| trn2.48xlarge      | 31                              | 242                          |
| trn2u.48xlarge     | 31                              | 242                          |
| vt1.3xlarge        | 3                               | 40                           |
| vt1.6xlarge        | 7                               | 60                           |
| vt1.24xlarge       | 14                              | 120                          |

## High performance computing

| Instance type  | Task limit without ENI trunking | Task limit with ENI trunking |
|----------------|---------------------------------|------------------------------|
| hpc6a.48xlarge | 1                               | 120                          |

| Instance type   | Task limit without ENI trunking | Task limit with ENI trunking |
|-----------------|---------------------------------|------------------------------|
| hpc6id.32xlarge | 1                               | 120                          |
| hpc7g.4xlarge   | 3                               | 120                          |
| hpc7g.8xlarge   | 3                               | 120                          |
| hpc7g.16xlarge  | 3                               | 120                          |
| hpc8a.96xlarge  | 3                               | -2                           |

## Reserving Amazon ECS Linux container instance memory

When the Amazon ECS container agent registers a container instance to a cluster, the agent must determine how much memory the container instance has available to reserve for your tasks. Because of platform memory overhead and memory occupied by the system kernel, this number is different than the installed memory amount that is advertised for Amazon EC2 instances. For example, an `m4.large` instance has 8 GiB of installed memory. However, this does not always translate to exactly 8192 MiB of memory available for tasks when the container instance registers.

## ECS Managed Instances memory resource determination

Amazon ECS Managed Instances uses a hierarchical approach to determine memory resource requirements for tasks. Unlike ECS on EC2 which relies on Docker's memory introspection, ECS Managed Instances calculates memory requirements directly from the task payload during scheduling decisions.

When the ECS Managed Instances agent receives a task, it calculates the memory requirement using the following priority order:

- 1. Task-level memory (highest priority)** - If task-level memory is specified in the task definition, the agent uses this value directly. This takes precedence over all container-level memory settings.
- 2. Container-level memory sum (fallback)** - If task-level memory is not specified (or is 0), the agent sums the memory requirements from all containers in the task. For each container, it uses:
  - a. *Memory reservation (soft limit)*** - If a container specifies `memoryReservation` in its configuration, the agent uses this value.

- b. *Container memory (hard limit)* - If `memoryReservation` is not specified, the agent uses the container's memory field.

### Example Task-level memory specified

When task-level memory is specified, it takes precedence over container-level settings:

```
{
  "family": "my-task",
  "memory": "2048",
  "containerDefinitions": [
    {
      "name": "container1",
      "memory": 1024,
      "memoryReservation": 512
    }
  ]
}
```

The agent reserves 2048 MiB (task-level memory takes precedence).

### Example Container-level memory with reservations

When task-level memory is not specified, the agent sums container memory requirements:

```
{
  "family": "my-task",
  "containerDefinitions": [
    {
      "name": "container1",
      "memory": 1024,
      "memoryReservation": 512
    },
    {
      "name": "container2",
      "memory": 512
    }
  ]
}
```

The agent reserves 512 MiB (container1 reservation) + 512 MiB (container2 memory) = 1024 MiB total.

The ECS Managed Instances agent performs memory calculation in three phases:

1. **Task reception** - When a task payload arrives from the ECS control plane, the agent immediately calculates the required memory.
2. **Resource storage** - The calculated memory requirement is stored in the task model for later use in resource accounting operations.
3. **Scheduling decision** - Before accepting a task, the agent checks if sufficient memory is available. If insufficient memory is available, the task is rejected and remains in the ECS service queue until resources become available.

 **Note**

Unlike ECS on EC2, ECS Managed Instances does not use the `ECS_RESERVED_MEMORY` configuration variable. Memory reservation for system processes is handled through the underlying platform's resource management, and the agent performs accurate resource accounting based on task definitions.

For ECS on EC2, the Amazon ECS container agent provides a configuration variable called `ECS_RESERVED_MEMORY`, which you can use to remove a specified number of MiB of memory from the pool that is allocated to your tasks. This effectively reserves that memory for critical system processes.

If you occupy all of the memory on a container instance with your tasks, then it is possible that your tasks will contend with critical system processes for memory and possibly start a system failure.

For example, if you specify `ECS_RESERVED_MEMORY=256` in your container agent configuration file, then the agent registers the total memory minus 256 MiB for that instance, and 256 MiB of memory could not be allocated by ECS tasks. For more information about agent configuration variables and how to set them, see [Amazon ECS container agent configuration](#) and [Bootstrapping Amazon ECS Linux container instances to pass data](#).

If you specify 8192 MiB for the task, and none of your container instances have 8192 MiB or greater of memory available to satisfy this requirement, then the task cannot be placed in your cluster. If you are using a managed compute environment, then AWS Batch must launch a larger instance type to accommodate the request.

The Amazon ECS container agent uses the `Docker ReadMemInfo()` function to query the total memory available to the operating system. Both Linux and Windows provide command line utilities to determine the total memory.

### Example- Determine Linux total memory

The **free** command returns the total memory that is recognized by the operating system.

```
$ free -b
```

Example output for an `m4.large` instance running the Amazon ECS-optimized Amazon Linux AMI.

|                    | total             | used      | free       | shared | buffers  | cached    |
|--------------------|-------------------|-----------|------------|--------|----------|-----------|
| Mem:               | <b>8373026816</b> | 348180480 | 8024846336 | 90112  | 25534464 | 205418496 |
| -/+ buffers/cache: |                   | 117227520 | 8255799296 |        |          |           |

This instance has 8373026816 bytes of total memory, which translates to 7985 MiB available for tasks.

### Example- Determine Windows total memory

The **wmic** command returns the total memory that is recognized by the operating system.

```
C:\> wmic ComputerSystem get TotalPhysicalMemory
```

Example output for an `m4.large` instance running the Amazon ECS-optimized Windows Server AMI.

```
TotalPhysicalMemory  
8589524992
```

This instance has 8589524992 bytes of total memory, which translates to 8191 MiB available for tasks.

### Viewing container instance memory

You can view how much memory a container instance registers with in the Amazon ECS console (or with the [DescribeContainerInstances](#) API operation). If you are trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, you can observe the memory available for that container instance and then assign your tasks that much memory.

## To view container instance memory

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**, and then choose the cluster that hosts your container instance.
3. Choose **Infrastructure**, and then under Container instances, choose a container instance.
4. The **Resources** section shows the registered and available memory for the container instance.

The **Registered** memory value is what the container instance; registered with Amazon ECS when it was first launched, and the **Available** memory value is what has not already been allocated to tasks.

## Managing Amazon ECS container instances remotely using AWS Systems Manager

You can use the Run Command capability in AWS Systems Manager (Systems Manager) to securely and remotely manage the configuration of your Amazon ECS container instances. Run Command provides a simple way to perform common administrative tasks without logging on locally to the instance. You can manage configuration changes across your clusters by simultaneously executing commands on multiple container instances. Run Command reports the status and results of each command.

Here are some examples of the types of tasks you can perform with Run Command:

- Install or uninstall packages.
- Perform security updates.
- Clean up Docker images.
- Stop or start services.
- View system resources.
- View log files.
- Perform file operations.

For more information about Run Command, see [AWS Systems Manager Run Command](#) in the *AWS Systems Manager User Guide*.

The following are prerequisites to using Systems Manager with Amazon ECS.

1. You must grant the container instance role (**ecsInstanceRole**) permissions to access the Systems Manager APIs. You can do this by assigning the **AmazonSSMManagedInstanceCore** to the `ecsInstanceRole` role. For information about how to attach a policy to a role, see [Update permissions for a role](#) in the *AWS Identity and Access Management User Guide*
2. Verify that SSM Agent is installed on your container instances. For more information, see [Manually installing and uninstalling SSM Agent on EC2 instances for Linux](#).

After you attach Systems Manager managed policies to your `ecsInstanceRole` and verify that AWS Systems Manager Agent (SSM Agent) is installed on your container instances, you can start using Run Command to send commands to your container instances. For information about running commands and shell scripts on your instances and viewing the resulting output, see [Running Commands Using Systems Manager Run Command](#) and [Run Command Walkthroughs](#) in the *AWS Systems Manager User Guide*.

A common use case is to update container instance software with Run Command. You can follow the procedues in the AWS Systems Manager User Guide with the following parameters.

| Parameter        | Value                       |  |
|------------------|-----------------------------|--|
| Command document | AWS-RunShellScript          |  |
| Command          | <div>\$ yum update -y</div> |  |
| Target instances | Your container instances    |  |

### Using an HTTP proxy for Amazon ECS Linux container instances

You can configure your Amazon ECS container instances to use an HTTP proxy for both the Amazon ECS container agent and the Docker daemon. This is useful if your container instances do not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

To configure your Amazon ECS Linux container instance to use an HTTP proxy, set the following variables in the relevant files at launch time (with Amazon EC2 user data). You can also manually edit the configuration file, and then restart the agent.

## `/etc/ecs/ecs.config` (Amazon Linux 2 and AmazonLinux AMI)

```
HTTP_PROXY=10.0.0.131:3128
```

Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for the Amazon ECS agent to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

```
NO_PROXY=169.254.169.254,169.254.170.2,/var/run/docker.sock
```

Set this value to `169.254.169.254,169.254.170.2,/var/run/docker.sock` to filter EC2 instance metadata, IAM roles for tasks, and Docker daemon traffic from the proxy.

## `/etc/systemd/system/ecs.service.d/http-proxy.conf` (Amazon Linux 2 only)

```
Environment="HTTP_PROXY=10.0.0.131:3128/"
```

Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for `ecs-init` to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

```
Environment="NO_PROXY=169.254.169.254,169.254.170.2,/var/run/  
docker.sock"
```

Set this value to `169.254.169.254,169.254.170.2,/var/run/docker.sock` to filter EC2 instance metadata, IAM roles for tasks, and Docker daemon traffic from the proxy.

## `/etc/init/ecs.override` (Amazon Linux AMI only)

```
env HTTP_PROXY=10.0.0.131:3128
```

Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for `ecs-init` to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

```
env NO_PROXY=169.254.169.254,169.254.170.2,/var/run/docker.sock
```

Set this value to `169.254.169.254,169.254.170.2,/var/run/docker.sock` to filter EC2 instance metadata, IAM roles for tasks, and Docker daemon traffic from the proxy.

/etc/systemd/system/docker.service.d/http-proxy.conf (Amazon Linux 2 only)

```
Environment="HTTP_PROXY=http://10.0.0.131:3128"
```

Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for the Docker daemon to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

```
Environment="NO_PROXY=169.254.169.254,169.254.170.2"
```

Set this value to 169.254.169.254,169.254.170.2 to filter EC2 instance metadata from the proxy.

/etc/sysconfig/docker (Amazon Linux AMI and Amazon Linux 2 only)

```
export HTTP_PROXY=http://10.0.0.131:3128
```

Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for the Docker daemon to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

```
export NO_PROXY=169.254.169.254,169.254.170.2
```

Set this value to 169.254.169.254,169.254.170.2 to filter EC2 instance metadata from the proxy.

Setting these environment variables in the preceding files only affects the Amazon ECS container agent, `ecs-init`, and the Docker daemon. They do not configure any other services (such as **yum**) to use the proxy.

For information about how to configure the proxy, see [How do I set up an HTTP proxy for Docker and the Amazon ECS container agent in Amazon Linux 2 or AL2023](#).

## Configuring pre-initialized instances for your Amazon ECS Auto Scaling group

Amazon ECS supports Amazon EC2 Auto Scaling warm pools. A warm pool is a group of pre-initialized Amazon EC2 instances ready to be placed into service. Whenever your application needs to scale out, Amazon EC2 Auto Scaling uses the pre-initialized instances from the warm pool rather than launching cold instances, allows for any final initialization process to run, and then places the instance into service.

To learn more about warm pools and how to add a warm pool to your Auto Scaling group, see [Warm pools for Amazon EC2 Auto Scaling](#) in the *Amazon EC2 Auto Scaling User Guide*.

When you create or update a warm pool for an Auto Scaling group for Amazon ECS, you cannot set the option that returns instances to the warm pool on scale in (`ReuseOnScaleIn`). For more information, see [put-warm-pool](#) in the *AWS Command Line Interface Reference*.

To use warm pools with your Amazon ECS cluster, set the `ECS_WARM_POOLS_CHECK` agent configuration variable to `true` in the **User data** field of your Amazon EC2 Auto Scaling group launch template.

The following shows an example of how the agent configuration variable can be specified in the **User data** field of an Amazon EC2 launch template for Linux instances. Replace *MyCluster* with the name of your cluster. For Windows instances, see [Using warm pools with Amazon ECS Windows instances](#).

