SUSPEND" | "CHOWN" | "DAC\_OVERRIDE" | "DAC\_READ\_SEARCH" | "FOWNER" | "FSETID" | "IPC\_LOCK" | "IPC\_OWNER" | "KILL" | "LEASE" | "LINUX\_IMMUTABLE" | "MAC\_ADMIN" | "MAC\_OVERRIDE" | "MKNOD" | "NET\_ADMIN" | "NET\_BIND\_SERVICE" | "NET\_BROADCAST" | "NET\_RAW" | "SETFCAP" | "SETGID" | "SETPCAP" | "SETUID" | "SYS\_ADMIN" | "SYS\_BOOT" | "SYS\_CHROOT" | "SYS\_MODULE" | "SYS\_NICE" | "SYS\_PACCT" | "SYS\_PTRACE" | "SYS\_RAWIO" | "SYS\_RESOURCE" | "SYS\_TIME" | "SYS\_TTY\_CONFIG" | "SYSLOG" | "WAKE\_ALARM"

Required: No

The Linux capabilities for the container to remove from the default configuration that's provided by Docker. This parameter maps to CapDrop in the docker create-container command and the --cap-drop option to docker run.

devices

Any host devices to expose to the container. This parameter maps to Devices in the docker create-container command and the --device option to Docker run.

 **Note**

The devices parameter isn't supported when you use the Fargate launch type.

Type: Array of [Device](#) objects

Required: No

hostPath

The path for the device on the host container instance.

Type: String

Required: Yes

`containerPath`

The path inside the container to expose the host device at.

Type: String

Required: No

`permissions`

The explicit permissions to provide to the container for the device. By default, the container has permissions for `read`, `write`, and `mknod` on the device.

Type: Array of strings

Valid Values: `read` | `write` | `mknod`

`initProcessEnabled`

Run an `init` process inside the container that forwards signals and reaps processes. This parameter maps to the `--init` option to `docker run`.

This parameter requires version 1.25 of the Docker Remote API or greater on your container instance.

`maxSwap`

This is not supported for tasks running on Fargate.

The total amount of swap memory (in MiB) a container can use. This parameter is translated to the `--memory-swap` option to `docker run` where the value is the sum of the container memory plus the `maxSwap` value.

If a `maxSwap` value of `0` is specified, the container doesn't use swap. Accepted values are `0` or any positive integer. If the `maxSwap` parameter is omitted, the container uses the swap configuration for the container instance that it's running on. A `maxSwap` value must be set for the `swappiness` parameter to be used.

`sharedMemorySize`

The value for the size (in MiB) of the `/dev/shm` volume. This parameter maps to the `--shm-size` option to `docker run`.

**Note**

If you're using tasks that use Fargate, the `sharedMemorySize` parameter isn't supported.

Type: Integer

`tmpfs`

The container path, mount options, and maximum size (in MiB) of the `tmpfs` mount. This parameter maps to the `--tmpfs` option to `docker run`.

Type: Array of [Tmpfs](#) objects

Required: No

`containerPath`

The absolute file path where the `tmpfs` volume is to be mounted.

Type: String

Required: Yes

`mountOptions`

The list of `tmpfs` volume mount options.

Type: Array of strings

Required: No

Valid Values: "defaults" | "ro" | "rw" | "suid" | "nosuid" | "dev" | "nodev" | "exec" | "noexec" | "sync" | "async" | "dirsync" | "remount" | "mand" | "nomand" | "atime" | "noatime" | "diratime" | "nodiratime" | "bind" | "rbind" | "unbindable" | "runbindable" | "private" | "rprivate" | "shared" | "rshared" | "slave" | "rslave" | "relatime" | "norelatime" | "strictatime" | "nostrictatime" | "mode" | "uid" | "gid" | "nr\_inodes" | "nr\_blocks" | "mpol"

`size`

The maximum size (in MiB) of the `tmpfs` volume.

Type: Integer

Required: Yes

## Container dependency

dependsOn

Type: Array of [ContainerDependency](#) objects

Required: No

The dependencies defined for container startup and shutdown. A container can contain multiple dependencies. When a dependency is defined for container startup, for container shutdown it is reversed. For an example, see [Container dependency](#).

### Note

If a container doesn't meet a dependency constraint or times out before meeting the constraint, Amazon ECS doesn't progress dependent containers to their next state.

This parameter requires that the task or service uses platform version 1.3.0 or later (Linux) or 1.0.0 (Windows).

```
"dependsOn": [  
  {  
    "containerName": "string",  
    "condition": "string"  
  }  
]
```

containerName

Type: String

Required: Yes

The container name that must meet the specified condition.

condition

Type: String

**Required: Yes**

The dependency condition of the container. The following are the available conditions and their behavior:

- **START** – This condition emulates the behavior of links and volumes today. The condition validates that a dependent container is started before permitting other containers to start.
- **COMPLETE** – This condition validates that a dependent container runs to completion (exits) before permitting other containers to start. This can be useful for non-essential containers that run a script and then exit. This condition can't be set on an essential container.
- **SUCCESS** – This condition is the same as **COMPLETE**, but it also requires that the container exits with a zero status. This condition can't be set on an essential container.
- **HEALTHY** – This condition validates that the dependent container passes its container health check before permitting other containers to start. This requires that the dependent container has health checks configured in the task definition. This condition is confirmed only at task startup.

**Container timeouts****startTimeout**

Type: Integer

Required: No

Example values: 120

Time duration (in seconds) to wait before giving up on resolving dependencies for a container.

For example, you specify two containers in a task definition with `containerA` having a dependency on `containerB` reaching a **COMPLETE**, **SUCCESS**, or **HEALTHY** status. If a `startTimeout` value is specified for `containerB` and it doesn't reach the desired status within that time, then `containerA` doesn't start.

**Note**

If a container doesn't meet a dependency constraint or times out before meeting the constraint, Amazon ECS doesn't progress dependent containers to their next state.

This parameter requires that the task or service uses platform version 1.3.0 or later (Linux). The maximum value is 120 seconds.

`stopTimeout`

Type: Integer

Required: No

Example values: 120

Time duration (in seconds) to wait before the container is forcefully killed if it doesn't exit normally on its own.

This parameter requires that the task or service uses platform version 1.3.0 or later (Linux). If the parameter isn't specified, then the default value of 30 seconds is used. The maximum value is 120 seconds.

## System controls

`systemControls`

Type: [SystemControl](#) object

Required: No

A list of namespace kernel parameters to set in the container. This parameter maps to `Sysctl`s in the `docker create-container` command and the `--sysctl` option to `docker run`. For example, you can configure `net.ipv4.tcp_keepalive_time` setting to maintain longer lived connections.

We don't recommend that you specify network-related `systemControls` parameters for multiple containers in a single task that also uses either the `awsvpc` or `host` network mode. Doing this has the following disadvantages:

- If you set `systemControls` for any container, it applies to all containers in the task. If you set different `systemControls` for multiple containers in a single task, the container that's started last determines which `systemControls` take effect.

If you're setting an IPC resource namespace to use for the containers in the task, the following conditions apply to your system controls. For more information, see [IPC mode](#).

- For tasks that use the host IPC mode, IPC namespace `systemControls` aren't supported.
- For tasks that use the task IPC mode, IPC namespace `systemControls` values apply to all containers within a task.

**Note**

This parameter is not supported for Windows containers.

**Note**

This parameter is only supported for tasks that are hosted on AWS Fargate if the tasks are using platform version 1.4.0 or later (Linux). This isn't supported for Windows containers on Fargate.

```
"systemControls": [  
  {  
    "namespace": "string",  
    "value": "string"  
  }  
]
```

## namespace

Type: String

Required: No

The namespace kernel parameter to set a value for.

Valid IPC namespace values: "kernel.msgmax" | "kernel.msgmnb" | "kernel.msgmni" | "kernel.sem" | "kernel.shmall" | "kernel.shmmax" | "kernel.shmmni" | "kernel.shm\_rmid\_forced", and Sysctls that start with "fs.mqueue.\*"

Valid network namespace values: Sysctls that start with "net.\*". On Fargate, only namespaced Sysctls that exist within the container are accepted.

All of these values are supported by Fargate.

`value`

Type: String

Required: No

The value for the namespace kernel parameter that's specified in namespace.

## Interactive

`interactive`

Type: Boolean

Required: No

When this parameter is `true`, you can deploy containerized applications that require `stdin` or a `tty` to be allocated. This parameter maps to `OpenStdin` in the `docker create-container` command and the `--interactive` option to `docker run`.

The default is `false`.

## Pseudo terminal

`pseudoTerminal`

Type: Boolean

Required: No

When this parameter is `true`, a TTY is allocated. This parameter maps to `Tty` in the `docker create-container` command and the `--tty` option to `docker run`.

The default is `false`.

## Elastic Inference accelerator name (deprecated)

The Elastic Inference accelerator resource requirement for your task definition.

**Note**

Amazon Elastic Inference (EI) is no longer available to customers.

The following parameters are allowed in a task definition:

`deviceName`

Type: String

Required: Yes

The Elastic Inference accelerator device name. The `deviceName` must also be referenced in a container definition see [Elastic Inference accelerator](#).

`deviceType`

Type: String

Required: Yes

The Elastic Inference accelerator to use.

## Proxy configuration

`proxyConfiguration`

Type: [ProxyConfiguration](#) object

Required: No

The configuration details for the App Mesh proxy.

**Note**

This parameter is not supported for Windows containers.

```
"proxyConfiguration": {
```

```
{
  "type": "APPMESH",
  "containerName": "string",
  "properties": [
    {
      "name": "string",
      "value": "string"
    }
  ]
}
```

## type

Type: String

Value values: APPMESH

Required: No

The proxy type. The only supported value is APPMESH.

## containerName

Type: String

Required: Yes

The name of the container that serves as the App Mesh proxy.

## properties

Type: Array of [KeyValuePair](#) objects

Required: No

The set of network configuration parameters to provide the Container Network Interface (CNI) plugin, specified as key-value pairs.

- IgnoredUID – (Required) The user ID (UID) of the proxy container as defined by the user parameter in a container definition. This is used to ensure the proxy ignores its own traffic. If IgnoredGID is specified, this field can be empty.
- IgnoredGID – (Required) The group ID (GID) of the proxy container as defined by the user parameter in a container definition. This is used to ensure the proxy ignores its own traffic. If IgnoredUID is specified, this field can be empty.

- **AppPorts** – (Required) The list of ports that the application uses. Network traffic to these ports is forwarded to the `ProxyIngressPort` and `ProxyEgressPort`.
- **ProxyIngressPort** – (Required) Specifies the port that incoming traffic to the `AppPorts` is directed to.
- **ProxyEgressPort** – (Required) Specifies the port that outgoing traffic from the `AppPorts` is directed to.
- **EgressIgnoredPorts** – (Required) The outbound traffic going to these specified ports is ignored and not redirected to the `ProxyEgressPort`. It can be an empty list.
- **EgressIgnoredIPs** – (Required) The outbound traffic going to these specified IP addresses is ignored and not redirected to the `ProxyEgressPort`. It can be an empty list.

name

Type: String

Required: No

The name of the key-value pair.

value

Type: String

Required: No

The value of the key-value pair.

## Volumes

When you register a task definition, you can optionally specify a list of volumes to be passed to the Docker daemon on a container instance, which then becomes available for access by other containers on the same container instance.

The following are the types of data volumes that can be used:

- **Amazon EBS volumes** — Provides cost-effective, durable, high-performance block storage for data intensive containerized workloads. You can attach 1 Amazon EBS volume per Amazon ECS task when running a standalone task, or when creating or updating a service. Amazon EBS volumes are supported for Linux tasks hosted on Fargate. For more information, see [Use Amazon EBS volumes with Amazon ECS](#).

- Amazon EFS volumes — Provides simple, scalable, and persistent file storage for use with your Amazon ECS tasks. With Amazon EFS, storage capacity is elastic. It grows and shrinks automatically as you add and remove files. Your applications can have the storage that they need and when they need it. Amazon EFS volumes are supported for tasks that are hosted on Fargate. For more information, see [Use Amazon EFS volumes with Amazon ECS](#).
- FSx for Windows File Server volumes — Provides fully managed Microsoft Windows file servers. These file servers are backed by a Windows file system. When using FSx for Windows File Server together with Amazon ECS, you can provision your Windows tasks with persistent, distributed, shared, and static file storage. For more information, see [Use FSx for Windows File Server volumes with Amazon ECS](#).

Windows containers on Fargate do not support this option.

- Bind mounts – A file or directory on the host machine that is mounted into a container. Bind mount host volumes are supported when running tasks. To use bind mount host volumes, specify a host and optional sourcePath value in your task definition.

For more information, see [Storage options for Amazon ECS tasks](#).

The following parameters are allowed in a container definition.

name

Type: String

Required: No

The name of the volume. Up to 255 letters (uppercase and lowercase), numbers, hyphens (-), and underscores (\_) are allowed. This name is referenced in the sourceVolume parameter of the container definition mountPoints object.

host

Required: No

The host parameter is used to tie the lifecycle of the bind mount to the host Amazon EC2 instance, rather than the task, and where it is stored. If the host parameter is empty, then the Docker daemon assigns a host path for your data volume, but the data is not guaranteed to persist after the containers associated with it stop running.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`.

**Note**

The `sourcePath` parameter is supported only when using tasks that are hosted on Amazon EC2 instances or Amazon ECS Managed Instances.

`sourcePath`

Type: String

Required: No

When the `host` parameter is used, specify a `sourcePath` to declare the path on the host Amazon EC2 instance that is presented to the container. If this parameter is empty, then the Docker daemon assigns a host path for you. If the `host` parameter contains a `sourcePath` file location, then the data volume persists at the specified location on the host Amazon EC2 instance until you delete it manually. If the `sourcePath` value does not exist on the host Amazon EC2 instance, the Docker daemon creates it. If the location does exist, the contents of the source path folder are exported.

`configuredAtLaunch`

Type: Boolean

Required: No

Specifies whether a volume is configurable at launch. When set to `true`, you can configure the volume when running a standalone task, or when creating or updating a service. When set to `true`, you won't be able to provide another volume configuration in the task definition. This parameter must be set to `true` to configure an Amazon EBS volume for attachment to a task. Setting `configuredAtLaunch` to `true` and deferring volume configuration to the launch phase allows you to create task definitions that aren't constrained to a volume type or to specific volume settings. Doing this makes your task definition reusable across different execution environments. For more information, see [Amazon EBS volumes](#).

`dockerVolumeConfiguration`

Type: [DockerVolumeConfiguration](#) Object

Required: No

This parameter is specified when using Docker volumes. Docker volumes are supported only when running tasks on EC2 instances. Windows containers support only the use of the `local` driver. To use bind mounts, specify a host instead.

`scope`

Type: String

Valid Values: `task` | `shared`

Required: No

The scope for the Docker volume, which determines its lifecycle. Docker volumes that are scoped to a task are automatically provisioned when the task starts and destroyed when the task stops. Docker volumes that are scoped as `shared` persist after the task stops.

`autoprovision`

Type: Boolean

Default value: `false`

Required: No

If this value is `true`, the Docker volume is created if it doesn't already exist. This field is used only if the scope is `shared`. If the scope is `task`, then this parameter must be omitted.

`driver`

Type: String

Required: No

The Docker volume driver to use. The driver value must match the driver name provided by Docker because this name is used for task placement. If the driver was installed by using the Docker plugin CLI, use `docker plugin ls` to retrieve the driver name from your container instance. If the driver was installed by using another method, use Docker plugin discovery to retrieve the driver name.

`driverOpts`

Type: String

Required: No

A map of Docker driver-specific options to pass through. This parameter maps to `DriverOpts` in the Create a volume section of Docker.

`labels`

Type: String

Required: No

Custom metadata to add to your Docker volume.

`efsVolumeConfiguration`

Type: [EFSVolumeConfiguration](#) Object

Required: No

This parameter is specified when using Amazon EFS volumes.

`fileSystemId`

Type: String

Required: Yes

The Amazon EFS file system ID to use.

`rootDirectory`

Type: String

Required: No

The directory within the Amazon EFS file system to mount as the root directory inside the host. If this parameter is omitted, the root of the Amazon EFS volume will be used. Specifying `/` has the same effect as omitting this parameter.

 **Important**

If an EFS access point is specified in the `authorizationConfig`, the `rootDirectory` parameter must either be omitted or set to `/`, which will enforce the path set on the EFS access point.

## transitEncryption

Type: String

Valid values: ENABLED | DISABLED

Required: No

Specifies whether to enable encryption for Amazon EFS data in transit between the Amazon ECS host and the Amazon EFS server. If Amazon EFS IAM authorization is used, transit encryption must be enabled. If this parameter is omitted, the default value of DISABLED is used. For more information, see [Encrypting Data in Transit](#) in the *Amazon Elastic File System User Guide*.

## transitEncryptionPort

Type: Integer

Required: No

The port to use when sending encrypted data between the Amazon ECS host and the Amazon EFS server. If you don't specify a transit encryption port, the task will use the port selection strategy that the Amazon EFS mount helper uses. For more information, see [EFS Mount Helper](#) in the *Amazon Elastic File System User Guide*.

## authorizationConfig

Type: [EFSAuthorizationConfig](#) Object

Required: No

The authorization configuration details for the Amazon EFS file system.

## accessPointId

Type: String

Required: No

The access point ID to use. If an access point is specified, the root directory value in the `efsVolumeConfiguration` must either be omitted or set to `/`, which will enforce the path set on the EFS access point. If an access point is used, transit encryption must be enabled in the `EFSVolumeConfiguration`. For more information, see [Working with Amazon EFS Access Points](#) in the *Amazon Elastic File System User Guide*.

iam

Type: String

Valid values: ENABLED | DISABLED

Required: No

Specifies whether to use the Amazon ECS task IAM role that's defined in a task definition when mounting the Amazon EFS file system. If enabled, transit encryption must be enabled in the `EFSVolumeConfiguration`. If this parameter is omitted, the default value of DISABLED is used. For more information, see [IAM Roles for Tasks](#).

`FSxWindowsFileServerVolumeConfiguration`

Type: [FSxWindowsFileServerVolumeConfiguration](#) Object

Required: Yes

This parameter is specified when you're using an [Amazon FSx for Windows File Server](#) file system for task storage.

`fileSystemId`

Type: String

Required: Yes

The FSx for Windows File Server file system ID to use.

`rootDirectory`

Type: String

Required: Yes

The directory within the FSx for Windows File Server file system to mount as the root directory inside the host.

`authorizationConfig`

`credentialsParameter`

Type: String

Required: Yes

The authorization credential options.

**options:**

- Amazon Resource Name (ARN) of an [AWS Secrets Manager](#) secret.
- ARN of an [AWS Systems Manager](#) parameter.

domain

Type: String

Required: Yes

A fully qualified domain name hosted by an [AWS Directory Service for Microsoft Active Directory](#) (AWS Managed Microsoft AD) directory or a self-hosted EC2 Active Directory.

## Tags

When you register a task definition, you can optionally specify metadata tags that are applied to the task definition. Tags help you categorize and organize your task definition. Each tag consists of a key and an optional value. You define both of them. For more information, see [Tagging Amazon ECS resources](#).

### Important

Don't add personally identifiable information or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including billing. Tags aren't intended to be used for private or sensitive data.

The following parameters are allowed in a tag object.

key

Type: String

Required: No

One part of a key-value pair that make up a tag. A key is a general label that acts like a category for more specific tag values.

value

Type: String

Required: No

The optional part of a key-value pair that make up a tag. A value acts as a descriptor within a tag category (key).

## Other task definition parameters

The following task definition parameters can be used when registering task definitions in the Amazon ECS console by using the **Configure via JSON** option. For more information, see [Creating an Amazon ECS task definition using the console](#).

### Topics

- [Ephemeral storage](#)
- [IPC mode](#)
- [PID mode](#)
- [Fault injection](#)

## Ephemeral storage

ephemeralStorage

Type: [EphemeralStorage](#) object

Required: No

The amount of ephemeral storage (in GB) to allocate for the task. This parameter is used to expand the total amount of ephemeral storage available, beyond the default amount, for tasks that are hosted on AWS Fargate. For more information, see [the section called “Bind mounts”](#).

### Note

This parameter is only supported on platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows).

## IPC mode

### ipcMode

This is not supported for tasks running on Fargate.

Type: String

Required: No

The IPC resource namespace to use for the containers in the task. The valid values are `host`, `task`, or `none`. If `host` is specified, then all the containers that are within the tasks that specified the host IPC mode on the same container instance share the same IPC resources with the host Amazon EC2 instance. If `task` is specified, all the containers that are within the specified task share the same IPC resources. If `none` is specified, then IPC resources within the containers of a task are private and not shared with other containers in a task or on the container instance. If no value is specified, then the IPC resource namespace sharing depends on the Docker daemon setting on the container instance.

If the host IPC mode is used, there's a heightened risk of undesired IPC namespace exposure.

If you're setting namespaced kernel parameters that use `systemControls` for the containers in the task, the following applies to your IPC resource namespace.

- For tasks that use the host IPC mode, IPC namespace that's related `systemControls` aren't supported.
- For tasks that use the task IPC mode, `systemControls` that relate to the IPC namespace apply to all containers within a task.

#### Note

This parameter is not supported for Windows containers or tasks using the Fargate launch type.

## PID mode

### pidMode

Type: String

Valid Values: `host` | `task`

Required: No

The process namespace to use for the containers in the task. The valid values are `host` or `task`. On Linux containers, the only valid value is `task`. For example, monitoring sidecars might need `pidMode` to access information about other containers running in the same task.

If `task` is specified, all containers within the specified task share the same process namespace.

If no value is specified, the default is a private namespace for each container.

#### Note

This parameter is only supported for tasks that are hosted on AWS Fargate if the tasks are using platform version `1.4.0` or later (Linux). This isn't supported for Windows containers on Fargate.

## Fault injection

`enableFaultInjection`

Type: Boolean

Valid Values: `true` | `false`

Required: No

If this parameter is set to `true`, in a task's payload, Amazon ECS and Fargate accept fault injection requests from the task's containers. By default, this parameter is set to `false`.

## Amazon ECS task definition parameters for Amazon EC2

Task definitions are split into separate parts: the task family, the AWS Identity and Access Management (IAM) task role, the network mode, container definitions, volumes, task placement constraints, and capacity. The family and container definitions are required in a task definition. In contrast, task role, network mode, volumes, task placement constraints, and launch type are optional.

You can use these parameters in a JSON file to configure your task definition.

The following are more detailed descriptions for each task definition parameter for Amazon EC2

## Family

`family`

Type: String

Required: Yes

When you register a task definition, you give it a family, which is similar to a name for multiple versions of the task definition, specified with a revision number. The first task definition that's registered into a particular family is given a revision of 1, and any task definitions registered after that are given a sequential revision number.

## Capacity

When you register a task definition, you can specify the capacity that Amazon ECS should validate the task definition against. If the task definition doesn't validate against the compatibilities specified, a client exception is returned.

The following parameter is allowed in a task definition.

`requiresCompatibilities`

Type: String array

Required: No

Valid Values: EC2

The capacity to validate the task definition against. This initiates a check to ensure that all of the parameters that are used in the task definition meet the requirements of Amazon EC2.

## Task role

`taskRoleArn`

Type: String

Required: No

When you register a task definition, you can provide a task role for an IAM role that allows the containers in the task permission to call the AWS APIs that are specified in its associated policies on your behalf. For more information, see [Amazon ECS task IAM role](#).

When you launch the Amazon ECS-optimized Windows Server AMI, IAM roles for tasks on Windows require that the `-EnableTaskIAMRole` option is set. Your containers must also run some configuration code to use the feature. For more information, see [Amazon EC2 Windows instance additional configuration](#).

## Task execution role

`executionRoleArn`

Type: String

Required: Conditional

The Amazon Resource Name (ARN) of the task execution role that grants the Amazon ECS container agent permission to make AWS API calls on your behalf.

### Note

The task execution IAM role is required depending on the requirements of your task. For more information, see [Amazon ECS task execution IAM role](#).

## Network mode

`networkMode`

Type: String

Required: No

The Docker networking mode to use for the containers in the task. For Amazon ECS tasks that are hosted on Amazon EC2 Linux instances, the valid values are `none`, `bridge`, `awsvpc`, and `host`. If no network mode is specified, the default network mode is `bridge`. For Amazon ECS

tasks hosted on Amazon EC2 Windows instances, the valid values are `default`, and `awsvpc`. If no network mode is specified, the `default` network mode is used.

If the network mode is set to `none`, the task's containers don't have external connectivity and port mappings can't be specified in the container definition.

If the network mode is `bridge`, the task uses Docker's built-in virtual network on Linux, which runs inside each Amazon EC2 instance that hosts the task. The built-in virtual network on Linux uses the `bridge` Docker network driver.

If the network mode is `host`, the task uses the host's network which bypasses Docker's built-in virtual network by mapping container ports directly to the ENI of the Amazon EC2 instance that hosts the task. Dynamic port mappings can't be used in this network mode. A container in a task definition that uses this mode must specify a specific `hostPort` number. A port number on a host can't be used by multiple tasks. As a result, you can't run multiple tasks of the same task definition on a single Amazon EC2 instance.

 **Important**

When running tasks that use the host network mode, do not run containers using the root user (UID 0) for better security. As a security best practice, always use a non-root user.

If the network mode is `awsvpc`, the task is allocated an elastic network interface, and you must specify a `NetworkConfiguration` when you create a service or run a task with the task definition. For more information, see [Amazon ECS task networking options for EC2](#).

If the network mode is `default`, the task uses Docker's built-in virtual network on Windows, which runs inside each Amazon EC2 instance that hosts the task. The built-in virtual network on Windows uses the `nat` Docker network driver.

The `host` and `awsvpc` network modes offer the highest networking performance for containers because they use the Amazon EC2 network stack. With the `host` and `awsvpc` network modes, exposed container ports are mapped directly to the corresponding host port (for the `host` network mode) or the attached elastic network interface port (for the `awsvpc` network mode). Because of this, you can't use dynamic host port mappings.

The allowable network mode depends on the underlying EC2 instance's operating system. If Linux, any network mode can be used. If Windows, the default, and awsvpc modes can be used.

## Runtime platform

### `operatingSystemFamily`

Type: String

Required: Conditional

Default: LINUX

When you register a task definition, you specify the operating system family.

The valid values are LINUX, WINDOWS\_SERVER\_2025\_FULL, WINDOWS\_SERVER\_2025\_CORE, WINDOWS\_SERVER\_2022\_CORE, WINDOWS\_SERVER\_2022\_FULL, WINDOWS\_SERVER\_2019\_FULL, and WINDOWS\_SERVER\_2019\_CORE, WINDOWS\_SERVER\_2016\_FULL, WINDOWS\_SERVER\_2004\_CORE, and WINDOWS\_SERVER\_20H2\_CORE.

All task definitions that are used in a service must have the same value for this parameter.

When a task definition is part of a service, this value must match the service `platformFamily` value.

### `cpuArchitecture`

Type: String

Required: Conditional

When you register a task definition, you can specify the CPU architecture. The valid values are X86\_64 and ARM64. If you don't specify a value, Amazon ECS attempts to place tasks on the available CPU architecture based on the capacity provider configuration. To ensure that tasks are placed on a specific CPU architecture, specify a value for `cpuArchitecture` in the task definition.

All task definitions that are used in a service must have the same value for this parameter.

When you have Linux tasks, you can set the value to ARM64. For more information, see [the section called “Task definitions for 64-bit ARM workloads”](#).

## Task size

When you register a task definition, you can specify the total CPU and memory used for the task. This is separate from the `cpu` and `memory` values at the container definition level. For tasks that are hosted on Amazon EC2 instances, these fields are optional.

### Note

Task-level CPU and memory parameters are ignored for Windows containers. We recommend specifying container-level resources for Windows containers.

### `cpu`

Type: String

Required: Conditional

### Note

This parameter is not supported for Windows containers.

The hard limit of CPU units to present for the task. You can specify CPU values in the JSON file as a string in CPU units or virtual CPUs (vCPUs). For example, you can specify a CPU value either as 1024 in CPU units or 1 vCPU in vCPUs. When the task definition is registered, a vCPU value is converted to an integer indicating the CPU units.

This field is optional. If your cluster doesn't have any registered container instances with the requested CPU units available, the task fails. Supported values are between 0.125 vCPUs and 192 vCPUs.

### `memory`

Type: String

Required: Conditional

 **Note**

This parameter is not supported for Windows containers.

The hard limit of memory to present to the task. You can specify memory values in the task definition as a string in mebibytes (MiB) or gigabytes (GB). For example, you can specify a memory value either as 3072 in MiB or 3 GB in GB. When the task definition is registered, a GB value is converted to an integer indicating the MiB.

This field is optional and any value can be used. If a task-level memory value is specified, then the container-level memory value is optional. If your cluster doesn't have any registered container instances with the requested memory available, the task fails. You can maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type. For more information, see [Reserving Amazon ECS Linux container instance memory](#).

## Container definitions

When you register a task definition, you must specify a list of container definitions that are passed to the Docker daemon on a container instance. The following parameters are allowed in a container definition.

### Topics

- [Standard container definition parameters](#)
- [Advanced container definition parameters](#)
- [Other container definition parameters](#)

## Standard container definition parameters

The following task definition parameters are either required or used in most container definitions.

### Topics

- [Name](#)
- [Image](#)

- [Memory](#)
- [Port mappings](#)
- [Private Repository Credentials](#)

## Name

name

Type: String

Required: Yes

The name of a container. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed. If you're linking multiple containers in a task definition, the name of one container can be entered in the `links` of another container. This is to connect the containers.

## Image

image

Type: String

Required: Yes

The image used to start a container. This string is passed directly to the Docker daemon. By default, images in the Docker Hub registry are available. You can also specify other repositories with either *repository-url/image:tag* or *repository-url/image@digest*. Up to 255 letters (uppercase and lowercase), numbers, hyphens, underscores, colons, periods, forward slashes, and number signs are allowed. This parameter maps to `Image` in the `docker create-container` command and the `IMAGE` parameter of the `Docker run` command.

- When a new task starts, the Amazon ECS container agent pulls the latest version of the specified image and tag for the container to use. However, subsequent updates to a repository image aren't propagated to already running tasks.
- When you don't specify a tag or digest in the image path in the task definition, the Amazon ECS container agent uses the latest tag to pull the specified image.
- Subsequent updates to a repository image aren't propagated to already running tasks.

- Images in private registries are supported. For more information, see [Using non-AWS container images in Amazon ECS](#).
- Images in Amazon ECR repositories can be specified by using either the full registry/repository:tag or registry/repository@digest naming convention (for example, `aws_account_id.dkr.ecr.region.amazonaws.com/my-web-app:latest` or `aws_account_id.dkr.ecr.region.amazonaws.com/my-web-app@sha256:94afd1f2e64d908bc90dbca0035a5b567EXAMPLE`).
- Images in official repositories on Docker Hub use a single name (for example, ubuntu or mongo).
- Images in other repositories on Docker Hub are qualified with an organization name (for example, amazon/amazon-ecs-agent).
- Images in other online repositories are qualified further by a domain name (for example, quay.io/assemblyline/ubuntu).

versionConsistency

Type: String

Valid values: enabled|disabled

Required: No

Specifies whether Amazon ECS will resolve the container image tag provided in the container definition to an image digest. By default, this behavior is enabled. If you set the value for a container as disabled, Amazon ECS will not resolve the container image tag to a digest and will use the original image URI specified in the container definition for deployment. For more information about container image resolution, see [Container image resolution](#).

## Memory

memory

Type: Integer

Required: No

The amount (in MiB) of memory to present to the container. If your container attempts to exceed the memory specified here, the container is killed. The total amount of memory reserved for all containers within a task must be lower than the task memory value, if one is

specified. This parameter maps to `Memory` in the `docker create-container` command and the `--memory` option to `docker run`.

You must specify either a task-level memory value or a container-level memory value. If you specify both a container-level memory and `memoryReservation` value, the memory value must be greater than the `memoryReservation` value. If you specify `memoryReservation`, then that value is subtracted from the available memory resources for the container instance that the container is placed on. Otherwise, the value of `memory` is used.

The Docker 20.10.0 or later daemon reserves a minimum of 6 MiB of memory for a container. So, don't specify less than 6 MiB of memory for your containers.

The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container. So, don't specify less than 4 MiB of memory for your containers.

 **Note**

If you're trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see [Reserving Amazon ECS Linux container instance memory](#).

## `memoryReservation`

Type: Integer

Required: No

The soft limit (in MiB) of memory to reserve for the container. When system memory is under contention, Docker attempts to keep the container memory to this soft limit. However, your container can use more memory when needed. The container can use up to the hard limit that's specified with the `memory` parameter (if applicable) or all of the available memory on the container instance, whichever comes first. This parameter maps to `MemoryReservation` in the `docker create-container` command and the `--memory-reservation` option to `docker run`.

If a task-level memory value isn't specified, you must specify a non-zero integer for one or both of `memory` or `memoryReservation` in a container definition. If you specify both, `memory` must be greater than `memoryReservation`. If you specify `memoryReservation`, then that value is subtracted from the available memory resources for the container instance that the container is placed on. Otherwise, the value of `memory` is used.

For example, suppose that your container normally uses 128 MiB of memory, but occasionally bursts to 256 MiB of memory for short periods of time. You can set a `memoryReservation` of 128 MiB, and a memory hard limit of 300 MiB. This configuration allows the container to only reserve 128 MiB of memory from the remaining resources on the container instance. At the same time, this configuration also allows the container to use more memory resources when needed.

**Note**

This parameter isn't supported for Windows containers.

The Docker 20.10.0 or later daemon reserves a minimum of 6 MiB of memory for a container. So, don't specify less than 6 MiB of memory for your containers.

The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container. So, don't specify less than 4 MiB of memory for your containers.

**Note**

If you're trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see [Reserving Amazon ECS Linux container instance memory](#).

## Port mappings

### `portMappings`

Type: Object array

Required: No

Port mappings expose your container's network ports to the outside world. This allows clients to access your application. It's also used for inter-container communication within the same task.

For task definitions that use the `awsvpc` network mode, only specify the `containerPort`. The `hostPort` is always ignored, and the container port is automatically mapped to a random high-numbered port on the host.

Port mappings on Windows use the NetNAT gateway address rather than localhost. There's no loopback for port mappings on Windows, so you can't access a container's mapped port from the host itself.

Most fields of this parameter (including `containerPort`, `hostPort`, `protocol`) map to `PortBindings` in the `docker create-container` command and the `--publish` option to `docker run`. If the network mode of a task definition is set to `host`, host ports must either be undefined or match the container port in the port mapping.

 **Note**

After a task reaches the `RUNNING` status, manual and automatic host and container port assignments are visible in the following locations:

- Console: The **Network Bindings** section of a container description for a selected task.
- AWS CLI: The `networkBindings` section of the **describe-tasks** command output.
- API: The `DescribeTasks` response.
- Metadata: The task metadata endpoint.

## `appProtocol`

Type: String

Required: No

The application protocol that's used for the port mapping. This parameter only applies to Service Connect. We recommend that you set this parameter to be consistent with the protocol that your application uses. If you set this parameter, Amazon ECS adds protocol-specific connection handling to the service connect proxy. If you set this parameter, Amazon ECS adds protocol-specific telemetry in the Amazon ECS console and CloudWatch.

If you don't set a value for this parameter, then TCP is used. However, Amazon ECS doesn't add protocol-specific telemetry for TCP.

For more information, see [the section called "Service Connect"](#).

Valid protocol values: `"http"` | `"http2"` | `"grpc"`

## `containerPort`

Type: Integer

Required: Yes, when `portMappings` are used

The port number on the container that's bound to the user-specified or automatically assigned host port.

For tasks that use the `awsvpc` network mode, you use `containerPort` to specify the exposed ports.

Suppose that you're using containers in a task with the EC2 capacity providers and you specify a container port and not a host port. Then, your container automatically receives a host port in the ephemeral port range. For more information, see `hostPort`. Port mappings that are automatically assigned in this way don't count toward the 100 reserved ports quota of a container instance.

`containerPortRange`

Type: String

Required: No

The port number range on the container that's bound to the dynamically mapped host port range.

You can only set this parameter by using the `register-task-definition` API. The option is available in the `portMappings` parameter. For more information, see [register-task-definition](#) in the *AWS Command Line Interface Reference*.

The following rules apply when you specify a `containerPortRange`:

- You must use either the `bridge` network mode or the `awsvpc` network mode.
- This parameter is available for both the Linux and Windows operating systems.
- The container instance must have at least version 1.67.0 of the container agent and at least version 1.67.0-1 of the `ecs-init` package.
- You can specify a maximum of 100 port ranges for each container.
- You don't specify a `hostPortRange`. The value of the `hostPortRange` is set as follows:
  - For containers in a task with the `awsvpc` network mode, the `hostPort` is set to the same value as the `containerPort`. This is a static mapping strategy.
  - For containers in a task with the `bridge` network mode, the Amazon ECS agent finds open host ports from the default ephemeral range and passes it to Docker to bind them to the container ports.