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_WARM_POOLS_CHECK=true
EOF
```

The `ECS_WARM_POOLS_CHECK` variable is only supported on agent versions 1.59.0 and later. For more information about the variable, see [Amazon ECS container agent configuration](#).

## Using warm pools with Amazon ECS Windows instances

When using warm pools with the **Stopped** pool state on Windows instances, use Amazon EC2 Auto Scaling lifecycle hooks to ensure user data execution completes before the instance is stopped. Without lifecycle hooks, the instance may be stopped before Amazon ECS initialization finishes.

To configure lifecycle hooks for Windows warm pool instances:

1. Add the following IAM policy to your container instance role to allow the instance to complete the lifecycle action:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```

        "Action": [
            "autoscaling:CompleteLifecycleAction"
        ],
        "Resource": "*"
    }
]
}

```

2. Add a lifecycle hook to your Auto Scaling group on *Instance Launching* with ABANDON as the default result and a heartbeat timeout that allows enough time for Amazon ECS initialization (for example, 10 minutes). For more information, see [Add lifecycle hooks](#) in the *Amazon EC2 Auto Scaling User Guide*.
3. Use the following user data that creates a scheduled task to complete the lifecycle action after a delay. The delay ensures EC2Launch finishes saving its state before the instance is stopped. Replace *MyCluster*, *my-lifecycle-hook*, and *my-asg-name* with your values.

```

<powershell>
$lifecycleHookName = "my-lifecycle-hook"
$autoScalingGroupName = "my-asg-name"

$scriptContent = @'
$token = Invoke-RestMethod -Method Put -Uri http://169.254.169.254/latest/api/token -
Headers @{ "X-aws-ec2-metadata-token-ttl-seconds" = "21600" }
$instanceId = Invoke-RestMethod -Method Get -Uri http://169.254.169.254/latest/meta-
data/instance-id -Headers @{ "X-aws-ec2-metadata-token" = $token }
$region = Invoke-RestMethod -Method Get -Uri http://169.254.169.254/latest/meta-data/
placement/region -Headers @{ "X-aws-ec2-metadata-token" = $token }
$lifecycleHookName = "my-lifecycle-hook"
$autoScalingGroupName = "my-asg-name"
Complete-ASLifecycleAction -LifecycleHookName $lifecycleHookName -
AutoScalingGroupName $autoScalingGroupName -InstanceId $instanceId -
LifecycleActionResult 'CONTINUE' -Region $region
'@
Set-Content -Path "C:\ProgramData\Amazon\ECS\complete-lifecycle.ps1" -Value
$scriptContent

try
{
    [Environment]::SetEnvironmentVariable("ECS_WARM_POOLS_CHECK", "true", "Machine")
    Import-Module ECSTools
    Initialize-ECSAgent -Cluster MyCluster -EnableTaskIAMRole
}

```

```

    $taskAction = New-ScheduledTaskAction -Execute "powershell.exe" -Argument
    "-NoProfile -ExecutionPolicy Bypass -File C:\ProgramData\Amazon\ECS\complete-
    lifecycle.ps1"
    $taskTriggerOnce = New-ScheduledTaskTrigger -Once -At ((Get-Date).AddSeconds(60))
    $taskTriggerStartup = New-ScheduledTaskTrigger -AtStartup
    $taskTriggerStartup.Delay = "PT60S"
    $settings = New-ScheduledTaskSettingsSet -StartWhenAvailable
    $taskPrincipal = New-ScheduledTaskPrincipal -UserId "SYSTEM" -LogonType
    ServiceAccount -RunLevel Highest
    Register-ScheduledTask -TaskName "CompleteLifecycleHook" -Action $taskAction -
    Trigger $taskTriggerOnce, $taskTriggerStartup -Principal $taskPrincipal -Settings
    $settings -Force
}
catch
{
    $token = Invoke-RestMethod -Method Put -Uri http://169.254.169.254/latest/api/
    token -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"}
    $INSTANCE = Invoke-RestMethod -Method Get -Uri http://169.254.169.254/latest/
    meta-data/instance-id -Headers @{"X-aws-ec2-metadata-token" = $token}
    $region = Invoke-RestMethod -Method Get -Uri http://169.254.169.254/latest/meta-
    data/placement/region -Headers @{"X-aws-ec2-metadata-token" = $token}
    Complete-ASLifecycleAction -InstanceId $INSTANCE -LifecycleHookName
    $lifecycleHookName -AutoScalingGroupName $autoScalingGroupName -
    LifecycleActionResult ABANDON -Region $region
}
</powershell>

```

This user data script does the following:

- Initializes the Amazon ECS agent with the warm pools check enabled.
- Creates a scheduled task that waits 60 seconds after user data completes, and then signals the lifecycle hook to proceed.
- Creates a scheduled task that runs on every subsequent reboot, and signals the lifecycle hook to proceed after 60 seconds.
- If initialization fails, the lifecycle action is completed with ABANDON so the instance is terminated and replaced.

## Updating the Amazon ECS container agent

Occasionally, you might need to update the Amazon ECS container agent to pick up bug fixes and new features. Updating the Amazon ECS container agent does not interrupt running tasks or services on the container instance. The process for updating the agent differs depending on whether your container instance was launched with an Amazon ECS-optimized AMI or another operating system.

### Note

Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

## Checking the Amazon ECS container agent version

You can check the version of the container agent that is running on your container instances to see if you need to update it. The container instance view in the Amazon ECS console provides the agent version. Use the following procedure to check your agent version.

### Amazon ECS console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, choose the Region where your external instance is registered.
3. In the navigation pane, choose **Clusters** and select the cluster that hosts the external instance.
4. On the **Cluster : *name*** page, choose the **Infrastructure** tab.
5. Under **Container instances**, note the **Agent version** column for your container instances. If the container instance does not contain the latest version of the container agent, the console alerts you with a message and flags the outdated agent version.

If your agent version is outdated, you can update your container agent with the following procedures:

- If your container instance is running an Amazon ECS-optimized AMI, see [Updating the Amazon ECS container agent on an Amazon ECS-optimized AMI](#).
- If your container instance is not running an Amazon ECS-optimized AMI, see [Manually updating the Amazon ECS container agent \(for non-Amazon ECS-Optimized AMIs\)](#).

**⚠ Important**

To update the Amazon ECS agent version from versions before v1.0.0 on your Amazon ECS-optimized AMI, we recommend that you terminate your current container instance and launch a new instance with the most recent AMI version. Any container instances that use a preview version should be retired and replaced with the most recent AMI. For more information, see [Launching an Amazon ECS Linux container instance](#).

## Amazon ECS container agent introspection API

You can also use the to check the agent Amazon ECS container agent introspection API version from the container instance itself. For more information, see [Amazon ECS container introspection](#).

### To check if your Amazon ECS container agent is running the latest version with the introspection API

1. Log in to your container instance via SSH.
2. Query the introspection API.

```
[ec2-user ~]$ curl -s 127.0.0.1:51678/v1/metadata | python3 -mjson.tool
```

**ℹ Note**

The introspection API added `Version` information in the version v1.0.0 of the Amazon ECS container agent. If `Version` is not present when querying the introspection API, or the introspection API is not present in your agent at all, then the version you are running is v0.0.3 or earlier. You should update your version.

## Updating the Amazon ECS container agent on an Amazon ECS-optimized AMI

If you are using an Amazon ECS-optimized AMI, you have several options to get the latest version of the Amazon ECS container agent (shown in order of recommendation):

- Terminate the container instance and launch the latest version of the Amazon ECS-optimized Amazon Linux 2 AMI (either manually or by updating your Auto Scaling launch configuration with the latest AMI). This provides a fresh container instance with the most current tested and validated versions of Amazon Linux, Docker, `ecs-init`, and the Amazon ECS container agent. For more information, see [Amazon ECS-optimized Linux AMIs](#).
- Connect to the instance with SSH and update the `ecs-init` package (and its dependencies) to the latest version. This operation provides the most current tested and validated versions of Docker and `ecs-init` that are available in the Amazon Linux repositories and the latest version of the Amazon ECS container agent. For more information, see [To update the `ecs-init` package on an Amazon ECS-optimized AMI](#).
- Update the container agent with the `UpdateContainerAgent` API operation, either through the console or with the AWS CLI or AWS SDKs. For more information, see [Updating the Amazon ECS container agent with the `UpdateContainerAgent` API operation](#).

**Note**

Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

**To update the `ecs-init` package on an Amazon ECS-optimized AMI**

1. Log in to your container instance via SSH.
2. Update the `ecs-init` package with the following command.

```
sudo yum update -y ecs-init
```

**Note**

The `ecs-init` package and the Amazon ECS container agent are updated immediately. However, newer versions of Docker are not loaded until the Docker daemon is restarted. Restart either by rebooting the instance, or by running the following commands on your instance:

- Amazon ECS-optimized Amazon Linux 2 AMI:

```
sudo systemctl restart docker
```

- Amazon ECS-optimized Amazon Linux AMI:

```
sudo service docker restart && sudo start ecs
```

## Updating the Amazon ECS container agent with the UpdateContainerAgent API operation

### Important

The UpdateContainerAgent API is only supported on Linux variants of the Amazon ECS-optimized AMI, with the exception of the Amazon ECS-optimized Amazon Linux 2 (arm64) AMI. For container instances using the Amazon ECS-optimized Amazon Linux 2 (arm64) AMI, update the `ecs-init` package to update the agent. For container instances that are running other operating systems, see [Manually updating the Amazon ECS container agent \(for non-Amazon ECS-Optimized AMIs\)](#). If you are using Windows container instances, we recommend that you launch new container instances to update the agent version in your Windows clusters.

The UpdateContainerAgent API process begins when you request an agent update, either through the console or with the AWS CLI or AWS SDKs. Amazon ECS checks your current agent version against the latest available agent version, and if an update is possible. If an update is not available, for example, if the agent is already running the most recent version, then a `NoUpdateAvailableException` is returned.

The stages in the update process are as follows:

#### PENDING

An agent update is available, and the update process has started.

#### STAGING

The agent has begun downloading the agent update. If the agent cannot download the update, or if the contents of the update are incorrect or corrupted, then the agent sends a notification of the failure and the update transitions to the `FAILED` state.

## STAGED

The agent download has completed and the agent contents have been verified.

## UPDATING

The `ecs-init` service is restarted and it picks up the new agent version. If the agent is for some reason unable to restart, the update transitions to the `FAILED` state; otherwise, the agent signals Amazon ECS that the update is complete.

### Note

Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

## To update the Amazon ECS container agent on an Amazon ECS-optimized AMI in the console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, choose the Region where your external instance is registered.
3. In the navigation pane, choose **Clusters** and select the cluster.
4. On the **Cluster : *name*** page, choose the **Infrastructure** tab.
5. Under **Container instances**, select the instances to update, and then choose **Actions, Update agent**.

## Manually updating the Amazon ECS container agent (for non-Amazon ECS-Optimized AMIs)

Occasionally, you might need to update the Amazon ECS container agent to pick up bug fixes and new features. Updating the Amazon ECS container agent does not interrupt running tasks or services on the container instance.

### Note

Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

1. Log in to your container instance via SSH.

2. Check to see if your agent uses the ECS\_DATADIR environment variable to save its state.

```
ubuntu:~$ docker inspect ecs-agent | grep ECS_DATADIR
```

Output:

```
"ECS_DATADIR=/data",
```

### Important

If the previous command does not return the ECS\_DATADIR environment variable, you must stop any tasks running on this container instance before updating your agent. Newer agents with the ECS\_DATADIR environment variable save their state and you can update them while tasks are running without issues.

3. Stop the Amazon ECS container agent.

```
ubuntu:~$ docker stop ecs-agent
```

4. Delete the agent container.

```
ubuntu:~$ docker rm ecs-agent
```

5. Ensure that the /etc/ecs directory and the Amazon ECS container agent configuration file exist at /etc/ecs/ecs.config.

```
ubuntu:~$ sudo mkdir -p /etc/ecs && sudo touch /etc/ecs/ecs.config
```

6. Edit the /etc/ecs/ecs.config file and ensure that it contains at least the following variable declarations. If you do not want your container instance to register with the default cluster, specify your cluster name as the value for ECS\_CLUSTER.

```
ECS_DATADIR=/data
ECS_ENABLE_TASK_IAM_ROLE=true
ECS_ENABLE_TASK_IAM_ROLE_NETWORK_HOST=true
ECS_LOGFILE=/log/ecs-agent.log
ECS_AVAILABLE_LOGGING_DRIVERS=["json-file", "awslogs"]
ECS_LOGLEVEL=info
ECS_CLUSTER=default
```

For more information about these and other agent runtime options, see [Amazon ECS container agent configuration](#).

**Note**

You can optionally store your agent environment variables in Amazon S3 (which can be downloaded to your container instances at launch time using Amazon EC2 user data). We recommend this approach for sensitive information such as authentication credentials for private repositories. For more information, see [Storing Amazon ECS container instance configuration in Amazon S3](#) and [Using non-AWS container images in Amazon ECS](#).

7. Pull the latest Amazon ECS container agent image from Amazon Elastic Container Registry Public.

```
ubuntu:~$ docker pull public.ecr.aws/ecs/amazon-ecs-agent:latest
```

Output:

```
Pulling repository amazon/amazon-ecs-agent
a5a56a5e13dc: Download complete
511136ea3c5a: Download complete
9950b5d678a1: Download complete
c48ddcf21b63: Download complete
Status: Image is up to date for amazon/amazon-ecs-agent:latest
```

8. Run the latest Amazon ECS container agent on your container instance.

**Note**

Use Docker restart policies or a process manager (such as **upstart** or **systemd**) to treat the container agent as a service or a daemon and ensure that it is restarted after exiting. The Amazon ECS-optimized AMI uses the `ecs-init` RPM for this purpose, and you can view the [source code for this RPM](#) on GitHub.

The following example of the agent run command is broken into separate lines to show each option. For more information about these and other agent runtime options, see [Amazon ECS container agent configuration](#).

### Important

Operating systems with SELinux enabled require the `--privileged` option in your **docker run** command. In addition, for SELinux-enabled container instances, we recommend that you add the `:Z` option to the `/log` and `/data` volume mounts. However, the host mounts for these volumes must exist before you run the command or you receive a `no such file or directory` error. Take the following action if you experience difficulty running the Amazon ECS agent on an SELinux-enabled container instance:

- Create the host volume mount points on your container instance.

```
ubuntu:~$ sudo mkdir -p /var/log/ecs /var/lib/ecs/data
```

- Add the `--privileged` option to the **docker run** command that follows.
- Append the `:Z` option to the `/log` and `/data` container volume mounts (for example, `--volume=/var/log/ecs:/log:Z`) to the **docker run** command that follows.

```
ubuntu:~$ sudo docker run --name ecs-agent \  
--detach=true \  
--restart=on-failure:10 \  
--volume=/var/run:/var/run \  
--volume=/var/log/ecs:/log \  
--volume=/var/lib/ecs/data:/data \  
--volume=/etc/ecs:/etc/ecs \  
--volume=/etc/ecs:/etc/ecs/pki \  
--net=host \  
--env-file=/etc/ecs/ecs.config \  
amazon/amazon-ecs-agent:latest
```

 **Note**

If you receive an `Error` response from `daemon: Cannot start container` message, you can delete the failed container with the **`sudo docker rm ecs-agent`** command and try running the agent again.