- The `containerPortRange` valid values are between 1 and 65535.
- A port can only be included in one port mapping for each container.
- You can't specify overlapping port ranges.
- The first port in the range must be less than last port in the range.
- Docker recommends that you turn off the Docker-proxy in the Docker daemon config file when you have a large number of ports.

For more information, see [Issue #11185](#) on GitHub.

For information about how to turn off the docker-proxy in the Docker daemon config file, see [Docker daemon](#) in the *Amazon ECS Developer Guide*.

You can call [DescribeTasks](#) to view the `hostPortRange`, which are the host ports that are bound to the container ports.

The port ranges aren't included in the Amazon ECS task events, which are sent to EventBridge. For more information, see [the section called "Automate responses to Amazon ECS errors using EventBridge"](#).

#### `hostPortRange`

Type: String

Required: No

The port number range on the host that's used with the network binding. This is assigned by Docker and delivered by the Amazon ECS agent.

#### `hostPort`

Type: Integer

Required: No

The port number on the container instance to reserve for your container.

You can specify a non-reserved host port for your container port mapping. This is referred to as *static* host port mapping. Or, you can omit the `hostPort` (or set it to 0) while specifying a `containerPort`. Your container automatically receives a port in the ephemeral port range for your container instance operating system and Docker version. This is referred to as *dynamic* host port mapping.

The default ephemeral port range Docker version 1.6.0 and later is listed on the instance under `/proc/sys/net/ipv4/ip_local_port_range`. If this kernel parameter is unavailable, the default ephemeral port range from 49153–65535 is used. Don't attempt to specify a host port in the ephemeral port range. This is because these are reserved for automatic assignment. In general, ports under 32768 are outside of the ephemeral port range. You may use `ECS_DYNAMIC_HOST_PORT_RANGE` setting in ECS container agent configuration to specify a custom range for dynamically assigned host ports. That may be helpful if your tasks are failing to start due to port conflicts with other processes on the container instance such as outbound connections that also use ports from the ephemeral port range. For more information, see [Amazon ECS container agent configuration](#).

The default reserved ports are 22 for SSH, the Docker ports 2375 and 2376, and the Amazon ECS container agent ports 51678–51680. Any host port that was previously user-specified for a running task is also reserved while the task is running. After a task stops, the host port is released. The current reserved ports are displayed in the `remainingResources` of the **describe-container-instances** output. A container instance might have up to 100 reserved ports at a time, including the default reserved ports. Automatically assigned ports don't count toward the 100 reserved ports quota.

name

Type: String

Required: No, required for Service Connect and VPC Lattice to be configured in a service

The name that's used for the port mapping. This parameter only applies to Service Connect and VPC Lattice. This parameter is the name that you use in the Service Connect and VPC Lattice configuration of a service.

For more information, see [Use Service Connect to connect Amazon ECS services with short names](#).

In the following example, both of the required fields for Service Connect and VPC Lattice are used.

```
"portMappings": [  
  {  
    "name": string,  
    "containerPort": integer  
  }  
]
```

```
]
```

## protocol

Type: String

Required: No

The protocol that's used for the port mapping. Valid values are `tcp` and `udp`. The default is `tcp`.

### Important

Only `tcp` is supported for Service Connect. Remember that `tcp` is implied if this field isn't set.

### Important

UDP support is only available on container instances that were launched with version 1.2.0 of the Amazon ECS container agent (such as the `amzn-ami-2015.03.c-amazon-ecs-optimized` AMI) or later, or with container agents that have been updated to version 1.3.0 or later. To update your container agent to the latest version, see [Updating the Amazon ECS container agent](#).

If you're specifying a host port, use the following syntax.

```
"portMappings": [  
  {  
    "containerPort": integer,  
    "hostPort": integer  
  }  
  ...  
]
```

If you want an automatically assigned host port, use the following syntax.

```
"portMappings": [  
  {  
    "containerPort": integer,  
    "hostPort": integer  
  }  
  ...  
]
```

```
{
    "containerPort": integer
}
...
]
```

## Private Repository Credentials

repositoryCredentials

Type: [RepositoryCredentials](#) object

Required: No

The repository credentials for private registry authentication.

For more information, see [Using non-AWS container images in Amazon ECS](#).

credentialsParameter

Type: String

Required: Yes, when repositoryCredentials are used

The Amazon Resource Name (ARN) of the secret containing the private repository credentials.

For more information, see [Using non-AWS container images in Amazon ECS](#).

### Note

When you use the Amazon ECS API, AWS CLI, or AWS SDKs, if the secret exists in the same Region as the task that you're launching then you can use either the full ARN or the name of the secret. When you use the AWS Management Console, you must specify the full ARN of the secret.

The following is a snippet of a task definition that shows the required parameters:

```
"containerDefinitions": [
  {
```

```
    "image": "private-repo/private-image",
    "repositoryCredentials": {
      "credentialsParameter":
        "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name"
    }
  }
]
```

## Advanced container definition parameters

The following advanced container definition parameters provide extended capabilities to the Docker run command that's used to launch containers on your Amazon ECS container instances.

### Topics

- [Restart policy](#)
- [Health check](#)
- [Environment](#)
- [Network settings](#)
- [Storage and logging](#)
- [Security](#)
- [Resource limits](#)
- [Docker labels](#)

### Restart policy

restartPolicy

The container restart policy and associated configuration parameters. When you set up a restart policy for a container, Amazon ECS can restart the container without needing to replace the task. For more information, see [Restart individual containers in Amazon ECS tasks with container restart policies](#).

enabled

Type: Boolean

Required: Yes

Specifies whether a restart policy is enabled for the container.

`ignoredExitCodes`

Type: Integer array

Required: No

A list of exit codes that Amazon ECS will ignore and not attempt a restart on. You can specify a maximum of 50 container exit codes. By default, Amazon ECS does not ignore any exit codes.

`restartAttemptPeriod`

Type: Integer

Required: No

A period of time (in seconds) that the container must run for before a restart can be attempted. A container can be restarted only once every `restartAttemptPeriod` seconds. If a container isn't able to run for this time period and exits early, it will not be restarted. You can set a minimum `restartAttemptPeriod` of 60 seconds and a maximum `restartAttemptPeriod` of 1800 seconds. By default, a container must run for 300 seconds before it can be restarted.

## Health check

`healthCheck`

The container health check command and the associated configuration parameters for the container. For more information, see [Determine Amazon ECS task health using container health checks](#).

`command`

A string array that represents the command that the container runs to determine if it's healthy. The string array can start with `CMD` to run the command arguments directly, or `CMD-SHELL` to run the command with the container's default shell. If neither is specified, `CMD` is used.

When registering a task definition in the AWS Management Console, use a comma separated list of commands. These commands are converted to a string after the task definition is created. An example input for a health check is the following.

```
CMD-SHELL, curl -f http://localhost/ || exit 1
```

When registering a task definition using the AWS Management Console JSON panel, the AWS CLI, or the APIs, enclose the list of commands in brackets. An example input for a health check is the following.

```
[ "CMD-SHELL", "curl -f http://localhost/ || exit 1" ]
```

An exit code of 0, with no `stderr` output, indicates success, and a non-zero exit code indicates failure.

#### `interval`

The period of time (in seconds) between each health check. You can specify between 5 and 300 seconds. The default value is 30 seconds.

#### `timeout`

The period of time (in seconds) to wait for a health check to succeed before it's considered a failure. You can specify between 2 and 60 seconds. The default value is 5 seconds.

#### `retries`

The number of times to retry a failed health check before the container is considered unhealthy. You can specify between 1 and 10 retries. The default value is three retries.

#### `startPeriod`

The optional grace period to provide containers time to bootstrap in before failed health checks count towards the maximum number of retries. You can specify between 0 and 300 seconds. By default, `startPeriod` is disabled.

If a health check succeeds within the `startPeriod`, then the container is considered healthy and any subsequent failures count toward the maximum number of retries.

## Environment

### `cpu`

Type: Integer

Required: No

The number of CPU units the Amazon ECS container agent reserves for the container. On Linux, this parameter maps to CpuShares in the [Create a container](#) section.

 **Note**

You can determine the number of CPU units that are available to each Amazon EC2 instance type. To do this, multiply the number of vCPUs listed for that instance type on the [Amazon EC2 Instances](#) detail page by 1,024.

Linux containers share unallocated CPU units with other containers on the container instance with the same ratio as their allocated amount. For example, assume that you run a single-container task on a single-core instance type with 512 CPU units specified for that container. Moreover, that task is the only task running on the container instance. In this example, the container can use the full 1,024 CPU unit share at any given time. However, assume then that you launched another copy of the same task on that container instance. Each task is guaranteed a minimum of 512 CPU units when needed. Similarly, if the other container isn't using the remaining CPU, each container can float to higher CPU usage. However, if both tasks were 100% active all of the time, they are limited to 512 CPU units.

On Linux container instances, the Docker daemon on the container instance uses the CPU value to calculate the relative CPU share ratios for running containers. The minimum valid CPU share value that the Linux kernel allows is 2, and the maximum valid CPU share value that the Linux kernel allows is 262144. However, the CPU parameter isn't required, and you can use CPU values below two and above 262144 in your container definitions. For CPU values below two (including null) and above 262144, the behavior varies based on your Amazon ECS container agent version:

- **Agent versions  $\leq$  1.1.0:** Null and zero CPU values are passed to Docker as 0. Docker then converts this value to 1,024 CPU shares. CPU values of one are passed to Docker as one, which the Linux kernel converts to two CPU shares.
- **Agent versions  $\geq$  1.2.0:** Null, zero, and CPU values of one are passed to Docker as two CPU shares.
- **Agent versions  $\geq$  1.84.0:** CPU values greater than 256 vCPU are passed to Docker as 256, which is equivalent to 262144 CPU shares.

On Windows container instances, the CPU quota is enforced as an absolute quota. Windows containers only have access to the specified amount of CPU that's defined in the task definition.

A null or zero CPU value is passed to Docker as 0. Windows then interprets this value as 1% of one CPU.

For more examples, see [How Amazon ECS manages CPU and memory resources](#).

## gpu

Type: [ResourceRequirement](#) object

Required: No

The number of physical GPUs that the Amazon ECS container agent reserves for the container. You can specify an integer value, a decimal value for fractional GPUs, or ALL. When you specify ALL, all GPUs on the container instance are allocated to the container. When you specify a decimal value (such as 0.125, 0.25, or 0.5), Amazon ECS places the task on a fractional GPU instance (G6f) that provides the requested GPU capacity. The number of GPUs reserved for all containers in a task must not exceed the number of available GPUs on the container instance the task is launched on. For more information, see [Amazon ECS task definitions for GPU workloads](#).

### Note

This parameter isn't supported for Windows containers.

## sharingStrategy

Type: SharingStrategy object

Required: No

The GPU sharing configuration for the container. Specify sharingStrategy to share a single physical GPU across multiple containers with NVIDIA Multi-Process Service (MPS). This object contains an nvidiaMps object with the following fields:

On a GPU resource requirement, value and sharingStrategy are mutually exclusive. When you specify sharingStrategy, you must omit value.

## memory

Type: Integer

Required: Yes

The GPU memory limit for the container, in MiB. This value is a hard ceiling on the GPU memory that the container can use. The value must be greater than 0.

`maxComputePercent`

Type: Integer

Required: No

The maximum percentage of GPU compute that the container can use, as an integer from 1 to 100. This value is a ceiling, not a reservation. If you omit it, the container can use up to 100 percent.

 **Note**

This parameter isn't supported for Windows containers.

Elastic Inference accelerator

Type: [ResourceRequirement](#) object

Required: No

For the `InferenceAccelerator` type, the value matches the `deviceName` for an `InferenceAccelerator` specified in a task definition. For more information, see [the section called "Elastic Inference accelerator name \(deprecated\)"](#).

 **Note**

This parameter isn't supported for Windows containers.

`essential`

Type: Boolean

Required: No

Suppose that the `essential` parameter of a container is marked as `true`, and that container fails or stops for any reason. Then, all other containers that are part of the task are stopped.

If the `essential` parameter of a container is marked as `false`, then its failure doesn't affect the rest of the containers in a task. If this parameter is omitted, a container is assumed to be essential.

All tasks must have at least one essential container. Suppose that you have an application that's composed of multiple containers. Then, group containers that are used for a common purpose into components, and separate the different components into multiple task definitions. For more information, see [Architect your application for Amazon ECS](#).

```
"essential": true|false
```

## entryPoint

### Important

Early versions of the Amazon ECS container agent don't properly handle `entryPoint` parameters. If you have problems using `entryPoint`, update your container agent or enter your commands and arguments as `command` array items instead.

Type: String array

Required: No

The entry point that's passed to the container.

```
"entryPoint": ["string", ...]
```

## command

Type: String array

Required: No

The command that's passed to the container. This parameter maps to `Cmd` in the `create-container` command and the `COMMAND` parameter to `docker run`. If there are multiple arguments, make sure that each argument is a separated string in the array.

```
"command": ["string", ...]
```

## workingDirectory

Type: String

Required: No

The working directory to run commands inside the container in. This parameter maps to `WorkingDir` in the [Create a container](#) section of the [Docker Remote API](#) and the `--workdir` option to [docker run](#).

```
"workingDirectory": "string"
```

## environmentFiles

Type: Object array

Required: No

A list of files containing the environment variables to pass to a container. This parameter maps to the `--env-file` option to the Docker run command.

When FIPS is enabled, bucket names that have periods (.) (for example, `amzn-s3-demo-bucket1.name.example`) aren't supported. Having periods (.) in the bucket name prevents the task from starting because the agent can't pull the environment variable file from Amazon S3.

This isn't available for Windows containers.

You can specify up to 10 environment files. The file must have a `.env` file extension. Each line in an environment file contains an environment variable in `VARIABLE=VALUE` format. Lines that start with `#` are treated as comments and are ignored.

If there are individual environment variables specified in the container definition, they take precedence over the variables contained within an environment file. If multiple environment files are specified that contain the same variable, they're processed from the top down. We recommend that you use unique variable names. For more information, see [Pass an individual environment variable to an Amazon ECS container](#).

## value

Type: String

Required: Yes

The Amazon Resource Name (ARN) of the Amazon S3 object containing the environment variable file.

type

Type: String

Required: Yes

The file type to use. The only supported value is s3.

environment

Type: Object array

Required: No

The environment variables to pass to a container. This parameter maps to Env in the docker create-container command and the --env option to the docker run command.

 **Important**

We do not recommend using plaintext environment variables for sensitive information, such as credential data.

name

Type: String

Required: Yes, when environment is used

The name of the environment variable.

value

Type: String

Required: Yes, when environment is used

The value of the environment variable.

```
"environment" : [
```

```
{ "name" : "string", "value" : "string" },  
{ "name" : "string", "value" : "string" }  
]
```

## secrets

Type: Object array

Required: No

An object that represents the secret to expose to your container. For more information, see [Pass sensitive data to an Amazon ECS container](#).

name

Type: String

Required: Yes

The value to set as the environment variable on the container.

valueFrom

Type: String

Required: Yes

The secret to expose to the container. The supported values are either the full Amazon Resource Name (ARN) of the AWS Secrets Manager secret or the full ARN of the parameter in the AWS Systems Manager Parameter Store.

### Note

If the Systems Manager Parameter Store parameter or Secrets Manager parameter exists in the same AWS Region as the task that you're launching, you can use either the full ARN or name of the secret. If the parameter exists in a different Region, then the full ARN must be specified.

```
"secrets": [  
  {  
    "name": "environment_variable_name",
```

```
    "valueFrom": "arn:aws:ssm:region:aws_account_id:parameter/parameter_name"
  }
]
```

## Network settings

### disableNetworking

Type: Boolean

Required: No

When this parameter is true, networking is off within the container.

#### Note

This parameter isn't supported for Windows containers or tasks using the awsvpc network mode.

The default is false.

```
"disableNetworking": true|false
```

### links

Type: String array

Required: No

The `link` parameter allows containers to communicate with each other without the need for port mappings. This parameter is only supported if the network mode of a task definition is set to `bridge`. The `name:internalName` construct is analogous to `name:alias` in Docker links. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed..

#### Note

This parameter isn't supported for Windows containers or tasks using the awsvpc network mode.

**⚠ Important**

Containers that are collocated on the same container instance might communicate with each other without requiring links or host port mappings. The network isolation on a container instance is controlled by security groups and VPC settings.

```
"links": ["name:internalName", ...]
```

**hostname**

Type: String

Required: No

The hostname to use for your container. This parameter maps to `Hostname` in the `docker create-container` and the `--hostname` option to `docker run`.

**ℹ Note**

If you're using the `awsvpc` network mode, the `hostname` parameter isn't supported.

```
"hostname": "string"
```

**dnsServers**

Type: String array

Required: No

A list of DNS servers that are presented to the container.

**ℹ Note**

This parameter isn't supported for Windows containers or tasks using the `awsvpc` network mode.

```
"dnsServers": ["string", ...]
```

## dnsSearchDomains

Type: String array

Required: No

Pattern: `^[a-zA-Z0-9-.]{0,253}[a-zA-Z0-9]$`

A list of DNS search domains that are presented to the container. This parameter maps to `DnsSearch` in the `docker create-container` command the `--dns-search` option to `docker run`.

### Note

This parameter isn't supported for Windows containers or tasks that use the `awsvpc` network mode.

```
"dnsSearchDomains": ["string", ...]
```

## extraHosts

Type: Object array

Required: No

A list of hostnames and IP address mappings to append to the `/etc/hosts` file on the container.

This parameter maps to `ExtraHosts` in the `docker create-container` command and the `--add-host` option to `docker run`.

### Note

This parameter isn't supported for Windows containers or tasks that use the `awsvpc` network mode.

```
"extraHosts": [
```

```
{
  "hostname": "string",
  "ipAddress": "string"
}
...
]
```

hostname

Type: String

Required: Yes, when `extraHosts` are used

The hostname to use in the `/etc/hosts` entry.

ipAddress

Type: String

Required: Yes, when `extraHosts` are used

The IP address to use in the `/etc/hosts` entry.

## Storage and logging

readonlyRootFilesystem

Type: Boolean

Required: No

When this parameter is true, the container is given read-only access to its root file system. This parameter maps to `ReadonlyRootfs` in the `docker create-container` command and the `--read-only` option to `docker run`.

### Note

This parameter is not supported for Windows containers.

The default is false.

```
"readonlyRootFilesystem": true|false
```

## mountPoints

Type: Object array

Required: No

The mount points for the data volumes in your container. This parameter maps to Volumes in the create-container Docker API and the `--volume` option to `docker run`.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`. Windows containers cannot mount directories on a different drive, and mount points cannot be used across drives. You must specify mount points to attach an Amazon EBS volume directly to an Amazon ECS task.

### sourceVolume

Type: String

Required: Yes, when `mountPoints` are used

The name of the volume to mount.

## containerPath

Type: String

Required: Yes, when `mountPoints` are used

The path in the container where the volume will be mounted.

## readOnly

Type: Boolean

Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

For tasks that run the Windows operating system, leave the value as the default of `false`.

## volumesFrom

Type: Object array

Required: No

Data volumes to mount from another container. This parameter maps to `VolumesFrom` in the `docker create-container` command and the `--volumes-from` option to `docker run`.

`sourceContainer`

Type: String

Required: Yes, when `volumesFrom` is used

The name of the container to mount volumes from.

`readOnly`

Type: Boolean

Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

```
"volumesFrom": [
  {
    "sourceContainer": "string",
    "readOnly": true|false
  }
]
```

`logConfiguration`

Type: [LogConfiguration](#) Object

Required: No

The log configuration specification for the container.

For example task definitions that use a log configuration, see [Example Amazon ECS task definitions](#).

This parameter maps to `LogConfig` in the `docker create-container` command and the `--log-driver` option to `docker run`. By default, containers use the same logging driver that the Docker daemon uses. However, the container might use a different logging driver than the

Docker daemon by specifying a log driver with this parameter in the container definition. To use a different logging driver for a container, the log system must be configured properly on the container instance (or on a different log server for remote logging options).

Consider the following when specifying a log configuration for your containers:

- Amazon ECS supports a subset of the logging drivers that are available to the Docker daemon.
- This parameter requires version 1.18 or later of the Docker Remote API on your container instance.
- The Amazon ECS container agent that runs on a container instance must register the logging drivers that are available on that instance with the ECS\_AVAILABLE\_LOGGING\_DRIVERS environment variable before containers that are placed on that instance can use these log configuration options. For more information, see [Amazon ECS container agent configuration](#).

```
"logConfiguration": {  
    "logDriver": "awslogs","fluentd","gelf","json-  
file","journald","splunk","syslog","awsfirelens",  
    "options": {"string": "string"  
        ...},  
    "secretOptions": [{  
        "name": "string",  
        "valueFrom": "string"  
    }]  
}
```

## logDriver

Type: String

Valid values: "awslogs", "fluentd", "gelf", "json-file", "journald", "splunk", "syslog", "awsfirelens"

Required: Yes, when logConfiguration is used

The log driver to use for the container. By default, the valid values that are listed earlier are log drivers that the Amazon ECS container agent can communicate with.

The supported log drivers are awslogs, fluentd, gelf, json-file, journald, syslog, splunk, and awsfirelens.

For more information about how to use the `awslogs` log driver in task definitions to send your container logs to CloudWatch Logs, see [Send Amazon ECS logs to CloudWatch](#).

For more information about using the `awsfirelens` log driver, see [Custom Log Routing](#).

 **Note**

If you have a custom driver that isn't listed, you can fork the Amazon ECS container agent project that's [available on GitHub](#) and customize it to work with that driver. We encourage you to submit pull requests for changes that you want to have included. However, we don't currently support running modified copies of this software.

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

## options

Type: String to string map

Required: No

The key/value map of configuration options to send to the log driver.

The options you can specify depend on the log driver. Some of the options you can specify when you use the `awslogs` router to route logs to Amazon CloudWatch include the following:

### `awslogs-create-group`

Required: No

Specify whether you want the log group to be created automatically. If this option isn't specified, it defaults to `false`.

 **Note**

Your IAM policy must include the `logs:CreateLogGroup` permission before you attempt to use `awslogs-create-group`.

## `awslogs-region`

Required: Yes

Specify the AWS Region that the `awslogs` log driver is to send your Docker logs to. You can choose to send all of your logs from clusters in different Regions to a single region in CloudWatch Logs. This is so that they're all visible in one location. Otherwise, you can separate them by Region for more granularity. Make sure that the specified log group exists in the Region that you specify with this option.

## `awslogs-group`

Required: Yes

Make sure to specify a log group that the `awslogs` log driver sends its log streams to.

## `awslogs-stream-prefix`

Required: Optional

Use the `awslogs-stream-prefix` option to associate a log stream with the specified prefix, the container name, and the ID of the Amazon ECS task that the container belongs to. If you specify a prefix with this option, then the log stream takes the following format.

```
prefix-name/container-name/ecs-task-id
```

If you don't specify a prefix with this option, then the log stream is named after the container ID that's assigned by the Docker daemon on the container instance. Because it's difficult to trace logs back to the container that sent them with just the Docker container ID (which is only available on the container instance), we recommend that you specify a prefix with this option.

For Amazon ECS services, you can use the service name as the prefix. Doing so, you can trace log streams to the service that the container belongs to, the name of the container that sent them, and the ID of the task that the container belongs to.

You must specify a stream-prefix for your logs to have your logs appear in the Log pane when using the Amazon ECS console.

## `awslogs-datetime-format`

Required: No

This option defines a multiline start pattern in Python `strftime` format. A log message consists of a line that matches the pattern and any following lines that don't match the pattern. The matched line is the delimiter between log messages.

One example of a use case for using this format is for parsing output such as a stack dump, which might otherwise be logged in multiple entries. The correct pattern allows it to be captured in a single entry.

For more information, see [awslogs-datetime-format](#).

You cannot configure both the `awslogs-datetime-format` and `awslogs-multiline-pattern` options.

 **Note**

Multiline logging performs regular expression parsing and matching of all log messages. This might have a negative impact on logging performance.

## `awslogs-multiline-pattern`

Required: No

This option defines a multiline start pattern that uses a regular expression. A log message consists of a line that matches the pattern and any following lines that don't match the pattern. The matched line is the delimiter between log messages.

For more information, see [awslogs-multiline-pattern](#).

This option is ignored if `awslogs-datetime-format` is also configured.

You cannot configure both the `awslogs-datetime-format` and `awslogs-multiline-pattern` options.

 **Note**

Multiline logging performs regular expression parsing and matching of all log messages. This might have a negative impact on logging performance.

The following options apply to all supported log drivers.

## mode

Required: No

Valid values: non-blocking | blocking

This option defines the delivery mode of log messages from the container to the log driver specified using `logDriver`. The delivery mode you choose affects application availability when the flow of logs from the container is interrupted.

If you use the `blocking` mode and the flow of logs is interrupted, calls from container code to write to the `stdout` and `stderr` streams will block. The logging thread of the application will block as a result. This may cause the application to become unresponsive and lead to container healthcheck failure.

If you use the `non-blocking` mode, the container's logs are instead stored in an in-memory intermediate buffer configured with the `max-buffer-size` option. This prevents the application from becoming unresponsive when logs cannot be sent. We recommend using this mode if you want to ensure service availability and are okay with some log loss. For more information, see [Preventing log loss with non-blocking mode in the awslogs container log driver](#).

You can set a default mode for all containers in a specific AWS Region by using the `defaultLogDriverMode` account setting. If you don't specify the mode option in the `logConfiguration` or configure the account setting, Amazon ECS will default to `non-blocking` mode. For more information about the account setting, see [Default log driver mode](#).

When `non-blocking` mode is used, the `max-buffer-size` log option controls the size of the buffer that's used for intermediate message storage. Make sure to specify an adequate buffer size based on your application. The total amount of memory allocated at the task level should be greater than the amount of memory that's allocated for all the containers in addition to the log driver memory buffer.

### Note

On June 25, 2025, Amazon ECS changed the default log driver mode from `blocking` to `non-blocking` to prioritize task availability over logging. To continue using the `blocking` mode after this change, do one of the following:

- Set the mode option in your container definition's logConfiguration as blocking.
- Set the defaultLogDriverMode account setting to blocking.

## max-buffer-size

Required: No

Default value: 10 m

When non-blocking mode is used, the max-buffer-size log option controls the size of the buffer that's used for intermediate message storage. Make sure to specify an adequate buffer size based on your application. When the buffer fills up, further logs cannot be stored. Logs that cannot be stored are lost.

To route logs using the splunk log router, you need to specify a splunk-token and a splunk-url.

When you use the awsfirelens log router to route logs to an AWS service or AWS Partner Network destination for log storage and analytics, you can set the log-driver-buffer-limit option to limit the number of log lines that are buffered in memory, before being sent to the log router container. It can help to resolve potential log loss issue because high throughput might result in memory running out for the buffer inside of Docker. For more information, see [the section called “Configuring logs for high throughput”](#).

Other options you can specify when using awsfirelens to route logs depend on the destination. When you export logs to Amazon Data Firehose, you can specify the AWS Region with region and a name for the log stream with delivery\_stream.

When you export logs to Amazon Kinesis Data Streams, you can specify an AWS Region with region and a data stream name with stream.

When you export logs to Amazon OpenSearch Service, you can specify options like Name, Host (OpenSearch Service endpoint without protocol), Port, Index, Type, Aws\_auth, Aws\_region, Suppress\_Type\_Name, and tls.

When you export logs to Amazon S3, you can specify the bucket using the bucket option. You can also specify region, total\_file\_size, upload\_timeout, and use\_put\_object as options.

This parameter requires version 1.19 of the Docker Remote API or greater on your container instance.

### secretOptions

Type: Object array

Required: No

An object that represents the secret to pass to the log configuration. Secrets that are used in log configuration can include an authentication token, certificate, or encryption key. For more information, see [Pass sensitive data to an Amazon ECS container](#).

#### name

Type: String

Required: Yes

The value to set as the environment variable on the container.

#### valueFrom

Type: String

Required: Yes

The secret to expose to the log configuration of the container.

```
"logConfiguration": {
  "logDriver": "splunk",
  "options": {
    "splunk-url": "https://cloud.splunk.com:8080",
    "splunk-token": "...",
    "tag": "...",
    ...
  },
  "secretOptions": [{
    "name": "splunk-token",
    "valueFrom": "/ecs/logconfig/splunkcred"
  }]
}
```

### firelensConfiguration

Type: [FirelensConfiguration](#) Object

Required: No

The FireLens configuration for the container. This is used to specify and configure a log router for container logs. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

```
{
  "firelensConfiguration": {
    "type": "fluentd",
    "options": {
      "KeyName": ""
    }
  }
}
```

options

Type: String to string map

Required: No

The key/value map of options to use when configuring the log router. This field is optional and can be used to specify a custom configuration file or to add additional metadata, such as the task, task definition, cluster, and container instance details to the log event. If specified, the syntax to use is "options":{"enable-ecs-log-metadata":"true|false", "config-file-type":"s3|file", "config-file-value":"arn:aws:s3:::*amzn-s3-demo-bucket*/fluent.conf|filepath"}. For more information, see [Example Amazon ECS task definition: Route logs to FireLens](#).

type

Type: String

Required: Yes

The log router to use. The valid values are fluentd or fluentbit.

## Security

For more information about container security, see [Amazon ECS task and container security best practices](#).

## credentialSpecs

Type: String array

Required: No

A list of ARNs in SSM or Amazon S3 to a credential spec (CredSpec) file that configures the container for Active Directory authentication. We recommend that you use this parameter instead of the `dockerSecurityOptions`. The maximum number of ARNs is 1.

There are two formats for each ARN.

`credentialSpecDomainless:MyARN`

You use `credentialSpecDomainless:MyARN` to provide a CredSpec with an additional section for a secret in Secrets Manager. You provide the login credentials to the domain in the secret.

Each task that runs on any container instance can join different domains.

You can use this format without joining the container instance to a domain.

`credentialSpec:MyARN`

You use `credentialSpec:MyARN` to provide a CredSpec for a single domain.

You must join the container instance to the domain before you start any tasks that use this task definition.

In both formats, replace MyARN with the ARN in SSM or Amazon S3.

The `credspec` must provide a ARN in Secrets Manager for a secret containing the username, password, and the domain to connect to. For better security, the instance isn't joined to the domain for domainless authentication. Other applications on the instance can't use the domainless credentials. You can use this parameter to run tasks on the same instance, even if the tasks need to join different domains. For more information, see [Using gMSAs for Windows Containers](#) and [Using gMSAs for Linux Containers](#).

## privileged

Type: Boolean

Required: No

When this parameter is true, the container is given elevated privileges on the host container instance (similar to the `root` user). We recommend against running containers with `privileged`. In most cases, you can specify the exact privileges that you need by using the specific parameters instead of using `privileged`.

This parameter maps to `Privileged` in the `docker create-container` command and the `--privileged` option to `docker run`.

 **Note**

This parameter is not supported for Windows containers or tasks using the Fargate launch type.

The default is `false`.

```
"privileged": true|false
```

## user

Type: String

Required: No

The user to use inside the container. This parameter maps to `User` in the `docker create-container` command and the `--user` option to `docker run`.

 **Important**

When running tasks that use the host network mode, don't run containers using the root user (UID 0). As a security best practice, always use a non-root user.

You can specify the `user` using the following formats. If specifying a UID or GID, you must specify it as a positive integer.

- `user`
- `user:group`
- `uid`
- `uid:gid`

- `user:gid`
- `uid:group`

**Note**

This parameter is not supported for Windows containers.

```
"user": "string"
```

## `dockerSecurityOptions`

Type: String array

Valid values: `"no-new-privileges"` | `"apparmor:PROFILE"` | `"label:value"` | `"credentialSpec:CredentialSpecFilePath"`

Required: No

A list of strings to provide custom configuration for multiple security systems.

For Linux tasks, this parameter can be used to reference custom labels for SELinux and AppArmor multi-level security systems.

This parameter can be used to reference a credential spec file that configures a container for Active Directory authentication. For more information, see [Learn how to use gMSAs for EC2 Windows containers for Amazon ECS](#) and [Using gMSA for EC2 Linux containers on Amazon ECS](#).

This parameter maps to `SecurityOpt` in the `docker create-container` command and the `--security-opt` option to `docker run`.

```
"dockerSecurityOptions": ["string", ...]
```

**Note**

The Amazon ECS container agent that runs on a container instance must register with the `ECS_SELINUX_CAPABLE=true` or `ECS_APPARMOR_CAPABLE=true` environment variables before containers that are placed on that instance can use these security options. For more information, see [Amazon ECS container agent configuration](#).

## Resource limits

### ulimits

Type: Object array

Required: No

A list of `ulimit` values to define for a container. This value overwrites the default resource quota setting for the operating system. This parameter maps to `Ulimits` in the `docker create-container` command and the `--ulimit` option to `docker run`.

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

#### Note

This parameter is not supported for Windows containers.

```
"ulimits": [  
  {  
    "name":  
    "core"|"cpu"|"data"|"fsize"|"locks"|"memlock"|"msgqueue"|"nice"|"nofile"|"nproc"|"rss"|"rtpr  
    "softLimit": integer,  
    "hardLimit": integer  
  }  
  ...  
]
```

### name

Type: String

Valid values: `"core"` | `"cpu"` | `"data"` | `"fsize"` | `"locks"` | `"memlock"` | `"msgqueue"` | `"nice"` | `"nofile"` | `"nproc"` | `"rss"` | `"rtprio"` | `"rttime"` | `"sigpending"` | `"stack"`

Required: Yes, when `ulimits` are used

The type of the `ulimit`.

## hardLimit

Type: Integer

Required: Yes, when ulimits are used

The hard limit for the ulimit type. The value can be specified in bytes, seconds, or as a count, depending on the type of the ulimit.

## softLimit

Type: Integer

Required: Yes, when ulimits are used

The soft limit for the ulimit type. The value can be specified in bytes, seconds, or as a count, depending on the type of the ulimit.

## Docker labels

### dockerLabels

Type: String to string map

Required: No

A key/value map of labels to add to the container. This parameter maps to Labels in the docker create-container command and the --label option to docker run.

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

```
"dockerLabels": {"string": "string"
  ...}
```

## Other container definition parameters

The following container definition parameters can be used when registering task definitions in the Amazon ECS console by using the **Configure via JSON** option. For more information, see [Creating an Amazon ECS task definition using the console](#).

## Topics

- [Linux parameters](#)
- [Container dependency](#)
- [Container timeouts](#)
- [System controls](#)
- [Interactive](#)
- [Pseudo terminal](#)

## Linux parameters

linuxParameters

Type: [LinuxParameters](#) object

Required: No

Linux-specific options that are applied to the container, such as [KernelCapabilities](#).

### Note

This parameter isn't supported for Windows containers.

```
"linuxParameters": {
  "capabilities": {
    "add": ["string", ...],
    "drop": ["string", ...]
  }
}
```

capabilities

Type: [KernelCapabilities](#) object

Required: No

The Linux capabilities for the container that are added to or dropped from the default configuration provided by Docker. For more information about these Linux capabilities, see the [capabilities\(7\)](#) Linux manual page.

## add

Type: String array

Valid values: "ALL" | "AUDIT\_CONTROL" | "AUDIT\_READ" | "AUDIT\_WRITE" | "BLOCK\_SUSPEND" | "CHOWN" | "DAC\_OVERRIDE" | "DAC\_READ\_SEARCH" | "FOWNER" | "FSETID" | "IPC\_LOCK" | "IPC\_OWNER" | "KILL" | "LEASE" | "LINUX\_IMMUTABLE" | "MAC\_ADMIN" | "MAC\_OVERRIDE" | "MKNOD" | "NET\_ADMIN" | "NET\_BIND\_SERVICE" | "NET\_BROADCAST" | "NET\_RAW" | "SETFCAP" | "SETGID" | "SETPCAP" | "SETUID" | "SYS\_ADMIN" | "SYS\_BOOT" | "SYS\_CHROOT" | "SYS\_MODULE" | "SYS\_NICE" | "SYS\_PACCT" | "SYS\_PTRACE" | "SYS\_RAWIO" | "SYS\_RESOURCE" | "SYS\_TIME" | "SYS\_TTY\_CONFIG" | "SYSLOG" | "WAKE\_ALARM"

Required: No

The Linux capabilities for the container to add to the default configuration provided by Docker. This parameter maps to CapAdd in the docker create-container command and the --cap-add option to docker run.

## add

Type: String array

Valid values: "SYS\_PTRACE"

Required: No

The Linux capabilities for the container to add to the default configuration that's provided by Docker. This parameter maps to CapAdd in the docker create-container command and the --cap-add option to docker run.

## drop

Type: String array

Valid values: "ALL" | "AUDIT\_CONTROL" | "AUDIT\_WRITE" | "BLOCK\_SUSPEND" | "CHOWN" | "DAC\_OVERRIDE" | "DAC\_READ\_SEARCH" | "FOWNER" | "FSETID" | "IPC\_LOCK" | "IPC\_OWNER" | "KILL" | "LEASE" | "LINUX\_IMMUTABLE" | "MAC\_ADMIN" | "MAC\_OVERRIDE" | "MKNOD" | "NET\_ADMIN" | "NET\_BIND\_SERVICE" | "NET\_BROADCAST" | "NET\_RAW"

| "SETFCAP" | "SETGID" | "SETPCAP" | "SETUID" | "SYS\_ADMIN" |  
"SYS\_BOOT" | "SYS\_CHROOT" | "SYS\_MODULE" | "SYS\_NICE" | "SYS\_PACCT"  
| "SYS\_PTRACE" | "SYS\_RAWIO" | "SYS\_RESOURCE" | "SYS\_TIME" |  
"SYS\_TTY\_CONFIG" | "SYSLOG" | "WAKE\_ALARM"

Required: No

The Linux capabilities for the container to remove from the default configuration that's provided by Docker. This parameter maps to CapDrop in the docker create-container command and the --cap-drop option to docker run.

## devices

Any host devices to expose to the container. This parameter maps to Devices in the docker create-container command and the --device option to Docker run.

Type: Array of [Device](#) objects

Required: No

### hostPath

The path for the device on the host container instance.

Type: String

Required: Yes

### containerPath

The path inside the container to expose the host device at.

Type: String

Required: No

### permissions

The explicit permissions to provide to the container for the device. By default, the container has permissions for read, write, and mknod on the device.

Type: Array of strings

Valid Values: read | write | mknod

## initProcessEnabled

Run an `init` process inside the container that forwards signals and reaps processes. This parameter maps to the `--init` option to `docker run`.

This parameter requires version 1.25 of the Docker Remote API or greater on your container instance.

## maxSwap

The total amount of swap memory (in MiB) a container can use. This parameter is translated to the `--memory-swap` option to `docker run` where the value is the sum of the container memory plus the `maxSwap` value.

If a `maxSwap` value of `0` is specified, the container doesn't use swap. Accepted values are `0` or any positive integer. If the `maxSwap` parameter is omitted, the container uses the swap configuration for the container instance that it's running on. A `maxSwap` value must be set for the `swappiness` parameter to be used.

## sharedMemorySize

The value for the size (in MiB) of the `/dev/shm` volume. This parameter maps to the `--shm-size` option to `docker run`.

Type: Integer

## swappiness

You can use this parameter to tune a container's memory swappiness behavior. A `swappiness` value of `0` prevents swapping from happening unless required. A `swappiness` value of `100` causes pages to be swapped frequently. Accepted values are whole numbers between `0` and `100`. If you don't specify a value, the default value of `60` is used. Moreover, if you don't specify a value for `maxSwap`, then this parameter is ignored. This parameter maps to the `--memory-swappiness` option to `docker run`.

### Note

If you're using tasks on Amazon Linux 2023 the `swappiness` parameter isn't supported.

## tmpfs

The container path, mount options, and maximum size (in MiB) of the tmpfs mount. This parameter maps to the `--tmpfs` option to `docker run`.

Type: Array of [Tmpfs](#) objects

Required: No

### containerPath

The absolute file path where the tmpfs volume is to be mounted.

Type: String

Required: Yes

### mountOptions

The list of tmpfs volume mount options.

Type: Array of strings

Required: No

Valid Values: "defaults" | "ro" | "rw" | "suid" | "nosuid" | "dev" | "nodev" | "exec" | "noexec" | "sync" | "async" | "dirsync" | "remount" | "mand" | "nomand" | "atime" | "noatime" | "diratime" | "nodiratime" | "bind" | "rbind" | "unbindable" | "runbindable" | "private" | "rprivate" | "shared" | "rshared" | "slave" | "rslave" | "relatime" | "norelatime" | "strictatime" | "nostrictatime" | "mode" | "uid" | "gid" | "nr\_inodes" | "nr\_blocks" | "mpol"

### size

The maximum size (in MiB) of the tmpfs volume.

Type: Integer

Required: Yes

## Container dependency

### dependsOn

Type: Array of [ContainerDependency](#) objects

Required: No

The dependencies defined for container startup and shutdown. A container can contain multiple dependencies. When a dependency is defined for container startup, for container shutdown it is reversed. For an example, see [Container dependency](#).

#### Note

If a container doesn't meet a dependency constraint or times out before meeting the constraint, Amazon ECS doesn't progress dependent containers to their next state.

The instances require at least version 1.26.0 of the container agent to enable container dependencies. However, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see [Updating the Amazon ECS container agent](#). If you're using an Amazon ECS-optimized Amazon Linux AMI, your instance needs at least version 1.26.0-1 of the `ecs-init` package. If your container instances are launched from version 20190301 or later, they contain the required versions of the container agent and `ecs-init`. For more information, see [Amazon ECS-optimized Linux AMIs](#).

```
"dependsOn": [  
  {  
    "containerName": "string",  
    "condition": "string"  
  }  
]
```

### containerName

Type: String

Required: Yes

The container name that must meet the specified condition.

## condition

Type: String

Required: Yes

The dependency condition of the container. The following are the available conditions and their behavior:

- **START** – This condition emulates the behavior of links and volumes today. The condition validates that a dependent container is started before permitting other containers to start.
- **COMPLETE** – This condition validates that a dependent container runs to completion (exits) before permitting other containers to start. This can be useful for non-essential containers that run a script and then exit. This condition can't be set on an essential container.
- **SUCCESS** – This condition is the same as **COMPLETE**, but it also requires that the container exits with a zero status. This condition can't be set on an essential container.
- **HEALTHY** – This condition validates that the dependent container passes its container health check before permitting other containers to start. This requires that the dependent container has health checks configured in the task definition. This condition is confirmed only at task startup.

## Container timeouts

### startTimeout

Type: Integer

Required: No

Example values: 120

Time duration (in seconds) to wait before giving up on resolving dependencies for a container.

For example, you specify two containers in a task definition with `containerA` having a dependency on `containerB` reaching a **COMPLETE**, **SUCCESS**, or **HEALTHY** status. If a `startTimeout` value is specified for `containerB` and it doesn't reach the desired status within that time, then `containerA` doesn't start.

**Note**

If a container doesn't meet a dependency constraint or times out before meeting the constraint, Amazon ECS doesn't progress dependent containers to their next state.

The maximum value is 120 seconds.

`stopTimeout`

Type: Integer

Required: No

Example values: 120

Time duration (in seconds) to wait before the container is forcefully killed if it doesn't exit normally on its own.

If the `stopTimeout` parameter isn't specified, the value set for the Amazon ECS container agent configuration variable `ECS_CONTAINER_STOP_TIMEOUT` is used. If neither the `stopTimeout` parameter or the `ECS_CONTAINER_STOP_TIMEOUT` agent configuration variable is set, the default values of 30 seconds for Linux containers and 30 seconds on Windows containers are used. Container instances require at least version 1.26.0 of the container agent to enable a container stop timeout value. However, we recommend using the latest container agent version. For information about how to check your agent version and update to the latest version, see [Updating the Amazon ECS container agent](#). If you're using an Amazon ECS-optimized Amazon Linux AMI, your instance needs at least version 1.26.0-1 of the `ecs-init` package. If your container instances are launched from version 20190301 or later, they contain the required versions of the container agent and `ecs-init`. For more information, see [Amazon ECS-optimized Linux AMIs](#).

## System controls

`systemControls`

Type: [SystemControl](#) object

Required: No

A list of namespace kernel parameters to set in the container. This parameter maps to `Sysctl`s in the `docker create-container` command and the `--sysctl` option to `docker run`. For example, you can configure `net.ipv4.tcp_keepalive_time` setting to maintain longer lived connections.

We don't recommend that you specify network-related `systemControls` parameters for multiple containers in a single task that also uses either the `awsvpc` or `host` network mode. Doing this has the following disadvantages:

- For tasks that use the `awsvpc` network mode, if you set `systemControls` for any container, it applies to all containers in the task. If you set different `systemControls` for multiple containers in a single task, the container that's started last determines which `systemControls` take effect.
- For tasks that use the `host` network mode, the network namespace `systemControls` aren't supported.

If you're setting an IPC resource namespace to use for the containers in the task, the following conditions apply to your system controls. For more information, see [IPC mode](#).

- For tasks that use the `host` IPC mode, IPC namespace `systemControls` aren't supported.
- For tasks that use the `task` IPC mode, IPC namespace `systemControls` values apply to all containers within a task.

 **Note**

This parameter is not supported for Windows containers.

```
"systemControls": [  
  {  
    "namespace": "string",  
    "value": "string"  
  }  
]
```

namespace

Type: String

Required: No

The namespace kernel parameter to set a value for.

Valid IPC namespace values: "kernel.msgmax" | "kernel.msgmnb" | "kernel.msgmni" | "kernel.sem" | "kernel.shmall" | "kernel.shmmax" | "kernel.shmmni" | "kernel.shm\_rmid\_forced", and Sysctls that start with "fs.mqueue.\*"

Valid network namespace values: Sysctls that start with "net.\*"

value

Type: String

Required: No

The value for the namespace kernel parameter that's specified in namespace.

## Interactive

interactive

Type: Boolean

Required: No

When this parameter is `true`, you can deploy containerized applications that require `stdin` or a `tty` to be allocated. This parameter maps to `OpenStdin` in the `docker create-container` command and the `--interactive` option to `docker run`.

The default is `false`.

## Pseudo terminal

pseudoTerminal

Type: Boolean

Required: No

When this parameter is `true`, a TTY is allocated. This parameter maps to `Tty` in the `docker create-container` command and the `--tty` option to `docker run`.

The default is `false`.

## Elastic Inference accelerator name (deprecated)

The Elastic Inference accelerator resource requirement for your task definition.

### Note

Amazon Elastic Inference (EI) is no longer available to customers.

The following parameters are allowed in a task definition:

`deviceName`

Type: String

Required: Yes

The Elastic Inference accelerator device name. The `deviceName` must also be referenced in a container definition see [Elastic Inference accelerator](#).

`deviceType`

Type: String

Required: Yes

The Elastic Inference accelerator to use.

## Task placement constraints

When you register a task definition, you can provide task placement constraints that customize how Amazon ECS places tasks.

You can use constraints to place tasks based on Availability Zone, instance type, or custom attributes. For more information, see [Define which container instances Amazon ECS uses for tasks](#).

The following parameters are allowed in a container definition:

`expression`

Type: String

Required: No

A cluster query language expression to apply to the constraint. For more information, see [Create expressions to define container instances for Amazon ECS tasks](#).

type

Type: String

Required: Yes

The type of constraint. Use `memberOf` to restrict the selection to a group of valid candidates.

## Proxy configuration

proxyConfiguration

Type: [ProxyConfiguration](#) object

Required: No

The configuration details for the App Mesh proxy.

For tasks that use EC2, the container instances require at least version 1.26.0 of the container agent and at least version 1.26.0-1 of the `ecs-init` package to enable a proxy configuration. If your container instances are launched from the Amazon ECS-optimized AMI version 20190301 or later, then they contain the required versions of the container agent and `ecs-init`. For more information, see [Amazon ECS-optimized Linux AMIs](#).

### Note

This parameter is not supported for Windows containers.

```
"proxyConfiguration": {  
  "type": "APPMESH",  
  "containerName": "string",  
  "properties": [  
    {  
      "name": "string",
```

```
        "value": "string"
      }
    ]
  }
```

## type

Type: String

Value values: APPMESH

Required: No

The proxy type. The only supported value is APPMESH.

## containerName

Type: String

Required: Yes

The name of the container that serves as the App Mesh proxy.

## properties

Type: Array of [KeyValuePair](#) objects

Required: No

The set of network configuration parameters to provide the Container Network Interface (CNI) plugin, specified as key-value pairs.

- **IgnoredUID** – (Required) The user ID (UID) of the proxy container as defined by the `user` parameter in a container definition. This is used to ensure the proxy ignores its own traffic. If `IgnoredGID` is specified, this field can be empty.
- **IgnoredGID** – (Required) The group ID (GID) of the proxy container as defined by the `user` parameter in a container definition. This is used to ensure the proxy ignores its own traffic. If `IgnoredUID` is specified, this field can be empty.
- **AppPorts** – (Required) The list of ports that the application uses. Network traffic to these ports is forwarded to the `ProxyIngressPort` and `ProxyEgressPort`.
- **ProxyIngressPort** – (Required) Specifies the port that incoming traffic to the `AppPorts` is directed to.

- **ProxyEgressPort** – (Required) Specifies the port that outgoing traffic from the `AppPorts` is directed to.
- **EgressIgnoredPorts** – (Required) The outbound traffic going to these specified ports is ignored and not redirected to the `ProxyEgressPort`. It can be an empty list.
- **EgressIgnoredIPs** – (Required) The outbound traffic going to these specified IP addresses is ignored and not redirected to the `ProxyEgressPort`. It can be an empty list.

name

Type: String

Required: No

The name of the key-value pair.

value

Type: String

Required: No

The value of the key-value pair.

## Volumes

When you register a task definition, you can optionally specify a list of volumes to be passed to the Docker daemon on a container instance, which then becomes available for access by other containers on the same container instance.

The following are the types of data volumes that can be used:

- **Amazon EBS volumes** — Provides cost-effective, durable, high-performance block storage for data intensive containerized workloads. You can attach 1 Amazon EBS volume per Amazon ECS task when running a standalone task, or when creating or updating a service. Amazon EBS volumes are supported for Linux tasks. For more information, see [Use Amazon EBS volumes with Amazon ECS](#).
- **Amazon EFS volumes** — Provides simple, scalable, and persistent file storage for use with your Amazon ECS tasks. With Amazon EFS, storage capacity is elastic. It grows and shrinks automatically as you add and remove files. Your applications can have the storage that they need and when they need it. Amazon EFS volumes are supported. For more information, see [Use Amazon EFS volumes with Amazon ECS](#).

- **FSx for Windows File Server volumes** — Provides fully managed Microsoft Windows file servers. These file servers are backed by a Windows file system. When using FSx for Windows File Server together with Amazon ECS, you can provision your Windows tasks with persistent, distributed, shared, and static file storage. For more information, see [Use FSx for Windows File Server volumes with Amazon ECS](#).

Windows containers on Fargate do not support this option.

- **Docker volumes** – A Docker-managed volume that is created under `/var/lib/docker/volumes` on the host Amazon EC2 instance. Docker volume drivers (also referred to as plugins) are used to integrate the volumes with external storage systems, such as Amazon EBS. The built-in `local` volume driver or a third-party volume driver can be used. Docker volumes are supported only when running tasks on Amazon EC2 instances. Windows containers support only the use of the `local` driver. To use Docker volumes, specify a `dockerVolumeConfiguration` in your task definition.
- **Bind mounts** – A file or directory on the host machine that is mounted into a container. Bind mount host volumes are supported. To use bind mount host volumes, specify a `host` and optional `sourcePath` value in your task definition.

For more information, see [Storage options for Amazon ECS tasks](#).

The following parameters are allowed in a container definition.

`name`

Type: String

Required: No

The name of the volume. Up to 255 letters (uppercase and lowercase), numbers, hyphens (-), and underscores (\_) are allowed. This name is referenced in the `sourceVolume` parameter of the container definition `mountPoints` object.

`host`

Required: No

The `host` parameter is used to tie the lifecycle of the bind mount to the host Amazon EC2 instance, rather than the task, and where it is stored. If the `host` parameter is empty, then the Docker daemon assigns a host path for your data volume, but the data is not guaranteed to persist after the containers associated with it stop running.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`.

 **Note**

The `sourcePath` parameter is supported only when using tasks that are hosted on Amazon EC2 instances or Amazon ECS Managed Instances.

`sourcePath`

Type: String

Required: No

When the `host` parameter is used, specify a `sourcePath` to declare the path on the host Amazon EC2 instance that is presented to the container. If this parameter is empty, then the Docker daemon assigns a host path for you. If the `host` parameter contains a `sourcePath` file location, then the data volume persists at the specified location on the host Amazon EC2 instance until you delete it manually. If the `sourcePath` value does not exist on the host Amazon EC2 instance, the Docker daemon creates it. If the location does exist, the contents of the source path folder are exported.

`configuredAtLaunch`

Type: Boolean

Required: No

Specifies whether a volume is configurable at launch. When set to `true`, you can configure the volume when running a standalone task, or when creating or updating a service. When set to `true`, you won't be able to provide another volume configuration in the task definition. This parameter must be set to `true` to configure an Amazon EBS volume for attachment to a task. Setting `configuredAtLaunch` to `true` and deferring volume configuration to the launch phase allows you to create task definitions that aren't constrained to a volume type or to specific volume settings. Doing this makes your task definition reusable across different execution environments. For more information, see [Amazon EBS volumes](#).

`dockerVolumeConfiguration`

Type: [DockerVolumeConfiguration](#) Object

Required: No

This parameter is specified when using Docker volumes. Docker volumes are supported only when running tasks on EC2 instances. Windows containers support only the use of the `local` driver. To use bind mounts, specify a host instead.

`scope`

Type: String

Valid Values: `task` | `shared`

Required: No

The scope for the Docker volume, which determines its lifecycle. Docker volumes that are scoped to a task are automatically provisioned when the task starts and destroyed when the task stops. Docker volumes that are scoped as `shared` persist after the task stops.

`autoprovision`

Type: Boolean

Default value: `false`

Required: No

If this value is `true`, the Docker volume is created if it doesn't already exist. This field is used only if the scope is `shared`. If the scope is `task`, then this parameter must be omitted.

`driver`

Type: String

Required: No

The Docker volume driver to use. The driver value must match the driver name provided by Docker because this name is used for task placement. If the driver was installed by using the Docker plugin CLI, use `docker plugin ls` to retrieve the driver name from your container instance. If the driver was installed by using another method, use Docker plugin discovery to retrieve the driver name.

`driverOpts`

Type: String

Required: No

A map of Docker driver-specific options to pass through. This parameter maps to `DriverOpts` in the Create a volume section of Docker.

labels

Type: String

Required: No

Custom metadata to add to your Docker volume.

efsVolumeConfiguration

Type: [EFSVolumeConfiguration](#) Object

Required: No

This parameter is specified when using Amazon EFS volumes.

fileSystemId

Type: String

Required: Yes

The Amazon EFS file system ID to use.

rootDirectory

Type: String

Required: No

The directory within the Amazon EFS file system to mount as the root directory inside the host. If this parameter is omitted, the root of the Amazon EFS volume will be used. Specifying `/` has the same effect as omitting this parameter.

 **Important**

If an EFS access point is specified in the `authorizationConfig`, the `rootDirectory` parameter must either be omitted or set to `/`, which will enforce the path set on the EFS access point.

## transitEncryption

Type: String

Valid values: ENABLED | DISABLED

Required: No

Specifies whether to enable encryption for Amazon EFS data in transit between the Amazon ECS host and the Amazon EFS server. If Amazon EFS IAM authorization is used, transit encryption must be enabled. If this parameter is omitted, the default value of DISABLED is used. For more information, see [Encrypting Data in Transit](#) in the *Amazon Elastic File System User Guide*.

## transitEncryptionPort

Type: Integer

Required: No

The port to use when sending encrypted data between the Amazon ECS host and the Amazon EFS server. If you don't specify a transit encryption port, the task will use the port selection strategy that the Amazon EFS mount helper uses. For more information, see [EFS Mount Helper](#) in the *Amazon Elastic File System User Guide*.

## authorizationConfig

Type: [EFSAuthorizationConfig](#) Object

Required: No

The authorization configuration details for the Amazon EFS file system.

## accessPointId

Type: String

Required: No

The access point ID to use. If an access point is specified, the root directory value in the `efsVolumeConfiguration` must either be omitted or set to `/`, which will enforce the path set on the EFS access point. If an access point is used, transit encryption must be enabled in the `EFSVolumeConfiguration`. For more information, see [Working with Amazon EFS Access Points](#) in the *Amazon Elastic File System User Guide*.

iam

Type: String

Valid values: ENABLED | DISABLED

Required: No

Specifies whether to use the Amazon ECS task IAM role that's defined in a task definition when mounting the Amazon EFS file system. If enabled, transit encryption must be enabled in the `EFSVolumeConfiguration`. If this parameter is omitted, the default value of DISABLED is used. For more information, see [IAM Roles for Tasks](#).

`FSxWindowsFileServerVolumeConfiguration`

Type: [FSxWindowsFileServerVolumeConfiguration](#) Object

Required: Yes

This parameter is specified when you're using an [Amazon FSx for Windows File Server](#) file system for task storage.

`fileSystemId`

Type: String

Required: Yes

The FSx for Windows File Server file system ID to use.

`rootDirectory`

Type: String

Required: Yes

The directory within the FSx for Windows File Server file system to mount as the root directory inside the host.

`authorizationConfig`

`credentialsParameter`

Type: String

Required: Yes

The authorization credential options.

**options:**

- Amazon Resource Name (ARN) of an [AWS Secrets Manager](#) secret.
- ARN of an [AWS Systems Manager](#) parameter.

domain

Type: String

Required: Yes

A fully qualified domain name hosted by an [AWS Directory Service for Microsoft Active Directory](#) (AWS Managed Microsoft AD) directory or a self-hosted EC2 Active Directory.

## Tags

When you register a task definition, you can optionally specify metadata tags that are applied to the task definition. Tags help you categorize and organize your task definition. Each tag consists of a key and an optional value. You define both of them. For more information, see [Tagging Amazon ECS resources](#).

### Important

Don't add personally identifiable information or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including billing. Tags aren't intended to be used for private or sensitive data.

The following parameters are allowed in a tag object.

key

Type: String

Required: No

One part of a key-value pair that make up a tag. A key is a general label that acts like a category for more specific tag values.

value

Type: String

Required: No

The optional part of a key-value pair that make up a tag. A value acts as a descriptor within a tag category (key).

## Other task definition parameters

The following task definition parameters can be used when registering task definitions in the Amazon ECS console by using the **Configure via JSON** option. For more information, see [Creating an Amazon ECS task definition using the console](#).

### Topics

- [IPC mode](#)
- [PID mode](#)
- [Fault injection](#)

## IPC mode

`ipcMode`

Type: String

Required: No

The IPC resource namespace to use for the containers in the task. The valid values are `host`, `task`, or `none`. If `host` is specified, then all the containers that are within the tasks that specified the `host` IPC mode on the same container instance share the same IPC resources with the host Amazon EC2 instance. If `task` is specified, all the containers that are within the specified task share the same IPC resources. If `none` is specified, then IPC resources within the containers of a task are private and not shared with other containers in a task or on the container instance. If no value is specified, then the IPC resource namespace sharing depends on the Docker daemon setting on the container instance.

If the `host` IPC mode is used, there's a heightened risk of undesired IPC namespace exposure.

If you're setting namespaced kernel parameters that use `systemControls` for the containers in the task, the following applies to your IPC resource namespace.

- For tasks that use the host IPC mode, IPC namespace that's related `systemControls` aren't supported.
- For tasks that use the task IPC mode, `systemControls` that relate to the IPC namespace apply to all containers within a task.

## PID mode

`pidMode`

Type: String

Valid Values: `host` | `task`

Required: No

The process namespace to use for the containers in the task. The valid values are `host` or `task`. For example, monitoring sidecars might need `pidMode` to access information about other containers running in the same task.

If `host` is specified, all containers within the tasks that specified the host PID mode on the same container instance share the same process namespace with the host Amazon EC2 instance.

If `task` is specified, all containers within the specified task share the same process namespace.

If no value is specified, the default is a private namespace for each container.

If the host PID mode is used, there's a heightened risk of undesired process namespace exposure.

### Note

This parameter is not supported for Windows containers.

## Fault injection

`enableFaultInjection`

Type: Boolean

Valid Values: `true` | `false`

Required: No

If this parameter is set to `true`, in a task's payload, Amazon ECS accepts fault injection requests from the task's containers. By default, this parameter is set to `false`.

## Amazon ECS task definition template

An empty task definition template is shown as follows. You can use this template to create your task definition, which can then be pasted into the console JSON input area or saved to a file and used with the AWS CLI `--cli-input-json` option. For more information, see [Amazon ECS task definition parameters for Fargate](#).

### EC2 template

```

## Fargate template

### Important

For Fargate, you must include the `operatingSystemFamily` parameter with one of the following values:

- LINUX
- WINDOWS\_SERVER\_2019\_FULL
- WINDOWS\_SERVER\_2019\_CORE
- WINDOWS\_SERVER\_2022\_FULL
- WINDOWS\_SERVER\_2022\_CORE

```
{
  "family": "",

        "containerName": "",
        "properties": [
            {
                "name": "",
                "value": ""
            }
        ]
    },
    },
    "inferenceAccelerators": [
        {
            "deviceName": "",
            "deviceType": ""
        }
    ]
}

```

You can generate this task definition template using the following AWS CLI command.

```
aws ecs register-task-definition --generate-cli-skeleton
```

# Example Amazon ECS task definitions

You can copy the examples and snippets to start creating your own task definitions.

You can copy the examples, and then paste them when you use the **Configure via JSON** option in the console. Make sure to customize the examples, such as using your account ID. You can include the snippets in your task definition JSON. For more information, see [Creating an Amazon ECS task definition using the console](#) and [Amazon ECS task definition parameters for Fargate](#).

For more task definition examples, see [AWS Sample Task Definitions](#) on GitHub.

## Webserver

The following is an example task definition using the Linux containers on Fargate that sets up a web server:

```
{
  "containerDefinitions": [
    {
      "command": [
        "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon
```

```

    ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-
foreground\"
    ],
    "entryPoint": [
        "sh",
        "-c"
    ],
    "essential": true,
    "image": "public.ecr.aws/docker/library/httpd:2.4",
    "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
            "awslogs-group" : "/ecs/fargate-task-definition",
            "awslogs-region": "us-east-1",
            "awslogs-stream-prefix": "ecs"
        }
    },
    "name": "sample-fargate-app",
    "portMappings": [
        {
            "containerPort": 80,
            "hostPort": 80,
            "protocol": "tcp"
        }
    ]
}
],
"cpu": "256",
"executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
"family": "fargate-task-definition",
"memory": "512",
"networkMode": "awsvpc",
"runtimePlatform": {
    "operatingSystemFamily": "LINUX"
},
"requiresCompatibilities": [
    "FARGATE"
]
}

```

The following is an example task definition using the Windows containers on Fargate that sets up a web server:

```
{
  "containerDefinitions": [
    {
      "command": ["New-Item -Path C:\\inetpub\\wwwroot\\index.html -Type file
-Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top:
40px; background-color: #333;} </style> </head><body> <div style=color:white;text-
align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your
application is now running on a container in Amazon ECS.</p>'; C:\\ServiceMonitor.exe
w3svc"],
      "entryPoint": [
        "powershell",
        "-Command"
      ],
      "essential": true,
      "cpu": 2048,
      "memory": 4096,
      "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-
ltsc2019",
      "name": "sample_windows_app",
      "portMappings": [
        {
          "hostPort": 80,
          "containerPort": 80,
          "protocol": "tcp"
        }
      ]
    }
  ],
  "memory": "4096",
  "cpu": "2048",
  "networkMode": "awsvpc",
  "family": "windows-simple-iis-2019-core",
  "executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
  "runtimePlatform": {"operatingSystemFamily": "WINDOWS_SERVER_2019_CORE"},
  "requiresCompatibilities": ["FARGATE"]
}
```

## splunk log driver

The following snippet demonstrates how to use the splunk log driver in a task definition that sends the logs to a remote service. The Splunk token parameter is specified as a secret option

because it can be treated as sensitive data. For more information, see [Pass sensitive data to an Amazon ECS container](#).

```
"containerDefinitions": [{
  "logConfiguration": {
    "logDriver": "splunk",
    "options": {
      "splunk-url": "https://cloud.splunk.com:8080",
      "tag": "tag_name",
    },
    "secretOptions": [{
      "name": "splunk-token",
      "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:splunk-token-
Kn1BkD"
    }],
  },
}
```

## fluentd log driver

The following snippet demonstrates how to use the fluentd log driver in a task definition that sends the logs to a remote service. The fluentd-address value is specified as a secret option as it may be treated as sensitive data. For more information, see [Pass sensitive data to an Amazon ECS container](#).

```
"containerDefinitions": [{
  "logConfiguration": {
    "logDriver": "fluentd",
    "options": {
      "tag": "fluentd demo"
    },
    "secretOptions": [{
      "name": "fluentd-address",
      "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:fluentd-address-
Kn1BkD"
    }],
  },
  "entryPoint": [],
  "portMappings": [{
    "hostPort": 80,
    "protocol": "tcp",
    "containerPort": 80
  },
  {
```

```
"hostPort": 24224,  
"protocol": "tcp",  
"containerPort": 24224  
}]  
}],
```

## gelf log driver

The following snippet demonstrates how to use the gelf log driver in a task definition that sends the logs to a remote host running Logstash that takes Gelf logs as an input. For more information, see [logConfiguration](#).

```
"containerDefinitions": [{  
  "logConfiguration": {  
    "logDriver": "gelf",  
    "options": {  
      "gelf-address": "udp://logstash-service-address:5000",  
      "tag": "gelf task demo"  
    }  
  },  
  "entryPoint": [],  
  "portMappings": [{  
    "hostPort": 5000,  
    "protocol": "udp",  
    "containerPort": 5000  
  },  
  {  
    "hostPort": 5000,  
    "protocol": "tcp",  
    "containerPort": 5000  
  }  
]  
}],
```

## Workloads on external instances

When registering an Amazon ECS task definition, use the `requiresCompatibilities` parameter and specify `EXTERNAL` which validates that the task definition is compatible to use when running Amazon ECS workloads on your external instances. If you use the console for registering a task definition, you must use the JSON editor. For more information, see [Creating an Amazon ECS task definition using the console](#).

**⚠ Important**

If your tasks require a task execution IAM role, make sure that it's specified in the task definition.

When you deploy your workload, use the EXTERNAL launch type when creating your service or running your standalone task.

The following is an example task definition.

**Linux**

```
{
  "requiresCompatibilities": [
    "EXTERNAL"
  ],
  "containerDefinitions": [{
    "name": "nginx",
    "image": "public.ecr.aws/nginx/nginx:latest",
    "memory": 256,
    "cpu": 256,
    "essential": true,
    "portMappings": [{
      "containerPort": 80,
      "hostPort": 8080,
      "protocol": "tcp"
    }]
  }],
  "networkMode": "bridge",
  "family": "nginx"
}
```

**Windows**

```
{
  "requiresCompatibilities": [
    "EXTERNAL"
  ],
  "containerDefinitions": [{
    "name": "windows-container",
    "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
```

```
"memory": 256,
"cpu": 512,
"essential": true,
"portMappings": [{
  "containerPort": 80,
  "hostPort": 8080,
  "protocol": "tcp"
}],
"networkMode": "bridge",
"family": "windows-container"
}
```

## Amazon ECR image and task definition IAM role

The following snippet uses an Amazon ECR image called `aws-nodejs-sample` with the `v1` tag from the `123456789012.dkr.ecr.us-west-2.amazonaws.com` registry. The container in this task inherits IAM permissions from the `arn:aws:iam::123456789012:role/AmazonECSTaskS3BucketRole` role. For more information, see [Amazon ECS task IAM role](#).

```
{
  "containerDefinitions": [
    {
      "name": "sample-app",
      "image": "123456789012.dkr.ecr.us-west-2.amazonaws.com/aws-nodejs-sample:v1",
      "memory": 200,
      "cpu": 10,
      "essential": true
    }
  ],
  "family": "example_task_3",
  "taskRoleArn": "arn:aws:iam::123456789012:role/AmazonECSTaskS3BucketRole"
}
```

## Entrypoint with command

The following snippet demonstrates the syntax for a Docker container that uses an entry point and a command argument. This container pings `example.com` four times and then exits.

```
{
```

```
"containerDefinitions": [  
  {  
    "memory": 32,  
    "essential": true,  
    "entryPoint": ["ping"],  
    "name": "alpine_ping",  
    "readonlyRootFilesystem": true,  
    "image": "alpine:3.4",  
    "command": [  
      "-c",  
      "4",  
      "example.com"  
    ],  
    "cpu": 16  
  },  
],  
"family": "example_task_2"  
}
```

## Container dependency

This snippet demonstrates the syntax for a task definition with multiple containers where container dependency is specified. In the following task definition, the envoy container must reach a healthy status, determined by the required container health check parameters, before the app container will start. For more information, see [Container dependency](#).

```
{  
  "family": "appmesh-gateway",  
  "runtimePlatform": {  
    "operatingSystemFamily": "LINUX"  
  },  
  "proxyConfiguration": {  
    "type": "APPMESH",  
    "containerName": "envoy",  
    "properties": [  
      {  
        "name": "IgnoredUID",  
        "value": "1337"  
      },  
      {  
        "name": "ProxyIngressPort",  
        "value": "15000"  
      }  
    ],  
  },  
}
```

```

        {
            "name": "ProxyEgressPort",
            "value": "15001"
        },
        {
            "name": "AppPorts",
            "value": "9080"
        },
        {
            "name": "EgressIgnoredIPs",
            "value": "169.254.170.2,169.254.169.254"
        }
    ]
},
"containerDefinitions": [
    {
        "name": "app",
        "image": "application_image",
        "portMappings": [
            {
                "containerPort": 9080,
                "hostPort": 9080,
                "protocol": "tcp"
            }
        ],
        "essential": true,
        "dependsOn": [
            {
                "containerName": "envoy",
                "condition": "HEALTHY"
            }
        ]
    },
    {
        "name": "envoy",
        "image": "840364872350.dkr.ecr.region-code.amazonaws.com/aws-appmesh-
envoy:v1.15.1.0-prod",
        "essential": true,
        "environment": [
            {
                "name": "APPMESH_VIRTUAL_NODE_NAME",
                "value": "mesh/meshName/virtualNode/virtualNodeName"
            }
        ]
    }
]

```

```
        "name": "ENVOY_LOG_LEVEL",
        "value": "info"
      }
    ],
    "healthCheck": {
      "command": [
        "CMD-SHELL",
        "echo hello"
      ],
      "interval": 5,
      "timeout": 2,
      "retries": 3
    }
  }
},
"executionRoleArn": "arn:aws:iam::123456789012:role/ecsTaskExecutionRole",
"networkMode": "awsvpc"
}
```

## Volumes in task definitions

Use the following to understand how to specify volumes in tasks.

- For information about how to configure an Amazon EBS volume, see [Specify Amazon EBS volume configuration at Amazon ECS deployment](#).
- For information about how to configure an Amazon EFS volume, see [Configuring Amazon EFS file systems for Amazon ECS using the console](#).
- For information about how to configure a FSx for Windows File Server volume, see [Learn how to configure FSx for Windows File Server file systems for Amazon ECS](#).
- For information about how to configure a Docker volume, see [Docker volume examples for Amazon ECS](#).
- For information about how to configure a bind mount, see [Bind mount examples for Amazon ECS](#).

## Windows sample task definitions

The following is a sample task definition to help you get started with Windows containers on Amazon ECS.

## Example Amazon ECS Console Sample Application for Windows

The following task definition is the Amazon ECS console sample application that is produced in the first-run wizard for Amazon ECS; it has been ported to use the `microsoft/iis` Windows container image.