## Amazon ECS-optimized Windows AMIs

The Amazon ECS-optimized AMIs are preconfigured with the necessary components that you need to run Amazon ECS workloads. Although you can create your own container instance AMI that meets the basic specifications needed to run your containerized workloads on Amazon ECS, the Amazon ECS-optimized AMIs are preconfigured and tested on Amazon ECS by AWS engineers. It is the simplest way for you to get started and to get your containers running on AWS quickly.

The Amazon ECS-optimized AMI metadata, including the AMI name, Amazon ECS container agent version, and Amazon ECS runtime version which includes the Docker version, for each variant can be retrieved programmatically. For more information, see [the section called “Retrieving Amazon ECS-optimized Windows AMI metadata”](#).

 **Important**

All ECS-optimized AMI variants produced after August 2022 will be migrating from Docker EE (Mirantis) to Docker CE (Moby project).

To ensure that customers have the latest security updates by default, Amazon ECS maintains at least the last three Windows Amazon ECS-optimized AMIs. After releasing new Windows Amazon ECS-optimized AMIs, Amazon ECS makes the Windows Amazon ECS-optimized AMIs that are older private. If there is a private AMI that you need access to, let us know by filing a ticket with Cloud Support.

## Amazon ECS-optimized AMI variants

The following Windows Server variants of the Amazon ECS-optimized AMI are available for your Amazon EC2 instances.

**⚠ Important**

All ECS-optimized AMI variants produced after August will be migrating from Docker EE (Mirantis) to Docker CE (Moby project).

- **Amazon ECS-optimized Windows Server 2025 Full AMI**
- **Amazon ECS-optimized Windows Server 2025 Core AMI**
- **Amazon ECS-optimized Windows Server 2022 Full AMI**
- **Amazon ECS-optimized Windows Server 2022 Core AMI**
- **Amazon ECS-optimized Windows Server 2019 Full AMI**
- **Amazon ECS-optimized Windows Server 2019 Core AMI**
- **Amazon ECS-optimized Windows Server 2016 Full AMI**

**⚠ Important**

Windows Server 2016 does not support the latest Docker version, for example 25.x.x. Therefore the Windows Server 2016 Full AMIs will not receive security or bug patches to the Docker runtime. We recommend that you move to one of the following Windows platforms:

- Windows Server 2022 Full
- Windows Server 2022 Core
- Windows Server 2019 Full
- Windows Server 2019 Core

On August 9, 2022, the Amazon ECS-optimized Windows Server 20H2 Core AMI reached its end of support date. No new versions of this AMI will be released. For more information, see [Windows Server release information](#).

Windows Server 2025, Windows Server 2022, Windows Server 2019, and Windows Server 2016 are Long-Term Servicing Channel (LTSC) releases. Windows Server 20H2 is a Semi-Annual Channel (SAC) release. For more information, see [Windows Server release information](#).

## Considerations

Here are some things you should know about Amazon EC2 Windows containers and Amazon ECS.

- Windows containers can't run on Linux container instances, and the opposite is also the case. For better task placement for Windows and Linux tasks, keep Windows and Linux container instances in separate clusters and only place Windows tasks on Windows clusters. You can ensure that Windows task definitions are only placed on Windows instances by setting the following placement constraint: `memberOf(ecs.os-type=='windows')`.
- Windows containers are supported for tasks that use the EC2 and Fargate.
- Windows containers and container instances can't support all the task definition parameters that are available for Linux containers and container instances. For some parameters, they aren't supported at all, and others behave differently on Windows than they do on Linux. For more information, see [Amazon ECS task definition differences for EC2 instances running Windows](#).
- For the IAM roles for tasks feature, you need to configure your Windows container instances to allow the feature at launch. Your containers must run some provided PowerShell code when they use the feature. For more information, see [Amazon EC2 Windows instance additional configuration](#).
- The IAM roles for tasks feature uses a credential proxy to provide credentials to the containers. This credential proxy occupies port 80 on the container instance, so if you use IAM roles for tasks, port 80 is not available for tasks. For web service containers, you can use an Application Load Balancer and dynamic port mapping to provide standard HTTP port 80 connections to your containers. For more information, see [Use load balancing to distribute Amazon ECS service traffic](#).
- The Windows Server Docker images are large (9 GiB). So, your Windows container instances require more storage space than Linux container instances.
- To run a Windows container on a Windows Server, the container's base image OS version must match that of the host. For more information, see [Windows container version compatibility](#) on the Microsoft documentation website. If your cluster runs multiple Windows versions, you can ensure that a task is placed on an EC2 instance running on the same version by using the placement constraint: `memberOf(attribute:ecs.os-family == WINDOWS_SERVER_<OS_Release>_<FULL or CORE>)`. For more information, see [the section called "Retrieving Amazon ECS-optimized Windows AMI metadata"](#).

## Retrieving Amazon ECS-optimized Windows AMI metadata

The AMI ID, image name, operating system, container agent version, and runtime version for each variant of the Amazon ECS-optimized AMIs can be programmatically retrieved by querying the Systems Manager Parameter Store API. For more information about the Systems Manager Parameter Store API, see [GetParameters](#) and [GetParametersByPath](#).

### Note

Your administrative user must have the following IAM permissions to retrieve the Amazon ECS-optimized AMI metadata. These permissions have been added to the AmazonECS\_FullAccess IAM policy.

- `ssm:GetParameters`
- `ssm:GetParameter`
- `ssm:GetParametersByPath`

## Systems Manager Parameter Store parameter format

### Note

The following Systems Manager Parameter Store API parameters are deprecated and should not be used to retrieve the latest Windows AMIs:

- `/aws/service/ecs/optimized-ami/windows_server/2016/english/full/recommended/image_id`
- `/aws/service/ecs/optimized-ami/windows_server/2019/english/full/recommended/image_id`

The following is the format of the parameter name for each Amazon ECS-optimized AMI variant.

- Windows Server 2025 Full AMI metadata:

```
/aws/service/ami-windows-latest/Windows_Server-2025-English-Full-ECS_Optimized
```

- Windows Server 2025 Core AMI metadata:

```
/aws/service/ami-windows-latest/Windows_Server-2025-English-Core-ECS_Optimized
```

- Windows Server 2022 Full AMI metadata:

```
/aws/service/ami-windows-latest/Windows_Server-2022-English-Full-ECS_Optimized
```

- Windows Server 2022 Core AMI metadata:

```
/aws/service/ami-windows-latest/Windows_Server-2022-English-Core-ECS_Optimized
```

- Windows Server 2019 Full AMI metadata:

```
/aws/service/ami-windows-latest/Windows_Server-2019-English-Full-ECS_Optimized
```

- Windows Server 2019 Core AMI metadata:

```
/aws/service/ami-windows-latest/Windows_Server-2019-English-Core-ECS_Optimized
```

- Windows Server 2016 Full AMI metadata:

```
/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-ECS_Optimized
```

The following parameter name format retrieves the metadata of the latest stable Windows Server 2019 Full AMI

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2019-English-Full-ECS_Optimized
```

The following is an example of the JSON object that is returned for the parameter value.

```
{
  "Parameters": [
    {
      "Name": "/aws/service/ami-windows-latest/Windows_Server-2019-English-Full-ECS_Optimized",
      "Type": "String",
      "Value": "{\"image_name\":\"Windows_Server-2019-English-Full-ECS_Optimized-2023.06.13\", \"image_id\":\"ami-0debc1fb48e4aee16\", \"ecs_runtime_version\":\"Docker (CE) version 20.10.21\", \"ecs_agent_version\":\"1.72.0\"}",
      "Version": 58,
    }
  ]
}
```

```
        "LastModifiedDate": "2023-06-22T19:37:37.841000-04:00",
        "ARN": "arn:aws:ssm:us-east-1::parameter/aws/service/ami-windows-latest/
Windows_Server-2019-English-Full-ECS_Optimized",
        "DataType": "text"
    }
],
    "InvalidParameters": []
}
```

Each of the fields in the preceding output are available to be queried as sub-parameters. Construct the parameter path for a sub-parameter by appending the sub-parameter name to the path for the selected AMI. The following sub-parameters are available:

- `schema_version`
- `image_id`
- `image_name`
- `os`
- `ecs_agent_version`
- `ecs_runtime_version`

## Examples

The following examples show ways in which you can retrieve the metadata for each Amazon ECS-optimized AMI variant.

### Retrieving the metadata of the latest stable Amazon ECS-optimized AMI

You can retrieve the latest stable Amazon ECS-optimized AMI using the AWS CLI with the following AWS CLI commands.

- **For the Amazon ECS-optimized Windows Server 2025 Full AMI:**

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2025-
English-Full-ECS_Optimized --region us-east-1
```

- **For the Amazon ECS-optimized Windows Server 2025 Core AMI:**

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2025-
English-Core-ECS_Optimized --region us-east-1
```

- **For the Amazon ECS-optimized Windows Server 2022 Full AMI:**

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2022-English-Full-ECS_Optimized --region us-east-1
```

- **For the Amazon ECS-optimized Windows Server 2022 Core AMI:**

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2022-English-Core-ECS_Optimized --region us-east-1
```

- **For the Amazon ECS-optimized Windows Server 2019 Full AMI:**

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2019-English-Full-ECS_Optimized --region us-east-1
```

- **For the Amazon ECS-optimized Windows Server 2019 Core AMI:**

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2019-English-Core-ECS_Optimized --region us-east-1
```

- **For the Amazon ECS-optimized Windows Server 2016 Full AMI:**

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2016-English-Full-ECS_Optimized --region us-east-1
```

## Using the latest recommended Amazon ECS-optimized AMI in an CloudFormation template

You can reference the latest recommended Amazon ECS-optimized AMI in an CloudFormation template by referencing the Systems Manager parameter store name.

```
Parameters:
  LatestECSOptimizedAMI:
    Description: AMI ID
    Type: AWS::SSM::Parameter::Value<AWS::EC2::Image::Id>
    Default: /aws/service/ami-windows-latest/Windows_Server-2019-English-Full-ECS_Optimized/image_id
```

## Amazon ECS-optimized Windows AMI versions

View the current and previous versions of the Amazon ECS-optimized AMIs and their corresponding versions of the Amazon ECS container agent, Docker, and the ecs-init package.

The Amazon ECS-optimized AMI metadata, including the AMI ID, for each variant can be retrieved programmatically. For more information, see [the section called “Retrieving Amazon ECS-optimized Windows AMI metadata”](#).

The following tabs display a list of Windows Amazon ECS-optimized AMIs versions. For details on referencing the Systems Manager Parameter Store parameter in an CloudFormation template, see [Using the latest recommended Amazon ECS-optimized AMI in an CloudFormation template](#).

### Important

To ensure that customers have the latest security updates by default, Amazon ECS maintains at least the last three Windows Amazon ECS-optimized AMIs. After releasing new Windows Amazon ECS-optimized AMIs, Amazon ECS makes the Windows Amazon ECS-optimized AMIs that are older private. If there is a private AMI that you need access to, let us know by filing a ticket with Cloud Support.

Windows Server 2016 does not support the latest Docker version, for example 25.x.x. Therefore the Windows Server 2016 Full AMIs will not receive security or bug patches to the Docker runtime. We recommend that you move to one of the following Windows platforms:

- Windows Server 2022 Full
- Windows Server 2022 Core
- Windows Server 2019 Full
- Windows Server 2019 Core

### Note

gMSA plugin logging has been migrated from file-based logging (C:\ProgramData\Amazon\gmsa) to Windows Event logging with the August 2025 AMI release. The public log collector script will collect all gMSA logs. For more information, see [Collecting container logs with Amazon ECS logs collector](#).

## Windows Server 2025 Full AMI versions

The following table lists the current and previous versions of the Amazon ECS-optimized Windows Server 2025 Full AMI and their corresponding versions of the Amazon ECS container agent and Docker.

| Amazon ECS-optimized Windows Server 2025 Full AMI                | Amazon ECS container agent version | Docker version      | Visibility |
|------------------------------------------------------------------|------------------------------------|---------------------|------------|
| <b>Windows_Server-2025-English-Full-ECS_Optimized-2026.10.16</b> | 1.108.0                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2025-English-Full-ECS_Optimized-2026.09.12</b> | 1.106.2                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2025-English-Full-ECS_Optimized-2026.08.15</b> | 1.106.1                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2025-English-Full-ECS_Optimized-2026.07.18</b> | 1.105.1                            | 25.0.16 (Docker CE) | Public     |

Use the following AWS CLI command to retrieve the current Amazon ECS-optimized Windows Server 2025 Full AMI.

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2025-English-Full-ECS_Optimized
```

## Windows Server 2025 Core AMI versions

The following table lists the current and previous versions of the Amazon ECS-optimized Windows Server 2025 Core AMI and their corresponding versions of the Amazon ECS container agent and Docker.

| Amazon ECS-optimized Windows Server 2025 Core AMI                | Amazon ECS container agent version | Docker version      | Visibility |
|------------------------------------------------------------------|------------------------------------|---------------------|------------|
| <b>Windows_Server-2025-English-Core-ECS_Optimized-2026.10.16</b> | 1.108.0                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2025-English-Core-ECS_Optimized-2026.09.12</b> | 1.106.2                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2025-English-Core-ECS_Optimized-2026.08.15</b> | 1.106.1                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2025-English-Core-ECS_Optimized-2026.07.18</b> | 1.105.1                            | 25.0.16 (Docker CE) | Public     |

Use the following AWS CLI command to retrieve the current Amazon ECS-optimized Windows Server 2025 Core AMI.

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2025-English-Core-ECS_Optimized
```

## Windows Server 2022 Full AMI versions

The following table lists the current and previous versions of the Amazon ECS-optimized Windows Server 2022 Full AMI and their corresponding versions of the Amazon ECS container agent and Docker.

| Amazon ECS-optimized Windows Server 2022 Full AMI                | Amazon ECS container agent version | Docker version      | Visibility |
|------------------------------------------------------------------|------------------------------------|---------------------|------------|
| <b>Windows_Server-2022-English-Full-ECS_Optimized-2026.10.16</b> | 1.108.0                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2022-English-Full-ECS_Optimized-2026.09.12</b> | 1.106.2                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2022-English-Full-ECS_Optimized-2026.08.15</b> | 1.106.1                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2022-English-Full-ECS_Optimized-2026.07.18</b> | 1.105.1                            | 25.0.16 (Docker CE) | Public     |

Use the following AWS CLI command to retrieve the current Amazon ECS-optimized Windows Server 2022 Full AMI.

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2022-English-Full-ECS_Optimized
```

## Windows Server 2022 Core AMI versions

The following table lists the current and previous versions of the Amazon ECS-optimized Windows Server 2022 Core AMI and their corresponding versions of the Amazon ECS container agent and Docker.

| Amazon ECS-optimized Windows Server 2022 Core AMI                | Amazon ECS container agent version | Docker version      | Visibility |
|------------------------------------------------------------------|------------------------------------|---------------------|------------|
| <b>Windows_Server-2022-English-Core-ECS_Optimized-2026.10.16</b> | 1.108.0                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2022-English-Core-ECS_Optimized-2026.09.12</b> | 1.106.2                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2022-English-Core-ECS_Optimized-2026.08.15</b> | 1.106.1                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2022-English-Core-ECS_Optimized-2026.07.18</b> | 1.105.1                            | 25.0.16 (Docker CE) | Public     |

Use the following AWS CLI command to retrieve the current Amazon ECS-optimized Windows Server 2022 Full AMI.

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2022-English-Core-ECS_Optimized
```

## Windows Server 2019 Full AMI versions

The following table lists the current and previous versions of the Amazon ECS-optimized Windows Server 2019 Full AMI and their corresponding versions of the Amazon ECS container agent and Docker.

| Amazon ECS-optimized Windows Server 2019 Full AMI                | Amazon ECS container agent version | Docker version      | Visibility |
|------------------------------------------------------------------|------------------------------------|---------------------|------------|
| <b>Windows_Server-2019-English-Full-ECS_Optimized-2026.10.16</b> | 1.108.0                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2019-English-Full-ECS_Optimized-2026.09.12</b> | 1.106.2                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2019-English-Full-ECS_Optimized-2026.08.15</b> | 1.106.1                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2019-English-Full-ECS_Optimized-2026.07.18</b> | 1.105.1                            | 25.0.16 (Docker CE) | Public     |

Use the following AWS CLI command to retrieve the current Amazon ECS-optimized Windows Server 2019 Full AMI.

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2019-English-Full-ECS_Optimized
```

## Windows Server 2019 Core AMI versions

The following table lists the current and previous versions of the Amazon ECS-optimized Windows Server 2019 Core AMI and their corresponding versions of the Amazon ECS container agent and Docker.

| Amazon ECS-optimized Windows Server 2019 Core AMI                | Amazon ECS container agent version | Docker version      | Visibility |
|------------------------------------------------------------------|------------------------------------|---------------------|------------|
| <b>Windows_Server-2019-English-Core-ECS_Optimized-2026.10.16</b> | 1.108.0                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2019-English-Core-ECS_Optimized-2026.09.12</b> | 1.106.2                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2019-English-Core-ECS_Optimized-2026.08.15</b> | 1.106.1                            | 25.0.16 (Docker CE) | Public     |
| <b>Windows_Server-2019-English-Core-ECS_Optimized-2026.07.18</b> | 1.105.1                            | 25.0.16 (Docker CE) | Public     |

Use the following AWS CLI command to retrieve the current Amazon ECS-optimized Windows Server 2019 Full AMI.

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2019-English-Core-ECS_Optimized
```

## Windows Server 2016 Full AMI versions

### Important

Windows Server 2016 does not support the latest Docker version, for example 25.x.x. Therefore the Windows Server 2016 Full AMIs will not receive security or bug patches to the Docker runtime. We recommend that you move to one of the following Windows platforms:

- Windows Server 2022 Full
- Windows Server 2022 Core
- Windows Server 2019 Full
- Windows Server 2019 Core

The following table lists the current and previous versions of the Amazon ECS-optimized Windows Server 2016 Full AMI and their corresponding versions of the Amazon ECS container agent and Docker.

| Amazon ECS-optimized Windows Server 2016 Full AMI                | Amazon ECS container agent version | Docker version          | Visibility |
|------------------------------------------------------------------|------------------------------------|-------------------------|------------|
| <b>Windows_Server-2016-English-Full-ECS_Optimized-2026.10.16</b> | 1.108.0                            | 20.10.23<br>(Docker CE) | Public     |
| <b>Windows_Server-2016-English-Full-ECS_Optimized-2026.09.12</b> | 1.106.2                            | 20.10.23<br>(Docker CE) | Public     |
| <b>Windows_Server-2016-English</b>                               | 1.106.1                            | 20.10.23<br>(Docker CE) | Public     |

| Amazon ECS-optimized Windows Server 2016 Full AMI         | Amazon ECS container agent version | Docker version          | Visibility |
|-----------------------------------------------------------|------------------------------------|-------------------------|------------|
| -Full-ECS_Optimized-2026.08.15                            |                                    |                         |            |
| Windows_Server-2016-English-Full-ECS_Optimized-2026.07.18 | 1.105.1                            | 20.10.23<br>(Docker CE) | Public     |

Use the following AWS CLI Amazon ECS-optimized Windows Server 2016 Full AMI.

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2016-English-Full-ECS_Optimized
```

## Building your own Amazon ECS-optimized Windows AMI

Use EC2 Image Builder to build your own custom Amazon ECS-optimized Windows AMI. This makes it easy to use a Windows AMI with your own license on Amazon ECS. Amazon ECS provides a managed Image Builder component which provides the system configuration needed to run Windows instances to host your containers. Each Amazon ECS managed component includes a specific container agent and Docker version. You can customize your image to use either the latest Amazon ECS managed component, or if an older container agent or Docker version is needed you can specify a different component.

For a full walkthrough of using EC2 Image Builder, see [Getting started with EC2 Image Builder](#) in the *EC2 Image Builder User Guide*.

When building your own Amazon ECS-optimized Windows AMI using EC2 Image Builder, you create an image recipe. Your image recipe must meet the following requirements:

- The **Source image** should be based on Windows Server 2019 Core, Windows Server 2019 Full, Windows Server 2022 Core, or Windows Server 2022 Full. Any other Windows operating system is not supported and may not be compatible with the component.

- When specifying the **Build components**, the `ecs-optimized-ami-windows` component is required. The `update-windows` component, which we recommend, ensures the image contains the latest security updates.

To specify a different component version, expand the **Versioning options** menu and specify the component version you want to use. For more information, see [Listing the ecs-optimized-ami-windows component versions](#).

## Listing the ecs-optimized-ami-windows component versions

When creating an EC2 Image Builder recipe and specifying the `ecs-optimized-ami-windows` component, you can either use the default option or you can specify a specific component version. To determine what component versions are available, along with the Amazon ECS container agent and Docker versions contained within the component, you can use the AWS Management Console.

### To list the available ecs-optimized-ami-windows component versions

1. Open the EC2 Image Builder console at <https://console.aws.amazon.com/imagebuilder/>.
2. On the navigation bar, select the Region that are building your image in.
3. In the navigation pane, under the **Saved configurations** menu, choose **Components**.
4. On the **Components** page, in the search bar type `ecs-optimized-ami-windows` and pull down the qualification menu and select **Quick start (Amazon-managed)**.
5. Use the **Description** column to determine the component version with the Amazon ECS container agent and Docker version your image requires.

## Amazon ECS Windows container instance management

When you use EC2 instances for your Amazon ECS workloads, you are responsible for maintaining the instances.

Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

### Management procedures

- [Launching an Amazon ECS Windows container instance](#)
- [Bootstrapping Amazon ECS Windows container instances to pass data](#)

- [Using an HTTP proxy for Amazon ECS Windows container instances](#)
- [Configuring Amazon ECS Windows container instances to receive Spot Instance notices](#)

## Launching an Amazon ECS Windows container instance

Your Amazon ECS container instances are created using the Amazon EC2 console. Before you begin, be sure that you've completed the steps in [Set up to use Amazon ECS](#).

For more information about the launch wizard, see [Launch an instance using the new launch instance wizard](#) in the *Amazon EC2 User Guide*.

You can use the new Amazon EC2 wizard to launch an instance. You can use the following list for the parameters and leave the parameters not listed as the default. The following instructions take you through each parameter group.

### Procedure

Before you begin, complete the steps in [Set up to use Amazon ECS](#).

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.

### Name and tags

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. You can tag the instance, the volumes, and elastic graphics. For Spot Instances, you can tag the Spot Instance request only.

Specifying an instance name and additional tags is optional.

- For **Name**, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
- To add additional tags, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

## Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Apache, and your website.

For the latest Amazon ECS-optimized AMIs and their values, see [Windows Amazon ECS-optimized AMI](#).

Use the **Search** bar to find a suitable Amazon ECS-optimized AMI published by AWS.

1. Based on your requirements, enter one of the following AMIs in the **Search** bar and press **Enter**.
  - Windows\_Server-2022-English-Full-ECS\_Optimized
  - Windows\_Server-2022-English-Core-ECS\_Optimized
  - Windows\_Server-2019-English-Full-ECS\_Optimized
  - Windows\_Server-2019-English-Core-ECS\_Optimized
  - Windows\_Server-2016-English-Full-ECS\_Optimized
2. On the **Choose an Amazon Machine Image (AMI)** page, select the **Community AMIs** tab.
3. From the list that appears, choose a Microsoft-verified AMI with the most recent publish date and click **Select**.

## Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see [Instance types](#).

- For **Instance type**, select the instance type for the instance.

The instance type that you select determines the resources available for your tasks to run on.

## Key pair (login)

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one.

### Important

If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

## Network settings

Configure the network settings, as necessary.

- **Networking platform:** Choose **Virtual Private Cloud (VPC)**, and then specify the subnet in the **Network interfaces** section.
- **VPC:** Select an existing VPC in which to create the security group.
- **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the launch instance wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

- **Auto-assign Public IP:** If your instance should be accessible from the internet, verify that the **Auto-assign Public IP** field is set to **Enable**. If not, set this field to **Disable**.

### Note

Container instances need access to communicate with the Amazon ECS service endpoint. This can be through an interface VPC endpoint or through your container instances having public IP addresses.

For more information about interface VPC endpoints, see [Amazon ECS interface VPC endpoints \(AWS PrivateLink\)](#)

If you do not have an interface VPC endpoint configured and your container instances do not have public IP addresses, then they must use network address translation (NAT)

to provide this access. For more information, see [NAT gateways](#) in the *Amazon VPC User Guide* and [Using an HTTP proxy for Amazon ECS Linux container instances](#) in this guide.

- **Firewall (security groups):** Use a security group to define firewall rules for your container instance. These rules specify which incoming network traffic is delivered to your container instance. All other traffic is ignored.
  - To select an existing security group, choose **Select existing security group**, and select the security group that you created in [Set up to use Amazon ECS](#)

## Configure storage

The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

You can use the **Simple** view.

- **Storage type:** Configure the storage for your container instance.

If you are using the Amazon ECS-optimized Amazon Linux AMI, your instance has two volumes configured. The **Root** volume is for the operating system's use, and the second Amazon EBS volume (attached to `/dev/xvdcz`) is for Docker's use.

You can optionally increase or decrease the volume sizes for your instance to meet your application needs.

## Advanced details

For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option:** Choose **Request Spot Instances** to request Spot Instances. You also need to set the other fields related to Spot Instances. For more information, see [Spot Instance Requests](#).

### Note

If you are using Spot Instances and see a Not available message, you may need to choose a different instance type.

- **IAM instance profile:** Select your container instance IAM role. This is usually named `ecsInstanceRole`.

### Important

If you do not launch your container instance with the proper IAM permissions, your Amazon ECS agent cannot connect to your cluster. For more information, see [Amazon ECS container instance IAM role](#).

- (Optional) **User data:** Configure your Amazon ECS container instance with user data, such as the agent environment variables from [Amazon ECS container agent configuration](#). Amazon EC2 user data scripts are executed only one time, when the instance is first launched. The following are common examples of what user data is used for:
  - By default, your container instance launches into your default cluster. To launch into a non-default cluster, choose the **Advanced Details** list. Then, paste the following script into the **User data** field, replacing *your\_cluster\_name* with the name of your cluster.

The `EnableTaskIAMRole` turns on the Task IAM roles feature for the tasks.

In addition, the following options are available when you use the `awsvpc` network mode.

- `EnableTaskENI`: This flag turns on task networking and is required when you use the `awsvpc` network mode.
- `AwsVpcBlockIMDS`: This optional flag blocks IMDS access for the task containers running in the `awsvpc` network mode.
- `AwsVpcAdditionalLocalRoutes`: This optional flag allows you to have additional routes in the task namespace.

Replace `ip-address` with the IP Address for the additional routes, for example `172.31.42.23/32`.