```
{
  "family": "windows-simple-iis",
  "containerDefinitions": [
    {
      "name": "windows_sample_app",
      "image": "mcr.microsoft.com/windows/servercore/iis",
      "cpu": 1024,
      "entryPoint": ["powershell", "-Command"],
      "command": ["New-Item -Path C:\\\\inetpub\\\\wwwroot\\\\index.html -Type file -",
        "Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top:",
        "40px; background-color: #333;} </style> </head><body> <div style=color:white;text-",
        "align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your",
        "application is now running on a container in Amazon ECS.</p>'; C:\\\\ServiceMonitor.exe",
        "w3svc"],
      "portMappings": [
        {
          "protocol": "tcp",
          "containerPort": 80
        }
      ],
      "memory": 1024,
      "essential": true
    }
  ],
  "networkMode": "awsvpc",
  "memory": "1024",
  "cpu": "1024"
}
```

# Amazon ECS clusters

An Amazon ECS cluster is a logical grouping of tasks or services that provides the infrastructure capacity for your containerized applications. When creating a cluster, you choose from the three primary infrastructure types, each optimized for different use cases and operational requirements.

## Choosing the right cluster type

Amazon ECS offers three infrastructure types for your clusters. Choose the type that best matches your workload requirements, operational preferences, and cost optimization goals:

### Amazon ECS Managed Instances (Recommended)

**Best for most workloads** - AWS fully manages the underlying Amazon EC2 instances, including provisioning, patching, and scaling. This option provides the optimal balance of performance, cost-effectiveness, and operational simplicity.

**Use when:**

- You want AWS to handle infrastructure management
- You need cost-effective compute with automatic optimization
- You want to focus on your applications rather than infrastructure
- You need predictable performance with flexible scaling

### Fargate

**Serverless compute** - Pay only for the resources your tasks use without managing any infrastructure. Ideal for variable workloads and getting started quickly.

**Use when:**

- You want completely serverless operations
- You have unpredictable or variable workloads
- You want to minimize operational overhead
- You need rapid deployment and scaling

### Amazon EC2 instances

**Full control** - You manage the underlying Amazon EC2 instances directly, including instance selection, configuration, and maintenance.

**Use when:**

- You need specific instance types or configurations
- You have existing Amazon EC2 infrastructure to leverage
- You require custom AMIs or specialized software
- You need maximum control over the underlying infrastructure

**Note**

Amazon ECS Managed Instances is the recommended choice for most new workloads as it provides the best combination of performance, cost optimization, and operational simplicity while allowing AWS to handle infrastructure management tasks.

## Cluster components

In addition to the infrastructure capacity, a cluster consists of the following resources:

- The network (VPC and subnet) where your tasks and services run

When you use Amazon ECS Managed Instances or Amazon EC2 instances for the capacity, the subnet can be in Availability Zones, Local Zones, Wavelength Zones, or AWS Outposts.

- An optional namespace

A namespace is used for service-to-service communication with Service Connect.

- A monitoring option

CloudWatch Container Insights comes at an additional cost and is a fully managed service. It automatically collects, aggregates, and summarizes Amazon ECS metrics and logs.

## Cluster concepts

The following are general concepts about Amazon ECS clusters.

- You create clusters to separate your resources.
- Clusters are AWS Region specific.
- Clusters can be in any of the following states.

## ACTIVE

The cluster is ready to accept tasks and, if applicable, you can register container instances with the cluster.

## PROVISIONING

The cluster has capacity providers associated with it and the resources needed for the capacity provider are being created.

## DEPROVISIONING

The cluster has capacity providers associated with it and the resources needed for the capacity provider are being deleted.

## FAILED

The cluster has capacity providers associated with it and the resources needed for the capacity provider have failed to create.

## INACTIVE

The cluster has been deleted. Clusters with an INACTIVE status may remain discoverable in your account for a period of time. This behavior is subject to change in the future, so make sure you do not rely on INACTIVE clusters persisting.

- A cluster can contain a mix of tasks that are hosted on Amazon ECS Managed Instances, AWS Fargate, Amazon EC2 instances, or external instances. Tasks can run on Amazon ECS Managed Instances, Fargate or EC2 infrastructure as a launch type or a capacity provider strategy. If you use EC2 capacity providers, Amazon ECS doesn't track and scale the capacity of Amazon EC2 Auto Scaling groups.
- A cluster can contain a mix of Amazon ECS Managed Instances capacity providers, Auto Scaling group capacity providers, and Fargate capacity providers. A capacity provider strategy can only contain Amazon ECS Managed Instances capacity providers, Auto Scaling group capacity providers, or Fargate capacity providers.
- You can use different instance types for the Amazon ECS Managed Instances and EC2, or Auto Scaling group capacity providers. An instance can only be registered to one cluster at a time.
- You can restrict access to clusters by creating custom IAM policies. For information, see [Amazon ECS cluster examples](#) section in [Identity-based policy examples for Amazon Elastic Container Service](#).

- You can use Service Auto Scaling to scale Fargate tasks. For more information, see [Automatically scale your Amazon ECS service](#).
- You can configure a default Service Connect namespace for a cluster. After you set a default Service Connect namespace, any new services created in the cluster can be added as client services in the namespace by turning on Service Connect. No additional configuration is required. For more information, see [Use Service Connect to connect Amazon ECS services with short names](#).

## Capacity providers

Amazon ECS capacity providers manage the scaling of infrastructure for tasks in your clusters. Each cluster can have one or more capacity providers and an optional capacity provider strategy. You can assign a default capacity provider strategy to the cluster. The capacity provider strategy determines how the tasks are spread across the cluster's capacity providers. When you run a standalone task or create a service, you either use the cluster's default capacity provider strategy or a capacity provider strategy that overrides the default one. The cluster's default capacity provider strategy only applies when you don't specify a launch type, or capacity provider strategy for your task or service. If you provide either of these parameters, the default strategy isn't used.

Amazon ECS offers three types of capacity providers for your clusters:

### Amazon ECS Managed Instances capacity providers

AWS fully manages the underlying Amazon EC2 instances, including provisioning, patching, scaling, and lifecycle management. This provides the optimal balance of performance, cost-effectiveness, and operational simplicity. Amazon ECS Managed Instances capacity providers automatically optimize instance selection and scaling based on your workload requirements.

With Amazon ECS Managed Instances, you benefit from:

- Automatic instance provisioning and scaling
- Managed patching and security updates
- Cost optimization through intelligent instance selection
- Reduced operational overhead

## Fargate capacity providers

Serverless compute where you pay only for the resources your tasks use without managing any infrastructure. You just need to associate the pre-defined capacity providers (Fargate and Fargate Spot) with the cluster.

## Auto Scaling group capacity providers

When you use Amazon EC2 instances for your capacity, you use Auto Scaling group to manage the Amazon EC2 instances. Auto Scaling helps ensure that you have the correct number of Amazon EC2 instances available to handle the application load. You have full control over the underlying infrastructure.

A cluster can contain a mix of tasks that are hosted on Amazon ECS Managed Instances, AWS Fargate, Amazon EC2 instances, or external instances. Tasks can run on Amazon ECS Managed Instances, Fargate or EC2 infrastructure as a launch type or a capacity provider strategy. If you use EC2 as a launch type, Amazon ECS doesn't track and scale the capacity of Amazon EC2 Auto Scaling groups.

A cluster can contain a mix of Amazon ECS Managed Instances capacity providers, Auto Scaling group capacity providers, and Fargate capacity providers. A capacity provider strategy can only contain Amazon ECS Managed Instances capacity providers, Auto Scaling group capacity providers, or Fargate capacity providers.

# Clusters for Amazon ECS Managed Instances

Amazon ECS capacity providers manage the scaling of infrastructure for tasks in your clusters. After you create the cluster, you create one or more capacity providers and an optional capacity provider strategy for the cluster. The capacity provider strategy determines how the tasks are spread across the cluster's capacity providers. When you run a standalone task or create a service, you either use the cluster's default capacity provider strategy or a capacity provider strategy that overrides the default one.

Amazon ECS Managed Instances has the following capacity providers.

| Type    | Criteria used to choose instances                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default | <p>The most cost-effective instances that meet the following task definition and service parameter requirements:</p> <ul style="list-style-type: none"><li>• Task definition<ul style="list-style-type: none"><li>• <code>operatingSystemFamily</code></li><li>• <code>cpuArchitecture</code></li><li>• <code>cpu</code></li><li>• <code>memory</code></li></ul></li><li>• Service definition<ul style="list-style-type: none"><li>• <code>placementConstraints</code></li><li>• <code>placementStrategy</code></li></ul></li></ul> |
| Custom  | <p>The instances that meet the attribute and type requirements that you specify when you create the cluster. For information about attributes, see <a href="#">Amazon ECS container instance attributes</a>. For information about instance types, see <a href="#">Amazon EC2 instance type specifications</a> in <i>Amazon EC2 Instance Types</i>.</p>                                                                                                                                                                             |

Amazon ECS launches the instances and associates them with the Amazon ECS Managed Instances capacity provider. For the custom capacity provider, Amazon ECS also creates the capacity provider.

## Creating a cluster for Amazon ECS Managed Instances

You create a cluster to define the infrastructure your tasks and services run on.

When you create a cluster for Amazon ECS Managed Instances, Amazon ECS automatically creates a managed instances capacity provider with default configurations. This capacity provider selects the most cost-optimized instance types for your workloads. You can also create custom capacity providers if you need specific instance attributes or types.

To make the cluster creation process as easy as possible, the console has default selections for many choices.

- Creates a default namespace in AWS Cloud Map that is the same name as the cluster. A namespace allows services that you create in the cluster to connect to the other services in the namespace without additional configuration.

For more information, see [Interconnect Amazon ECS services](#).

You can modify the following options:

- Change the default namespace associated with the cluster.

A namespace allows services that you create in the cluster to connect to the other services in the namespace without additional configuration. The default namespace is the same as the cluster name. For more information, see [Interconnect Amazon ECS services](#).

- Assign a AWS KMS key for your managed storage. For information about how to create a key, see [Create a KMS key](#) in the *AWS Key Management Service User Guide*.
- Add tags to help you identify your cluster.

## Prerequisites

Before you begin, be sure that you've completed the steps in [Set up to use Amazon ECS](#) and assign the appropriate IAM permission. For more information, see [the section called “Amazon ECS cluster examples”](#).

The user creating the cluster must have an additional permission:

`iam:CreateServiceLinkedRole`.

When you don't specify `instanceRequirements`, Amazon ECS automatically selects the most cost-optimized instance types based on your task definition requirements. To use specific instance attributes or types, create a capacity provider with `instanceRequirements`.

Understand how to choose your instances. For more information, see [Instance selection best practices for Amazon ECS Managed Instances](#).

You have the required IAM roles for Amazon ECS Managed Instances. This includes:

- **Infrastructure role** - Allows Amazon ECS to make calls to AWS services on your behalf to manage Amazon ECS Managed Instances infrastructure.

For more information, see [Amazon ECS infrastructure IAM role](#).

- **Instance profile** - Provides permissions for the Amazon ECS container agent and Docker daemon running on managed instances.

For more information, see [Amazon ECS Managed Instances instance profile](#).

## Console procedure

### To create a new cluster (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, configure the following:

- For **Cluster name**, enter a unique name.

The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.

- (Optional) To have the namespace used for Service Connect be different from the cluster name, for **Namespace**, enter a unique name.

6. For **Custom Capacity Provider**, do the following:

- For **Select a method of obtaining EC2 capacity**, choose **Amazon ECS Managed Instances**.
- For Instance profile, choose the instance profile role.
- For Infrastructure role, choose the infrastructure role.
- To use a custom capacity provider, for **Instance selection**, choose **Use custom**. Then, for each attribute, enter the **Attribute value**.

7. (Optional) Use Container Insights, expand **Monitoring**, and then choose one of the following options:

- To use the recommended Container Insights with enhanced observability, choose **Container Insights with enhanced observability**.

- To use Container Insights, choose **Container Insights**.
8. (Optional) Encrypt the data on managed storage. Under **Encryption**, for **Managed storage**, enter the ARN of the AWS KMS key you want to use to encrypt the managed storage data.
  9. (Optional) To help identify your cluster, expand **Tags**, and then configure your tags.

[Add a tag] Choose **Add tag** and do the following:

- For **Key**, enter the key name.
  - For **Value**, enter the key value.
10. Choose **Create**.

## AWS CLI procedure

You can create a cluster for Amazon ECS Managed Instances using the AWS CLI. Use the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing or updating to the latest version of the AWS CLI](#).

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [the section called "Using dual-stack endpoints"](#).

## To create a new cluster (AWS CLI)

1. Create your cluster with a unique name using the following command:

```
aws ecs create-cluster --cluster-name managed-instances-cluster
```

Output:

```
{
  "cluster": {
    "status": "ACTIVE",
    "defaultCapacityProviderStrategy": [],
    "statistics": [],
    "capacityProviders": [],
```

```
    "tags": [],
    "clusterName": "managed-instances-cluster",
    "settings": [
      {
        "name": "containerInsights",
        "value": "disabled"
      }
    ],
    "registeredContainerInstancesCount": 0,
    "pendingTasksCount": 0,
    "runningTasksCount": 0,
    "activeServicesCount": 0,
    "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/managed-instances-
cluster"
  }
}
```

2. (Optional) To enable Container Insights with enhanced observability for your cluster, use the following command:

```
aws ecs put-account-setting --name containerInsights --value enhanced
```

3. (Optional) To add tags to your cluster, use the following command:

```
aws ecs tag-resource --resource-arn
arn:aws:ecs:region:aws_account_id:cluster/managed-instances-cluster --tags
key=Environment,value=Production
```

## Next steps

Create a task definition for Amazon ECS Managed Instances. For more information, see [Creating an Amazon ECS task definition using the console](#).

Run your applications as standalone tasks, or as part of a service. For more information, see the following:

- [Running an application as an Amazon ECS task](#)
- [Creating an Amazon ECS rolling update deployment](#)

# Updating a cluster to use Amazon ECS Managed Instances

You can update an existing cluster to use Amazon ECS Managed Instances.

When you add Amazon ECS Managed Instances to your cluster, Amazon ECS automatically creates a managed instances capacity provider with default configurations. This capacity provider selects the most cost-optimized general-purpose instance types for your workloads. You can also create custom capacity providers if you need specific instance attributes or types.

## Prerequisites

When you don't specify `instanceRequirements`, Amazon ECS automatically selects the most cost-optimized instance types based on your task definition requirements. To use specific instance attributes or types, create a capacity provider with `instanceRequirements`.

You have the required IAM roles for Amazon ECS Managed Instances. This includes:

- **Infrastructure role** - Allows Amazon ECS to make calls to AWS services on your behalf to manage Amazon ECS Managed Instances infrastructure.

For more information, see [Amazon ECS infrastructure IAM role](#).

- **Instance profile** - Provides permissions for the Amazon ECS container agent and Docker daemon running on managed instances.

For more information, see [Amazon ECS Managed Instances instance profile](#).

## Update considerations

When updating a cluster for Amazon ECS Managed Instances, consider the following:

- **Running tasks** - Updating cluster settings does not affect currently running tasks. Changes will apply to new tasks launched after the update.
- **Capacity provider changes** - If you modify capacity provider settings, existing managed instances will continue to run, but new instances will use the updated configuration.
- **Monitoring changes** - Enabling or disabling Container Insights will affect metric collection for the entire cluster.

## Console procedure

### To update a cluster (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, select the cluster you want to update.
5. Choose **Update cluster**.
6. (Optional) To modify capacity provider settings, under **Custom Capacity Provider**, update the following as needed:
  - For **Instance profile**, choose a different instance profile role if needed.
  - For **Infrastructure role**, choose a different infrastructure role if needed.
  - To use a custom capacity provider, for **Instance selection**, update the **Attribute value** settings.
7. Choose **Update**.

## AWS CLI procedure

You can update a cluster for Amazon ECS Managed Instances using the AWS CLI. Use the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing or updating to the latest version of the AWS CLI](#).

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [the section called "Using dual-stack endpoints"](#).

### To update a cluster (AWS CLI)

1. Create a capacity provider for . Run the following command:

Replace the *user-input* with your values.

```
aws ecs create-capacity-provider \  
  --name my-managed-instances-provider \  
  --managed-instances-provider \  
  --instance-profile arn:aws:iam::123456789012:instance-profile/  
ecsInstanceProfile \  
  --infrastructure-role-arn arn:aws:iam::123456789012:role/ecsInfrastructureRole  
  \  
  --instance-requirements '{  
    "vCpuCount": {"min": 2, "max": 8},  
    "memoryMiB": {"min": 4096, "max": 16384}  
  }'
```

2. Add the capacity provider to the cluster, use the following command:

Replace the *user-input* with your values.

```
aws ecs put-cluster-capacity-providers --cluster managed-instances-cluster --  
capacity-providers my-managed-instances-provider --default-capacity-provider-  
strategy capacityProvider=my-managed-instances-provider,weight=1
```

## Amazon ECS Managed Instances capacity providers

Amazon ECS Managed Instances capacity providers provide a container compute model that gives you access to the full range of AWS capabilities and Amazon EC2 offerings while AWS manages operational and security responsibilities. AWS handles software and OS patching, instance scaling, and maintenance, giving you the operational benefits of Fargate while maintaining access to all AWS capabilities and integrations.

Amazon ECS creates launch templates for your Amazon ECS Managed Instances. This defines how Amazon ECS launches Amazon ECS Managed Instances, including the instance profile for your tasks, network and storage configuration, capacity options, and instance requirements for flexible instance type selection.

### When to use custom capacity providers

Consider custom capacity providers when your workloads require:

- **Specific compute requirements:** Applications requiring accelerated compute, specific CPU instruction sets, high network performance, or large memory configurations that aren't available with standard Fargate options.
- **GPU workloads:** Machine learning inference, real-time image rendering, video encoding, or other GPU-accelerated applications that need access to NVIDIA or AMD GPUs.
- **Capacity reservations:** Mission-critical workloads that require predictable capacity availability.
- **Advanced observability:** Security and monitoring tools that require privileged access to the underlying OS, such as eBPF-based monitoring solutions or network analysis tools.
- **Cost optimization:** Workloads that can benefit from multi-task placement, shared infrastructure components, or need to maximize utilization of larger instance types.

## Monitoring options

Amazon ECS Managed Instances provide comprehensive monitoring capabilities to help you track performance, health, and resource utilization of your containerized workloads. You can choose from different monitoring levels based on your operational requirements.

- **Basic monitoring** – Provides essential metrics at 5-minute intervals for most metrics and 1-minute intervals for status checks. This is enabled by default and incurs no additional charges.
- **Detailed monitoring** – Offers enhanced visibility with all metrics available at 1-minute intervals, enabling faster detection and response to operational issues. For more information, see [Detailed monitoring for Amazon ECS Managed Instances](#).

Both monitoring options integrate seamlessly with CloudWatch to provide dashboards, alarms, and automated responses to help maintain optimal application performance and availability.

## Capacity provider considerations

A cluster can contain a mix of Amazon ECS Managed Instances capacity providers, Auto Scaling group capacity providers, and Fargate capacity providers. A capacity provider strategy can only contain Amazon ECS Managed Instances capacity providers, Auto Scaling group capacity providers, or Fargate capacity providers.

## Tag propagation

Capacity providers for Amazon ECS Managed Instances support tag propagation. With tag propagation, all resources managed by the capacity provider — the managed instance, the Amazon

ECS container instance, launch template, volumes, Elastic Network Interfaces — are tagged with the same tags specified at the capacity provider level. You can specify tags during capacity provider creation and enable tag propagation by specifying the `propagateTags` parameter as `CAPACITY_PROVIDER`.

For more information about tagging Amazon ECS Managed Instances, see [Tags for Amazon ECS Managed Instances](#).

## Best practices for updating capacity providers for Amazon ECS Managed Instances

For the highest level of safety and rollback support, we recommend treating capacity providers as immutable resources. When you need to update a capacity provider configuration, follow this recommended workflow:

1. **Create a new capacity provider** with your updated configuration instead of modifying the existing one.
2. **Update each service** to use the new capacity provider and allow the deployments to complete.
3. **Delete the old capacity provider** after confirming the new configuration works as expected.

This approach provides several benefits:

- **Controlled rollout** - You can update services one at a time and monitor the impact.
- **Easy rollback** - If issues occur, you can quickly revert services to use the previous capacity provider.
- **Reduced blast radius** - Problems with the new configuration don't immediately affect all workloads.

### Note

If you're using CloudFormation, consider keeping the old capacity provider until a later deployment to preserve the ability to roll back your stack changes.

While you can update capacity providers in place, this approach creates a larger uncontrolled blast radius. In-place updates apply new settings to all new capacity provisioned going forward, but don't trigger service deployments. This means you might not discover configuration issues until much later when your services need to scale.

## Creating a capacity provider for Amazon ECS Managed Instances

Amazon ECS Managed Instances uses capacity providers to manage compute capacity for your workloads. When you create a capacity provider without specifying `instanceRequirements`, Amazon ECS automatically selects the most cost-optimized [general-purpose instance types](#). You can create capacity providers with `instanceRequirements` to specify instance attributes such as instance types, CPU manufacturers, accelerator types, and other requirements.

Custom capacity providers use attribute-based instance type selection, which allows you to express instance requirements as a set of attributes. These requirements are automatically translated to all matching Amazon EC2 instance types, simplifying the creation and maintenance of instance type configurations. To learn more about instance requirements and attribute-based selection, see the [Amazon EC2 Fleet attribute-based instance type selection](#) documentation in the *Amazon EC2 User Guide*.

### Prerequisites

Before you begin, ensure that you have completed the following:

- Determine what type of monitoring to use. For more information, see [the section called “Detailed monitoring for Amazon ECS Managed Instances”](#).
- Have an existing cluster or plan to create one. For more information, see [Creating a cluster for Amazon ECS Managed Instances](#).
- You have the required IAM roles for Amazon ECS Managed Instances. This includes:
  - **Infrastructure role** - Allows Amazon ECS to make calls to AWS services on your behalf to manage Amazon ECS Managed Instances infrastructure.

For more information, see [Amazon ECS infrastructure IAM role](#).

- **Instance profile** - Provides permissions for the Amazon ECS container agent and Docker daemon running on managed instances.

For more information, see [Amazon ECS Managed Instances instance profile](#).

Understand how to choose your instances. For more information, see [Instance selection best practices for Amazon ECS Managed Instances](#).

## Console procedure

### To create a capacity provider for Amazon ECS Managed Instances (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose your cluster name.
5. On the cluster page, choose the **Infrastructure** tab.
6. In the **Capacity providers** section, choose **Create capacity provider**.
7. Under **Capacity provider configuration**, configure the following:
  - For **Capacity provider name**, enter a unique name for your capacity provider.
  - For **Capacity provider type**, choose **Amazon ECS Managed Instances**.
8. Under **Instance configuration**, configure the following:
  - For **Instance profile**, choose the instance profile role created for Amazon ECS Managed Instances.
  - For **Infrastructure role**, choose the infrastructure role created for Amazon ECS Managed Instances.
9. Under **Instance requirements**, specify the attributes for your instances. You can configure any combination of the following:
  - **vCPU count** - Specify the number of vCPUs (for example, 4 or 8-16 for a range).
  - **Memory (MiB)** - Specify the amount of memory in MiB (for example, 8192 or 16384-32768 for a range).
  - **Instance types** - Specify specific instance types (for example, `m5.large`, `m5.xlarge`, `c5.large`).
  - **CPU manufacturers** - Choose from `intel`, `amd`, or `amazon-web-services`.
  - **Accelerator types** - Specify accelerator types such as `gpu`, `fpga`, or `inference`.
  - **Accelerator count** - Specify the number of accelerators (for example, 1 or 2-4 for a range).
10. Under **Advanced configuration**, choose one of the following monitoring options:
  - To have CloudWatch send status-check metrics, choose **Basic**.
  - To have CloudWatch send all metrics metrics, choose **Detailed**.

## 11. (Optional) To help identify your capacity provider, expand **Tags**, and then configure your tags.

To enable tag propagation from capacity provider to managed resources such as instances launched from the capacity provider, for **Propagate tags from**, choose **Capacity provider**.

[Add a tag] Choose **Add tag** and do the following:

- For **Key**, enter the key name.
- For **Value**, enter the key value.

## 12. Choose **Create**.

### AWS CLI procedure

You can create a capacity provider for Amazon ECS Managed Instances using the AWS CLI. Use the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing or updating to the latest version of the AWS CLI](#).

### To create a capacity provider for Amazon ECS Managed Instances (AWS CLI)

#### 1. Run the following command:

```
aws ecs create-capacity-provider --cli-input-json file://capacity-provider-definition.json
```

The following `capacity-provider-definition.json` can be used to specify basic instance requirements, instance storage size, and enable tag propagation:

```
{
  "name": "my-managed-instances-provider",
  "cluster": "my-cluster",
  "tags": [
    {
      "key": "version",
      "value": "test"
    }
  ],
  "managedInstancesProvider": {
    "infrastructureRoleArn": "arn:aws:iam::123456789012:role/ecsInfrastructureRole",
    "instanceLaunchTemplate": {
```

```

        "ec2InstanceProfileArn": "arn:aws:iam::123456789012:instance-profile/
ecsInstanceRole",
        "instanceRequirements": {
            "vCpuCount": {
                "min": 4,
                "max": 8
            },
            "memoryMiB": {
                "min": 8192,
                "max": 16384
            }
        },
        "networkConfiguration": {
            "subnets": [
                "subnet-abcdef01234567",
                "subnet-bcdefa98765432"
            ],
            "securityGroups": [
                "sg-0123456789abcdef"
            ]
        },
        "storageConfiguration": {
            "storageSizeGiB": 100
        },
        "monitoring": "basic"
    },
    "propagateTags": "CAPACITY_PROVIDER"
}

```

## 2. Verify that your capacity provider was created successfully:

```

aws ecs describe-capacity-providers \
    --capacity-providers my-managed-instances-provider

```

## Next steps

After creating your capacity provider, you can use it when creating services or running tasks:

- To use the capacity provider with a service, see [Creating an Amazon ECS rolling update deployment](#).

- To use the capacity provider with standalone tasks, see [Running an application as an Amazon ECS task](#).

## Updating Amazon ECS Managed Instances monitoring

You can modify the monitoring option for your Amazon ECS Managed Instances capacity provider to change between basic and detailed monitoring. This allows you to adjust the level of monitoring data collected without recreating the capacity provider.

For more information about monitoring options, see [Monitoring Amazon ECS Managed Instances](#).

### Console procedure

#### To update monitoring for Amazon ECS Managed Instances (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose your cluster name.
5. On the cluster page, choose the **Infrastructure** tab.
6. Under **Advanced configuration**, choose one of the following monitoring options:
  - To have CloudWatch send status-check metrics, choose **Basic**.
  - To have CloudWatch send all metrics metrics, choose **Detailed**.
7. Choose **Update**.

To update tags associated with an existing Amazon ECS Managed Instances capacity provider, follow these steps:

1. In the navigation pane, choose **Clusters**.
2. On the clusters page, choose **Infrastructure**.
3. On the infrastructure page, choose the capacity provider that you created.
4. On the capacity provider page, choose **Tags**.
5. Under **Tags**, choose **Manage tags**.

6. To add a tag, specify the key and value of the tag that you want to add and then choose **Save**. To add multiple tags at once, choose **Add tag** for each tag that you want to add. You can add a maximum of 50 tags.

To remove a tag, choose **Remove**.

 **Note**

If tag propagation is enabled, tags added or removed after capacity provider creation don't apply to resources previously created by the capacity provider.

## AWS CLI procedure

You can update a capacity provider for Amazon ECS Managed Instances using the AWS CLI. Use the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing or updating to the latest version of the AWS CLI](#).

### To update monitoring for Amazon ECS Managed Instances (AWS CLI)

1. To enable detailed monitoring, use the following command:

```
aws ecs update-capacity-provider \
  --name my-managed-instances-provider \
  --managed-instances-provider '{
    "instanceLaunchTemplateUpdate": {
      "monitoring": "DETAILED"
    }
  }'
```

2. To enable basic monitoring, use the following command:

```
aws ecs update-capacity-provider \
  --name my-managed-instances-provider \
  --managed-instances-provider '{
    "instanceLaunchTemplateUpdate": {
      "monitoring": "BASIC"
    }
  }'
```

## Deleting an Amazon ECS Managed Instances capacity provider

If you are finished using an Amazon ECS Managed Instances capacity provider, you can delete it. After the group is deleted, the Amazon ECS Managed Instances capacity provider transitions to the INACTIVE state. Capacity providers with an INACTIVE status may remain discoverable in your account for a period of time. However, this behavior is subject to change in the future, so you should not rely on INACTIVE capacity providers persisting. Before the Amazon ECS Managed Instances capacity provider is deleted, the capacity provider must be removed from the capacity provider strategy from all services. You can use the UpdateService API or the update service workflow in the Amazon ECS console to remove a capacity provider from a service's capacity provider strategy. Use the **Force new deployment** option to ensure that any tasks using the Amazon ECS Managed Instances capacity provided by the capacity provider are transitioned to use the capacity from the remaining capacity providers.

### To delete a capacity provider for the cluster (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster.
4. On the **Cluster : *name*** page, choose **Infrastructure**, the Amazon ECS Managed Instances capacity provider, and then choose **Delete**.
5. In the confirmation box, enter **delete *Amazon ECS Managed Instances capacity provider name***
6. Choose **Delete**.

## Safely stop Amazon ECS workloads running on Amazon ECS Managed Instances

You can use Amazon ECS task scale-in protection to protect your tasks from being terminated by scale-in events from either service scaling or deployments.

Certain applications require a mechanism to safeguard mission-critical tasks from termination by scale-in events during times of low utilization or during service deployments. For example:

- You have a queue-processing asynchronous application such as a video transcoding job where some tasks need to run for hours even when cumulative service utilization is low.

- You have a gaming application that runs game servers as tasks that need to continue running even if all users have logged-out to reduce start-up latency of a server reboot.
- When you deploy a new code version, you need tasks to continue running because it would be expensive to reprocess.

To protect tasks that belong to your service from terminating in a scale-in event, set the `ProtectionEnabled` attribute to `true`. When you set `ProtectionEnabled` to `true`, tasks are protected for 2 hours by default. You can then customize the protection period by using the `ExpiresInMinutes` attribute. You can protect your tasks for a minimum of 1 minute and up to a maximum of 2880 minutes (48 hours). If you're using the AWS CLI, you can specify the `--protection-enabled` option.

After a task finishes its requisite work, you can set the `ProtectionEnabled` attribute to `false`, allowing the task to be terminated by subsequent scale-in events. If you're using the AWS CLI, you can specify the `--no-protection-enabled` option.

## Task scale-in protection mechanisms

You can set and get task scale-in protection using either the Amazon ECS container agent endpoint or the Amazon ECS API.

- **Amazon ECS container agent endpoint**

We recommend using the Amazon ECS container agent endpoint for tasks that can self-determine the need to be protected. Use this approach for queue-based or job-processing workloads.

When a container starts processing work, for example by consuming an SQS message, you can set the `ProtectionEnabled` attribute through the task scale-in protection endpoint path `$ECS_AGENT_URI/task-protection/v1/state` from within the container. Amazon ECS will not terminate this task during scale-in events. After your task finishes its work, you can clear the `ProtectionEnabled` attribute using the same endpoint, making the task eligible for termination during subsequent scale-in events.

For more information about the Amazon ECS container agent endpoint, see [Amazon ECS task scale-in protection endpoint](#).

- **Amazon ECS API**

You can use the Amazon ECS API to set and retrieve task scale-in protection if your application has a component that tracks the status of active tasks. Use `UpdateTaskProtection` to mark one or more tasks as protected. Use `GetTaskProtection` to retrieve the protection status.

An example of this approach would be if your application is hosting game server sessions as Amazon ECS tasks. When a user logs in to a session on the server (task), you can mark the task as protected. After the user logs out, you can either clear the protection specifically for this task or periodically clear protection for similar tasks that no longer have active sessions, depending on your requirement to keep idle servers.

For more information, see [UpdateTaskProtection](#) and [GetTaskProtection](#) in the *Amazon Elastic Container Service API Reference*.

You can combine both approaches. For example, use the Amazon ECS agent endpoint to set task protection from within a container and use the Amazon ECS API to remove task protection from your external controller service.

## Considerations

Consider the following points before using task scale-in protection:

- Task scale-in protection is only supported with tasks deployed from a service.
- Task scale-in protection is supported with tasks deployed from a service running on Amazon ECS Managed Instances.
- We recommend using the Amazon ECS container agent endpoint because the Amazon ECS agent has built-in retry mechanisms and a simpler interface.
- You can reset the task scale-in protection expiration period by calling `UpdateTaskProtection` for a task that already has protection turned on.
- Determine how long a task would need to complete its requisite work and set the `expiresInMinutes` property accordingly. If you set the protection expiration longer than necessary, then you will incur costs and face delays in the deployment of new tasks.
- Deployment considerations:
  - If the service uses a rolling update, new tasks will be created but tasks running older version will not be terminated until `protectionEnabled` is cleared or expires. You can adjust the `maximumPercentage` parameter in deployment configuration to a value that allows new tasks to be created when old tasks are protected.

- If you use CloudFormation, the update-stack has a 3 hour timeout. Therefore, if you set your task protection for longer than 3 hours, then your CloudFormation deployment may result in failure and rollback.

During the time your old tasks are protected, the CloudFormation stack shows `UPDATE_IN_PROGRESS`. If task scale-in protection is removed or expires within the 3 hour window, your deployment will succeed and move to the `UPDATE_COMPLETE` status. If the deployment is stuck in `UPDATE_IN_PROGRESS` for more than 3 hours, it will fail and show `UPDATE_FAILED` state, and will then be rolled back to old task set.

- Amazon ECS sends service events when protected tasks keep a deployment (rolling or blue/green) from reaching the steady state, so that you can take remedial actions. While trying to update the protection status of a task, if you receive a `DEPLOYMENT_BLOCKED` error message, it means the service has more protected tasks than the desired count of tasks for the service. To resolve this error, do one the following:
  - Wait for the current task protection to expire. Then set task protection.
  - Determine which tasks can be stopped. Then use `UpdateTaskProtection` with the `protectionEnabled` option set to `false` for these tasks.
  - Increase the desired task count of the service to more than the number of protected tasks.

## IAM permissions required for task scale-in protection

The task must have the Amazon ECS task role with the following permissions:

- `ecs:GetTaskProtection`: Allows the Amazon ECS container agent to call `GetTaskProtection`.
- `ecs:UpdateTaskProtection`: Allows the Amazon ECS container agent to call `UpdateTaskProtection`.

## Amazon ECS task scale-in protection endpoint

The Amazon ECS container agent automatically injects the `ECS_AGENT_URI` environment variable into the containers of Amazon ECS tasks to provide a method to interact with the container agent API endpoint.

We recommend using the Amazon ECS container agent endpoint for tasks that can self-determine the need to be protected.

When a container starts processing work, you can set the `protectionEnabled` attribute using the task scale-in protection endpoint path `$_ECS_AGENT_URI/task-protection/v1/state` from within the container.

Use a PUT request to this URI from within a container to set task scale-in protection. A GET request to this URI returns the current protection status of a task.

### Task scale-in protection request parameters

You can set task scale-in protection using the `$_ECS_AGENT_URI/task-protection/v1/state` endpoint with the following request parameters.

#### `ProtectionEnabled`

Specify `true` to mark a task for protection. Specify `false` to remove protection and make the task eligible for termination.

Type: Boolean

Required: Yes

#### `ExpiresInMinutes`

The number of minutes the task is protected. You can specify a minimum of 1 minute to up to 2,880 minutes (48 hours). During this time period, your task will not be terminated by scale-in events from service Auto Scaling or deployments. After this time period lapses, the `protectionEnabled` parameter is set to `false`.

If you don't specify the time, then the task is automatically protected for 120 minutes (2 hours).

Type: Integer

Required: No

The following examples show how to set task protection with different durations.

### Example of how to protect a task with the default time period

This example shows how to protect a task with the default time period of 2 hours.

```
curl --request PUT --header 'Content-Type: application/json' $_ECS_AGENT_URI/task-protection/v1/state --data '{"ProtectionEnabled":true}'
```

## Example of how to protect a task for 60 minutes

This example shows how to protect a task for 60 minutes using the `expiresInMinutes` parameter.

```
curl --request PUT --header 'Content-Type: application/json' ${ECS_AGENT_URI}/task-protection/v1/state --data '{"ProtectionEnabled":true,"ExpiresInMinutes":60}'
```

## Example of how to protect a task for 24 hours

This example shows how to protect a task for 24 hours using the `expiresInMinutes` parameter.

```
curl --request PUT --header 'Content-Type: application/json' ${ECS_AGENT_URI}/task-protection/v1/state --data '{"ProtectionEnabled":true,"ExpiresInMinutes":1440}'
```

The PUT request returns the following response.

```
{
  "protection": {
    "ExpirationDate": "2023-12-20T21:57:44.837Z",
    "ProtectionEnabled": true,
    "TaskArn": "arn:aws:ecs:us-west-2:111122223333:task/1234567890abcdef0"
  }
}
```

## Task scale-in protection response parameters

The following information is returned from the task scale-in protection endpoint `${ECS_AGENT_URI}/task-protection/v1/state` in the JSON response.

### ExpirationDate

The epoch time when protection for the task will expire. If the task is not protected, this value is null.

### ProtectionEnabled

The protection status of the task. If scale-in protection is enabled for a task, the value is `true`. Otherwise, it is `false`.

### TaskArn

The full Amazon Resource Name (ARN) of the task that the container belongs to.

The following example shows the details returned for a protected task.