```
<powershell>
Import-Module ECSTools
Initialize-ECSAgent -Cluster your_cluster_name -EnableTaskIAMRole -EnableTaskENI -
AwsVpcBlockIMDS -AwsVpcAdditionalLocalRoutes
'["ip-address"]'
```

```
</powershell>
```

## Bootstrapping Amazon ECS Windows container instances to pass data

When you launch an Amazon EC2 instance, you can pass user data to the EC2 instance. The data can be used to perform common automated configuration tasks and even run scripts when the instance boots. For Amazon ECS, the most common use cases for user data are to pass configuration information to the Docker daemon and the Amazon ECS container agent.

You can pass multiple types of user data to Amazon EC2, including cloud boothooks, shell scripts, and `cloud-init` directives. For more information about these and other format types, see the [Cloud-Init documentation](#).

You can pass this user data when using the Amazon EC2 launch wizard. For more information, see [Launching an Amazon ECS Linux container instance](#).

### Default Windows user data

This example user data script shows the default user data that your Windows container instances receive if you use the console. The following script does the following:

- Sets the cluster name to the name you entered.
- Sets the IAM roles for tasks.
- Sets `json-file` and `awslogs` as the available logging drivers.

In addition, the following options are available when you use the `awsvpc` network mode.

- `EnableTaskENI`: This flag turns on task networking and is required when you use the `awsvpc` network mode.
- `AwsvpcBlockIMDS`: This optional flag blocks IMDS access for the task containers running in `awsvpc` network mode.
- `AwsvpcAdditionalLocalRoutes`: This optional flag allows you to have additional routes.

Replace `ip-address` with the IP Address for the additional routes, for example `172.31.42.23/32`.

You can use this script for your own container instances (provided that they are launched from the Amazon ECS-optimized Windows Server AMI).

Replace the `-Cluster cluster-name` line to specify your own cluster name.

```
<powershell>
Initialize-ECSAgent -Cluster cluster-name -EnableTaskIAMRole -LoggingDrivers '["json-
file","awslogs"]' -EnableTaskENI -AwsvpcBlockIMDS -AwsvpcAdditionalLocalRoutes
'["ip-address"]'
</powershell>
```

For Windows tasks that are configured to use the `awslogs` logging driver, you must also set the `ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE` environment variable on your container instance. Use the following syntax.

Replace the `-Cluster cluster-name` line to specify your own cluster name.

```
<powershell>
[Environment]::SetEnvironmentVariable("ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE",
$TRUE, "Machine")
Initialize-ECSAgent -Cluster cluster-name -EnableTaskIAMRole -LoggingDrivers '["json-
file","awslogs"]'
</powershell>
```

## Windows agent installation user data

This example user data script installs the Amazon ECS container agent on an instance launched with a **Windows\_Server-2016-English-Full-Containers** AMI. It has been adapted from the agent installation instructions on the [Amazon ECS Container Agent GitHub repository](#) README page.

### Note

This script is shared for example purposes. It is much easier to get started with Windows containers by using the Amazon ECS-optimized Windows Server AMI. For more information, see [Creating an Amazon ECS cluster for Fargate workloads](#).

For information about how to install the Amazon ECS agent on Windows Server 2022 Full, see [Issue 3753](#) on GitHub.

You can use this script for your own container instances (provided that they are launched with a version of the **Windows\_Server-2016-English-Full-Containers** AMI). Be sure to replace the *windows* line to specify your own cluster name (if you are not using a cluster called windows).

```

<powershell>
# Set up directories the agent uses
New-Item -Type directory -Path ${env:ProgramFiles}\Amazon\ECS -Force
New-Item -Type directory -Path ${env:ProgramData}\Amazon\ECS -Force
New-Item -Type directory -Path ${env:ProgramData}\Amazon\ECS\data -Force
# Set up configuration
$ecsExeDir = "${env:ProgramFiles}\Amazon\ECS"
[Environment]::SetEnvironmentVariable("ECS_CLUSTER", "windows", "Machine")
[Environment]::SetEnvironmentVariable("ECS_LOGFILE", "${env:ProgramData}\Amazon\ECS\log\ecs-agent.log", "Machine")
[Environment]::SetEnvironmentVariable("ECS_DATADIR", "${env:ProgramData}\Amazon\ECS\data", "Machine")
# Download the agent
$agentVersion = "latest"
$agentZipUri = "https://s3.amazonaws.com/amazon-ecs-agent/ecs-agent-windows-$agentVersion.zip"
$zipFile = "${env:TEMP}\ecs-agent.zip"
Invoke-RestMethod -OutFile $zipFile -Uri $agentZipUri
# Put the executables in the executable directory.
Expand-Archive -Path $zipFile -DestinationPath $ecsExeDir -Force
Set-Location ${ecsExeDir}
# Set $EnableTaskIAMRoles to $true to enable task IAM roles
# Note that enabling IAM roles will make port 80 unavailable for tasks.
[bool]$EnableTaskIAMRoles = $false
if ($EnableTaskIAMRoles) {
    $HostSetupScript = Invoke-WebRequest https://raw.githubusercontent.com/aws/amazon-ecs-agent/master/misc/windows-deploy/hostsetup.ps1
    Invoke-Expression $($HostSetupScript.Content)
}
# Install the agent service
New-Service -Name "AmazonECS" `
    -BinaryPathName "$ecsExeDir\amazon-ecs-agent.exe -windows-service" `
    -DisplayName "Amazon ECS" `
    -Description "Amazon ECS service runs the Amazon ECS agent" `
    -DependsOn Docker `
    -StartupType Manual
sc.exe failure AmazonECS reset=300 actions=restart/5000/restart/30000/restart/60000
sc.exe failureflag AmazonECS 1
Start-Service AmazonECS
</powershell>

```

## Using an HTTP proxy for Amazon ECS Windows container instances

You can configure your Amazon ECS container instances to use an HTTP proxy for both the Amazon ECS container agent and the Docker daemon. This is useful if your container instances do not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

To configure your Amazon ECS Windows container instance to use an HTTP proxy, set the following variables at launch time (with Amazon EC2 user data).

```
[Environment]::SetEnvironmentVariable("HTTP_PROXY",  
"http://proxy.mydomain:port", "Machine")
```

Set HTTP\_PROXY to the hostname (or IP address) and port number of an HTTP proxy to use for the Amazon ECS agent to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

```
[Environment]::SetEnvironmentVariable("NO_PROXY",  
"169.254.169.254,169.254.170.2,\\.\pipe\docker_engine", "Machine")
```

Set NO\_PROXY to 169.254.169.254,169.254.170.2,\\.\pipe\docker\_engine to filter EC2 instance metadata, IAM roles for tasks, and Docker daemon traffic from the proxy.

### Example Windows HTTP proxy user data script

The following example user data PowerShell script configures the Amazon ECS container agent and the Docker daemon to use an HTTP proxy that you specify. You can also specify a cluster into which the container instance registers itself.

To use this script when you launch a container instance, follow the steps in [the section called “Launching a container instance”](#). Just copy and paste the PowerShell script that follows into the **User data** field (be sure to substitute the red example values with your own proxy and cluster information).

#### Note

The `-EnableTaskIAMRole` option is required to enable IAM roles for tasks. For more information, see [Amazon EC2 Windows instance additional configuration](#).

```
<powershell>
Import-Module ECSTools

$proxy = "http://proxy.mydomain:port"
[Environment]::SetEnvironmentVariable("HTTP_PROXY", $proxy, "Machine")
[Environment]::SetEnvironmentVariable("NO_PROXY", "169.254.169.254,169.254.170.2,\\.
\pipe\docker_engine", "Machine")

Restart-Service Docker
Initialize-ECSAgent -Cluster MyCluster -EnableTaskIAMRole
</powershell>
```

## Configuring Amazon ECS Windows container instances to receive Spot Instance notices

Amazon EC2 terminates, stops, or hibernates your Spot Instance when the Spot price exceeds the maximum price for your request or capacity is no longer available. Amazon EC2 provides a Spot Instance interruption notice, which gives the instance a two-minute warning before it is interrupted. If Amazon ECS Spot Instance draining is enabled on the instance, ECS receives the Spot Instance interruption notice and places the instance in DRAINING status.

### Important

Amazon ECS monitors for the Spot Instance interruption notices that have the `terminate` and `stop` instance-actions. If you specified either the `hibernate` instance interruption behavior when requesting your Spot Instances or Spot Fleet, then Amazon ECS Spot Instance draining is not supported for those instances.

When a container instance is set to DRAINING, Amazon ECS prevents new tasks from being scheduled for placement on the container instance. Service tasks on the draining container instance that are in the PENDING state are stopped immediately. If there are container instances in the cluster that are available, replacement service tasks are started on them.

You can turn on Spot Instance draining when you launch an instance. You must set the `ECS_ENABLE_SPOT_INSTANCE_DRAINING` parameter before you start the container agent. Replace *my-cluster* with the name of your cluster.

```
[Environment]::SetEnvironmentVariable("ECS_ENABLE_SPOT_INSTANCE_DRAINING", "true",
"Machine")
```

```
# Initialize the agent
Initialize-ECSAgent -Cluster my-cluster
```

For more information, see [the section called “Launching a container instance”](#).

## Amazon ECS clusters for external instances

Amazon ECS Anywhere provides support for registering an *external instance* such as an on-premises server or virtual machine (VM), to your Amazon ECS cluster. External instances are optimized for running applications that generate outbound traffic or process data. If your application requires inbound traffic, the lack of Elastic Load Balancing support makes running these workloads less efficient. Amazon ECS added a new EXTERNAL launch type that you can use to create services or run tasks on your external instances.

## Supported operating systems and system architectures

The following is the list of supported operating systems. The x86\_64 and ARM64 CPU architectures are supported.

- Amazon Linux 2023
- Ubuntu 20, Ubuntu 22, Ubuntu 24
- RHEL 9 — You must ensure that Docker is installed before you run the [ECS Anywhere install script](#). For more information, see [Install Docker Engine on RHEL](#) in the Docker documentation.

Beginning August 7 2026, the following operating systems are no longer supported by Amazon ECS Anywhere:

- Amazon Linux 2
- CentOS Stream 9
- RHEL 7, RHEL 8
- Fedora 32, Fedora 33, Fedora 40
- openSUSE Tumbleweed
- Ubuntu 18
- Debian 9, Debian 10, Debian 11, Debian 12

- SUSE Enterprise Server 15
- Windows Server 2022, Windows Server 2019, Windows Server 2016, Windows Server 20H2

## Considerations

Before you start using external instances, be aware of the following considerations.

- You can register an external instance to one cluster at a time. For instructions on how to register an external instance with a different cluster, see [Deregistering an Amazon ECS external instance](#).
- Your external instances require an IAM role that allows them to communicate with AWS APIs. For more information, see [Amazon ECS Anywhere IAM role](#).
- Your external instances should not have a preconfigured instance credential chain defined locally as this will interfere with the registration script.
- To send container logs to CloudWatch Logs, make sure that you create and specify a task execution IAM role in your task definition.
- When an external instance is registered to a cluster, the `ecs.capability.external` attribute is associated with the instance. This attribute identifies the instance as an external instance. You can add custom attributes to your external instances to use as a task placement constraint. For more information, see [Custom attributes](#).
- You can add resource tags to your external instance. For more information, see [Adding tags to External container instances for Amazon ECS](#).
- ECS Exec is supported on external instances. For more information, see [Monitor Amazon ECS containers with ECS Exec](#).
- The following are additional considerations that are specific to networking with your external instances. For more information, see [Networking](#).
  - Service load balancing isn't supported.
  - Service discovery isn't supported.
  - Tasks that run on external instances must use the `bridge`, `host`, or `none` network modes. The `awsvpc` network mode isn't supported.
  - There are Amazon ECS service domains in each AWS Region. These service domains must be allowed to send traffic to your external instances.
  - The SSM Agent installed on your external instance maintains IAM credentials that are rotated every 30 minutes using a hardware fingerprint. If your external instance loses connection to AWS, the SSM Agent automatically refreshes the credentials after the connection is re-

established. For more information, see [Validating on-premises servers and virtual machines using a hardware fingerprint](#) in the *AWS Systems Manager User Guide*.

- You can run Linux tasks on external instances in an IPv6-only configuration as long as the instances are in IPv6-only subnets. For more information, see [Using a VPC in IPv6-only mode](#).
- The UpdateContainerAgent API isn't supported. For instructions on how to update the SSM Agent or the Amazon ECS agent on your external instances, see [Updating the AWS Systems Manager agent and Amazon ECS container agent on an external instance](#).
- Amazon ECS capacity providers aren't supported. To create a service or run a standalone task on your external instances, use the EXTERNAL launch type.
- SELinux isn't supported.
- Using Amazon EFS volumes or specifying an EFSVolumeConfiguration isn't supported.
- Integration with App Mesh isn't supported.
- If you use the console to create an external instance task definition, you must create the task definition with the console JSON editor.
- When you use a non Amazon ECS-optimized AMI, run the following commands on the external container instance to configure rules to use IAM roles for tasks. For more information, see [External instance additional configuration](#).

```
$ sysctl -w net.ipv4.conf.all.route_localnet=1
$ iptables -t nat -A PREROUTING -p tcp -d 169.254.170.2 --dport 80 -j DNAT --to-destination 127.0.0.1:51679
$ iptables -t nat -A OUTPUT -d 169.254.170.2 -p tcp -m tcp --dport 80 -j REDIRECT --to-ports 51679
```

## Networking

Amazon ECS external instances are optimized for running applications that generate outbound traffic or process data. If your application requires inbound traffic, such as a web service, the lack of Elastic Load Balancing support makes running these workloads less efficient because there isn't support for placing these workloads behind a load balancer.

The following are additional considerations that are specific to networking with your external instances.

- Service load balancing isn't supported.

- Service discovery isn't supported.
- Linux tasks that run on external instances must use the bridge, host, or none network modes. The awsvpc network mode isn't supported.

For more information about each network mode, see [Amazon ECS task networking options for EC2 instances](#).

- You can run Linux tasks on external instances in an IPv6-only configuration as long as the instances are in IPv6-only subnets. For more information, see [Using a VPC in IPv6-only mode](#).
- There are Amazon ECS service domains in each Region and must be allowed to send traffic to your external instances.
- The SSM Agent installed on your external instance maintains IAM credentials that are rotated every 30 minutes using a hardware fingerprint. If your external instance loses connection to AWS, the SSM Agent automatically refreshes the credentials after the connection is re-established. For more information, see [Validating on-premises servers and virtual machines using a hardware fingerprint](#) in the *AWS Systems Manager User Guide*.

The following domains are used for communication between the Amazon ECS service and the Amazon ECS agent that's installed on your external instance. Make sure that traffic is allowed and that DNS resolution works. For each endpoint, *region* represents the Region identifier for an AWS Region that's supported by Amazon ECS, such as `us-east-2` for the US East (Ohio) Region. The endpoints for all Regions that you use should be allowed. For the `ecs-a` and `ecs-t` endpoints, you should include an asterisk (for example, `ecs-a-*`).

- `ecs-a-*.region.amazonaws.com` — This endpoint is used when managing tasks.
- `ecs-t-*.region.amazonaws.com` — This endpoint is used to manage task and container metrics.
- `ecs.region.amazonaws.com` — This is the service endpoint for Amazon ECS.
- `ssm.region.amazonaws.com` — This is the service endpoint for AWS Systems Manager.
- `ec2messages.region.amazonaws.com` — This is the service endpoint that AWS Systems Manager uses to communicate between the Systems Manager agent and the Systems Manager service in the cloud.
- `ssmmessages.region.amazonaws.com` — This is the service endpoint that is required to create and delete session channels with the Session Manager service in the cloud.
- If your tasks require communication with any other AWS services, make sure that those service endpoints are allowed. Example applications include using Amazon ECR to pull container images

or using CloudWatch for CloudWatch Logs. For more information, see [Service endpoints](#) in the *AWS General Reference*.

## Amazon FSx for Windows File Server with ECS Anywhere

### Important

Windows support for Amazon ECS Anywhere has been deprecated. This section is no longer applicable.

In order to use the Amazon FSx for Windows File Server with Amazon ECS external instances you must establish a connection between your on-premises data center and the AWS Cloud. For information about the options for connecting your network to your VPC, see [Amazon Virtual Private Cloud Connectivity Options](#).

## gMSA with ECS Anywhere

### Important

Windows support for Amazon ECS Anywhere has been deprecated. This section is no longer applicable.

The following use cases were supported for ECS Anywhere when Windows was a supported operating system.

- The Active Directory is in the AWS Cloud - For this configuration, you create a connection between your on-premises network and the AWS Cloud using an AWS Direct Connect connection. For information about how to create the connection, see [Amazon Virtual Private Cloud Connectivity Options](#). You create an Active Directory in the AWS Cloud. For information about how to get started with AWS Directory Service, see [Setting up AWS Directory Service](#) in the *AWS Directory Service Administration Guide*. You can then join your external instances to the domain using the AWS Direct Connect connection. For information about working with gMSA with Amazon ECS, see [the section called “Learn how to use gMSAs for EC2 Windows containers”](#).
- The Active Directory is in the on-premises data center. - For this configuration, you join your external instances to the on-premises Active Directory. You then use the locally available credentials when you run the Amazon ECS tasks.

# Creating an Amazon ECS cluster for External instance workloads

You create a cluster to define the infrastructure your tasks and services run on.

Before you begin, be sure that you've completed the steps in [Set up to use Amazon ECS](#) and assign the appropriate IAM permission. For more information, see [the section called "Amazon ECS cluster examples"](#). The Amazon ECS console provides a simple way to create the resources that are needed by an Amazon ECS cluster by creating a CloudFormation stack.

To make the cluster creation process as easy as possible, the console has default selections for many choices which we describe below. There are also help panels available for most of the sections in the console which provide further context.

You can modify the following options:

- Add a namespace to the cluster.

A namespace allows services that you create in the cluster can connect to the other services in the namespace without additional configuration. For more information, see [Interconnect Amazon ECS services](#).

- Configure the cluster for external instances
- Assign a AWS KMS key for your managed storage. For information about how to create a key, see [Create a KMS key](#) in the *AWS Key Management Service User Guide*.
- Add tags to help you identify your cluster.

## To create a new cluster (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, configure the following:

- For **Cluster name**, enter a unique name.

The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.

- (Optional) To have the namespace used for Service Connect be different from the cluster name, for **Namespace**, enter a unique name.

6. (Optional) Use Container Insights, expand **Monitoring**, and then choose one of the following options:
  - To use the recommended Container Insights with enhanced observability, choose **Container Insights with enhanced observability**.
  - To use Container Insights, choose **Container Insights**.
7. (Optional) To use ECS Exec to debug tasks in the cluster, expand **Troubleshooting configuration**, and then configure the following:
  - Select **Turn on ECS Exec**.
  - (Optional) For **AWS KMS key for ECS Exec**, enter the ARN of the AWS KMS key you want to use to encrypt the ECS Exec session data.
  - (Optional) For **ECS Exec logging**, choose the log destination:
    - To send logs to CloudWatch Logs, choose **Amazon CloudWatch**.
    - To send logs to Amazon S3, choose **Amazon S3**.
    - To disable logging, choose **None**.
8. (Optional) Encrypt the data on managed storage. Under **Encryption**, for **Managed storage**, enter the ARN of the AWS KMS key you want to use to encrypt the managed storage data.
9. (Optional) To help identify your cluster, expand **Tags**, and then configure your tags.

[Add a tag] Choose **Add tag** and do the following:

  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
10. Choose **Create**.

## Next steps

You must register the instances with the cluster. For more information, see [Registering an external instance to an Amazon ECS cluster](#).

Create a task definition for the external launch type. For more information, see [Creating an Amazon ECS task definition using the console](#)

Run your applications as standalone tasks, or as part of a service. For more information, see the following:

- [Running an application as an Amazon ECS task](#)
- [Creating an Amazon ECS rolling update deployment](#)

## Registering an external instance to an Amazon ECS cluster

For each external instance you register with an Amazon ECS cluster, it must have the SSM Agent, the Amazon ECS container agent, and Docker installed. To register the external instance to an Amazon ECS cluster, it must first be registered as an AWS Systems Manager managed instance. You can create the installation script in a few clicks on the Amazon ECS console. The installation script includes an Systems Manager activation key and commands to install each of the required agents and Docker. The installation script must be run on your on-premises server or VM to complete the installation and registration steps.

### Note

Before registering your Linux external instance with the cluster, create the `/etc/ecs/ecs.config` file on your external instance and add any container agent configuration parameters that you want. You can't do this after registering the external instance to a cluster. For more information, see [Amazon ECS container agent configuration](#).

### AWS Management Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose a cluster to register your external instance to.
5. On the **Cluster : *name*** page, choose the **Infrastructure** tab.
6. On the **Register external instances** page, complete the following steps.
  - a. For **Activation key duration (in days)**, enter the number of days that the activation key remains active for. After the number of days you entered pass, the key no longer works when registering an external instance.
  - b. For **Number of instances**, enter the number of external instances that you want to register to your cluster with the activation key.

- c. For **Instance role**, choose the IAM role to associate with your external instances. If a role wasn't already created, choose **Create new role** to have Amazon ECS create a role on your behalf. For more information about what IAM permissions are required for your external instances, see [Amazon ECS Anywhere IAM role](#).
- d. Copy the registration command. This command should be run on each external instance you want to register to the cluster.

**⚠ Important**

The bash portion of the script must be run as root. If the command isn't run as root, an error is returned.

- e. Choose **Close**.

## AWS CLI for Linux operating systems

1. Create an Systems Manager activation pair. This is used for Systems Manager managed instance activation. The output includes an `ActivationId` and `ActivationCode`. You use these in a later step. Make sure that you specify the ECS Anywhere IAM role that you created. For more information, see [Amazon ECS Anywhere IAM role](#).

```
aws ssm create-activation --iam-role ecsAnywhereRole | tee ssm-activation.json
```

2. On your on-premises server or virtual machine (VM), download the installation script.

```
curl --proto "https" -o "/tmp/ecs-anywhere-install.sh" "https://amazon-ecs-agent.s3.amazonaws.com/ecs-anywhere-install-latest.sh"
```

3. (Optional) On your on-premises server or virtual machine (VM), use the following steps to verify the installation script using the script signature file.
  - a. Download and install GnuPG. For more information about GNUUpg, see the [GnuPG website](#). For Linux systems, install `gpg` using the package manager on your flavor of Linux.
  - b. Retrieve the Amazon ECS PGP public key.

```
gpg --keyserver hkp://keys.gnupg.net:80 --recv BCE9D9A42D51784F
```

- c. Download the installation script signature. The signature is an ascii detached PGP signature stored in a file with the .asc extension.

```
curl --proto "https" -o "/tmp/ecs-anywhere-install.sh.asc" "https://amazon-ecs-agent.s3.amazonaws.com/ecs-anywhere-install-latest.sh.asc"
```

- d. Verify the installation script file using the key.

```
gpg --verify /tmp/ecs-anywhere-install.sh.asc /tmp/ecs-anywhere-install.sh
```

The following is the expected output.

```
gpg: Signature made Tue 25 May 2021 07:16:29 PM UTC
gpg:                using RSA key 50DECCC4710E61AF
gpg: Good signature from "Amazon ECS <ecs-security@amazon.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:                There is no indication that the signature belongs to the
gpg:                owner.
Primary key fingerprint: F34C 3DDA E729 26B0 79BE  AEC6 BCE9 D9A4 2D51 784F
Subkey fingerprint: D64B B6F9 0CF3 77E9 B5FB  346F 50DE CCC4 710E 61AF
```

4. On your on-premises server or virtual machine (VM), run the installation script. Specify the cluster name, Region, and the Systems Manager activation ID and activation code from the first step.

```
sudo bash /tmp/ecs-anywhere-install.sh \
  --region $REGION \
  --cluster $CLUSTER_NAME \
  --activation-id $ACTIVATION_ID \
  --activation-code $ACTIVATION_CODE
```

For an on-premises server or virtual machine (VM) that has the NVIDIA driver installed for GPU workloads, you must add the `--enable-gpu` flag to the installation script. When this flag is specified, the install script verifies that the NVIDIA driver is running and then adds the required configuration variables to run your Amazon ECS tasks. For more information about running GPU workloads and specifying GPU requirements in a task definition, see [Specifying GPUs in an Amazon ECS task definition](#).

```
sudo bash /tmp/ecs-anywhere-install.sh \
  --region $REGION \
```

```
--cluster $CLUSTER_NAME \  
--activation-id $ACTIVATION_ID \  
--activation-code $ACTIVATION_CODE \  
--enable-gpu
```

Use the following steps to register an existing external instance with a different cluster.

### To register an existing external instance with a different cluster

1. Stop the Amazon ECS container agent.

```
sudo systemctl stop ecs.service
```

2. Edit the `/etc/ecs/ecs.config` file and on the `ECS_CLUSTER` line, ensure the cluster name matches the name of the cluster to register the external instance with.
3. Remove the existing Amazon ECS agent data.

```
sudo rm /var/lib/ecs/data/agent.db
```

4. Start the Amazon ECS container agent.

```
sudo systemctl start ecs.service
```

### AWS CLI for Windows operating systems

1. Create an Systems Manager activation pair. This is used for Systems Manager managed instance activation. The output includes an `ActivationId` and `ActivationCode`. You use these in a later step. Make sure that you specify the ECS Anywhere IAM role that you created. For more information, see [Amazon ECS Anywhere IAM role](#).

```
aws ssm create-activation --iam-role ecsAnywhereRole | tee ssm-activation.json
```

2. On your on-premises server or virtual machine (VM), download the installation script.

```
Invoke-RestMethod -URI "https://amazon-ecs-agent.s3.amazonaws.com/ecs-anywhere-  
install.ps1" -OutFile "ecs-anywhere-install.ps1"
```

3. (Optional) The Powershell script is signed by Amazon and therefore, Windows automatically performs the certificate validation on the same. You do not need to perform any manual validation.

To manually verify the certificate, right-click on the file, navigate to properties and use the Digital Signatures tab to obtain more details.

This option is only available when the host has the certificate in the certificate store.

The verification should return information similar to the following:

```
# Verification (PowerShell)
Get-AuthenticodeSignature -FilePath .\ecs-anywhere-install.ps1

SignerCertificate              Status      Path
-----
EXAMPLECERTIFICATE           Valid      ecs-anywhere-install.ps1

...

Subject      : CN="Amazon Web Services, Inc.",...

----
```

4. On your on-premises server or virtual machine (VM), run the installation script. Specify the cluster name, Region, and the Systems Manager activation ID and activation code from the first step.

```
.\ecs-anywhere-install.ps1 -Region $Region -Cluster $Cluster -
ActivationID $ActivationID -ActivationCode $ActivationCode
```

5. Verify the Amazon ECS container agent is running.

#### Get-Service AmazonECS

```
Status      Name              DisplayName
-----
Running     AmazonECS        Amazon ECS
```

Use the following steps to register an existing external instance with a different cluster.

## To register an existing external instance with a different cluster

1. Stop the Amazon ECS container agent.

```
Stop-Service AmazonECS
```

2. Modify the ECS\_CLUSTER parameter so that the cluster name matches the name of the cluster to register the external instance with.

```
[Environment]::SetEnvironmentVariable("ECS_CLUSTER", $ECSCluster,  
[System.EnvironmentVariableTarget]::Machine)
```

3. Remove the existing Amazon ECS agent data.

```
Remove-Item -Recurse -Force $env:ProgramData\Amazon\ECS\data\*
```

4. Start the Amazon ECS container agent.