```
curl --request GET ${ECS_AGENT_URI}/task-protection/v1/state
```

```
{
  "protection":{
    "ExpirationDate":"2023-12-20T21:57:44Z",
    "ProtectionEnabled":true,
    "TaskArn":"arn:aws:ecs:us-west-2:111122223333:task/1234567890abcdef0"
  }
}
```

The following information is returned when a failure occurs.

**Arn**

The full Amazon Resource Name (ARN) of the task.

**Detail**

The details related to the failure.

**Reason**

The reason for the failure.

The following example shows the details returned for a task that is not protected.

```
{
  "failure":{
    "Arn":"arn:aws:ecs:us-west-2:111122223333:task/1234567890abcdef0",
    "Detail":null,
    "Reason":"TASK_NOT_VALID"
  }
}
```

The following information is returned when an exception occurs.

**requestID**

The AWS request ID for the Amazon ECS API call that results in an exception.

## Arn

The full Amazon Resource Name (ARN) of the task or service.

## Code

The error code.

## Message

The error message.

### Note

If a `RequestError` or `RequestTimeout` error appears, it is likely that it's a networking issue. Try using VPC endpoints for Amazon ECS.

The following example shows the details returned when an error occurs.

```
{
  "requestID": "12345-abc-6789-0123-abc",
  "error": {
    "Arn": "arn:aws:ecs:us-west-2:555555555555:task/my-cluster-name/1234567890abcdef0",
    "Code": "AccessDeniedException",
    "Message": "User: arn:aws:sts::444455556666:assumed-role/my-ecs-task-role/1234567890abcdef0 is not authorized to perform: ecs:GetTaskProtection on resource: arn:aws:ecs:us-west-2:555555555555:task/test/1234567890abcdef0 because no identity-based policy allows the ecs:GetTaskProtection action"
  }
}
```

The following error appears if the Amazon ECS agent is unable to get a response from the Amazon ECS endpoint for reasons such as network issues or the Amazon ECS control plane is down.

```
{
  "error": {
    "Arn": "arn:aws:ecs:us-west-2:555555555555:task/my-cluster-name/1234567890abcdef0",
    "Code": "RequestCanceled",
    "Message": "Timed out calling Amazon ECS Task Protection API"
  }
}
```

```
}
```

The following error appears when the Amazon ECS agent gets a throttling exception from Amazon ECS.

```
{
  "requestID": "12345-abc-6789-0123-abc",
  "error": {
    "Arn": "arn:aws:ecs:us-west-2:555555555555:task/my-cluster-name/1234567890abcdef0",
    "Code": "ThrottlingException",
    "Message": "Rate exceeded"
  }
}
```

## Amazon ECS clusters for Fargate

With Amazon ECS on AWS Fargate capacity providers, you can use both Fargate and Fargate Spot capacity with your Amazon ECS tasks.

With Fargate Spot, you can run interruption tolerant Amazon ECS tasks at a rate that's discounted compared to the Fargate price. Fargate Spot runs tasks on spare compute capacity. When AWS needs the capacity back, your tasks are interrupted with a two-minute warning.

When tasks that use the Fargate and Fargate Spot capacity providers are stopped, the task state change event is sent to Amazon EventBridge. The stopped reason describes the cause. For more information, see [Amazon ECS task state change events](#).

A cluster can contain a mix of Fargate and Auto Scaling group capacity providers. However, a capacity provider strategy can only contain either Fargate or Auto Scaling group capacity providers, but not both. For more information, see [Auto Scaling Group Capacity Providers](#).

Consider the following when using capacity providers:

- You must associate a capacity provider with a cluster before you associate it with the capacity provider strategy.
- You can specify a maximum of 20 capacity providers for a capacity provider strategy.
- You can't update a service using an Auto Scaling group capacity provider to use a Fargate capacity provider. The opposite is also the case.

- In a capacity provider strategy, if no `weight` value is specified for a capacity provider in the console, then the default value of 1 is used. If using the API or AWS CLI, the default value of 0 is used.
- When multiple capacity providers are specified within a capacity provider strategy, at least one of the capacity providers must have a weight value that's greater than zero. Any capacity providers with a weight of zero aren't used to place tasks. If you specify multiple capacity providers in a strategy with all the same weight of zero, then any `RunTask` or `CreateService` actions using the capacity provider strategy fail.
- In a capacity provider strategy, only one capacity provider can have a defined *base* value. If no base value is specified, the default value of zero is used.
- A cluster can contain a mix of both Auto Scaling group capacity providers and Fargate capacity providers. However, a capacity provider strategy can only contain Auto Scaling group, or Fargate capacity providers, but not both.
- A cluster can contain a mix of services and standalone tasks that use both capacity providers. A service can be updated to use a capacity provider strategy rather than a launch type. However, you must force a new deployment when doing so.

## Fargate Spot termination notices

During periods of extremely high demand, Fargate Spot capacity might be unavailable. This can cause Fargate Spot tasks to be delayed. When this happens, Amazon ECS services retry launching tasks until the required capacity becomes available. Fargate doesn't replace Spot capacity with on-demand capacity.

When tasks using Fargate Spot capacity are stopped due to a Spot interruption, a two-minute warning is sent before a task is stopped. The warning is sent as a task state change event to Amazon EventBridge and as a SIGTERM signal to the running task. If you use Fargate Spot as part of a service, then in this scenario the service scheduler receives the interruption signal and attempts to launch additional tasks on Fargate Spot if there's capacity available. A service with only one task is interrupted until capacity is available. For more information about a graceful shutdown, see [Graceful shutdowns with ECS](#).

To ensure that your containers exit gracefully before the task stops, you can configure the following:

- A `stopTimeout` value of 120 seconds or less can be specified in the container definition that the task is using. The default `stopTimeout` value is 30 seconds. You can specify a longer

`stopTimeout` value to give yourself more time between the moment that the task state change event is received and the point in time when the container is forcefully stopped. For more information, see [Container timeouts](#).

- The `SIGTERM` signal must be received from within the container to perform any cleanup actions. Failure to process this signal results in the task receiving a `SIGKILL` signal after the configured `stopTimeout` and may result in data loss or corruption.

The following is a snippet of a task state change event. This snippet displays the stopped reason and stop code for a Fargate Spot interruption.

```
{
  "version": "0",
  "id": "9bcdac79-b31f-4d3d-9410-fbd727c29fab",
  "detail-type": "ECS Task State Change",
  "source": "aws.ecs",
  "account": "111122223333",
  "resources": [
    "arn:aws:ecs:us-east-1:111122223333:task/b99d40b3-5176-4f71-9a52-9dbd6f1cebef"
  ],
  "detail": {
    "clusterArn": "arn:aws:ecs:us-east-1:111122223333:cluster/default",
    "createdAt": "2016-12-06T16:41:05.702Z",
    "desiredStatus": "STOPPED",

    ...
  }
}
```

The following is an event pattern that's used to create an EventBridge rule for Amazon ECS task state change events. You can optionally specify a cluster in the `detail` field. Doing so means that you will receive task state change events for that cluster. For more information about creating an EventBridge rule, see [Getting started with Amazon EventBridge](#) in the *Amazon EventBridge User Guide*.

```
{

    "ECS Task State Change"
  ],
  "detail": {
    "clusterArn": [
      "arn:aws:ecs:us-west-2:111122223333:cluster/default"
    ]
  }
}
```

## Creating an Amazon ECS cluster for Fargate workloads

You create a cluster to define the infrastructure your tasks and services run on.

Before you begin, be sure that you've completed the steps in [Set up to use Amazon ECS](#) and assign the appropriate IAM permission. For more information, see [the section called “Amazon ECS cluster examples”](#). The Amazon ECS console creates the resources that are needed by an Amazon ECS cluster by creating a CloudFormation stack.

The console automatically associates the Fargate and Fargate Spot capacity providers with the cluster.

You can modify the following options:

- Add a namespace to the cluster.

A namespace allows services that you create in the cluster can connect to the other services in the namespace without additional configuration. For more information, see [Interconnect Amazon ECS services](#).

- Enable task events to receive EventBridge notifications for task state changes.
- Add tags to help you identify your cluster.
- Assign an AWS KMS key for your managed storage. For information about how to create a key, see [Create a KMS key](#) in the *AWS Key Management Service User Guide*.
- Assign an AWS KMS key for your Fargate ephemeral storage. For information about how to create a key, see [Create a KMS key](#) in the *AWS Key Management Service User Guide*.
- Configure the AWS KMS key and logging for ECS Exec.

## Procedure

### To create a new cluster (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, configure the following:

- For **Cluster name**, enter a unique name.

The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.

- (Optional) To have the namespace used for Service Connect be different from the cluster name, under **Service Connect defaults**, for **Default namespace**, choose or enter a namespace name. To use a shared namespace, choose or enter a namespace ARN. For more information about using shared namespaces, see [Amazon ECS Service Connect with shared AWS Cloud Map namespaces](#).
6. (Optional) Use Container Insights, expand **Monitoring**, and then choose one of the following options:
    - To use the recommended Container Insights with enhanced observability, choose **Container Insights with enhanced observability**.
    - To use Container Insights, choose **Container Insights**.
  7. (Optional) To enable task events, expand **Task events**, and then turn on **Enable task events**.

When you enable task events, Amazon ECS sends task state change events to EventBridge. This allows you to monitor and respond to task lifecycle changes automatically.

8. (Optional) To use ECS Exec to debug tasks in the cluster, expand **Troubleshooting configuration**, and then configure the following:
  - (Optional) For **AWS KMS key for ECS Exec**, enter the ARN of the AWS KMS key you want to use to encrypt the ECS Exec session data.
  - (Optional) For **ECS Exec logging**, choose the log destination:
    - To send logs to CloudWatch Logs, choose **Amazon CloudWatch**.
    - To send logs to Amazon S3, choose **Amazon S3**.

- To disable logging, choose **None**.

9. (Optional), Under **Encryption**, you can configure the following:

- Encrypt your data on Fargate ephemeral storage. Under **Encryption**, for **Fargate ephemeral storage**, enter the ARN of the AWS KMS key you want to use to encrypt the Fargate ephemeral storage data.
- Encrypt the data on managed storage. Under **Encryption**, for **Managed storage**, enter the ARN of the AWS KMS key you want to use to encrypt the managed storage data.

10. (Optional) To help identify your cluster, expand **Tags**, and then configure your tags.

[Add a tag] Choose **Add tag** and do the following:

- For **Key**, enter the key name.
- For **Value**, enter the key value.

[Remove a tag] Choose **Remove** to the right of the tag's Key and Value.

11. Choose **Create**.

## Next steps

After you create the cluster, you can create task definitions for your applications and then run them as standalone tasks, or as part of a service. For more information, see the following:

- [Amazon ECS task definitions](#)
- [Running an application as an Amazon ECS task](#)
- [Creating an Amazon ECS rolling update deployment](#)

## Amazon ECS capacity providers for EC2 workloads

When you use Amazon EC2 instances for your capacity, you use Auto Scaling groups to manage the Amazon EC2 instances registered to their clusters. Auto Scaling helps ensure that you have the correct number of Amazon EC2 instances available to handle the application load.

You can use the managed scaling feature to have Amazon ECS manage the scale-in and scale-out actions of the Auto Scaling group, or you can manage the scaling actions yourself. For more information, see [Automatically manage Amazon ECS capacity with cluster auto scaling](#).

We recommend that you create a new empty Auto Scaling group. If you use an existing Auto Scaling group, any Amazon EC2 instances that are associated with the group that were already running and registered to an Amazon ECS cluster before the Auto Scaling group being used to create a capacity provider might not be properly registered with the capacity provider. This might cause issues when using the capacity provider in a capacity provider strategy. Use `DescribeContainerInstances` to confirm whether a container instance is associated with a capacity provider or not.

 **Note**

To create an empty Auto Scaling group, set the desired count to zero. After you created the capacity provider and associated it with a cluster, you can then scale it out.

When you use the Amazon ECS console, Amazon ECS creates an Amazon EC2 launch template and Auto Scaling group on your behalf as part of the CloudFormation stack. They are prefixed with `EC2ContainerService-<ClusterName>`. You can use the Auto Scaling group as a capacity provider for that cluster.

We recommend you use managed instance draining to allow for graceful termination of Amazon EC2 instances that won't disrupt your workloads. This feature is on by default. For more information, see [Safely stop Amazon ECS workloads running on EC2 instances](#)

Consider the following when using Auto Scaling group capacity providers in the console:

- An Auto Scaling group must have a `MaxSize` greater than zero to scale out.
- The Auto Scaling group can't have instance weighting settings.
- If the Auto Scaling group can't scale out to accommodate the number of tasks run, the tasks fails to transition beyond the `PROVISIONING` state.
- Don't modify the scaling policy resource associated with your Auto Scaling groups that are managed by capacity providers.
- If managed scaling is turned on when you create a capacity provider, the Auto Scaling group desired count can be set to 0. When managed scaling is turned on, Amazon ECS manages the scale-in and scale-out actions of the Auto Scaling group.
- You must associate capacity provider with a cluster before you associate it with the capacity provider strategy.
- You can specify a maximum of 20 capacity providers for a capacity provider strategy.

- You can't update a service using an Auto Scaling group capacity provider to use a Fargate capacity provider. The opposite is also the case.
- In a capacity provider strategy, if no `weight` value is specified for a capacity provider in the console, then the default value of 1 is used. If using the API or AWS CLI, the default value of 0 is used.
- When multiple capacity providers are specified within a capacity provider strategy, at least one of the capacity providers must have a weight value that's greater than zero. Any capacity providers with a weight of zero aren't used to place tasks. If you specify multiple capacity providers in a strategy with all the same weight of zero, then any `RunTask` or `CreateService` actions using the capacity provider strategy fail.
- In a capacity provider strategy, only one capacity provider can have a defined `base` value. If no base value is specified, the default value of zero is used.
- A cluster can contain a mix of both Auto Scaling group capacity providers and Fargate capacity providers. However, a capacity provider strategy can only contain Auto Scaling group or Fargate capacity providers, but not both.
- A cluster can contain a mix of services and standalone tasks that use both capacity providers and launch types. A service can be updated to use a capacity provider strategy rather than a launch type. However, you must force a new deployment when doing so.
- Amazon ECS supports Amazon EC2 Auto Scaling warm pools. A warm pool is a group of pre-initialized Amazon EC2 instances ready to be placed into service. Whenever your application needs to scale out, Amazon EC2 Auto Scaling uses the pre-initialized instances from the warm pool rather than launching cold instances. This allows for any final initialization process to run before the instance is placed into service. For more information, see [Configuring pre-initialized instances for your Amazon ECS Auto Scaling group](#).

For more information about creating an Amazon EC2 Auto Scaling launch template, see [Auto Scaling launch templates](#) in the *Amazon EC2 Auto Scaling User Guide*. For more information about creating an Amazon EC2 Auto Scaling group, see [Auto Scaling groups](#) in the *Amazon EC2 Auto Scaling User Guide*.

## Amazon EC2 container instance security considerations for Amazon ECS

You should consider a single container instance and its access within your threat model. For example, a single affected task might be able to leverage the IAM permissions of a non-infected task on the same instance.

We recommend that you use the following to help prevent this:

- Do not use administrator privileges when running your tasks.
- Assign a task role with least-privileged access to your tasks.

The container agent automatically creates a token with a unique credential ID which are used to access Amazon ECS resources.

- To prevent containers run by tasks that use the `awsvpc` network mode from accessing the credential information supplied to the Amazon EC2 instance profile, while still allowing the permissions that are provided by the task role set the `ECS_AWSVPC_BLOCK_IMDS` agent configuration variable to `true` in the agent configuration file and restart the agent.
- Use Amazon GuardDuty Runtime Monitoring to detect threats for clusters and containers within your AWS environment. Runtime Monitoring uses a GuardDuty security agent that adds runtime visibility into individual Amazon ECS workloads, for example, file access, process execution, and network connections. For more information, see [GuardDuty Runtime Monitoring](#) in the *GuardDuty User Guide*.

## Creating an Amazon ECS cluster for Amazon EC2 workloads

You create a cluster to define the infrastructure your tasks and services run on.

Before you begin, be sure that you've completed the steps in [Set up to use Amazon ECS](#) and assign the appropriate IAM permission. For more information, see [the section called "Amazon ECS cluster examples"](#). The Amazon ECS console provides a simple way to create the resources that are needed by an Amazon ECS cluster by creating a CloudFormation stack.

To make the cluster creation process as easy as possible, the console has default selections for many choices which we describe in the following sections. There are also help panels available for most of the sections in the console which provide further context.

You can register Amazon EC2 instances when you create the cluster or register additional instances with the cluster after it has been created.

You can modify the following default options:

- Change the subnets where your instances launch.
- Change the security groups used to control traffic to the container instances.
- Add a namespace to the cluster.

A namespace allows services that you create in the cluster can connect to the other services in the namespace without additional configuration. For more information, see [Interconnect Amazon ECS services](#).

- Enable task events to receive EventBridge notifications for task state changes.
- Assign a AWS KMS key for your managed storage. For information about how to create a key, see [Create a KMS key](#) in the *AWS Key Management Service User Guide*.
- Assign a AWS KMS key for your Fargate ephemeral storage. For information about how to create a key, see [Create a KMS key](#) in the *AWS Key Management Service User Guide*.
- Configure the AWS KMS key and logging for ECS Exec.
- Add tags to help you identify your cluster.

## Auto Scaling group options

When you use Amazon EC2 instances, you must specify an Auto Scaling group to manage the infrastructure that your tasks and services run on.

When you choose to create a new Auto Scaling group, it is automatically configured for the following behavior:

- Amazon ECS manages the scale-in and scale-out actions of the Auto Scaling group.
- Amazon ECS will not prevent Amazon EC2 instances that contain tasks and that are in an Auto Scaling group from being terminated during a scale-in action. For more information, see [Instance Protection](#) in the *AWS Auto Scaling User Guide*.

You configure the following Auto Scaling group properties which determine the type and number of instances to launch for the group:

- The Amazon ECS-optimized AMI.
- The instance type.
- The SSH key pair that proves your identity when you connect to the instance. For information about how to create SSH keys, see [Amazon EC2 key pairs and Linux instances](#) in the *Amazon EC2 User Guide*.
- The minimum number of instances to launch for the Auto Scaling group.
- The maximum number of instances that are started for the Auto Scaling group.

In order for the group to scale out, the maximum must be greater than 0.

Amazon ECS creates an Amazon EC2 Auto Scaling launch template and Auto Scaling group on your behalf as part of the CloudFormation stack. The values that you specified for the AMI, the instance types, and the SSH key pair are part of the launch template. The templates are prefixed with `EC2ContainerService-<ClusterName>`, which makes them easy to identify. The Auto Scaling groups are prefixed with `<ClusterName>-ECS-Infra-ECSAutoScalingGroup`.

Instances launched for the Auto Scaling group use the launch template.

## Networking options

By default instances are launched into the default subnets for the Region. The security groups, which control the traffic to your container instances, currently associated with the subnets are used. You can change the subnets and security groups for the instances.

You can choose an existing subnet. You can either use an existing security group, or create a new one. To create tasks in an IPv6-only configuration, use subnets that include only an IPv6 CIDR block.

When you create a new security group, you need to specify at least one inbound rule.

The inbound rules determine what traffic can reach your container instances and include the following properties:

- The protocol to allow
- The range of ports to allow
- The inbound traffic (source)

To allow inbound traffic from a specific address or CIDR block, use **Custom** for **Source** with the allowed CIDR.

To allow inbound traffic from all destinations, use **Anywhere** for **Source**. This automatically adds the 0.0.0.0/0 IPv4 CIDR block and ::/0 IPv6 CIDR block.

To allow inbound traffic from your local computer, use **Source group** for **Source**. This automatically adds the current IP address of your local computer as the allowed source.

## To create a new cluster (Amazon ECS console)

Before you begin, assign the appropriate IAM permission. For more information, see [the section called “Amazon ECS cluster examples”](#).

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, configure the following:
  - For **Cluster name**, enter a unique name.

The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.

- (Optional) To have the namespace used for Service Connect be different from the cluster name, under **Service Connect defaults**, for **Default namespace**, choose or enter a namespace name. To use a shared namespace, choose or enter a namespace ARN. For more information about using shared namespaces, see [Amazon ECS Service Connect with shared AWS Cloud Map namespaces](#).
6. Add Amazon EC2 instances to your cluster, expand **Infrastructure** and then select **Fargate and Self-managed instances**.

Next, configure the Auto Scaling group which acts as the capacity provider:

- a. To using an existing Auto Scaling group, from **Auto Scaling group (ASG)**, select the group.
- b. To create a Auto Scaling group, from **Auto Scaling group (ASG)**, select **Create new group**, and then provide the following details about the group:
  - For **Provisioning model**, choose whether to use **On-demand** instances or **Spot** Instances.
  - If you choose to use Spot Instances, for **Allocation Strategy**, choose what Spot capacity pools (instance types and Availability Zones) are used for the instances.

For most workloads, you can choose **Price capacity optimized**.

For more information, see [Allocation strategies for Spot Instances](#) in the *Amazon EC2 User Guide*.

- For **Container instance Amazon Machine Image (AMI)**, choose the Amazon ECS-optimized AMI for the Auto Scaling group instances.
- For **EC2 instance type**, choose the instance type for your workloads.

Managed scaling works best if your Auto Scaling group uses the same or similar instance types.

- For **EC2 instance role**, choose an existing container instance role, or you can create a new one.

For more information, see [Amazon ECS container instance IAM role](#).

- For **Capacity**, enter the minimum number and the maximum number of instances to launch in the Auto Scaling group.
- For **SSH key pair**, choose the pair that proves your identity when you connect to the instance.
- To allow for larger image and storage, for **Root EBS volume size**, enter the value in GiB.

7. (Optional) To change the VPC and subnets, under **Networking for Amazon EC2 instances**, perform any of the following operations:

- To remove a subnet, under **Subnets**, choose **X** for each subnet that you want to remove.
- To change to a VPC other than the **default** VPC, under **VPC**, choose an existing **VPC**, and then under **Subnets**, choose the subnets. For an IPv6-only configuration, choose a VPC that has an IPv6 CIDR block and subnets that have only an IPv6 CIDR block.
- Choose the security groups. Under **Security group**, choose one of the following options:
  - To use an existing security group, choose **Use an existing security group**, and then choose the security group.
  - To create a security group, choose **Create a new security group**. Then, choose **Add rule** for each inbound rule.

For information about inbound rules, see [Networking options](#).

- To automatically assign public IP addresses to your Amazon EC2 container instances, for **Auto-assign public IP**, choose one of the following options:
  - **Use subnet setting** – Assign a public IP address to the instances when the subnet that the instances launch in are a public subnet.
  - **Turn on** – Assign a public IP address to the instances.

8. (Optional) Use Container Insights, expand **Monitoring**, and then choose one of the following options:
  - To use the recommended Container Insights with enhanced observability, choose **Container Insights with enhanced observability**.
  - To use Container Insights, choose **Container Insights**.
9. (Optional) To enable task events, expand **Task events**, and then turn on **Enable task events**.

When you enable task events, Amazon ECS sends task state change events to EventBridge. This allows you to monitor and respond to task lifecycle changes automatically.

10. (Optional) To use ECS Exec to debug tasks in the cluster, expand **Troubleshooting configuration**, and then configure the following:
  - (Optional) For **AWS KMS key for ECS Exec**, enter the ARN of the AWS KMS key you want to use to encrypt the ECS Exec session data.
  - (Optional) For **ECS Exec logging**, choose the log destination:
    - To send logs to CloudWatch Logs, choose **Amazon CloudWatch**.
    - To send logs to Amazon S3, choose **Amazon S3**.
    - To disable logging, choose **None**.

11. (Optional)

If you use Runtime Monitoring with the manual option and you want to have this cluster monitored by GuardDuty, choose **Add tag** and do the following:

- For **Key**, enter **guardDutyRuntimeMonitoringManaged**
  - For **Value**, enter **true**.
12. (Optional) Encrypt the data on managed storage. Under **Encryption**, for **Managed storage**, enter the ARN of the AWS KMS key you want to use to encrypt the managed storage data.
  13. (Optional) To manage the cluster tags, expand **Tags**, and then perform one of the following operations:

[Add a tag] Choose **Add tag** and do the following:

- For **Key**, enter the key name.
- For **Value**, enter the key value.

[Remove a tag] Choose **Remove** to the right of the tag's Key and Value.

14. Choose **Create**.

## Next steps

After you create the cluster, you can create task definitions for your applications and then run them as standalone tasks, or as part of a service. For more information, see the following:

- [Amazon ECS task definitions](#)
- [Running an application as an Amazon ECS task](#)
- [Creating an Amazon ECS rolling update deployment](#)

## Automatically manage Amazon ECS capacity with cluster auto scaling

Amazon ECS can manage the scaling of Amazon EC2 instances that are registered to your cluster. This is referred to as Amazon ECS *cluster auto scaling*. You turn on managed scaling when you create the Amazon ECS Auto Scaling group capacity provider. Then, you set a target percentage (the `targetCapacity`) for the instance utilization in this Auto Scaling group. Amazon ECS creates two custom CloudWatch metrics and a target tracking scaling policy for your Auto Scaling group. Amazon ECS then manages the scale-in and scale-out actions based on the resource utilization that your tasks use.

For each Auto Scaling group capacity provider that's associated with a cluster, Amazon ECS creates and manages the following resources:

- A low metric value CloudWatch alarm
- A high metric value CloudWatch alarm
- A target tracking scaling policy

### Note

Amazon ECS creates the target tracking scaling policy and attaches it to the Auto Scaling group. To update the target tracking scaling policy, update the capacity provider managed scaling settings, rather than updating the scaling policy directly.

When you turn off managed scaling or disassociate the capacity provider from a cluster, Amazon ECS removes both CloudWatch metrics and the target tracking scaling policy resources.

Amazon ECS uses the following metrics to determine what actions to take:

### CapacityProviderReservation

The percent of container instances in use for a specific capacity provider. Amazon ECS generates this metric.

Amazon ECS sets the CapacityProviderReservation value to a number between 0-100. Amazon ECS uses the following formula to represent the ratio of how much capacity remains in the Auto Scaling group. Then, Amazon ECS publishes the metric to CloudWatch. For more information about how the metric is calculated, see [Deep Dive on Amazon ECS Cluster Auto Scaling](#).

$$\text{CapacityProviderReservation} = (\text{number of instances needed}) / (\text{number of running instances}) \times 100$$

### DesiredCapacity

The amount of capacity for the Auto Scaling group. This metric isn't published to CloudWatch.

Amazon ECS publishes the CapacityProviderReservation metric to CloudWatch in the AWS/ECS/ManagedScaling namespace. The CapacityProviderReservation metric causes one of the following actions to occur:

#### **The CapacityProviderReservation value equals targetCapacity**

The Auto Scaling group doesn't need to scale in or scale out. The target utilization percentage has been reached.

#### **The CapacityProviderReservation value is greater than targetCapacity**

There are more tasks using a higher percentage of the capacity than your targetCapacity percentage. The increased value of the CapacityProviderReservation metric causes the associated CloudWatch alarm to act. This alarm updates the DesiredCapacity value for the Auto Scaling group. The Auto Scaling group uses this value to launch EC2 instances, and then register them with the cluster.

When the `targetCapacity` is the default value of 100 %, the new tasks are in the PENDING state during the scale-out because there is no available capacity on the instances to run the tasks. After the new instances register with ECS, these tasks will start on the new instances.

### The `CapacityProviderReservation` value is less than `targetCapacity`

There are fewer tasks using a lower percentage of the capacity than your `targetCapacity` percentage and there is at least one instance that can be terminated. The decreased value of the `CapacityProviderReservation` metric causes the associated CloudWatch alarm to act. This alarm updates the `DesiredCapacity` value for the Auto Scaling group. The Auto Scaling group uses this value to terminate EC2 container instances, and then deregister them from the cluster.

The Auto Scaling group follows the group termination policy to determine which instances it terminates first during scale-in events. Additionally it avoids instances with the instance scale-in protection setting turned on. Cluster auto scaling can manage which instances have the instance scale-in protection setting if you turn on managed termination protection. For more information about managed termination protection, see [Control the instances Amazon ECS terminates](#). For more information about how Auto Scaling groups terminate instances, see [Control which Auto Scaling instances terminate during scale in](#) in the *Amazon EC2 Auto Scaling User Guide*.

Consider the following when using cluster auto scaling:

- Don't change or manage the desired capacity for the Auto Scaling group that's associated with a capacity provider with any scaling policies other than the one Amazon ECS manages.
- When Amazon ECS scales out from 0 instances, it automatically launches 2 instances.
- Amazon ECS uses the `AWSServiceRoleForECS` service-linked IAM role for the permissions that it requires to call AWS Auto Scaling on your behalf. For more information, see [Using service-linked roles for Amazon ECS](#).
- When using capacity providers with Auto Scaling groups, the user, group, or role that creates the capacity providers requires the `autoscaling:CreateOrUpdateTags` permission. This is because Amazon ECS adds a tag to the Auto Scaling group when it associates it with the capacity provider.

**⚠ Important**

Make sure any tooling that you use doesn't remove the AmazonECSManaged tag from the Auto Scaling group. If this tag is removed, Amazon ECS can't manage the scaling.

- Cluster auto scaling doesn't modify the **MinimumCapacity** or **MaximumCapacity** for the group. For the group to scale out, the value for **MaximumCapacity** must be greater than zero.
- When Auto Scaling (managed scaling) is turned on, a capacity provider can only be connected to one cluster at the same time. If your capacity provider has managed scaling turned off, you can associate it with multiple clusters.
- When managed scaling is turned off, the capacity provider doesn't scale in or scale out. You can use a capacity provider strategy to balance your tasks between capacity providers.
- The binpack strategy is the most efficient strategy in terms of capacity.
- When the target capacity is less than 100%, within the placement strategy, the binpack strategy must have a higher order than the spread strategy. This prevents the capacity provider from scaling out until each task has a dedicated instance or the limit is reached.

## Turn on cluster auto scaling

You can turn on cluster auto scaling by using the Console or the AWS CLI.

When you create a cluster that uses EC2 capacity providers using the console, Amazon ECS creates an Auto Scaling group on your behalf and sets the target capacity. For more information, see [Creating an Amazon ECS cluster for Amazon EC2 workloads](#).

You can also create an Auto Scaling group, and then assign it to a cluster. For more information, see [Updating an Amazon ECS capacity provider](#).

When you use the AWS CLI, after you create the cluster

1. Before you create the capacity provider, you need to create an Auto Scaling group. For more information, see [Auto Scaling groups](#) in the *Amazon EC2 Auto Scaling User Guide*.
2. Use `put-cluster-capacity-providers` to modify the cluster capacity provider. For more information, see [Turning on Amazon ECS cluster auto scaling](#).

## Optimize Amazon ECS cluster auto scaling

Customers who run Amazon ECS on Amazon EC2 can take advantage of cluster auto scaling to manage the scaling of Amazon EC2 Auto Scaling groups. With cluster auto scaling, you can configure Amazon ECS to scale your Auto Scaling group automatically, and just focus on running your tasks. Amazon ECS ensures the Auto Scaling group scales in and out as needed with no further intervention required. Amazon ECS capacity providers are used to manage the infrastructure in your cluster by ensuring there are enough container instances to meet the demands of your application. To learn how cluster auto scaling works under the hood, see [Deep Dive on Amazon ECS Cluster Auto Scaling](#).

Cluster auto scaling relies on a CloudWatch based integration with Auto Scaling group for adjusting cluster capacity. Therefore it has inherent latency associated with

- Publishing the CloudWatch metrics,
- The time taken for the metric `CapacityProviderReservation` to breach CloudWatch alarms (both high and low)
- The time taken by a newly launched Amazon EC2 instance to warm-up. You can take the following actions to make cluster auto scaling more responsive for faster deployments:

### Capacity provider step scaling sizes

Amazon ECS capacity providers will grow/shrink the container instances to meet the demands of your application. The minimum number of instances that Amazon ECS will launch is set to 1 by default. This may add additional time to your deployments, if several instances are required for placing your pending tasks. You can increase the [minimumScalingStepSize](#) via the Amazon ECS API to increase the minimum number of instances that Amazon ECS scales in or out at a time. A [maximumScalingStepSize](#) that is too low can limit how many container instances are scaled in or out at a time, which can slow down your deployments.

#### Note

This configuration is currently only available via the [CreateCapacityProvider](#) or [UpdateCapacityProvider](#) APIs.

## Instance warm-up period

The instance warm-up period is the period of time after which a newly launched Amazon EC2 instance can contribute to CloudWatch metrics for the Auto Scaling group. After the specified warm-up period expires, the instance is counted toward the aggregated metrics of the Auto Scaling group, and cluster auto scaling proceeds with its next iteration of calculations to estimate the number instances required.

The default value for [instanceWarmupPeriod](#) is 300 seconds, which you can configure to a lower value via the [CreateCapacityProvider](#) or [UpdateCapacityProvider](#) APIs for more responsive scaling. We recommend that you set the value to greater than 60 seconds so that you can avoid over-provisioning.

## Spare capacity

If your capacity provider has no container instances available for placing tasks, then it needs to increase (scale out) cluster capacity by launching Amazon EC2 instances on the fly, and wait for them to boot up before it can launch containers on them. This can significantly lower the task launch rate. You have two options here.

In this case, having spare Amazon EC2 capacity already launched and ready to run tasks will increase the effective task launch rate. You can use the `Target Capacity` configuration to indicate that you wish to maintain spare capacity in your clusters. For example, by setting `Target Capacity` at 80%, you indicate that your cluster needs 20% spare capacity at all times. This spare capacity can allow any standalone tasks to be immediately launched, ensuring task launches are not throttled. The trade-off for this approach is potential increased costs of keeping spare cluster capacity.

An alternate approach you can consider is adding headroom to your service, not to the capacity provider. This means that instead of reducing `Target Capacity` configuration to launch spare capacity, you can increase the number of replicas in your service by modifying the target tracking scaling metric or the step scaling thresholds of the service auto scaling. Note that this approach will only be helpful for spiky workloads, but won't have an effect when you're deploying new services and going from 0 to N tasks for the first time. For more information about the related scaling policies, see [Target Tracking Scaling Policies](#) or [Step Scaling Policies](#) in the *Amazon Elastic Container Service Developer Guide*.

## Amazon ECS managed scaling behavior

When you have Auto Scaling group capacity providers that use managed scaling, Amazon ECS estimates the optimal number of instances to add to your cluster and uses the value to determine how many instances to request or release.

### Managed scale-out behavior

Amazon ECS selects a capacity provider for each task by following the capacity provider strategy from the service, standalone task, or the cluster default. Amazon ECS follows the rest of these steps for a single capacity provider.

Tasks without a capacity provider strategy are ignored by capacity providers. A pending task that doesn't have a capacity provider strategy won't cause any capacity provider to scale out. Tasks or services can't set a capacity provider strategy if that task or service sets a launch type.

The following describes the scale-out behavior in more detail.

- Group all of the provisioning tasks for this capacity provider so that each group has the same exact resource requirements.
- When you use multiple instance types in an Auto Scaling group, the instance types in the Auto Scaling group are sorted by their parameters. These parameters include vCPU, memory, elastic network interfaces (ENIs), ports, and GPUs. The smallest and the largest instance types for each parameter are selected. For more information about how to choose the instance type, see [Amazon EC2 container instances for Amazon ECS](#).

#### Important

If a group of tasks have resource requirements that are greater than the smallest instance type in the Auto Scaling group, then that group of tasks can't run with this capacity provider. The capacity provider doesn't scale the Auto Scaling group. The tasks remain in the PROVISIONING state.

To prevent tasks from staying in the PROVISIONING state, we recommend that you create separate Auto Scaling groups and capacity providers for different minimum resource requirements. When you run tasks or create services, only add capacity providers to the capacity provider strategy that can run the task on the smallest instance type in the Auto Scaling group. For other parameters, you can use placement constraints

- For each group of tasks, Amazon ECS calculates the number of instances that are required to run the unplaced tasks. This calculation uses a binpack strategy. This strategy accounts for the vCPU, memory, elastic network interfaces (ENI), ports, and GPUs requirements of the tasks. It also accounts for the resource availability of the Amazon EC2 instances. The values for the largest instance types are treated as the maximum calculated instance count. The values for the smallest instance type are used as protection. If the smallest instance type can't run at least one instance of the task, the calculation considers the task as not compatible. As a result, the task is excluded from scale-out calculation. When all the tasks aren't compatible with the smallest instance type, cluster auto scaling stops and the CapacityProviderReservation value remains at the targetCapacity value.
- Amazon ECS publishes the CapacityProviderReservation metric to CloudWatch with respect to the minimumScalingStepSize if either of the following is the case.
  - The maximum calculated instance count is less than the minimum scaling step size.
  - The lower value of either the minimumScalingStepSize or the maximum calculated instance count.
- CloudWatch alarms use the CapacityProviderReservation metric for capacity providers. When the CapacityProviderReservation metric is greater than the targetCapacity value, alarms also increase the DesiredCapacity of the Auto Scaling group. The targetCapacity value is a capacity provider setting that's sent to the CloudWatch alarm during the cluster auto scaling activation phase.

The default targetCapacity is 100%.

- The Auto Scaling group launches additional EC2 instances. To prevent over-provisioning, Auto Scaling makes sure that recently launched EC2 instance capacity is stabilized before it launches new instances. Auto Scaling checks if all existing instances have passed the instanceWarmupPeriod (now minus the instance launch time). The scale-out is blocked for instances that are within the instanceWarmupPeriod.

The default number of seconds for a newly launched instance to warm up is 300.

For more information, see [Deep dive on Amazon ECS cluster auto scaling](#).

## Scale-out considerations

Consider the following for the scale-out process:

- Although there are multiple placement constraints, we recommend that you only use the `distinctInstance` task placement constraint. This prevents the scale-out process from stopping because you're using a placement constraint that's not compatible with the sampled instances.
- Managed scaling works best if your Auto Scaling group uses the same or similar instance types.
- When a scale-out process is required and there are no currently running container instances, Amazon ECS always scales-out to two instances initially, and then performs additional scale-out or scale-in processes. Any additional scale-out waits for the instance warmup period. For scale-in processes, Amazon ECS waits 15 minutes after a scale-out process before starting scale-in processes at all times.
- The second scale-out step needs to wait until the `instanceWarmupPeriod` expires, which might affect the overall scale limit. If you need to reduce this time, make sure that `instanceWarmupPeriod` is large enough for the EC2 instance to launch and start the Amazon ECS agent (which prevents over provisioning).
- Cluster auto scaling supports Launch Configuration, Launch Templates, and multiple instance types in the capacity provider Auto Scaling group. You can also use attribute-based instance type selection without multiple instances types.
- When using an Auto Scaling group with On-Demand instances and multiple instance types or Spot Instances, place the larger instance types higher in the priority list and don't specify a weight. Specifying a weight isn't supported at this time. For more information, see [Auto Scaling groups with multiple instance types](#) in the *AWS Auto Scaling User Guide*.
- Amazon ECS then launch either the `minimumScalingStepSize`, if the maximum calculated instance count is less than the minimum scaling step size, or the lower of either the `maximumScalingStepSize` or the maximum calculated instance count value.
- If an Amazon ECS service or run-task launches a task and the capacity provider container instances don't have enough resources to start the task, then Amazon ECS limits the number of tasks with this status for each cluster and prevents any tasks from exceeding this limit. For more information, see [Service quotas](#).

## Managed scale-in behavior

Amazon ECS monitors container instances for each capacity provider within a cluster. When a container instance isn't running any tasks, the container instance is considered empty and Amazon ECS starts the scale-in process.

CloudWatch scale-in alarms require 15 data points (15 minutes) before the scale-in process for the Auto Scaling group starts. After the scale-in process starts until Amazon ECS needs to reduce the number of registered container instances, the Auto Scaling group sets the `DesiredCapacity` value to be greater than one instance and less than 50% each minute.

When Amazon ECS requests a scale-out (when `CapacityProviderReservation` is greater than 100) while a scale-in process is in progress, the scale-in process is stopped and starts from the beginning if required.

The following describes the scale-in behavior in more detail:

1. Amazon ECS calculates the number of container instances that are empty. A container instance is considered empty even when daemon tasks are running.
2. Amazon ECS sets the `CapacityProviderReservation` value to a number between 0-100 that uses the following formula to represent the ratio of how big the Auto Scaling group needs to be relative to how big it actually is, expressed as a percentage. Then, Amazon ECS publishes the metric to CloudWatch. For more information about how the metric is calculated, see [Deep Dive on Amazon ECS Cluster Auto Scaling](#)

$$\text{CapacityProviderReservation} = (\text{number of instances needed}) / (\text{number of running instances}) \times 100$$

3. The `CapacityProviderReservation` metric generates a CloudWatch alarm. This alarm updates the `DesiredCapacity` value for the Auto Scaling group. Then, one of the following actions occurs:
  - If you don't use capacity provider managed termination, the Auto Scaling group selects EC2 instances using the Auto Scaling group termination policy and terminates the instances until the number of EC2 instances reaches the `DesiredCapacity`. The container instances are then deregistered from the cluster.
  - If all the container instances use managed termination protection, Amazon ECS removes the scale-in protection on the container instances that are empty. The Auto Scaling group will then be able to terminate the EC2 instances. The container instances are then deregistered from the cluster.

## Control the instances Amazon ECS terminates

### Important

You must turn on Auto Scaling *instance scale-in protection* on the Auto Scaling group to use the managed termination protection feature of cluster auto scaling.

Managed termination protection allows cluster auto scaling to control which instances are terminated. When you used managed termination protection, Amazon ECS only terminates EC2 instances that don't have any running Amazon ECS tasks. Tasks that are run by a service that uses the DAEMON scheduling strategy are ignored and an instance can be terminated by cluster auto scaling even when the instance is running these tasks. This is because all of the instances in the cluster are running these tasks.

Amazon ECS first turns on the *instance scale-in protection* option for the EC2 instances in the Auto Scaling group. Then, Amazon ECS places the tasks on the instances. When all non-daemon tasks are stopped on an instance, Amazon ECS initiates the scale-in process and turns off scale-in protection for the EC2 instance. The Auto Scaling group can then terminate the instance.

Auto Scaling *instance scale-in protection* controls which EC2 instances can be terminated by Auto Scaling. Instances with the scale-in feature turned on can't be terminated during the scale-in process. For more information about Auto Scaling instance scale-in protection, see [Using instance scale-in protection](#) in the *Amazon EC2 Auto Scaling User Guide*.

You can set the `targetCapacity` percentage so that you have spare capacity. This helps future tasks launch more quickly because the Auto Scaling group does not have to launch more instances. Amazon ECS uses the target capacity value to manage the CloudWatch metric that the service creates. Amazon ECS manages the CloudWatch metric. The Auto Scaling group is treated as a steady state so that no scaling action is required. The values can be from 0-100%. For example, to configure Amazon ECS to keep 10% free capacity on top of that used by Amazon ECS tasks, set the target capacity value to 90%. Consider the following when setting the `targetCapacity` value on a capacity provider.

- A `targetCapacity` value of less than 100% represents the amount of free capacity (Amazon EC2 instances) that need to be present in the cluster. Free capacity means that there are no running tasks.

- Placement constraints such as Availability Zones, without additional binpack forces Amazon ECS to eventually run one task for each instance, which might not be the desired behavior.

You must turn on Auto Scaling instance scale-in protection on the Auto Scaling group to use managed termination protection. If you don't turn on scale-in protection, then turning on managed termination protection can lead to undesirable behavior. For example, you may have instances stuck in draining state. For more information, see [Using instance scale-in protection](#) in the *Amazon EC2 Auto Scaling User Guide*.

When you use termination protection with a capacity provider, don't perform any manual actions, like detaching the instance, on the Auto Scaling group associated with the capacity provider. Manual actions can break the scale-in operation of the capacity provider. If you detach an instance from the Auto Scaling group, you need to also [deregister the detached instance](#) from the Amazon ECS cluster.

## Updating managed termination protection for Amazon ECS capacity providers

When you use managed termination protection, you need to update the setting for existing capacity providers.

### Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster page, choose the **Infrastructure** tab.
4. Choose the capacity provider.
5. Choose **Update** to modify the capacity provider settings.
6. Under **Auto Scaling group settings**, toggle **Managed termination protection** to enable or disable the feature.
7. Choose **Update**.

### AWS CLI

You can update a capacity provider's managed termination protection setting using the `update-capacity-provider` command:

To enable managed termination protection:

```
aws ecs update-capacity-provider \  
  --name CapacityProviderName \  
  --auto-scaling-group-provider  
    "managedScaling={status=ENABLED,targetCapacity=70,minimumScalingStepSize=1,maximumScalingStepS
```

To disable managed termination protection:

```
aws ecs update-capacity-provider \  
  --name CapacityProviderName \  
  --auto-scaling-group-provider  
    "managedScaling={status=ENABLED,targetCapacity=70,minimumScalingStepSize=1,maximumScalingStepS
```

#### Note

It might take a few minutes for the changes to take effect across your cluster. When enabling managed termination protection, instances that are already running tasks will be protected from scale-in events. When disabling managed termination protection, the protection flag will be removed from instances during the next ECS capacity provider management cycle.

## Console for running tasks

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster page, choose the **Tasks** tab.
4. Choose the task.
5. Under **Configuration**, toggle **Managed termination protection** to enable or disable the feature.
6. Choose **Configure task scale-in protection**.

The **Configure task scale-in protection** dialog box displays

- a. Under **Task scale-in protection**, toggle **Turn on**.
- b. For **Expires in minutes**, enter the number of minutes before task scale-in protection ends.
- c. Choose **Update**

## Turning on Amazon ECS cluster auto scaling

You turn on cluster auto scaling so that Amazon ECS manages the scaling of Amazon EC2 instances that are registered to your cluster.

If you want to use the console to turn on Cluster auto scaling, see [Creating a capacity provider for Amazon ECS](#).

Before you begin, create an Auto Scaling group and a capacity provider. For more information, see [the section called “Amazon ECS capacity providers for EC2 workloads”](#).

To turn on cluster auto scaling, you associate the capacity provider with the cluster, Then you turn on cluster auto scaling.

1. Use the `put-cluster-capacity-providers` command to associate one or more capacity providers with the cluster.

To add the AWS Fargate capacity providers, include the FARGATE and FARGATE\_SPOT capacity providers in the request. For more information, see [put-cluster-capacity-providers](#) in the *AWS CLI Command Reference*.

```
aws ecs put-cluster-capacity-providers \
  --cluster ClusterName \
  --capacity-providers CapacityProviderName FARGATE FARGATE_SPOT \
  --default-capacity-provider-strategy capacityProvider=CapacityProvider,weight=1
```

To add an Auto Scaling group for EC2, include the Auto Scaling group name in the request. For more information, see [put-cluster-capacity-providers](#) in the *AWS CLI Command Reference*.

```
aws ecs put-cluster-capacity-providers \
  --cluster ClusterName \
  --capacity-providers CapacityProviderName \
  --default-capacity-provider-strategy capacityProvider=CapacityProvider,weight=1
```

2. Use the `describe-clusters` command to verify that the association was successful. For more information, see [describe-clusters](#) in the *AWS CLI Command Reference*.

```
aws ecs describe-clusters \
  --cluster ClusterName \
```

```
--include ATTACHMENTS
```

3. Use the `update-capacity-provider` command to turn on managed auto scaling for the capacity provider. For more information, see [update-capacity-provider](#) in the *AWS CLI Command Reference*.

```
aws ecs update-capacity-provider \  
  --name CapacityProviderName \  
  --auto-scaling-group-provider "managedScaling={status=ENABLED}"
```

## Turning off Amazon ECS cluster auto scaling

You turn off cluster auto scaling when you need more granular control of the EC2 instances that are registered to your cluster,

To turn off cluster auto scaling for a cluster, you can either disassociate the capacity provider with managed scaling turned on from the cluster or update the capacity provider to turn off managed scaling.

### Disassociate the capacity provider

Use the following steps to disassociate a capacity provider with a cluster.

1. Use the `put-cluster-capacity-providers` command to disassociate the Auto Scaling group capacity provider with the cluster. The cluster can keep the association with the AWS Fargate capacity providers. For more information, see [put-cluster-capacity-providers](#) in the *AWS CLI Command Reference*.

```
aws ecs put-cluster-capacity-providers \  
  --cluster ClusterName \  
  --capacity-providers FARGATE FARGATE_SPOT \  
  --default-capacity-provider-strategy '[]'
```

Use the `put-cluster-capacity-providers` command to disassociate the Auto Scaling group capacity provider with the cluster. For more information, see [put-cluster-capacity-providers](#) in the *AWS CLI Command Reference*.

```
aws ecs put-cluster-capacity-providers \  
  --cluster ClusterName \  
  --auto-scaling-group-provider "managedScaling={status=DISABLED}"
```

```
--capacity-providers [] \  
--default-capacity-provider-strategy '[]'
```

2. Use the `describe-clusters` command to verify that the disassociation was successful. For more information, see [describe-clusters](#) in the *AWS CLI Command Reference*.

```
aws ecs describe-clusters \  
  --cluster ClusterName \  
  --include ATTACHMENTS
```

## Turn off managed scaling for the capacity provider

Use the following steps to turn off managed scaling for the capacity provider.

- Use the `update-capacity-provider` command to turn off managed auto scaling for the capacity provider. For more information, see [update-capacity-provider](#) in the *AWS CLI Command Reference*.

```
aws ecs update-capacity-provider \  
  --name CapacityProviderName \  
  --auto-scaling-group-provider "managedScaling={status=DISABLED}"
```

## Creating a capacity provider for Amazon ECS

After the cluster creation completes, you can create a new capacity provider (Auto Scaling group) for EC2. Capacity providers help to manage and scale your the infrastructure for your applications.

Before you create the capacity provider, you need to create an Auto Scaling group. For more information, see [Auto Scaling groups](#) in the *Amazon EC2 Auto Scaling User Guide*.

### To create a capacity provider for the cluster (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster.
4. On the **Cluster : *name*** page, choose **Infrastructure**, and then choose **Create**.
5. On the **Create capacity providers** page, configure the following options.

- a. Under **Basic details**, for **Capacity provider name**, enter a unique capacity provider name.
  - b. Under **Auto Scaling group**, for **Use an existing Auto Scaling group**, choose the Auto Scaling group.
  - c. (Optional) To configure a scaling policy, under **Scaling policies**, configure the following options.
    - To have Amazon ECS manage the scale-in and scale-out actions, select **Turn on managed scaling**.
    - To prevent EC2 instance with running Amazon ECS tasks from being terminated, select **Turn on scaling protection**.
    - For **Set target capacity**, enter the target value for the CloudWatch metric used in the Amazon ECS-managed target tracking scaling policy.
6. Choose **Create**.

## Updating an Amazon ECS capacity provider

When you use an Auto Scaling group as a capacity provider, you can modify the group's scaling policy.

### To update a capacity provider for the cluster (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster.
4. On the **Cluster : *name*** page, choose **Infrastructure**, and then choose **Update**.
5. On the **Create capacity providers** page, configure the following options.
  - Under **Auto Scaling group**, under **Scaling policies**, configure the following options.
    - To have Amazon ECS manage the scale-in and scale-out actions, select **Turn on managed scaling**.
    - To prevent EC2 instances with running Amazon ECS tasks from being terminated, select **Turn on scaling protection**.
    - For **Set target capacity**, enter the target value for the CloudWatch metric used in the Amazon ECS-managed target tracking scaling policy.

## 6. Choose **Update**.

### Deleting an Amazon ECS capacity provider

If you are finished using an Auto Scaling group capacity provider, you can delete it. After the group is deleted, the Auto Scaling group capacity provider transitions to the INACTIVE state. Capacity providers with an INACTIVE status may remain discoverable in your account for a period of time. However, this behavior is subject to change in the future, so you should not rely on INACTIVE capacity providers persisting. Before the Auto Scaling group capacity provider is deleted, the capacity provider must be removed from the capacity provider strategy from all services. You can use the `UpdateService` API or the update service workflow in the Amazon ECS console to remove a capacity provider from a service's capacity provider strategy. Use the **Force new deployment** option to ensure that any tasks using the Amazon EC2 instance capacity provided by the capacity provider are transitioned to use the capacity from the remaining capacity providers.

#### To delete a capacity provider for the cluster (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster.
4. On the **Cluster : *name*** page, choose **Infrastructure**, the Auto Scaling group, and then choose **Delete**.
5. In the confirmation box, enter **delete *Auto Scaling group name***
6. Choose **Delete**.

### Safely stop Amazon ECS workloads running on EC2 instances

Managed instance draining facilitates graceful termination of Amazon EC2 instances. This allows your workloads to stop safely and be rescheduled to non-terminating instances. Infrastructure maintenance and updates are performed without worrying about disruption to workloads. By using managed instance draining, you simplify your infrastructure management workflows that require replacement of Amazon EC2 instances while you ensure resilience and availability of your applications.

Amazon ECS managed instance draining works with Auto Scaling group instance replacements. Based on instance refresh and maximum instance lifetime, customers can ensure that they stay compliant with the latest OS and security mandates for their capacity.

Managed instance draining can only be used with Amazon ECS capacity providers. You can turn on managed instance draining when you create or update your Auto Scaling group capacity providers using the Amazon ECS console, AWS CLI, or SDK.

The following events are covered by Amazon ECS managed instance draining.

- [Auto Scaling group instance refresh](#) - Use instance refresh to perform rolling replacement of your Amazon EC2 instances in your Auto Scaling group instead of manually doing it in batches. This is useful when you need to replace a large number of instances. An instance refresh is initiated through the Amazon EC2 console or the `StartInstanceRefresh` API. Make sure you select `Replace for Scale-in` protection when calling `StartInstanceRefresh` if you're using managed termination protection.
- [Maximum instance lifetime](#) - You can define a maximum lifetime when it comes to replacing Auto Scaling group instances. This is helpful for scheduling replacement instances based on internal security policies or compliance.
- Auto Scaling group scale-in - Based on scaling policies and scheduled scaling actions, Auto Scaling group supports automatic scaling of instances. By using an Auto Scaling group as an Amazon ECS capacity provider, you can scale-in Auto Scaling group instances when no tasks are running in them.
- [Auto Scaling group health checks](#) - Auto Scaling group supports many health checks to manage termination of unhealthy instances.
- [CloudFormation stack updates](#) - You can add an `UpdatePolicy` attribute to your CloudFormation stack to perform rolling updates when group changes.
- [Spot capacity rebalancing](#) - The Auto Scaling group tries to proactively replace Spot Instances that have a higher risk of interruption based on Amazon EC2 capacity rebalance notice. The Auto Scaling group terminates the old instance when the replacement is launched and healthy. Amazon ECS managed instance draining drains the Spot Instance the same way it drains a non-Spot Instance.
- [Spot interruption](#) - Spot Instances are terminated with a two minute notice. Amazon ECS-managed instance draining puts the instance in draining state in response.

## Amazon EC2 Auto Scaling lifecycle hooks with managed instance draining

Auto Scaling group lifecycle hooks enable customer to create solutions that are triggered by certain events in the instance lifecycle and perform a custom action when that certain event occurs. An Auto Scaling group allows for up to 50 hooks. Multiple termination hooks can exist and are performed in parallel, and Auto Scaling group waits for all hooks to finish before terminating an instance.

In addition to the Amazon ECS-managed hook termination, you can also configure your own lifecycle termination hooks. Lifecycle hooks have a default `action`, and we recommend setting `continue` as the default to ensure other hooks, such as the Amazon ECS managed hook, aren't impacted by any errors from custom hooks.

If you've already configured an Auto Scaling group termination lifecycle hook and also enabled Amazon ECS managed instance draining, both lifecycle hooks are performed. The relative timings, however, are not guaranteed. Lifecycle hooks have a default `action` setting to specify the action to take when timeout elapses. In case of failures we recommend using `continue` as the default result in your custom hook. This ensures other hooks, particularly the Amazon ECS managed hooks, aren't impacted by any errors in your custom lifecycle hook. The alternative result of `abandon` causes all other hooks to be skipped and should be avoided. For more information about Auto Scaling group lifecycle hooks see [Amazon EC2 Auto Scaling lifecycle hooks](#) in the *Amazon EC2 Auto Scaling User Guide*.

## Tasks and managed instance draining

Amazon ECS managed instance draining uses the existing draining feature found in container instances. The [container instance draining](#) feature performs replacement and stops for replica tasks that belong to an Amazon ECS service. A standalone task, like one invoked by `RunTask`, that is in the `PENDING` or `RUNNING` state remain unaffected. You have to wait for these to either complete or stop them manually. The container instance remains in the `DRAINING` state until either all tasks are stopped or 48 hours has passed. Daemon tasks are the last to stop after all replica tasks have stopped.

## Managed instance draining and managed termination protection

Managed instance draining works even if managed termination is disabled. For information about managed termination protection, see [Control the instances Amazon ECS terminates](#).

The following table summarizes the behavior for different combinations of managed termination and managed draining.

| Managed termination | Managed draining | Outcome                                                                                                                                                                                                                                                                                                        |
|---------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enabled             | Enabled          | Amazon ECS protects Amazon EC2 instances that are running tasks from being terminated by scaled by scale-in events. Any instances undergoing termination, such as those that don't have termination protection set, have received Spot interruption, or are forced by instance refresh are gracefully drained. |

| Managed termination | Managed draining | Outcome                                                                                                                                                      |
|---------------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Disabled            | Enabled          | Amazon ECS doesn't protect Amazon EC2 instances running tasks from being scaled-in. However, any instances that are being terminated are gracefully drained. |

| Managed termination | Managed draining | Outcome                                                                                                                                                                                                                                                                                  |
|---------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enabled             | Disabled         | Amazon ECS protects Amazon EC2 instances that are running tasks from being terminated by scale-in events. However, instances can still get terminated by Spot interruption or forced instance refresh, or if they aren't running any tasks. Amazon ECS doesn't perform graceful draining |

| Managed termination | Managed draining | Outcome                                                                                                                                                                       |
|---------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     |                  | for these instances , and launches replacement service tasks after they stop.                                                                                                 |
| Disabled            | Disabled         | Amazon EC2 instances can be scaled-in or terminated at any time, even if they are running Amazon ECS tasks. Amazon ECS will launch replacement service tasks after they stop. |

Managed instance draining and Spot Instance draining

With Spot Instance draining, you can set an environment variable `ECS_ENABLE_SPOT_INSTANCE_DRAINING` on the Amazon ECS agent which enables Amazon ECS to place an instance in the draining status in response to the two-minute Spot interruption.

Amazon ECS managed instance draining facilitates graceful shutdown of Amazon EC2 instances undergoing termination due to many reasons, not just Spot interruption. For instance, you can use Amazon EC2 Auto Scaling capacity rebalancing to proactively replace Spot Instance at elevated risk of interruption, and managed instance draining performs graceful shutdown of Spot Instance being replaced. When you use managed instance draining, you don't need to enable Spot instance draining separately, so `ECS_ENABLE_SPOT_INSTANCE_DRAINING` in Auto Scaling group user data is redundant. For more information about Spot Instance draining, see [Spot Instances](#).

## How managed instance draining works with EventBridge

Amazon ECS managed instance draining events are published to Amazon EventBridge, and Amazon ECS creates an EventBridge managed rule in your account's default bus to support managed instance draining. You can filter these events to other AWS services like Lambda, Amazon SNS, and Amazon SQS to monitor and troubleshoot.

- Amazon EC2 Auto Scaling sends an event to EventBridge when a lifecycle hook is invoked.
- Spot interruption notices are published to EventBridge.
- Amazon ECS generates error messages that you can retrieve through the Amazon ECS console and APIs.
- EventBridge has retry mechanisms built in as mitigations for temporary failures.

## Configuring Amazon ECS capacity providers to safely shut down instances

You can turn on managed instance draining when you create or update your Auto Scaling group capacity providers using the Amazon ECS console and AWS CLI.

### Note

Managed instance draining is on by default when you create a capacity provider.

The following are examples using the AWS CLI for creating a capacity provider with managed instance draining enabled and enabling managed instance draining for a cluster's existing capacity provider.

## Create a capacity provider with managed instance draining enabled

To create a capacity provider with managed instance draining enabled, use the `create-capacity-provider` command. Set the `managedDraining` parameter to `ENABLED`.

```
aws ecs create-capacity-provider \  
--name capacity-provider \  
--auto-scaling-group-provider '{  
  "autoScalingGroupArn": "asg-arn",  
  "managedScaling": {  
    "status": "ENABLED",  
    "targetCapacity": 100,  
    "minimumScalingStepSize": 1,  
    "maximumScalingStepSize": 1  
  },  
  "managedDraining": "ENABLED",  
  "managedTerminationProtection": "ENABLED",  
'
```

Response:

```
{  
  "capacityProvider": {  
    "capacityProviderArn": "capacity-provider-arn",  
    "name": "capacity-provider",  
    "status": "ACTIVE",  
    "autoScalingGroupProvider": {  
      "autoScalingGroupArn": "asg-arn",  
      "managedScaling": {  
        "status": "ENABLED",  
        "targetCapacity": 100,  
        "minimumScalingStepSize": 1,  
        "maximumScalingStepSize": 1  
      },  
      "managedTerminationProtection": "ENABLED"  
    },  
    "managedDraining": "ENABLED"  
  }  
}
```

## Enable managed instance draining for a cluster's existing capacity provider

Enable managed instance draining for a cluster's existing capacity provider uses the `update-capacity-provider` command. You see that `managedDraining` currently says `DISABLED` and `updateStatus` says `UPDATE_IN_PROGRESS`.

```
aws ecs update-capacity-provider \  

```

```
--name cp-draining \
--auto-scaling-group-provider '{
  "managedDraining": "ENABLED"
}
```

Response:

```
{
  "capacityProvider": {
    "capacityProviderArn": "cp-draining-arn",
    "name": "cp-draining",
    "status": "ACTIVE",
    "autoScalingGroupProvider": {
      "autoScalingGroupArn": "asg-draining-arn",
      "managedScaling": {
        "status": "ENABLED",
        "targetCapacity": 100,
        "minimumScalingStepSize": 1,
        "maximumScalingStepSize": 1,
        "instanceWarmupPeriod": 300
      },
      "managedTerminationProtection": "DISABLED",
      "managedDraining": "DISABLED" // before update
    },
    "updateStatus": "UPDATE_IN_PROGRESS", // in progress and need describe again to
    find out the result
    "tags": [
    ]
  }
}
```

Use the `describe-clusters` command and include `ATTACHMENTS`. The status of the managed instance draining attachment is `PRECREATED`, and the overall `attachmentsStatus` is `UPDATING`.

```
aws ecs describe-clusters --clusters cluster-name --include ATTACHMENTS
```

Response:

```
{
  "clusters": [
```

```

{
    ...

    "capacityProviders": [
        "cp-draining"
    ],
    "defaultCapacityProviderStrategy": [],
    "attachments": [
        # new precreated managed draining attachment
        {
            "id": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "type": "managed_draining",
            "status": "PRECREATED",
            "details": [
                {
                    "name": "capacityProviderName",
                    "value": "cp-draining"
                },
                {
                    "name": "autoScalingLifecycleHookName",
                    "value": "ecs-managed-draining-termination-hook"
                }
            ]
        },
        ...
    ],
    "attachmentsStatus": "UPDATING"
}
],
"failures": []
}

```

When the update is finished, use `describe-capacity-providers`, and you see `managedDraining` is now `ENABLED`.

```
aws ecs describe-capacity-providers --capacity-providers cp-draining
```

Response:

```

{
    "capacityProviders": [

```

```

    {
      "capacityProviderArn": "cp-draining-arn",
      "name": "cp-draining",
      "status": "ACTIVE",
      "autoScalingGroupProvider": {
        "autoScalingGroupArn": "asg-draning-arn",
        "managedScaling": {
          "status": "ENABLED",
          "targetCapacity": 100,
          "minimumScalingStepSize": 1,
          "maximumScalingStepSize": 1,
          "instanceWarmupPeriod": 300
        },
        "managedTerminationProtection": "DISABLED",
        "managedDraining": "ENABLED" // successfully update
      },
      "updateStatus": "UPDATE_COMPLETE",
      "tags": []
    }
  ]
}

```

## Amazon ECS Managed instance draining troubleshooting

You might need to troubleshoot issues with managed instance draining. The following is an example of an issue and resolution you may come across while using it.

### Instances don't terminate after exceeding maximum instance lifetime when using auto scaling.

If your instances aren't terminating even after reaching and exceeding the maximum instance lifetime while using an auto scaling group, it may be because they're protected from scale-in. You can turn off managed termination and allow managed draining to handle instance recycling.

### Draining behavior for Amazon ECS Managed Instances

Amazon ECS Managed Instances termination ensures graceful workload transitions while optimizing costs and maintaining system health. The termination system provides three distinct decision paths for instance termination, each with different timing characteristics and customer impact profiles.

## Termination decision paths

### Customer-initiated termination

Provides direct control over instance removal when you need to remove container instances from service immediately. You invoke the `DeregisterContainerInstance` API with the `force` flag set to `true`, indicating that immediate termination is required despite any running workloads.

### System-initiated idle termination

Amazon ECS Managed Instances continuously monitors and proactively optimizes costs by terminating idle Amazon ECS container instances not running any tasks. ECS uses a heuristic delay to give container instances a chance to acquire newly launched tasks before being terminated. This can be customized with the `scaleInAfter` Amazon ECS Managed Instances capacity provider configuration parameter.

### Infrastructure refresh termination

Amazon ECS Managed Instances automatically manages and updates software on managed container instances to ensure security and compliance while maintaining workload availability. For more information, see [patching in Amazon ECS Managed Instances](#).

## Graceful draining and workload migration

The graceful draining system implements sophisticated coordination with Amazon ECS service management to ensure that service-managed tasks are properly migrated away from instances scheduled for termination.

### Service task draining coordination

When an instance transitions to `DRAINING` state, the Amazon ECS scheduler automatically stops placing new tasks on the instance while implementing graceful shutdown procedures for existing service tasks. The service task draining includes coordination with service deployment strategies, health check requirements, and your draining preferences to ensure optimal migration timing and success rates.

### Standalone task handling

Standalone tasks require different handling because they do not benefit from automatic service management. The system evaluates standalone task characteristics including task duration estimates, completion probability analysis, and customer impact assessment. The

graceful completion strategy allows standalone tasks to complete naturally during an extended grace period, while forced termination ensures infrastructure refresh occurs within acceptable timeframes when tasks have not completed naturally.

## Two-phase completion strategy

The termination system implements a two-phase approach that balances workload continuity against infrastructure management requirements.

### Phase 1: Graceful completion period

During this phase, the system implements graceful draining strategies that prioritize workload continuity. Service tasks are gracefully drained through normal Amazon ECS scheduling processes, standalone tasks continue running and may complete naturally, and the system monitors for all tasks to reach stopped state through natural completion processes.

### Phase 2: Hard deadline enforcement

When graceful completion does not achieve termination objectives within acceptable timeframes, the system implements hard deadline enforcement. The hard deadline is typically set to draining initiation time plus seven days, providing substantial time for graceful completion while maintaining operational requirements. The enforcement includes automatic invocation of force deregistration procedures and immediate termination of all remaining tasks regardless of completion status.

## Creating resources for Amazon ECS cluster auto scaling using the AWS Management Console

Learn how to create the resources for cluster auto scaling using the AWS Management Console. Where resources require a name, we use the prefix `ConsoleTutorial` to ensure they all have unique names and to make them easy to locate.

### Topics

- [Prerequisites](#)
- [Step 1: Create an Amazon ECS cluster](#)
- [Step 2: Register a task definition](#)
- [Step 3: Run a task](#)
- [Step 4: Verify](#)

- [Step 5: Clean up](#)

## Prerequisites

This tutorial assumes that the following prerequisites have been completed:

- The steps in [Set up to use Amazon ECS](#) have been completed.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.
- The Amazon ECS container instance IAM role is created. For more information, see [Amazon ECS container instance IAM role](#).
- The Amazon ECS service-linked IAM role is created. For more information, see [Using service-linked roles for Amazon ECS](#).
- The Auto Scaling service-linked IAM role is created. For more information, see [Service-Linked Roles for Amazon EC2 Auto Scaling](#) in the *Amazon EC2 Auto Scaling User Guide*.
- You have a VPC and security group created to use. For more information, see [the section called "Create a virtual private cloud"](#).

## Step 1: Create an Amazon ECS cluster

Use the following steps to create an Amazon ECS cluster.

Amazon ECS creates an Amazon EC2 Auto Scaling launch template and Auto Scaling group on your behalf as part of the CloudFormation stack.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**, and then choose **Create cluster**.
3. Under **Cluster configuration**, for **Cluster name**, enter `ConsoleTutorial-cluster`.
4. Under **Infrastructure**, clear AWS Fargate (serverless), and then select **Amazon EC2 instances**. Next, configure the Auto Scaling group which acts as the capacity provider.
  - Under **Auto Scaling group (ASG)** . Select **Create new ASG**, and then provide the following details about the group:
    - For **Operating system/Architecture**, choose **Amazon Linux 2**.
    - For **EC2 instance type**, choose **t3.nano**.

- For **Capacity**, enter the minimum number and the maximum number of instances to launch in the Auto Scaling group.
5. (Optional) To manage the cluster tags, expand **Tags**, and then perform one of the following operations:

[Add a tag] Choose **Add tag** and do the following:

- For **Key**, enter the key name.
- For **Value**, enter the key value.

[Remove a tag] Choose **Remove** to the right of the tag's Key and Value.

6. Choose **Create**.

## Step 2: Register a task definition

Before you can run a task on your cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that uses an `amazonlinux` image from Docker Hub and simply sleeps. For more information about the available task definition parameters, see [Amazon ECS task definitions](#).

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task definitions**.
3. Choose **Create new task definition**, **Create new task definition with JSON**.
4. In the **JSON editor** box, paste the following contents.