```
Start-Service AmazonECS
```

The AWS CLI can be used to create a Systems Manager activation before running the installation script to complete the external instance registration process.

## Deregistering an Amazon ECS external instance

We recommend that you deregister the instance from both Amazon ECS and AWS Systems Manager after you are done with the instance. Following deregistration, the external instance is no longer able to accept new tasks.

If you have tasks that are running on the container instance when you deregister it, the tasks remain running until they stop through some other means. However, these tasks are no longer monitored or accounted for by Amazon ECS. If these tasks on your external instance are part of an Amazon ECS service, then the service scheduler starts another copy of that task, on a different instance, if possible.

After you deregister the instance, clean up the remaining AWS resources on the instance. You can then register it to a new cluster.

## Procedure

### AWS Management Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, choose the Region where your external instance is registered.
3. In the navigation pane, choose **Clusters** and select the cluster that hosts the external instance.
4. On the **Cluster : *name*** page, choose the **Infrastructure** tab.
5. Under **Container instances**, select the external instance ID to deregister. You're redirected to the container instance detail page.
6. On the **Container Instance : *id*** page, choose **Deregister**.
7. Review the deregistration message. Select **Deregister from AWS Systems Manager** to also deregister the external instance as an Systems Manager managed instance. Choose **Deregister**.

 **Note**

You can deregister the external instance as an Systems Manager managed instance in the Systems Manager console. For instructions, see [Deregistering managed nodes in a hybrid and multicloud environment](#) in the *AWS Systems Manager User Guide*.

8. After you deregister the instance, clean up AWS resources on your on-premises server or VM.

| Operating system | Steps                                                                                                                                                            |  |

## AWS CLI

1. You need the instance ID and the container instance ARN to deregister the container instance. If you do not have these values, run the following commands

Run the following command to get the instance ID.

You use the instance ID (`instanceID`) to get the container instance ARN (`containerInstanceARN`).

```
instanceId=$(aws ssm describe-instance-information --region "{{ region }}" |
jq ".InstanceInformationList[] |select(.IPAddress==\"{{ IPv4 Address }}\")
| .InstanceId" | tr -d '"')
```

Run the following commands.

You use the `containerInstanceArn` as a parameter in the command to deregister the instance (`deregister-container-instance`).

```
instances=$(aws ecs list-container-instances --cluster "{{ cluster }}" --region
"{{ region }}" | jq -c '.containerInstanceArns')
containerInstanceArn=$(aws ecs describe-container-instances --cluster
"{{ cluster }}" --region "{{ region }}" --container-instances $instances
| jq ".containerInstances[] | select(.ec2InstanceId==\"{{ instanceId }}\")
| .containerInstanceArn" | tr -d '')
```

2. Run the following command to drain the instance.

```
aws ecs update-container-instances-state --cluster "{{ cluster }}" --region
"{{ region }}" --container-instances "{{ containerInstanceArn }}" --status
DRAINING
```

3. After the container instance finishes draining, run the following command to deregister the instance.

```
aws ecs deregister-container-instance --cluster "{{ cluster }}" --region
"{{ region }}" --container-instance "{{ containerInstanceArn }}"
```

4. Run the following command to remove the container instance from SSM.

```
aws ssm deregister-managed-instance --region "{{ region }}" --instance-id
"{{ instanceId }}"
```

5. After you deregister the instance, clean up AWS resources on your on-premises server or VM.

| Operating system | Steps                                                                                                                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Linux            | <ol style="list-style-type: none"> <li>a. Stop the Amazon ECS container agent and the SSM Agent services on the instance.</li> </ol> <pre>sudo systemctl stop ecs amazon-ssm- agent</pre> |

| Operating system | Steps                                                                                                                                                                                                                                                                                                                                                       |  |

# Updating the AWS Systems Manager agent and Amazon ECS container agent on an external instance

Your on-premises server or VM must run both the AWS Systems Manager Agent (SSM Agent) and the Amazon ECS container agent when running Amazon ECS workloads. AWS releases new versions of these agents when any capabilities are added or updated. If your external instances are using an earlier version of either agent, you can update them using the following procedures.

## Updating the SSM Agent on an external instance

AWS Systems Manager recommends that you automate the process of updating the SSM Agent on your instances. They provide several methods to automate updates. For more information, see [Automating updates to SSM Agent](#) in the *AWS Systems Manager User Guide*.

## Updating the Amazon ECS agent on an external instance

On your external instances, the Amazon ECS container agent is updated by upgrading the `ecs-init` package. Updating the Amazon ECS agent doesn't interrupt the running tasks or services. Amazon ECS provides the `ecs-init` package and signature file in an Amazon S3 bucket in each Region. Beginning with `ecs-init` version 1.52.1-1, Amazon ECS provides separate `ecs-init` packages for use depending on the operating system and system architecture your external instance uses.

Use the following table to determine the `ecs-init` package that you should download based on the operating system and system architecture your external instance uses.

### Note

You can determine which operating system and system architecture that your external instance uses by using the following commands.

```
cat /etc/os-release  
uname -m
```

| Operating systems (architecture)   | ecs-init package                   |
|------------------------------------|------------------------------------|
| CentOS 7 (x86_64)                  | amazon-ecs-init-latest.x86_64.rpm  |
| CentOS 8 (x86_64)                  |                                    |
| CentOS Stream 9 (x86_64)           |                                    |
| SUSE Enterprise Server 15 (x86_64) |                                    |
| RHEL 7 (x86_64)                    |                                    |
| RHEL 8 (x86_64)                    |                                    |
| CentOS 7 (aarch64)                 | amazon-ecs-init-latest.aarch64.rpm |
| CentOS 8 (aarch64)                 |                                    |
| CentOS Stream 9 (aarch64)          |                                    |
| RHEL 7 (aarch64)                   |                                    |
| Debian 9 (x86_64)                  | amazon-ecs-init-latest.amd64.deb   |
| Debian 10 (x86_64)                 |                                    |
| Debian 11 (x86_64)                 |                                    |
| Debian 12 (x86_64)                 |                                    |
| Ubuntu 18 (x86_64)                 |                                    |
| Ubuntu 20 (x86_64)                 |                                    |
| Ubuntu 22 (x86_64)                 |                                    |
| Ubuntu 24 (x86_64)                 |                                    |
| Debian 9 (aarch64)                 | amazon-ecs-init-latest.arm64.deb   |
| Debian 10 (aarch64)                |                                    |
| Debian 11 (aarch64)                |                                    |

| Operating systems (architecture) | ecs-init package |
|----------------------------------|------------------|
| Debian 12 (aarch64)              |                  |
| Ubuntu 18 (aarch64)              |                  |
| Ubuntu 20 (aarch64)              |                  |
| Ubuntu 22 (aarch64)              |                  |
| Ubuntu 24 (aarch64)              |                  |

Follow these steps to update the Amazon ECS agent.

### To update the Amazon ECS agent

1. Confirm the Amazon ECS agent version that you're running.

```
curl -s 127.0.0.1:51678/v1/metadata | python3 -mjson.tool
```

2. Download the ecs-init package for your operating system and system architecture. Amazon ECS provides the ecs-init package file in an Amazon S3 bucket in each Region. Make sure that you replace the *<region>* identifier in the command with the Region name (for example, us-west-2) that you're geographically closest to.

#### amazon-ecs-init-latest.x86\_64.rpm

```
curl -o amazon-ecs-init.rpm https://s3.<region>.amazonaws.com/amazon-ecs-agent-<region>/amazon-ecs-init-latest.x86_64.rpm
```

#### amazon-ecs-init-latest.aarch64.rpm

```
curl -o amazon-ecs-init.rpm https://s3.<region>.amazonaws.com/amazon-ecs-agent-<region>/amazon-ecs-init-latest.aarch64.rpm
```

#### amazon-ecs-init-latest.amd64.deb

```
curl -o amazon-ecs-init.deb https://s3.<region>.amazonaws.com/amazon-ecs-agent-<region>/amazon-ecs-init-latest.amd64.deb
```

## amazon-ecs-init-latest.arm64.deb

```
curl -o amazon-ecs-init.deb https://s3.<region>.amazonaws.com/amazon-ecs-agent-<region>/amazon-ecs-init-latest.arm64.deb
```

3. (Optional) Verify the validity of the `ecs-init` package file using the PGP signature.
  - a. Download and install GnuPG. For more information about GnuPG, see the [GnuPG website](#). For Linux systems, install `gpg` using the package manager on your flavor of Linux.
  - b. Retrieve the Amazon ECS PGP public key.

```
gpg --keyserver hkp://keys.gnupg.net:80 --recv BCE9D9A42D51784F
```

- c. Download the `ecs-init` package signature. The signature is an ASCII detached PGP signature that's stored in a file with the `.asc` extension. Amazon ECS provides the signature file in an Amazon S3 bucket in each Region. Make sure that you replace the `<region>` identifier in the command with the Region name (for example, `us-west-2`) that you're geographically closest to.

## amazon-ecs-init-latest.x86\_64.rpm

```
curl -o amazon-ecs-init.rpm.asc https://s3.<region>.amazonaws.com/amazon-ecs-agent-<region>/amazon-ecs-init-latest.x86_64.rpm.asc
```

## amazon-ecs-init-latest.aarch64.rpm

```
curl -o amazon-ecs-init.rpm.asc https://s3.<region>.amazonaws.com/amazon-ecs-agent-<region>/amazon-ecs-init-latest.aarch64.rpm.asc
```

## amazon-ecs-init-latest.amd64.deb

```
curl -o amazon-ecs-init.deb.asc https://s3.<region>.amazonaws.com/amazon-ecs-agent-<region>/amazon-ecs-init-latest.amd64.deb.asc
```

## amazon-ecs-init-latest.arm64.deb

```
curl -o amazon-ecs-init.deb.asc https://s3.<region>.amazonaws.com/amazon-ecs-agent-<region>/amazon-ecs-init-latest.arm64.deb.asc
```

- d. Verify the `ecs-init` package file using the key.

#### For the rpm packages

```
gpg --verify amazon-ecs-init.rpm.asc ./amazon-ecs-init.rpm
```

#### For the deb packages

```
gpg --verify amazon-ecs-init.deb.asc ./amazon-ecs-init.deb
```

The following is the expected output.

```
gpg: Signature made Fri 14 May 2021 09:31:36 PM UTC
gpg:                using RSA key 50DECCC4710E61AF
gpg: Good signature from "Amazon ECS <ecs-security@amazon.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:                There is no indication that the signature belongs to the owner.
Primary key fingerprint: F34C 3DDA E729 26B0 79BE  AEC6 BCE9 D9A4 2D51 784F
Subkey fingerprint: D64B B6F9 0CF3 77E9 B5FB  346F 50DE CCC4 710E 61AF
```

4. Install the `ecs-init` package.

#### For the rpm package on CentOS 7, CentOS 8, and RHEL 7

```
sudo yum install -y ./amazon-ecs-init.rpm
```

#### For the rpm package on SUSE Enterprise Server 15

```
sudo zypper install -y --allow-unsigned-rpm ./amazon-ecs-init.rpm
```

#### For the deb package

```
sudo dpkg -i ./amazon-ecs-init.deb
```

5. Restart the `ecs` service.

```
sudo systemctl restart ecs
```

6. Verify the Amazon ECS agent version was updated.