```
{
  "family": "ConsoleTutorial-taskdef",
  "containerDefinitions": [
    {
      "name": "sleep",
      "image": "public.ecr.aws/amazonlinux/amazonlinux:latest",
      "memory": 20,
      "essential": true,
      "command": [
        "sh",
        "-c",
        "sleep infinity"
      ]
    }
  ]
}
```

```
    }  
  ],  
  "requiresCompatibilities": [  
    "EC2"  
  ]  
}
```

5. Choose **Create**.

### Step 3: Run a task

After you have registered a task definition for your account, you can run a task in the cluster. For this tutorial, you run five instances of the `ConsoleTutorial-taskdef` task definition in your `ConsoleTutorial-cluster` cluster.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose **ConsoleTutorial-cluster**.
3. Under **Tasks**, choose **Run new task**.
4. In the **Environment** section, under **Compute options**, choose **Capacity provider strategy**.
5. Under **Deployment configuration**, for **Application type**, choose **Task**.
6. Choose **ConsoleTutorial-taskdef** from the **Family** dropdown list.
7. Under **Desired tasks**, enter 5.
8. Choose **Create**.

### Step 4: Verify

At this point in the tutorial, you should have a cluster with five tasks running and an Auto Scaling group with a capacity provider. The capacity provider has Amazon ECS managed scaling enabled.

We can verify that everything is working properly by viewing the CloudWatch metrics, the Auto Scaling group settings, and finally the Amazon ECS cluster task count.

#### To view the CloudWatch metrics for your cluster

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. On the navigation bar at the top of the screen, select the Region.
3. On the navigation pane, under **Metrics**, choose **All metrics**.
4. On the **All metrics** page, under the **Browse** tab, choose **AWS/ECS/ManagedScaling**.

5. Choose **CapacityProviderName**, **ClusterName**.
6. Select the check box that corresponds to the `ConsoleTutorial-cluster` **ClusterName**.
7. Under the **Graphed metrics** tab, change **Period** to **30 seconds** and **Statistic** to **Maximum**.

The value displayed in the graph shows the target capacity value for the capacity provider. It should begin at 100, which was the target capacity percent we set. You should see it scale up to 200, which will trigger an alarm for the target tracking scaling policy. The alarm will then trigger the Auto Scaling group to scale out.

Use the following steps to view your Auto Scaling group details to confirm that the scale-out action occurred.

### To verify the Auto Scaling group scaled out

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation bar at the top of the screen, select the Region.
3. On the navigation pane, under **Auto Scaling**, choose **Auto Scaling Groups**.
4. Choose the `ConsoleTutorial-cluster` Auto Scaling group created in this tutorial. View the value under **Desired capacity** and view the instances under the **Instance management** tab to confirm your group scaled out to two instances.

Use the following steps to view your Amazon ECS cluster to confirm that the Amazon EC2 instances were registered with the cluster and your tasks transitioned to a RUNNING status.

### To verify the instances in the Auto Scaling group

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the `ConsoleTutorial-cluster` cluster.
4. On the **Tasks** tab, confirm you see five tasks in the RUNNING status.

## Step 5: Clean up

When you have finished this tutorial, clean up the resources associated with it to avoid incurring charges for resources that you aren't using. Deleting capacity providers and task definitions are not supported, but there is no cost associated with these resources.

## To clean up the tutorial resources

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose **ConsoleTutorial-cluster**.
4. On the **ConsoleTutorial-cluster** page, choose the **Tasks** tab, and then choose **Stop, Stop all**.
5. In the navigation pane, choose **Clusters**.
6. On the **Clusters** page, choose **ConsoleTutorial-cluster**.
7. Choose **Delete cluster**.
8. In the confirmation box, enter **delete ConsoleTutorial-cluster** and choose **Delete**.
9. Delete the Auto Scaling groups using the following steps.
  - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
  - b. On the navigation bar at the top of the screen, select the Region.
  - c. On the navigation pane, under **Auto Scaling**, choose **Auto Scaling Groups**.
  - d. Select the ConsoleTutorial-cluster Auto Scaling group, then choose **Actions**.
  - e. From the **Actions** menu, choose **Delete**. Enter **delete** in the confirmation box and then choose **Delete**.

## Amazon EC2 container instances for Amazon ECS

An Amazon ECS container instance is an Amazon EC2 instance that runs the Amazon ECS container agent and is registered to a cluster. When you run tasks with Amazon ECS using the capacity provider, External capacity provider or an Auto Scaling group capacity provider, your tasks are placed on your active container instances. You are responsible for the container instance management and maintenance.

Although you can create your own Amazon EC2 instance AMI that meets the basic specifications needed to run your containerized workloads on Amazon ECS, the Amazon ECS-optimized AMIs are preconfigured and tested on Amazon ECS by AWS engineers. It is the simplest way for you to get started and to get your containers running on AWS quickly.

When you create a cluster using the console, Amazon ECS creates a launch template for your instances with the latest AMI associated with the selected operating system.

When you use CloudFormation to create a cluster, the SSM parameter is part of the Amazon EC2 launch template for the Auto Scaling group instances. You can configure the template to use a dynamic Systems Manager parameter to determine what Amazon ECS Optimized AMI to deploy. This parameter ensures that each time you deploy the stack it will check to see if there is available update that needs to be applied to the EC2 instances. For an example of how to use the Systems Manager parameter, see [Create an Amazon ECS cluster with the Amazon ECS-optimized Amazon Linux 2023 AMI](#) in the *AWS CloudFormation User Guide*.

- [Retrieving Amazon ECS-optimized Linux AMI metadata](#)
- [Retrieving Amazon ECS-optimized Bottlerocket AMI metadata](#)
- [Retrieving Amazon ECS-optimized Windows AMI metadata](#)

You can choose from the instance types that are compatible with your application. With larger instances, you can launch more tasks at the same time. With smaller instances, you can scale out in a more fine-grained way to save costs. You don't need to choose a single Amazon EC2 instance type that to fit all the applications in your cluster. Instead, you can create multiple Auto Scaling groups where each group has a different instance type. Then, you can create an Amazon EC2 capacity provider for each one of these groups.

Use the following guidelines to determine the instance family types and instance type to use:

- Eliminate the instance types or instance families that don't meet the specific requirements of your application. For example, if your application requires a GPU, you can exclude any instance types that don't have a GPU.
- Consider requirements including network throughput and storage.
- Consider the CPU and memory. As a general rule, the CPU and memory must be large enough to hold at least one replica of the task that you want to run.

## Spot Instances

Spot capacity can provide significant cost savings over on-demand instances. Spot capacity is excess capacity that's priced significantly lower than on-demand or reserved capacity. Spot capacity is suitable for batch processing and machine-learning workloads, and development and staging environments. More generally, it's suitable for any workload that tolerates temporary downtime.

Understand that the following consequences because Spot capacity might not be available all the time.

- During periods of extremely high demand, Spot capacity might be unavailable. This can cause Amazon EC2 Spot instance launches to be delayed. In these events, Amazon ECS services retry launching tasks, and Amazon EC2 Auto Scaling groups also retry launching instances, until the required capacity becomes available. Amazon EC2 doesn't replace Spot capacity with on-demand capacity.
- When the overall demand for capacity increases, Spot Instances and tasks might be terminated with only a two-minute warning. After the warning is sent, tasks should begin an orderly shutdown if necessary before the instance is fully terminated. This helps minimize the possibility of errors. For more information about a graceful shutdown, see [Graceful shutdowns with ECS](#).

To help minimize Spot capacity shortages, consider the following recommendations:

- Use multiple Regions and Availability Zones - Spot capacity varies by Region and Availability Zone. You can improve Spot availability by running your workloads in multiple Regions and Availability Zones. If possible, specify subnets in all the Availability Zones in the Regions where you run your tasks and instances.
- Use multiple Amazon EC2 instance types - When you use Mixed Instance Policies with Amazon EC2 Auto Scaling, multiple instance types are launched into your Auto Scaling Group. This ensures that a request for Spot capacity can be fulfilled when needed. To maximize reliability and minimize complexity, use instance types with roughly the same amount of CPU and memory in your Mixed Instances Policy. These instances can be from a different generation, or variants of the same base instance type. Note that they might come with additional features that you might not require. An example of such a list could include m4.large, m5.large, m5a.large, m5d.large, m5n.large, m5dn.large, and m5ad.large. For more information, see [Auto Scaling groups with multiple instance types and purchase options](#) in the *Amazon EC2 Auto Scaling User Guide*.
- Use the capacity-optimized Spot allocation strategy - With Amazon EC2 Spot, you can choose between the capacity- and cost-optimized allocation strategies. If you choose the capacity-optimized strategy when launching a new instance, Amazon EC2 Spot selects the instance type with the greatest availability in the selected Availability Zone. This helps reduce the possibility that the instance is terminated soon after it launches.

For information about how to configure spot termination notices on your container instances, see:

- [Configuring Amazon ECS Linux container instances to receive Spot Instance notices](#)
- [Configuring Amazon ECS Windows container instances to receive Spot Instance notices](#)

## Amazon ECS-optimized Linux AMIs

### Important

The Amazon ECS-Optimized Amazon Linux 2 AMI reaches end-of-life on June 30, 2026, mirroring the same EOL date of the upstream Amazon Linux 2 operating system (for more information, see the [Amazon Linux 2 FAQs](#)). We encourage customers to upgrade their applications to use Amazon Linux 2023, which includes long term support through 2028. For information about migrating from Amazon Linux 2 to Amazon Linux 2023, see [Migrating from the Amazon Linux 2 Amazon ECS-optimized AMI to the Amazon Linux 2023 Amazon ECS-optimized AMI](#).

By default, the deprecation date of all Amazon ECS-optimized AMIs are set to two years after the AMI creation date. You can use the Amazon EC2 `DescribeImages` API to check the deprecation status and date of an AMI. For more information, see [DescribeImages](#) in the *Amazon Elastic Compute Cloud API Reference*.

Amazon ECS provides the Amazon ECS-optimized AMIs that are preconfigured with the requirements and recommendations to run your container workloads. We recommend that you use the Amazon ECS-optimized Amazon Linux 2023 AMI for your Amazon EC2 instances. Launching your container instances from the most recent Amazon ECS-Optimized AMI ensures that you receive the current security updates and container agent version. For information about how to launch an instance, see [Launching an Amazon ECS Linux container instance](#).

When you create a cluster using the console, Amazon ECS creates a launch template for your instances with the latest AMI associated with the selected operating system.

When you use CloudFormation to create a cluster, the SSM parameter is part of the Amazon EC2 launch template for the Auto Scaling group instances. You can configure the template to use a dynamic Systems Manager parameter to determine what Amazon ECS Optimized AMI to deploy. This parameter ensures that each time you deploy the stack it will check to see if there is available update that needs to be applied to the EC2 instances. For an example of how to use the Systems Manager parameter, see [Create an Amazon ECS cluster with the Amazon ECS-optimized Amazon Linux 2023 AMI](#) in the *AWS CloudFormation User Guide*.

If you need to customize the Amazon ECS-optimized AMI, see [Amazon ECS Optimized AMI Build Recipes](#) on GitHub.

The following variants of the Amazon ECS-optimized AMI are available for your Amazon EC2 instances with the Amazon Linux 2023 operating system.

| Operating system  | AMI                                        | Description                                                                                                                                                                                                                                                                            | Storage configuration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Amazon Linux 2023 | Amazon ECS-optimized Amazon Linux 2023 AMI | Amazon Linux 2023 is the next generation of Amazon Linux from AWS. For most cases, recommended for launching your Amazon EC2 instances for your Amazon ECS workloads. For more information, see <a href="#">What is Amazon Linux 2023</a> in the <i>Amazon Linux 2023 User Guide</i> . | <p>By default, the Amazon ECS-optimized Amazon Linux 2023 AMI ships with a single 30-GiB root volume. You can modify the 30-GiB root volume size at launch time to increase the available storage on your container instance. This storage is used for the operating system and for Docker images and metadata.</p> <p>The default filesystem for the Amazon ECS-optimized Amazon Linux 2023 AMI is xfs, and Docker uses the overlay2 storage driver. For more information, see <a href="#">Use the OverlayFS storage driver</a> in the Docker documentation.</p> |

| Operating system                 | AMI                                                       | Description                                                                                                                                                                                                                                                                                                                                                              | Storage configuration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Amazon ECS provides a changelog for the Linux variant of the Amazon ECS-optimized AMI on GitHub. For more information, see [Changelog](#).

The Linux variants of the Amazon ECS-optimized AMI use the Amazon Linux 2 AMI or Amazon Linux 2023 AMI as their base. You can retrieve the AMI name for each variant by querying the Systems Manager Parameter Store API. For more information, see [Retrieving Amazon ECS-optimized Linux AMI metadata](#). The Amazon Linux 2 AMI release notes are available as well. For more information, see [Amazon Linux 2 release notes](#). The Amazon Linux 2023 release notes are available as well. For more information see, [Amazon Linux 2023 release notes](#).

The following pages provide additional information about the changes:

- [Source AMI release](#) notes on GitHub
- [Docker Engine release notes](#) in the Docker documentation
- [NVIDIA Driver Documentation](#) in the NVIDIA documentation
- [Amazon ECS agent changelog](#) on GitHub

The source code for the `ecs-init` application and the scripts and configuration for packaging the agent are now part of the agent repository. For older versions of `ecs-init` and packaging, see [Amazon ecs-init changelog](#) on GitHub

## Applying security updates to the Amazon ECS-optimized AMI

The Amazon ECS-optimized AMIs based on Amazon Linux contain a customized version of cloud-init. Cloud-init is a package that is used to bootstrap Linux images in a cloud computing environment and perform desired actions when launching an instance. By default, all Amazon ECS-optimized AMIs based on Amazon Linux released before June 12, 2024 have all "Critical" and "Important" security updates applied upon instance launch.

Beginning with the June 12, 2024 releases of the Amazon ECS-optimized AMIs based on Amazon Linux 2, the default behavior will no longer include updating packages at launch. Instead, we

recommend that you update to a new Amazon ECS-optimized AMI as releases are made available. The Amazon ECS-optimized AMIs are released when there are available security updates or base AMI changes. This will ensure you are receiving the latest package versions and security updates, and that the package versions are immutable through instance launches. For more information on retrieving the latest Amazon ECS-optimized AMI, see [Retrieving Amazon ECS-optimized Linux AMI metadata](#).

We recommend automating your environment to update to a new AMI as they are made available. For information about the available options, see [Amazon ECS enables easier EC2 capacity management, with managed instance draining](#).

To continue applying "Critical" and "Important" security updates manually on an AMI version, you can run the following command on your Amazon EC2 instance.

```
yum update --security
```

#### Warning

Updating docker or containerd packages will stop all running containers on the host, which means all running Amazon ECS tasks will be stopped. Plan accordingly to minimize service disruption.

If you want to re-enable security updates at launch, you can add the following line to the `#cloud-config` section of the cloud-init user data when launching your Amazon EC2 instance. For more information, see [Using cloud-init on Amazon Linux 2](#) in the *Amazon Linux User Guide*.

```
#cloud-config
repo_upgrade: security
```

### Version-locked packages in Amazon ECS-optimized AL2023 GPU AMIs

Certain packages are critical for correct, performant behavior of GPU functionality in Amazon ECS-optimized AL2023 GPU AMIs. These include:

- NVIDIA drivers (`nvidia*`)
- Kernel modules (`kmod*`)
- NVIDIA libraries (`libnvidia*`)

- Kernel packages (`kernel*`)
- Xorg server packages (`xorg*`)
- NVIDIA Data Center GPU Manager (DCGM) (`datacenter-gpu-manager-*`)

 **Note**

This is not an exhaustive list. The complete list of locked packages are available with `dnf versionlock list`

These packages are version-locked to ensure stability and prevent unintentional changes that could disrupt GPU workloads. As a result, these packages should generally be modified within the bounds of a managed process that gracefully handles potential issues and maintains GPU functionality.

To prevent unintended modifications, the `dnf versionlock` plugin is used on these packages.

If you wish to modify a locked package, you can:

```
# unlock a single package
sudo dnf versionlock delete $PACKAGE_NAME

# unlock all packages
sudo dnf versionlock clear
```

 **Important**

When updates to these packages are necessary, customers should consider using the latest AMI version that includes the required updates. If updating existing instances is required, a careful approach involving unlocking, updating, and re-locking packages should be employed, always ensuring GPU functionality is maintained throughout the process.

## Retrieving Amazon ECS-optimized Linux AMI metadata

You can programmatically retrieve the Amazon ECS-optimized AMI metadata. The metadata includes the AMI name, Amazon ECS container agent version, and Amazon ECS runtime version which includes the Docker version.

When you create a cluster using the console, Amazon ECS creates a launch template for your instances with the latest AMI associated with the selected operating system.

When you use CloudFormation to create a cluster, the SSM parameter is part of the Amazon EC2 launch template for the Auto Scaling group instances. You can configure the template to use a dynamic Systems Manager parameter to determine what Amazon ECS Optimized AMI to deploy. This parameter ensures that each time you deploy the stack it will check to see if there is available update that needs to be applied to the EC2 instances. For an example of how to use the Systems Manager parameter, see [Create an Amazon ECS cluster with the Amazon ECS-optimized Amazon Linux 2023 AMI](#) in the *AWS CloudFormation User Guide*.

The AMI ID, image name, operating system, container agent version, source image name, and runtime version for each variant of the Amazon ECS-optimized AMIs can be programmatically retrieved by querying the Systems Manager Parameter Store API. For more information about the Systems Manager Parameter Store API, see [GetParameters](#) and [GetParametersByPath](#).

#### Note

Your administrative user must have the following IAM permissions to retrieve the Amazon ECS-optimized AMI metadata. These permissions have been added to the AmazonECS\_FullAccess IAM policy.

- ssm:GetParameters
- ssm:GetParameter
- ssm:GetParametersByPath

## Systems Manager Parameter Store parameter format

The following is the format of the parameter name for each Amazon ECS-optimized AMI variant.

### Linux Amazon ECS-optimized AMIs

- Amazon Linux 2023 AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2023/<version>
```

- Amazon Linux 2023 (arm64) AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2023/arm64/<version>
```

- Amazon Linux 2023 (Neuron) AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2023/neuron/<version>
```

- Amazon Linux 2023 (GPU) AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2023/gpu/<version>
```

#### Amazon Linux 2 AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2/<version>
```

- Amazon Linux 2 kernel 5.10 AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/<version>
```

- Amazon Linux 2 (arm64) AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2/arm64/<version>
```

- Amazon Linux 2 kernel 5.10 (arm64) AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/arm64/<version>
```

- Amazon ECS GPU-optimized kernel 5.10 AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/gpu/<version>
```

- Amazon Linux 2 (GPU) AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2/gpu/<version>
```

- Amazon ECS optimized Amazon Linux 2 (Neuron) kernel 5.10 AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/inf/<version>
```

- Amazon Linux 2 (Neuron) AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2/inf/<version>
```

The following parameter name format retrieves the image ID of the latest recommended Amazon ECS-optimized Amazon Linux 2 AMI by using the sub-parameter `image_id`.

```
/aws/service/ecs/optimized-ami/amazon-linux-2/recommended/image_id
```

The following parameter name format retrieves the metadata of a specific Amazon ECS-optimized AMI version by specifying the AMI name.

- Amazon ECS-optimized Amazon Linux 2 AMI metadata:

```
/aws/service/ecs/optimized-ami/amazon-linux-2/amzn2-ami-ecs-hvm-2.0.20181112-x86_64-ebs
```

#### Note

All versions of the Amazon ECS-optimized Amazon Linux 2 AMI are available for retrieval. Only Amazon ECS-optimized AMI versions `amzn-ami-2017.09.1-amazon-ecs-optimized (Linux)` and later can be retrieved.

## Examples

The following examples show ways in which you can retrieve the metadata for each Amazon ECS-optimized AMI variant.

### Retrieving the metadata of the latest recommended Amazon ECS-optimized AMI

You can retrieve the latest recommended Amazon ECS-optimized AMI using the AWS CLI with the following AWS CLI commands.

#### Linux Amazon ECS-optimized AMIs

- For the Amazon ECS-optimized Amazon Linux 2023 AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/  
recommended --region us-east-1
```

- For the Amazon ECS-optimized Amazon Linux 2023 (arm64) AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/  
arm64/recommended --region us-east-1
```

- For the Amazon ECS-optimized Amazon Linux 2023 (Neuron) AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/  
neuron/recommended --region us-east-1
```

- For the Amazon ECS-optimized Amazon Linux 2023 GPU AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/gpu/  
recommended --region us-east-1
```

- For the Amazon ECS-optimized Amazon Linux 2 kernel 5.10 AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/  
kernel-5.10/recommended --region us-east-1
```

- For the Amazon ECS-optimized Amazon Linux 2 AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/  
recommended --region us-east-1
```

- For the Amazon ECS-optimized Amazon Linux 2 kernel 5.10 (arm64) AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/  
kernel-5.10/arm64/recommended --region us-east-1
```

- For the Amazon ECS-optimized Amazon Linux 2 (arm64) AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/arm64/  
recommended --region us-east-1
```

- For the Amazon ECS GPU-optimized kernel 5.10 AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/
kernel-5.10/gpu/recommended --region us-east-1
```

- For the Amazon ECS GPU-optimized AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/gpu/
recommended --region us-east-1
```

- For the Amazon ECS optimized Amazon Linux 2 (Neuron) kernel 5.10 AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/
kernel-5.10/inf/recommended --region us-east-1
```

- For the Amazon ECS optimized Amazon Linux 2 (Neuron) AMIs:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/inf/
recommended --region us-east-1
```

## Retrieving the image ID of the latest recommended Amazon ECS-optimized Amazon Linux 2023 AMI

You can retrieve the image ID of the latest recommended Amazon ECS-optimized Amazon Linux 2023 AMI ID by using the sub-parameter `image_id`.

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-
linux-2023/recommended/image_id --region us-east-1
```

To retrieve the `image_id` value only, you can query the specific parameter value; for example:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/
recommended/image_id --region us-east-1 --query "Parameters[0].Value"
```

## Retrieving the metadata of a specific Amazon ECS-optimized Amazon Linux 2 AMI version

Retrieve the metadata of a specific Amazon ECS-optimized Amazon Linux AMI version using the AWS CLI with the following AWS CLI command. Replace the AMI name with the name of the Amazon ECS-optimized Amazon Linux AMI to retrieve.

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/amzn2-ami-ecs-hvm-2.0.20200928-x86_64-ebs --region us-east-1
```

## Retrieving the Amazon ECS-optimized Amazon Linux 2 kernel 5.10 AMI metadata using the Systems Manager GetParametersByPath API

Retrieve the Amazon ECS-optimized Amazon Linux 2 AMI metadata with the Systems Manager GetParametersByPath API using the AWS CLI with the following command.

```
aws ssm get-parameters-by-path --path /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/ --region us-east-1
```

## Retrieving the image ID of the latest recommended Amazon ECS-optimized Amazon Linux 2 kernel 5.10 AMI

You can retrieve the image ID of the latest recommended Amazon ECS-optimized Amazon Linux 2 kernel 5.10 AMI ID by using the sub-parameter `image_id`.

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/recommended/image_id --region us-east-1
```

To retrieve the `image_id` value only, you can query the specific parameter value; for example:

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/recommended/image_id --region us-east-1 --query "Parameters[0].Value"
```

## Using the latest recommended Amazon ECS-optimized AMI in an CloudFormation template

You can reference the latest recommended Amazon ECS-optimized AMI in an CloudFormation template by referencing the Systems Manager parameter store name.

### Linux example

```
Parameters:kernel-5.10
LatestECSOptimizedAMI:
  Description: AMI ID
  Type: AWS::SSM::Parameter::Value<AWS::EC2::Image::Id>
  Default: /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/recommended/image_id
```

## Migrating from an Amazon Linux 2 to an Amazon Linux 2023 Amazon ECS-optimized AMI

Following [Amazon Linux](#), Amazon ECS ends standard support for Amazon Linux 2 Amazon ECS-optimized AMIs effective June 30, 2026. After this date, the Amazon ECS agent version is pinned and new Amazon Linux 2 Amazon ECS-optimized AMIs are only published when the source Amazon Linux 2 AMI is updated. Complete End of Life (EOL) occurs on June 30, 2026, after which no more Amazon ECS-optimized Amazon Linux 2 AMIs are published, even if the source AMI is updated.

Amazon Linux 2023 provides a secure-by-default approach with preconfigured security policies, SELinux in permissive mode, IMDSv2-only mode enabled by default, optimized boot times, and improved package management for enhanced security and performance.

There is a high degree of compatibility between the Amazon Linux 2 and Amazon Linux 2023 Amazon ECS-optimized AMIs, and most customers will experience minimal-to-zero changes in their workloads between the two operating systems.

For more information, see [Comparing Amazon Linux 2 and Amazon Linux 2023](#) in the *Amazon Linux 2023 User Guide* and the [AL2023 FAQs](#).

### Compatibility considerations

#### Package management and OS updates

Unlike previous versions of Amazon Linux, Amazon ECS-optimized Amazon Linux 2023 AMIs are locked to a specific version of the Amazon Linux repository. This insulates users from inadvertently updating packages that might bring in unwanted or breaking changes. For more information, see [Managing repositories and OS updates in Amazon Linux 2023](#) in the *Amazon Linux 2023 User Guide*.

#### Linux kernel versions

Amazon Linux 2 AMIs are based on Linux kernels 4.14 and 5.10, while Amazon Linux 2023 uses Linux kernel 6.1 and 6.12. For more information, see [Comparing Amazon Linux 2 and Amazon Linux 2023 kernels](#) in the *Amazon Linux 2023 User Guide*.

#### Package availability changes

The following are notable package changes in Amazon Linux 2023:

- Some source binary packages in Amazon Linux 2 are no longer available in Amazon Linux 2023. For more information, see [Packages removed from Amazon Linux 2023](#) in the *Amazon Linux 2023 Release Notes*.

- Changes in how Amazon Linux supports different versions of packages. The `amazon-linux-extras` system used in Amazon Linux 2 does not exist in Amazon Linux 2023. All packages are simply available in the "core" repository.
- Extra packages for Enterprise Linux (EPEL) are not supported in Amazon Linux 2023. For more information, see [EPEL compatibility in Amazon Linux 2023](#) in the *Amazon Linux 2023 User Guide*.
- 32-bit applications are not supported in Amazon Linux 2023. For more information, see [Deprecated features from Amazon Linux 2](#) in the *Amazon Linux 2023 User Guide*.

## Control Groups (cgroups) changes

A Control Group (cgroup) is a Linux kernel feature to hierarchically organize processes and distribute system resources between them. Control Groups are used extensively to implement a container runtime, and by `systemd`.

Amazon Linux 2023 uses `cgroupv2` by default, while Amazon Linux 2 used `cgroupv1`. The Amazon ECS agent, Docker, and `containerd` all support both `cgroupv1` and `cgroupv2`. For further details on `cgroupv2`, see [Control groups v2 in Amazon Linux 2023](#) in the *Amazon Linux 2023 User Guide*.

## Memory usage reporting

`cgroupv2` changes how container memory usage is calculated. In `cgroupv1` (Amazon Linux 2), container memory utilization as reported by the container runtime typically excludes page cache. In `cgroupv2` (Amazon Linux 2023), page cache is included in the reported memory usage. The same workload may report higher memory utilization on Amazon Linux 2023 compared to Amazon Linux 2, even when actual application memory consumption has not changed.

We recommend benchmarking memory usage on Amazon Linux 2023 instances before migrating production workloads, and adjusting task and container memory limits if needed. You can use [Container Insights](#) to compare memory utilization between Amazon Linux 2 and Amazon Linux 2023.

## Task memory limit visibility

When you set memory at the task level without setting a container-level memory limit, Amazon ECS applies the limit to the task's cgroup. This acts as the effective memory limit for all the containers belonging to the task. On `cgroupv1` (Amazon Linux 2), child cgroups could read the effective memory limit at their own level. They did not need to traverse the cgroup hierarchy. On `cgroupv2` (Amazon Linux 2023), the effective limit is not visible to the container. Additionally,

Docker runs containers in a private cgroup namespace by default, which prevents them from traversing up the cgroup hierarchy to discover the parent's limit.

Any process inside the container that reads cgroup memory limits to determine available memory will see the full host memory rather than the task-level limit. For example, the Java Virtual Machine (JVM) is known to be affected by this issue. It uses cgroup limits to automatically size the heap. When it cannot detect the true limit, it over-allocates memory, which increases the risk of out-of-memory (OOM) kills. Other runtimes or frameworks that read cgroup limits for resource decisions may be similarly affected.

This occurs when task-level memory is set but container-level memory is not set in the task definition.

To resolve this issue, choose one of the following workarounds:

### **Set container-level memory limits (recommended)**

Explicitly set the `memory` parameter at the container level in your task definition, equal to the task-level memory value. This approach is safe, reliable, and requires no infrastructure changes.

### **Enable agent-level task memory limit propagation**

Set the `ECS_PROPAGATE_TASK_MEMORY_LIMIT_CGROUPV2` environment variable to `true` on the Amazon ECS agent. When enabled and on cgroupv2, the agent automatically sets each container's memory limit to the task-level value if the container does not already have an explicit container-level memory limit. This makes the task memory limit visible inside the container without requiring task definition changes.

You can set this in the Amazon ECS agent configuration file (`/etc/ecs/ecs.config`) on your Amazon EC2 instances:

```
ECS_PROPAGATE_TASK_MEMORY_LIMIT_CGROUPV2=true
```

This option requires Amazon ECS agent version 1.104.0 or later. It only applies on Linux instances using cgroupv2. It is not supported on Windows.

### **Instance Metadata Service (IMDS) changes**

Amazon Linux 2023 requires Instance Metadata Service version 2 (IMDSv2) by default. IMDSv2 has several benefits that help improve security posture. It uses a session-oriented authentication

method that requires the creation of a secret token in a simple HTTP PUT request to start the session. A session's token can be valid for anywhere between 1 second and 6 hours.

For more information on how to transition from IMDSv1 to IMDSv2, see [Transition to using Instance Metadata Service Version 2](#) in the *Amazon EC2 User Guide*.

If you would like to use IMDSv1, you can still do so by manually overriding the settings using instance metadata option launch properties.

### Memory swappiness changes

Per-container memory swappiness is not supported on Amazon Linux 2023 and cgroups v2. For more information, see [Managing container swap memory space on Amazon ECS](#).

### FIPS validation changes

Amazon Linux 2 is certified under FIPS 140-2 and Amazon Linux 2023 is certified under FIPS 140-3.

To enable FIPS mode on Amazon Linux 2023, install the necessary packages on your Amazon EC2 instance and follow the configuration steps using the instructions in [Enable FIPS Mode on Amazon Linux 2023](#) in the *Amazon Linux 2023 User Guide*.

### Accelerated instance support

The Amazon ECS-optimized Amazon Linux 2023 AMIs support both Neuron and GPU accelerated instance types. For more information, see [Amazon ECS-optimized Linux AMIs](#).

### Building custom AMIs

While we recommend moving to officially supported and published Amazon ECS-optimized AMIs for Amazon Linux 2023, you can continue to build custom Amazon Linux 2 Amazon ECS-optimized AMIs using the open-source build scripts that are used to build the Linux variants of the Amazon ECS-optimized AMI. For more information, see [Amazon ECS-optimized Linux AMI build script](#).

### Migration strategies

We recommend creating and implementing a migration plan that includes thorough application testing. The following sections outline different migration strategies based on how you manage your Amazon ECS infrastructure.

## Migrating with Amazon ECS capacity providers

1. Create a new capacity provider with a new launch template. This should reference an Auto Scaling group with a launch template similar to your existing one, but instead of the Amazon Linux 2 Amazon ECS-optimized AMI, it should specify one of the Amazon Linux 2023 variants. Add this new capacity provider to your existing Amazon ECS cluster.
2. Update your cluster's default capacity provider strategy to include both the existing Amazon Linux 2 capacity provider and the new Amazon Linux 2023 capacity provider. Start with a higher weight on the Amazon Linux 2 provider and a lower weight on the Amazon Linux 2023 provider (for example, Amazon Linux 2: weight 80, Amazon Linux 2023: weight 20). This causes Amazon ECS to begin provisioning Amazon Linux 2023 instances as new tasks are scheduled. Verify that the instances register correctly and that tasks are able to run successfully on the new instances.
3. Gradually adjust the capacity provider weights in your cluster's default strategy, increasing the weight for the Amazon Linux 2023 provider while decreasing the Amazon Linux 2 provider weight over time (for example, 60/40, then 40/60, then 20/80). You can also update individual service capacity provider strategies to prioritize Amazon Linux 2023 instances. Monitor task placement to ensure they're successfully running on Amazon Linux 2023 instances.
4. Optionally drain Amazon Linux 2 container instances to accelerate task migration. If you have sufficient Amazon Linux 2023 replacement capacity, you can manually drain your Amazon Linux 2 container instances through the Amazon ECS console or AWS CLI to speed up the transition of your tasks from Amazon Linux 2 to Amazon Linux 2023. After the migration is complete, remove the Amazon Linux 2 capacity provider from your cluster and delete the associated Auto Scaling group.

## Migrating with an Amazon EC2 Auto Scaling group

1. Create a new Amazon EC2 Auto Scaling group with a new launch template. This should be similar to your existing launch template, but instead of the Amazon Linux 2 Amazon ECS-optimized AMI, it should specify one of the Amazon Linux 2023 variants. This new Auto Scaling group can launch instances to your existing cluster.
2. Scale up the Auto Scaling group so that you begin to have Amazon Linux 2023 instances registering to your cluster. Verify that the instances register correctly and that tasks are able to run successfully on the new instances.

3. After your tasks have been verified to work on Amazon Linux 2023, scale up the Amazon Linux 2023 Auto Scaling group while gradually scaling down the Amazon Linux 2 Auto Scaling group, until you have completely replaced all Amazon Linux 2 instances.
4. If you have sufficient Amazon Linux 2023 replacement capacity, you might want to explicitly drain the container instances to speed up the transition of your tasks from Amazon Linux 2 to Amazon Linux 2023. For more information, see [Draining Amazon ECS container instances](#).

## Migrating with manually managed instances

1. Manually launch (or adjust scripts that launch) new Amazon EC2 instances using the Amazon ECS-optimized Amazon Linux 2023 AMI instead of Amazon Linux 2. Ensure these instances use the same security groups, subnets, IAM roles, and cluster configuration as your existing Amazon Linux 2 instances. The instances should automatically register to your existing Amazon ECS cluster upon launch.
2. Verify the new Amazon Linux 2023 instances are successfully registering to your Amazon ECS cluster and are in an ACTIVE state. Test that tasks can be scheduled and run properly on these new instances by either waiting for natural task placement or manually stopping/starting some tasks to trigger rescheduling.
3. Gradually replace your Amazon Linux 2 instances by launching additional Amazon Linux 2023 instances as needed, then manually draining and terminating the Amazon Linux 2 instances one by one. You can drain instances through the Amazon ECS console by setting the instance to DRAINING status, which will stop placing new tasks on it and allow existing tasks to finish or be rescheduled elsewhere.

## Amazon ECS-optimized Linux AMI build script

Amazon ECS has open-sourced the build scripts that are used to build the Linux variants of the Amazon ECS-optimized AMI. These build scripts are now available on GitHub. For more information, see [amazon-ecs-ami](#) on GitHub.

If you need to customize the Amazon ECS-optimized AMI, see [Amazon ECS Optimized AMI Build Recipes](#) on GitHub.

The build scripts repository includes a [HashiCorp packer](#) template and build scripts to generate each of the Linux variants of the Amazon ECS-optimized AMI. These scripts are the source of truth for Amazon ECS-optimized AMI builds, so you can follow the GitHub repository to monitor changes

to our AMIs. For example, perhaps you want your own AMI to use the same version of Docker that the Amazon ECS team uses for the official AMI.

For more information, see the Amazon ECS AMI repository at [aws/amazon-ecs-ami](https://github.com/aws/amazon-ecs-ami) on GitHub.

## To build an Amazon ECS-optimized Linux AMI

1. Clone the `aws/amazon-ecs-ami` GitHub repo.

```
git clone https://github.com/aws/amazon-ecs-ami.git
```

2. Add an environment variable for the AWS Region to use when creating the AMI. Replace the `us-west-2` value with the Region to use.

```
export REGION=us-west-2
```

3. A Makefile is provided to build the AMI. From the root directory of the cloned repository, use one of the following commands, corresponding to the Linux variant of the Amazon ECS-optimized AMI you want to build.

- Amazon ECS-optimized Amazon Linux 2 AMI

```
make al2
```

- Amazon ECS-optimized Amazon Linux 2 (arm64) AMI

```
make al2arm
```

- Amazon ECS GPU-optimized AMI

```
make al2gpu
```

- Amazon ECS optimized Amazon Linux 2 (Neuron) AMI

```
make al2inf
```

- Amazon ECS-optimized Amazon Linux 2023 AMI

```
make al2023
```

- Amazon ECS-optimized Amazon Linux 2023 (arm64) AMI

```
make a12023arm
```

- Amazon ECS-optimized Amazon Linux 2023 GPU AMI

```
make a12023gpu
```

- Amazon ECS optimized Amazon Linux 2023 (Neuron) AMI

```
make a12023neu
```

## Amazon ECS-optimized Bottlerocket AMIs

Bottlerocket is a Linux based open-source operating system that is purpose built by AWS for running containers on virtual machines or bare metal hosts. The Amazon ECS-optimized Bottlerocket AMI is secure and only includes the minimum number of packages that's required to run containers. This improves resource usage, reduces security attack surface, and helps lower management overhead. The Bottlerocket AMI is also integrated with Amazon ECS to help reduce the operational overhead involved in updating container instances in a cluster.

Bottlerocket differs from Amazon Linux in the following ways:

- Bottlerocket doesn't include a package manager, and its software can only be run as containers. Updates to Bottlerocket are both applied and can be rolled back in a single step, which reduces the likelihood of update errors.
- The primary mechanism to manage Bottlerocket hosts is with a container scheduler. Unlike Amazon Linux, logging into individual Bottlerocket instances is intended to be an infrequent operation for advanced debugging and troubleshooting purposes only.

For more information about Bottlerocket, see the [documentation](#) and [releases](#) on GitHub.

There are variants of the Amazon ECS-optimized Bottlerocket AMI for kernel 6.1 and kernel 5.10.

The following variants use kernel 6.1:

- `aws-ecs-2`
- `aws-ecs-2-nvidia`

The following variants use kernel 5.10:

- `aws-ecs-1`
- `aws-ecs-1-nvidia`

For more information about the `aws-ecs-1-nvidia` variant, see [Announcing NVIDIA GPU support for Bottlerocket on Amazon ECS](#).

## Considerations

Consider the following when using a Bottlerocket AMI with Amazon ECS.

- Bottlerocket supports Amazon EC2 instances with `x86_64` and `arm64` processors. The Bottlerocket AMI isn't recommended for use with Amazon EC2 instances with an Inferentia chip.
- Bottlerocket images don't include an SSH server or a shell. However, you can use out-of-band management tools to gain SSH administrator access and perform bootstrapping.

For more information, see these sections in the [bottlerocket README.md](#) on GitHub:

- [Exploration](#)
- [Admin container](#)
- By default, Bottlerocket has a [control container](#) that's enabled. This container runs the [AWS Systems Manager agent](#) that you can use to run commands or start shell sessions on Amazon EC2 Bottlerocket instances. For more information, see [Setting up Session Manager](#) in the *AWS Systems Manager User Guide*.
- Bottlerocket is optimized for container workloads and has a focus on security. Bottlerocket doesn't include a package manager and is immutable.

For information about the security features and guidance, see [Security Features](#) and [Security Guidance](#) on GitHub.

- The `awsvpc` network mode is supported for Bottlerocket AMI version `1.1.0` or later.
- App Mesh in a task definition is supported for Bottlerocket AMI version `1.15.0` or later.
- The `initProcessEnabled` task definition parameter is supported for Bottlerocket AMI version `1.19.0` or later.
- The Bottlerocket AMIs also don't support the following services and features:
  - ECS Anywhere

- Service Connect
- Amazon EFS in encrypted mode
- Amazon EFS in awsvpc network mode
- Amazon EBS volumes can't be mounted
- Elastic Inference Accelerator

## Retrieving Amazon ECS-optimized Bottlerocket AMI metadata

You can retrieve the Amazon Machine Image (AMI) ID for Amazon ECS-optimized AMIs by querying the AWS Systems Manager Parameter Store API. Using this parameter, you don't need to manually look up Amazon ECS-optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see [GetParameter](#). The user that you use must have the `ssm:GetParameter` IAM permission to retrieve the Amazon ECS-optimized AMI metadata.

### aws-ecs-2 Bottlerocket AMI variant

You can retrieve the latest stable `aws-ecs-2` Bottlerocket AMI variant by AWS Region and architecture with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon ECS-optimized Bottlerocket AMI with the following AWS CLI command by using the subparameter `image_id`. Replace the *region* with the Region code that you want the AMI ID for.

For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub. To retrieve a version other than the latest, replace `latest` with the version number.

- For the 64-bit (x86\_64) architecture:

```
aws ssm get-parameter --region us-east-2 --name "/aws/service/bottlerocket/aws-ecs-2/x86_64/latest/image_id" --query Parameter.Value --output text
```

- For the 64-bit Arm (arm64) architecture:

```
aws ssm get-parameter --region us-east-2 --name "/aws/service/bottlerocket/aws-ecs-2/arm64/latest/image_id" --query Parameter.Value --output text
```

- **AWS Management Console** – You can query for the recommended Amazon ECS-optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems

Manager console with the value of the ID for the parameter. In the following URL, replace *region* with the Region code that you want the AMI ID for.

For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub.

- For the 64-bit (x86\_64) architecture:

```
https://console.aws.amazon.com/systems-manager/parameters/aws/service/bottlerocket/
aws-ecs-2/x86_64/latest/image_id/description?region=region#
```

- For the 64-bit Arm (arm64) architecture:

```
https://console.aws.amazon.com/systems-manager/parameters/aws/service/bottlerocket/
aws-ecs-2/arm64/latest/image_id/description?region=region#
```

### aws-ecs-2-nvidia Bottlerocket AMI variant

You can retrieve the latest stable aws-ecs-2-nvidia Bottlerocket AMI variant by Region and architecture with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon ECS-optimized Bottlerocket AMI with the following AWS CLI command by using the subparameter `image_id`. Replace the *region* with the Region code that you want the AMI ID for.

For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub. To retrieve a version other than the latest, replace `latest` with the version number.

- For the 64-bit (x86\_64) architecture:

```
aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-
ecs-2-nvidia/x86_64/latest/image_id" --query Parameter.Value --output text
```

- For the 64 bit Arm (arm64) architecture:

```
aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-
ecs-2-nvidia/arm64/latest/image_id" --query Parameter.Value --output text
```

- **AWS Management Console** – You can query for the recommended Amazon ECS optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace *region* with the Region code that you want the AMI ID for.

For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub.

- For the 64 bit (x86\_64) architecture:

```
https://regionconsole.aws.amazon.com/systems-manager/parameters/aws/service/  
bottlerocket/aws-ecs-2-nvidia/x86_64/latest/image_id/description?region=region#
```

- For the 64 bit Arm (arm64) architecture:

```
https://regionconsole.aws.amazon.com/systems-manager/parameters/aws/service/  
bottlerocket/aws-ecs-2-nvidia/arm64/latest/image_id/description?region=region#
```

### aws-ecs-1 Bottlerocket AMI variant

You can retrieve the latest stable aws-ecs-1 Bottlerocket AMI variant by AWS Region and architecture with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon ECS-optimized Bottlerocket AMI with the following AWS CLI command by using the subparameter `image_id`. Replace the *region* with the Region code that you want the AMI ID for.

For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub. To retrieve a version other than the latest, replace `latest` with the version number.

- For the 64-bit (x86\_64) architecture:

```
aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-  
ecs-1/x86_64/latest/image_id" --query Parameter.Value --output text
```

- For the 64-bit Arm (arm64) architecture:

```
aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-  
ecs-1/arm64/latest/image_id" --query Parameter.Value --output text
```

- **AWS Management Console** – You can query for the recommended Amazon ECS-optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace *region* with the Region code that you want the AMI ID for.

For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub.

- For the 64-bit (x86\_64) architecture:

```
https://region.console.aws.amazon.com/systems-manager/parameters/aws/service/  
bottlerocket/aws-ecs-1/x86_64/latest/image_id/description
```

- For the 64-bit Arm (arm64) architecture:

```
https://region.console.aws.amazon.com/systems-manager/parameters/aws/service/  
bottlerocket/aws-ecs-1/arm64/latest/image_id/description
```

## aws-ecs-1-nvidia Bottlerocket AMI variant

You can retrieve the latest stable aws-ecs-1-nvidia Bottlerocket AMI variant by Region and architecture with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon ECS-optimized Bottlerocket AMI with the following AWS CLI command by using the subparameter `image_id`. Replace the *region* with the Region code that you want the AMI ID for.

For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub.

- For the 64-bit (x86\_64) architecture:

```
aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-  
ecs-1-nvidia/x86_64/latest/image_id" --query Parameter.Value --output text
```

- For the 64 bit Arm (arm64) architecture:

```
aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-  
ecs-1-nvidia/arm64/latest/image_id" --query Parameter.Value --output text
```

- **AWS Management Console** – You can query for the recommended Amazon ECS optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace *region* with the Region code that you want the AMI ID for.

For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub.

- For the 64 bit (x86\_64) architecture:

```
https://console.aws.amazon.com/systems-manager/parameters/aws/service/bottlerocket/  
aws-ecs-1-nvidia/x86_64/latest/image_id/description?region=region#
```

- For the 64 bit Arm (arm64) architecture:

```
https://console.aws.amazon.com/systems-manager/parameters/aws/service/bottlerocket/  
aws-ecs-1-nvidia/arm64/latest/image_id/description?region=region#
```

## Next steps

For a detailed tutorial on how to get started with the Bottlerocket operating system on Amazon ECS, see [Using a Bottlerocket AMI with Amazon ECS](#) on GitHub and [Getting started with Bottlerocket and Amazon ECS](#) on the AWS blog site.

For information about how to launch a Bottlerocket instance, see [Launching a Bottlerocket instance for Amazon ECS](#)

## Launching a Bottlerocket instance for Amazon ECS

You can launch a Bottlerocket instance so that you can run your container workloads.

You can use the AWS CLI to launch the Bottlerocket instance.

1. Create a file that's called `userdata.toml`. This file is used for the instance user data. Replace *cluster-name* with the name of your cluster.

```
[settings.ecs]  
cluster = "cluster-name"
```

2. Use one of the commands that are included in [the section called "Retrieving Amazon ECS-optimized Bottlerocket AMI metadata"](#) to get the Bottlerocket AMI ID. You use this in the following step.
3. Run the following command to launch the Bottlerocket instance. Remember to replace the following parameters:
  - Replace *subnet* with the ID of the private or public subnet that your instance will launch in.
  - Replace *bottlerocket\_ami* with the AMI ID from the previous step.
  - Replace *t3.large* with the instance type that you want to use.

- Replace *region* with the Region code.

```
aws ec2 run-instances --key-name ecs-bottlerocket-example \
  --subnet-id subnet \
  --image-id bottlerocket_ami \
  --instance-type t3.large \
  --region region \
  --tag-specifications
  'ResourceType=instance,Tags=[{Key=bottlerocket,Value=example}]' \
  --user-data file://userdata.toml \
  --iam-instance-profile Name=ecsInstanceRole
```

4. Run the following command to verify that the container instance is registered to the cluster. When you run this command, remember to replace the following parameters:

- Replace *cluster* with your cluster name.
- Replace *region* with your Region code.

```
aws ecs list-container-instances --cluster cluster-name --region region
```

For a detailed walkthrough of how to get started with the Bottlerocket operating system on Amazon ECS, see [Using a Bottlerocket AMI with Amazon ECS](#) on GitHub and [Getting started with Bottlerocket and Amazon ECS](#) on the AWS blog site.

## Amazon ECS Linux container instance management

When you use EC2 instances for your Amazon ECS workloads, you are responsible for maintaining the instances

### Management procedures

- [Launching an Amazon ECS Linux container instance](#)
- [Bootstrapping Amazon ECS Linux container instances to pass data](#)
- [Configuring Amazon ECS Linux container instances to receive Spot Instance notices](#)
- [Running a script when you launch an Amazon ECS Linux container instance](#)
- [Increasing Amazon ECS Linux container instance network interfaces](#)
- [Reserving Amazon ECS Linux container instance memory](#)

- [Managing Amazon ECS container instances remotely using AWS Systems Manager](#)
- [Using an HTTP proxy for Amazon ECS Linux container instances](#)
- [Configuring pre-initialized instances for your Amazon ECS Auto Scaling group](#)
- [Updating the Amazon ECS container agent](#)

Each Amazon ECS container agent version supports a different feature set and provides bug fixes from previous versions. When possible, we always recommend using the latest version of the Amazon ECS container agent. To update your container agent to the latest version, see [Updating the Amazon ECS container agent](#).

To see which features and enhancements are included with each agent release, see <https://github.com/aws/amazon-ecs-agent/releases>.

#### Important

The minimum Docker version for reliable metrics is Docker version v20.10.13 and newer, which is included in Amazon ECS-optimized AMI 20220607 and newer.

Amazon ECS agent versions 1.20.0 and newer have deprecated support for Docker versions older than 18.01.0.

## Launching an Amazon ECS Linux container instance

You can create Amazon ECS container instances using the Amazon EC2 console.

You can launch an instance by various methods including the Amazon EC2 console, AWS CLI, and SDK. For information about the other methods for launching an instance, see [Launch your instance](#) in the *Amazon EC2 User Guide*.

For more information about the launch wizard, see [Launch an instance using the new launch instance wizard](#) in the *Amazon EC2 User Guide*.

Before you begin, complete the steps in [Set up to use Amazon ECS](#).

You can use the new Amazon EC2 wizard to launch an instance. The launch instance wizard specifies the launch parameters that are required for launching an instance.

## Parameters for instance configuration

- [Procedure](#)
- [Name and tags](#)
- [Application and OS Images \(Amazon Machine Image\)](#)
- [Instance type](#)
- [Key pair \(login\)](#)
- [Network settings](#)
- [Configure storage](#)
- [Advanced details](#)

## Procedure

Before you begin, complete the steps in [Set up to use Amazon ECS](#).

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.

## Name and tags

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. You can tag the instance, the volumes, and elastic graphics. For Spot Instances, you can tag the Spot Instance request only.

Specifying an instance name and additional tags is optional.

- For **Name**, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
- To add additional tags, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

## Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Apache, and your website.

Use the **Search** bar to find a suitable Amazon ECS-optimized AMI published by AWS.

1. Enter one of the following terms in the **Search** bar.

- **ami-ecs**
- The **Value** of an Amazon ECS-optimized AMI.

For the latest Amazon ECS-optimized AMIs and their values, see [Linux Amazon ECS-optimized AMI](#).

2. Press **Enter**.

3. On the **Choose an Amazon Machine Image (AMI)** page, select the **AWS Marketplace AMIs** tab.

4. From the left **Refine results** pane, select **Amazon Web Services** as the **Publisher**.

5. Choose **Select** on the row of the AMI that you want to use.

Alternatively, choose **Cancel** to return to the launch instance wizard without choosing an AMI.

A default AMI will be selected. Ensure that the AMI meets the requirements outlined in [Amazon ECS-optimized Linux AMIs](#).

## Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see [Instance types](#) in the *Amazon EC2 User Guide*. If you want to run an IPv6-only workload, certain instance types don't support IPv6 addresses. For more information, see [IPv6 addresses](#) in the *Amazon EC2 User Guide*.

- For **Instance type**, select the instance type for the instance.

The instance type that you select determines the resources available for your tasks to run on.

## Key pair (login)

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one.

### Important

If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

## Network settings

Configure the network settings as necessary after choosing the **Edit** button for the **Network settings** section of the form.

- For **VPC**, choose the VPC that you want to launch the instance into. To run an IPv6-only workload, choose a dual stack VPC that includes both an IPv4 and an IPv6 CIDR block.
- For **Subnet**, choose the subnet to launch the instance in. You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the launch instance wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

To run an IPv6-only workload, choose a subnet that includes only an IPv6 CIDR block.

- **Auto-assign Public IP**: If your instance should be accessible from the internet, verify that the **Auto-assign Public IP** field is set to **Enable**. If not, set this field to **Disable**.

### Note

Container instances need access to communicate with the Amazon ECS service endpoint. This can be through an interface VPC endpoint or through your container instances having public IP addresses.

For more information about interface VPC endpoints, see [Amazon ECS interface VPC endpoints \(AWS PrivateLink\)](#)

If you do not have an interface VPC endpoint configured and your container instances do not have public IP addresses, then they must use network address translation (NAT) to provide this access. For more information, see [NAT gateways](#) in the *Amazon VPC User Guide* and [Using an HTTP proxy for Amazon ECS Linux container instances](#) in this guide.

- If you choose a dual stack VPC and an IPv6-only subnet, for **Auto-assign IPv6 IP**, choose **Enable**.

- **Firewall (security groups):** Use a security group to define firewall rules for your container instance. These rules specify which incoming network traffic is delivered to your container instance. All other traffic is ignored.
  - To select an existing security group, choose **Select existing security group**, and select the security group that you created in [Set up to use Amazon ECS](#).
- If you are launching the instance for an IPv6-only workload, choose **Advanced network configuration**, and then for **Assign Primary IPv6 IP**, choose **Yes**.

#### Note

Without a primary IPv6 address, tasks running on the container instance in the host or bridge network modes will fail to register with load balancers or with AWS Cloud Map.

## Configure storage

The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

You can use the **Simple** view.

- **Storage type:** Configure the storage for your container instance.

If you are using the Amazon ECS-optimized Amazon Linux 2 AMI, your instance has a single 30 GiB volume configured, which is shared between the operating system and Docker.

If you are using the Amazon ECS-optimized AMI, your instance has two volumes configured. The **Root** volume is for the operating system's use, and the second Amazon EBS volume (attached to `/dev/xvdcz`) is for Docker's use.

You can optionally increase or decrease the volume sizes for your instance to meet your application needs.

## Advanced details

For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option:** Choose **Request Spot Instances** to request Spot Instances. You also need to set the other fields related to Spot Instances. For more information, see [Spot Instance Requests](#).

 **Note**

If you are using Spot Instances and see a Not available message, you may need to choose a different instance type.

- **IAM instance profile:** Select your container instance IAM role. This is usually named `ecsInstanceRole`.

 **Important**

If you do not launch your container instance with the proper IAM permissions, your Amazon ECS agent cannot connect to your cluster. For more information, see [Amazon ECS container instance IAM role](#).

- **User data:** Configure your Amazon ECS container instance with user data, such as the agent environment variables from [Amazon ECS container agent configuration](#). Amazon EC2 user data scripts are executed only one time, when the instance is first launched. The following are common examples of what user data is used for:
  - By default, your container instance launches into your default cluster. To launch into a non-default cluster, choose the **Advanced Details** list. Then, paste the following script into the **User data** field, replacing *your\_cluster\_name* with the name of your cluster.

```
#!/bin/bash
echo ECS_CLUSTER=your_cluster_name >> /etc/ecs/ecs.config
```

- If you have an `ecs.config` file in Amazon S3 and have enabled Amazon S3 read-only access to your container instance role, choose the **Advanced Details** list. Then, paste the following script into the **User data** field. Replace *your-cluster-name* with your cluster name. Replace *amzn-s3-demo-bucket* with your bucket name.

 **Note**

For more information about this configuration, see [Storing Amazon ECS container instance configuration in Amazon S3](#).

```
#!/bin/bash -e
# Shut down after a user data failure.
# Set InstanceInitiatedShutdownBehavior=terminate in the launch template to
  terminate the instance.
trap 'status=$?; if [ "$status" -ne 0 ]; then shutdown -h now; fi' EXIT

# Set the cluster before any command that can fail.
echo ECS_CLUSTER=your-cluster-name >> /etc/ecs/ecs.config
yum install -y aws-cli
aws s3 cp s3://amzn-s3-demo-bucket/ecs.config /tmp/ecs.config
sed -i '/^ECS_CLUSTER=/d' /tmp/ecs.config
echo ECS_CLUSTER=your-cluster-name >> /tmp/ecs.config
install -m 0644 /tmp/ecs.config /etc/ecs/ecs.config
```

- Specify tags for your container instance using the ECS\_CONTAINER\_INSTANCE\_TAGS configuration parameter. This creates tags that are associated with Amazon ECS only, they cannot be listed using the Amazon EC2 API.

### Important

If you launch your container instances using an Amazon EC2 Auto Scaling group, then you should use the ECS\_CONTAINER\_INSTANCE\_TAGS agent configuration parameter to add tags. This is due to the way in which tags are added to Amazon EC2 instances that are launched using Auto Scaling groups.

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=your_cluster_name
ECS_CONTAINER_INSTANCE_TAGS={"tag_key": "tag_value"}
EOF
```

- Specify tags for your container instance and then use the ECS\_CONTAINER\_INSTANCE\_PROPAGATE\_TAGS\_FROM configuration parameter to propagate them from Amazon EC2 to Amazon ECS

The following is an example of a user data script that would propagate the tags associated with a container instance, as well as register the container instance with a cluster named `your_cluster_name`:

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=your_cluster_name
ECS_CONTAINER_INSTANCE_PROPAGATE_TAGS_FROM=ec2_instance
EOF
```

- By default, the Amazon ECS container agent will try to detect the container instance's compatibility for an IPv6-only configuration by looking at the instance's default IPv4 and IPv6 routes. To override this behavior, you can set the `ECS_INSTANCE_IP_COMPATIBILITY` parameter to `ipv4` or `ipv6` in the instance's `/etc/ecs/ecs.config` file.

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=your_cluster_name
ECS_INSTANCE_IP_COMPATIBILITY=ipv6
EOF
```

For more information, see [Bootstrapping Amazon ECS Linux container instances to pass data](#).

## Bootstrapping Amazon ECS Linux container instances to pass data

When you launch an Amazon EC2 instance, you can pass user data to the EC2 instance. The data can be used to perform common automated configuration tasks and even run scripts when the instance boots. For Amazon ECS, the most common use cases for user data are to pass configuration information to the Docker daemon and the Amazon ECS container agent.

You can pass multiple types of user data to Amazon EC2, including cloud boothooks, shell scripts, and `cloud-init` directives. For more information about these and other format types, see the [Cloud-Init documentation](#).

To pass the user data when using the Amazon EC2 launch wizard, see [Launching an Amazon ECS Linux container instance](#).

You can configure the container instance to pass data in the container agent configuration or in the Docker daemon configuration.

### Amazon ECS container agent

The Linux variants of the Amazon ECS-optimized AMI look for agent configuration data in the `/etc/ecs/ecs.config` file when the container agent starts. You can specify this configuration

data at launch with Amazon EC2 user data. For more information about available Amazon ECS container agent configuration variables, see [Amazon ECS container agent configuration](#).

To set only a single agent configuration variable, such as the cluster name, use **echo** to copy the variable to the configuration file:

```
#!/bin/bash
echo "ECS_CLUSTER=MyCluster" >> /etc/ecs/ecs.config
```

If you have multiple variables to write to `/etc/ecs/ecs.config`, use the following heredoc format. This format writes everything between the lines beginning with **cat** and EOF to the configuration file.

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_ENGINE_AUTH_TYPE=docker
ECS_ENGINE_AUTH_DATA={"https://index.docker.io/v1/":
  {"username":"my_name","password":"my_password","email":"email@example.com"}}
ECS_LOGLEVEL=debug
ECS_WARM_POOLS_CHECK=true
EOF
```

To set custom instance attributes, set the `ECS_INSTANCE_ATTRIBUTES` environment variable.

```
#!/bin/bash
cat <<'EOF' >> ecs.config
ECS_INSTANCE_ATTRIBUTES={"envtype":"prod"}
EOF
```

## Docker daemon

You can specify Docker daemon configuration information with Amazon EC2 user data. For more information about configuration options, see [the Docker daemon documentation](#).

### Note

AWS doesn't support custom Docker configurations, because they can sometimes conflict with future Amazon ECS changes or features without warning.

In the following example, the custom options are added to the Docker daemon configuration file, `/etc/docker/daemon.json` which is then specified in the user data when the instance is launched.

```
#!/bin/bash
cat <<EOF >/etc/docker/daemon.json
{"debug": true}
EOF
systemctl restart docker --no-block
```

In the following example, the custom options are added to the Docker daemon configuration file, `/etc/docker/daemon.json` which is then specified in the user data when the instance is launched. This example shows how to disable the Docker-proxy in the Docker daemon config file.

```
#!/bin/bash
cat <<EOF >/etc/docker/daemon.json
{"userland-proxy": false}
EOF
systemctl restart docker --no-block
```

## Configuring Amazon ECS Linux container instances to receive Spot Instance notices

Amazon EC2 terminates, stops, or hibernates your Spot Instance when the Spot price exceeds the maximum price for your request or capacity is no longer available. Amazon EC2 provides a Spot Instance two-minute interruption notice for terminate and stop actions. It does not provide the two-minute notice for the hibernate action. If Amazon ECS Spot Instance draining is turned on on the instance, Amazon ECS receives the Spot Instance interruption notice and places the instance in DRAINING status.

### Important

Amazon ECS does not receive a notice from Amazon EC2 when instances are removed by Auto Scaling Capacity Rebalancing. For more information, see [Amazon EC2 Auto Scaling Capacity Rebalancing](#).

When a container instance is set to DRAINING, Amazon ECS prevents new tasks from being scheduled for placement on the container instance. Service tasks on the draining container

instance that are in the PENDING state are stopped immediately. If there are container instances in the cluster that are available, replacement service tasks are started on them.

Spot Instance draining is turned off by default.

You can turn on Spot Instance draining when you launch an instance. Add the following script into the **User data** field. Replace *MyCluster* with the name of the cluster to register the container instance to.

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_ENABLE_SPOT_INSTANCE_DRAINING=true
EOF
```

For more information, see [Launching an Amazon ECS Linux container instance](#).

### To turn on Spot Instance draining for an existing container instance

1. Connect to the Spot Instance over SSH.
2. Edit the `/etc/ecs/ecs.config` file and add the following:

```
ECS_ENABLE_SPOT_INSTANCE_DRAINING=true
```

3. Restart the `ecs` service.
  - For the Amazon ECS-optimized Amazon Linux 2 AMI:

```
sudo systemctl restart ecs
```

4. (Optional) You can verify that the agent is running and see some information about your new container instance by querying the agent introspection API operation. For more information, see [the section called "Container introspection"](#).

```
curl http://localhost:51678/v1/metadata
```

### Running a script when you launch an Amazon ECS Linux container instance

You might need to run a specific container on every container instance to deal with operations or security concerns such as monitoring, security, metrics, service discovery, or logging.

To do this, you can configure your container instances to call the **docker run** command with the user data script at launch, or in some init system such as Upstart or **systemd**. While this method works, it has some disadvantages because Amazon ECS has no knowledge of the container and cannot monitor the CPU, memory, ports, or any other resources used. To ensure that Amazon ECS can properly account for all task resources, create a task definition for the container to run on your container instances. Then, use Amazon ECS to place the task at launch time with Amazon EC2 user data.

The Amazon EC2 user data script in the following procedure uses the Amazon ECS introspection API to identify the container instance. Then, it uses the AWS CLI and the **start-task** command to run a specified task on itself during startup.

### To start a task at container instance launch time

1. Modify your `ecsInstanceRole` IAM role to add permissions for the `StartTask` API operation. For more information, see [Update permissions for a role](#) in the *AWS Identity and Access Management User Guide*.
2. Launch one or more container instances using the Amazon ECS-optimized Amazon Linux 2 AMI. Launch new container instances and use the following example script in the EC2 User data. Replace *your\_cluster\_name* with the cluster for the container instance to register into and *my\_task\_def* with the task definition to run on the instance at launch.

For more information, see [Launching an Amazon ECS Linux container instance](#).

#### Note

The following MIME multi-part content uses a shell script to set configuration values and install packages. It also uses a `systemd` job to start the task after the `ecs` service is running and the introspection API is available.

```
Content-Type: multipart/mixed; boundary=="==BOUNDARY=="
MIME-Version: 1.0
```

```
--==BOUNDARY==
```

```
Content-Type: text/x-shellscript; charset="us-ascii"
```

```
#!/bin/bash
```

```
# Specify the cluster that the container instance should register into
```

```
cluster=your_cluster_name

# Write the cluster configuration variable to the ecs.config file
# (add any other configuration variables here also)
echo ECS_CLUSTER=$cluster >> /etc/ecs/ecs.config

START_TASK_SCRIPT_FILE="/etc/ecs/ecs-start-task.sh"
cat <<- 'EOF' > ${START_TASK_SCRIPT_FILE}
  exec 2>>/var/log/ecs/ecs-start-task.log
  set -x

# Install prerequisite tools
yum install -y jq aws-cli

# Wait for the ECS service to be responsive
until curl -s http://localhost:51678/v1/metadata
do
  sleep 1
done

# Grab the container instance ARN and AWS Region from instance metadata
instance_arn=$(curl -s http://localhost:51678/v1/metadata | jq -r '.
| .ContainerInstanceArn' | awk -F/ '{print $NF}' )
cluster=$(curl -s http://localhost:51678/v1/metadata | jq -r '. | .Cluster' | awk
-F/ '{print $NF}' )
region=$(curl -s http://localhost:51678/v1/metadata | jq -r '.
| .ContainerInstanceArn' | awk -F: '{print $4}')
```

```
# Specify the task definition to run at launch
task_definition=my_task_def

# Run the AWS CLI start-task command to start your task on this container instance
aws ecs start-task --cluster $cluster --task-definition $task_definition --
container-instances $instance_arn --started-by $instance_arn --region $region
EOF

# Write systemd unit file
UNIT="ecs-start-task.service"
cat <<- EOF > /etc/systemd/system/${UNIT}
  [Unit]
  Description=ECS Start Task
  Requires=ecs.service
  After=ecs.service
```

```

[Service]
Restart=on-failure
RestartSec=30
ExecStart=/usr/bin/bash ${START_TASK_SCRIPT_FILE}

[Install]
WantedBy=default.target
EOF

# Enable our ecs.service dependent service with `--no-block` to prevent systemd
# deadlock
# See https://github.com/aws/amazon-ecs-agent/issues/1707
systemctl enable --now --no-block "${UNIT}"
--==BOUNDARY==--

```

3. Verify that your container instances launch into the correct cluster and that your tasks have started.
  - a. Open the console at <https://console.aws.amazon.com/ecs/v2>.
  - b. From the navigation bar, choose the Region that your cluster is in.
  - c. In the navigation pane, choose **Clusters** and select the cluster that hosts your container instances.
  - d. On the **Cluster** page, choose **Tasks**, and then choose your tasks.

Each container instance you launched should have your task running on it.

If you do not see your tasks, you can log in to your container instances with SSH and check the `/var/log/ecs/ecs-start-task.log` file for debugging information.

## Increasing Amazon ECS Linux container instance network interfaces

### Note

This feature is not available on Fargate.

Each task that uses the `awsvpc` network mode receives its own elastic network interface (ENI), which is attached to the container instance that hosts it. There is a default limit to the number of network interfaces that can be attached to an Amazon EC2 instance, and the primary network interface counts as one. For example, by default a `c5.large` instance may have up to three ENIs

attached to it. The primary network interface for the instance counts as one, so you can attach an additional two ENIs to the instance. Because each task using the `awsvpc` network mode requires an ENI, you can typically only run two such tasks on this instance type.

Amazon ECS supports launching container instances with increased ENI density using supported Amazon EC2 instance types. When you use these instance types and turn on the `awsvpcTrunking` account setting, additional ENIs are available on newly launched container instances. This configuration allows you to place more tasks on each container instance. To use the console to turn on the feature, see [Modifying Amazon ECS account settings](#). To use the AWS CLI to turn on the feature, see [Managing Amazon ECS account settings using the AWS CLI](#).

For example, a `c5.large` instance with `awsvpcTrunking` has an increased ENI limit of twelve. The container instance will have the primary network interface and Amazon ECS creates and attaches a "trunk" network interface to the container instance. So this configuration allows you to launch ten tasks on the container instance instead of the current two tasks.

The trunk network interface is fully managed by Amazon ECS and is deleted when you either terminate or deregister your container instance from the cluster. For more information, see [Amazon ECS task networking options for EC2](#).

## Considerations

Consider the following when using the ENI trunking feature.

- Only Linux variants of the Amazon ECS-optimized AMI, or other Amazon Linux variants with version `1.28.1` or later of the container agent and version `1.28.1-2` or later of the `ecs-init` package, support the increased ENI limits. If you use the latest Linux variant of the Amazon ECS-optimized AMI, these requirements will be met. Windows containers are not supported at this time.
- Only new Amazon EC2 instances launched after enabling `awsvpcTrunking` receive the increased ENI limits and the trunk network interface. Previously launched instances do not receive these features regardless of the actions taken.
- Amazon EC2 instances must have resource-based IPv4 DNS requests turned off. To disable this option, clear the **Enable resource-based IPV4 (A record) DNS requests** option when you create a new instance in the Amazon EC2 console. To disable this option using the AWS CLI, use the following command.

```
aws ec2 modify-private-dns-name-options --instance-id i-xxxxxxx --no-enable-resource-name-dns-a-record --no-dry-run
```

- Amazon EC2 instances in shared subnets are not supported. They will fail to register to a cluster if they are used.
- Your tasks must use the `awsvpc` network mode and the EC2. Tasks using Fargate always received a dedicated ENI regardless of how many are launched, so this feature is not needed.
- Your tasks must be launched in the same Amazon VPC as your container instance. Your tasks will fail to start with an attribute error if they are not within the same VPC.
- When launching a new container instance, the instance transitions to a `REGISTERING` status while the trunk elastic network interface is provisioned for the instance. If the registration fails, the instance transitions to a `REGISTRATION_FAILED` status. You can troubleshoot a failed registration by describing the container instance to view the `statusReason` field which describes the reason for the failure. The container instance then can be manually deregistered or terminated. Once the container instance is successfully deregistered or terminated, Amazon ECS will delete the trunk ENI.

 **Note**

Amazon ECS emits container instance state change events which you can monitor for instances that transition to a `REGISTRATION_FAILED` state. For more information, see [Amazon ECS container instance state change events](#).

- Once the container instance is terminated, the instance transitions to a `DEREGISTERING` status while the trunk elastic network interface is deprovisioned. The instance then transitions to an `INACTIVE` status.
- If a container instance in a public subnet with the increased ENI limits is stopped and then restarted, the instance loses its public IP address, and the container agent loses its connection.
- When you enable `awsvpcTrunking`, container instances receive an additional ENI that uses the VPC's default security group, and is managed by Amazon ECS.

A default VPC comes with a public subnet in each Availability Zone, an internet gateway, and settings to enable DNS resolution. The subnet is a public subnet, because the main route table sends the subnet's traffic that is destined for the internet to the internet gateway. You can make a default subnet into a private subnet by removing the route from the destination `0.0.0.0/0` to the internet gateway. However, if you do this, no container instance running in that subnet can access the internet. You can add or delete security group rules to control the traffic into and out of your subnets. For more information, see [Security group rules](#) in the *Amazon Virtual Private Cloud User Guide*.

## Prerequisites

Before you launch a container instance with the increased ENI limits, the following prerequisites must be completed.

- The service-linked role for Amazon ECS must be created. The Amazon ECS service-linked role provides Amazon ECS with the permissions to make calls to other AWS services on your behalf. This role is created for you automatically when you create a cluster, or if you create or update a service in the AWS Management Console. For more information, see [Using service-linked roles for Amazon ECS](#). You can also create the service-linked role with the following AWS CLI command.

```
aws iam create-service-linked-role --aws-service-name ecs.amazonaws.com
```

- Your account or container instance IAM role must enable the `awsvpcTrunking` account setting. We recommend that you create 2 container instance roles (`ecsInstanceRole`). You can then enable the `awsvpcTrunking` account setting for one role and use that role for tasks that require ENI trunking. For information about the container instance role, see [Amazon ECS container instance IAM role](#).

After the prerequisites are met, you can launch a new container instance using one of the supported Amazon EC2 instance types, and the instance will have the increased ENI limits. For a list of supported instance types, see [Supported instances for increased Amazon ECS container network interfaces](#). The container instance must have version 1.28.1 or later of the container agent and version 1.28.1-2 or later of the `ecs-init` package. If you use the latest Linux variant of the Amazon ECS-optimized AMI, these requirements will be met. For more information, see [Launching an Amazon ECS Linux container instance](#).

### Important

Amazon EC2 instances must have resource-based IPv4 DNS requests turned off. To disable this option, ensure the **Enable resource-based IPV4 (A record) DNS requests** option is deselected when creating a new instance using the Amazon EC2 console. To disable this option using the AWS CLI, use the following command.

```
aws ec2 modify-private-dns-name-options --instance-id i-xxxxxxx --no-enable-resource-name-dns-a-record --no-dry-run
```

## To view your container instances with increased ENI limits with the AWS CLI

Each container instance has a default network interface, referred to as a trunk network interface. Use the following command to list your container instances with increased ENI limits by querying for the `ecs.aws-vpc-trunk-id` attribute, which indicates it has a trunk network interface.

- [list-attributes](#) (AWS CLI)

```
aws ecs list-attributes \
    --target-type container-instance \
    --attribute-name ecs.aws-vpc-trunk-id \
    --cluster cluster_name \
    --region us-east-1
```

- [Get-ECSAttributeList](#) (AWS Tools for Windows PowerShell)

```
Get-ECSAttributeList -TargetType container-instance -AttributeName ecs.aws-vpc-trunk-id -Region us-east-1
```

## Supported instances for increased Amazon ECS container network interfaces

The following shows the supported Amazon EC2 instance types and how many tasks using the `aws-vpc` network mode can be launched on each instance type before and after enabling the `aws-vpc-trunking` account setting.

### Important

Although other instance types are supported in the same instance family, the `a1.metal`, `c5.metal`, `c5a.8xlarge`, `c5ad.8xlarge`, `c5d.metal`, `m5.metal`, `p3dn.24xlarge`, `r5.metal`, `r5.8xlarge`, and `r5d.metal` instance types are not supported. The `c5n`, `d3`, `d3en`, `g3`, `g3s`, `g4dn`, `i3`, `i3en`, `inf1`, `m5dn`, `m5n`, `m5zn`, `mac1`, `r5b`, `r5n`, `r5dn`, `u-12tb1`, `u-6tb1`, `u-9tb1`, and `z1d` instance families are not supported.

## General purpose

| Instance type | Task limit without ENI trunking | Task limit with ENI trunking |
|---------------|---------------------------------|------------------------------|
| a1.medium     | 1                               | 10                           |
| a1.large      | 2                               | 10                           |
| a1.xlarge     | 3                               | 20                           |
| a1.2xlarge    | 3                               | 40                           |
| a1.4xlarge    | 7                               | 60                           |
| m5.large      | 2                               | 10                           |
| m5.xlarge     | 3                               | 20                           |
| m5.2xlarge    | 3                               | 40                           |
| m5.4xlarge    | 7                               | 60                           |
| m5.8xlarge    | 7                               | 60                           |
| m5.12xlarge   | 7                               | 60                           |
| m5.16xlarge   | 14                              | 120                          |
| m5.24xlarge   | 14                              | 120                          |
| m5a.large     | 2                               | 10                           |
| m5a.xlarge    | 3                               | 20                           |
| m5a.2xlarge   | 3                               | 40                           |

| Instance type | Task limit without ENI trunking | Task limit with ENI trunking |
|---------------|---------------------------------|------------------------------|
| m5a.4xlarge   | 7                               | 60                           |
| m5a.8xlarge   | 7                               | 60                           |
| m5a.12xlarge  | 7                               | 60                           |
| m5a.16xlarge  | 14                              | 120                          |
| m5a.24xlarge  | 14                              | 120                          |
| m5ad.large    | 2                               | 10                           |
| m5ad.xlarge   | 3                               | 20                           |
| m5ad.2xlarge  | 3                               | 40                           |
| m5ad.4xlarge  | 7                               | 60                           |
| m5ad.8xlarge  | 7                               | 60                           |
| m5ad.12xlarge | 7                               | 60                           |
| m5ad.16xlarge | 14                              | 120                          |
| m5ad.24xlarge | 14                              | 120                          |
| m5d.large     | 2                               | 10                           |
| m5d.xlarge    | 3                               | 20                           |
| m5d.2xlarge   | 3                               | 40                           |
| m5d.4xlarge   | 7                               | 60                           |
| m5d.8xlarge   | 7                               | 60                           |
| m5d.12xlarge  | 7                               | 60                           |
| m5d.16xlarge  | 14                              | 120                          |

| Instance type | Task limit without ENI trunking | Task limit with ENI trunking |
|---------------|---------------------------------|------------------------------|