```
curl -s 127.0.0.1:51678/v1/metadata | python3 -mjson.tool
```

## Updating an Amazon ECS cluster

You can modify the following cluster properties:

- Set a default capacity provider

Each cluster can have one or more capacity providers and an optional capacity provider strategy. The capacity provider strategy determines how the tasks are spread across the cluster's capacity providers. When you run a standalone task or create a service, you either use the cluster's default capacity provider strategy or a capacity provider strategy that overrides the default one.

- Turn on Container Insights.

CloudWatch Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. Container Insights also provides diagnostic information, such as container restart failures, that you use to isolate issues and resolve them quickly. For more information, see [the section called “Monitor Amazon ECS containers using Container Insights with enhanced observability”](#).

- Add tags to help you identify your clusters.

### Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster.
4. On the **Cluster : *name*** page, choose **Update cluster**.
5. To set the default capacity provider, under **Default capacity provider strategy**, choose **Add more**.
  - a. For **Capacity provider**, choose the capacity provider.
  - b. (Optional) For **Base**, enter the minimum number of tasks that run on the capacity provider.

You can only set a **Base** value for one capacity provider.

- c. (Optional) For **Weight**, enter the relative percentage of the total number of launched tasks that use the specified capacity provider.
  - d. (Optional) Repeat the steps for any additional capacity providers.
6. To turn on or off Container Insights, expand **Monitoring**, and then turn on **Use Container Insights**.
7. To help identify your cluster, expand **Tags**, and then configure your tags.

[Add a tag] Choose **Add tag** and do the following:

- For **Key**, enter the key name.
- For **Value**, enter the key value.

[Remove a tag] Choose **Remove** to the right of the tag's Key and Value.

8. Choose **Update**.

## Deleting an Amazon ECS cluster

If you are finished using a cluster, you can delete it. After you delete the cluster, it transitions to the INACTIVE state. Clusters with an INACTIVE status may remain discoverable in your account for a period of time. However, this behavior is subject to change in the future, so you should not rely on INACTIVE clusters persisting.

Before you delete a cluster, you must perform the following operations:

- Delete all services in the cluster. For more information, see [the section called "Deleting a service"](#).
- Stop all currently running tasks. For more information, see [the section called "Stopping a task"](#).
- Deregister all registered container instances in the cluster. For more information, see [the section called "Deregistering a container instance"](#).
- Delete the namespace. For more information, see [Deleting namespaces](#) in the *AWS Cloud Map Developer Guide*.

### Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, select the cluster to delete.
5. Choose **Delete Cluster**.

A message is displayed when you did not delete all the resources associated with the cluster.

6. In the confirmation box, enter **delete *cluster name***.

## Deregistering an Amazon ECS container instance

### Important

This topic is for container instances created in Amazon EC2 only. For more information about deregistering external instances, see [Deregistering an Amazon ECS external instance](#).

When you are finished with an Amazon EC2 backed container instance, you should deregister it from your cluster. Following deregistration, the container instance is no longer able to accept new tasks.

If you have tasks running on the container instance when you deregister it, these tasks remain running until you terminate the instance or the tasks stop through some other means. However, these tasks are orphaned which means they are no longer monitored or accounted for by Amazon ECS. If an orphaned task on your container instance is part of an Amazon ECS service, then the service scheduler starts another copy of that task, on a different container instance, if possible. Any containers in orphaned service tasks that are registered with an Application Load Balancer target group are deregistered. They begin connection draining according to the settings on the load balancer or target group. If an orphaned task is using the awsvpc network mode, their elastic network interfaces are deleted.

If you intend to use the container instance for some other purpose after deregistration, you should stop all of the tasks running on the container instance before deregistration. This stops any orphaned tasks from consuming resources.

When deregistering a container instance, be aware of the following considerations.

- Because each container instance has unique state information, they should not be deregistered from one cluster and re-registered into another. To relocate container instance resources, we recommend that you terminate container instances from one cluster and launch new container instances in the new cluster. For more information, see [Terminate your instance](#) in the *Amazon EC2 User Guide* and [Launching an Amazon ECS Linux container instance](#).
- If the container instance is managed by an Auto Scaling group or a CloudFormation stack, terminate the instance by updating the Auto Scaling group or CloudFormation stack. Otherwise, the Auto Scaling group or CloudFormation will create a new instance after you terminate it.
- If you terminate a running container instance with a connected Amazon ECS container agent, the agent automatically deregisters the instance from your cluster. Stopped container instances or instances with disconnected agents are not automatically deregistered when terminated.
- Deregistering a container instance removes the instance from a cluster, but it does not terminate the Amazon EC2 instance. If you are finished using the instance, be sure to terminate it to stop billing. For more information, see [Terminate your instance](#) in the *Amazon EC2 User Guide*.

## Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, choose the Region where your external instance is registered.
3. In the navigation pane, choose **Clusters** and select the cluster that hosts the instance.
4. On the **Cluster : *name*** page, choose the **Infrastructure** tab.
5. Under **Container instances**, select the instance ID to deregister. You're redirected to the container instance detail page.
6. On the **Container Instance : *id*** page, choose **Deregister**.
7. On the confirmation screen, choose **Deregister**.
8. If you are finished with the container instance, terminate the underlying Amazon EC2 instance. For more information, see [Terminate Your Instance](#) in the *Amazon EC2 User Guide*.

## Draining Amazon ECS container instances

There might be times when you need to remove a container instance from your cluster, for example, to perform system updates or to scale down the cluster capacity. Amazon ECS provides the ability to transition a container instance to a DRAINING status. This is referred to as *container*

*instance draining.* When a container instance is set to DRAINING, Amazon ECS prevents new tasks from being scheduled for placement on the container instance.

## Draining behavior for services

Any tasks that are part of a service that are in a PENDING state are stopped immediately. If there is available container instance capacity in the cluster, the service scheduler will start replacement tasks. If there isn't enough container instance capacity, a service event message will be sent indicating the issue.

Tasks that are part of a service on the container instance that are in a RUNNING state are transitioned to a STOPPED state. The service scheduler attempts to replace the tasks according to the service's deployment type and deployment configuration parameters, `minimumHealthyPercent` and `maximumPercent`. For more information, see [Amazon ECS services](#) and [Amazon ECS service definition parameters](#).

- If `minimumHealthyPercent` is below 100%, the scheduler can ignore `desiredCount` temporarily during task replacement. For example, `desiredCount` is four tasks, a minimum of 50% allows the scheduler to stop two existing tasks before starting two new tasks. If the minimum is 100%, the service scheduler can't remove existing tasks until the replacement tasks are considered healthy. If tasks for services that do not use a load balancer are in the RUNNING state, they are considered healthy. Tasks for services that use a load balancer are considered healthy if they are in the RUNNING state and the container instance they are hosted on is reported as healthy by the load balancer.

### Important

If you use Spot Instances and `minimumHealthyPercent` is greater than or equal to 100%, then the service will not have enough time to replace the task before the Spot Instance terminates.

- The `maximumPercent` parameter represents an upper limit on the number of running tasks during task replacement, which allows you to define the replacement batch size. For example, if `desiredCount` of four tasks, a maximum of 200% starts four new tasks before stopping the four tasks to be drained (provided that the cluster resources required to do this are available). If the maximum is 100%, then replacement tasks can't start until the draining tasks have stopped.

**⚠ Important**

If both `minimumHealthyPercent` and `maximumPercent` are 100%, then the service can't remove existing tasks, and also cannot start replacement tasks. This prevents successful container instance draining and prevents making new deployments.

## Draining behavior for standalone tasks

Any standalone tasks in the `PENDING` or `RUNNING` state are unaffected; you must wait for them to stop on their own or stop them manually. The container instance will remain in `DRAINING` status.

## Draining behavior for Amazon ECS Managed Instances

Amazon ECS Managed Instances termination ensures graceful workload transitions while optimizing costs and maintaining system health. The termination system provides three distinct decision paths for instance termination, each with different timing characteristics and customer impact profiles.

### Customer-initiated termination

Provides direct control over instance removal when you need to remove container instances from service immediately. You run `deregister-container-instance` with the `force` request parameter set to `true`. This means that immediate termination is required despite any running workloads.

### System-initiated idle termination

Amazon ECS Managed Instances continuously monitors and proactively optimizes costs by terminating idle Amazon ECS container instances not running any tasks. ECS uses a heuristic delay to give container instances a chance to acquire newly launched tasks before being terminated. This can be customized with the `scaleInAfter` Amazon ECS Managed Instances capacity provider configuration parameter.

### Infrastructure refresh termination

Amazon ECS Managed Instances automatically manages and updates software on managed container instances to ensure security and compliance while maintaining workload availability. For more information, see [patching in Amazon ECS Managed Instances](#).

The termination system implements a two-phase approach that balances workload continuity against infrastructure management requirements.

### Phase 1: Graceful completion period

During this phase, the system implements graceful draining strategies that prioritize workload continuity. Service tasks are gracefully drained through normal Amazon ECS scheduling processes. Standalone tasks continue running because they might complete naturally. The system monitors for all tasks to reach stopped state through natural completion processes.

### Phase 2: Hard deadline enforcement

When graceful completion does not achieve termination objectives within acceptable timeframes, the system implements hard deadline enforcement. The hard deadline is typically set to draining initiation time plus seven days, providing substantial time for graceful completion while maintaining operational requirements. The enforcement includes automatic force deregistration procedures and immediate termination of all remaining tasks regardless of the completion status.

A container instance has completed draining when all tasks running on the instance transition to a STOPPED state. The container instance remains in a DRAINING state until it is activated again or deleted. You can verify the state of the tasks on the container instance by using the [ListTasks](#) operation with the `containerInstance` parameter to get a list of tasks on the instance followed by a [DescribeTasks](#) operation with the Amazon Resource Name (ARN) or ID of each task to verify the task state.

When you are ready for the container instance to start hosting tasks again, you change the state of the container instance from DRAINING to ACTIVE. The Amazon ECS service scheduler then considers the container instance for task placement again.

## Procedure

The following steps can be used to set a container instance to draining using the new AWS Management Console.

You can also use the [UpdateContainerInstancesState](#) API action or the [update-container-instances-state](#) command to change the status of a container instance to DRAINING.

### AWS Management Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.

3. On the **Clusters** page, choose a cluster that hosts your instances.
4. On the **Cluster : *name*** page, choose the **Infrastructure** tab. Then, under **Container instances** select the check box for each container instance you want to drain.
5. Choose **Actions, Drain**.

## Changing the instance type or size outside of the Auto Scaling group

AWS recommends that you keep your infrastructure immutable. If you need to change instance sizes, you can either:

- Scale horizontally and add additional instances. Then, place additional tasks on those instances, or you
- Scale vertically by launching a new, larger/smaller instance and then drain the old instance.

Both of these approaches will help minimize application availability impact.

If you used another method to change the instance, you might receive the following error:

```
Container instance type changes are not supported.
```

When you get this error, perform the following steps:

1. Launch new instances with the desired instance type.
2. Drain your old instance types. For more information, see [the section called “Container instance draining”](#).

## Amazon ECS EC2 Container Instances

The Amazon ECS agent is a process that runs on every container instance that is registered with your cluster. It facilitates the communication between your container instances and Amazon ECS.

### Note

On Linux container instances, the agent container mounts top-level directories such as `/lib`, `/lib64`, and `/proc`. This is necessary for ECS features and functionalities such as

Amazon EBS volumes, aws-vpc network mode, Amazon ECS Service Connect, and FireLens for Amazon ECS.

Each Amazon ECS container agent version supports a different feature set and provides bug fixes from previous versions. When possible, we always recommend using the latest version of the Amazon ECS container agent. To update your container agent to the latest version, see [Updating the Amazon ECS container agent](#).

The Amazon ECS container agent contains the `amazon-ecs-pause` image. Amazon ECS uses this image for tasks that use `aws-vpc` network mode.

To see which features and enhancements are included with each agent release, see <https://github.com/aws/amazon-ecs-agent/releases>.

### Important

The minimum Docker version for reliable metrics is Docker version `v20.10.13` and newer, which is included in Amazon ECS-optimized AMI `20220607` and newer. Amazon ECS agent versions `1.20.0` and newer have deprecated support for Docker versions older than `18.01.0`.

## Lifecycle

When the Amazon ECS container agent registers an Amazon EC2 instance to your cluster, the Amazon EC2 instance reports its status as `ACTIVE` and its agent connection status as `TRUE`. This container instance can accept run task requests.

If you stop (not terminate) a container instance, the status remains `ACTIVE`, but the agent connection status transitions to `FALSE` within a few minutes. Any tasks that were running on the container instance stop. If you start the container instance again, the container agent reconnects with the Amazon ECS service, and you are able to run tasks on the instance again.

If you change the status of a container instance to `DRAINING`, new tasks are not placed on the container instance. Any service tasks running on the container instance are removed, if possible, so that you can perform system updates. For more information, see [Draining Amazon ECS container instances](#).

If you deregister or terminate a container instance, the container instance status changes to `INACTIVE` immediately, and the container instance is no longer reported when you list your container instances. However, you can still describe the container instance for one hour following termination. After one hour, the instance description is no longer available.

You can drain the instances manually, or build an Auto Scaling group lifecycle hook to set the instance status to `DRAINING`. See [Amazon EC2 Auto Scaling lifecycle hooks](#) for more information about Auto Scaling lifecycle hooks.

## Docker Support

Amazon ECS supports the last two major versions of Docker published on Amazon Linux. Currently, this includes Docker 20.10.x and Docker 25.x.

The minimum required Docker version for Amazon ECS can be found in the [Amazon ECS Agent specification file](#) on GitHub.

When using the Amazon ECS-optimized AMI, Docker is pre-installed and configured to work with the Amazon ECS container agent. The AMI includes a Docker version that is tested and supported by Amazon ECS.

### Note

While Amazon ECS supports multiple Docker versions, we recommend using the Docker version that comes with the Amazon ECS-optimized AMI for the best compatibility and support.

## Amazon ECS-optimized AMI

For more information about the Amazon ECS-optimized AMI, see [Amazon ECS-optimized Linux AMIs](#).

## Additional information

The following pages provide additional information about the changes:

- [Amazon ECS Agent changelog](#) on GitHub
- [Amazon Linux 2 release notes](#).

- [Docker Engine release notes](#) in the Docker documentation
- [NVIDIA Driver Documentation](#) in the NVIDIA documentation

## Amazon ECS container agent configuration

**Applies to:** EC2 instances

The Amazon ECS container agent supports a number of configuration options, most of which you set through environment variables.

If your container instance was launched with a Linux variant of the Amazon ECS-optimized AMI, you can set these environment variables in the `/etc/ecs/ecs.config` file and then restart the agent. You can also write these configuration variables to your container instances with Amazon EC2 user data at launch time. For more information, see [Bootstrapping Amazon ECS Linux container instances to pass data](#).

If your container instance was launched with a Windows variant of the Amazon ECS-optimized AMI, you can set these environment variables with the PowerShell `SetEnvironmentVariable` command and then restart the agent. For more information, see [Run commands when you launch an EC2 instance with user data input](#) in the *Amazon EC2 User Guide* and [the section called “Bootstrapping container instances”](#).

If you are manually starting the Amazon ECS container agent (for non Amazon ECS-optimized AMIs), you can use these environment variables in the **docker run** command that you use to start the agent. Use these variables with the syntax `--env=VARIABLE_NAME=VARIABLE_VALUE`. For sensitive information, such as authentication credentials for private repositories, you should store your agent environment variables in a file and pass them all at one time with the `--env-file path_to_env_file` option. You can use the following commands to add the variables.

```
sudo systemctl stop ecs
sudo vi /etc/ecs/ecs.config
# And add the environment variables with VARIABLE_NAME=VARIABLE_VALUE format.
sudo systemctl start ecs
```

## Run the Amazon ECS agent with the host PID namespace

By default, the Amazon ECS agent runs with its own PID namespace. In the following configurations, you can configure the Amazon ECS agent to run with the host PID namespace:

- SELinux enforcing mode is enabled.
- Docker's SELinux security policy is set to true.

You can configure this behavior by setting the `ECS_AGENT_PID_NAMESPACE_HOST` environment variable to `true` in your `/etc/ecs/ecs.config` file. When this variable is enabled, `ecs-init` will start the Amazon ECS agent container with the host's PID namespace (`--pid=host`), allowing the agent to bootstrap itself properly in SELinux-enforcing environments. This feature is available in Amazon ECS agent version `1.94.0` and later.

To enable this feature, add the following line to your `/etc/ecs/ecs.config` file:

```
ECS_AGENT_PID_NAMESPACE_HOST=true
```

After making this change, restart the Amazon ECS agent for the change to take effect:

```
sudo systemctl restart ecs
```

The following features will not work SELinux enforcing mode is enabled and the Docker security policy is set to true, even when `ECS_AGENT_PID_NAMESPACE_HOST=true` is set.

- Amazon ECS Exec
- Amazon EBS task attach
- Service Connect
- FireLens for Amazon ECS

## Available parameters

For information about the available Amazon ECS container agent configuration parameters, see [Amazon ECS Container Agent](#) on GitHub.

## Storing Amazon ECS container instance configuration in Amazon S3

Amazon ECS container agent configuration is controlled with the environment variable. Linux variants of the Amazon ECS-optimized AMI look for these variables in `/etc/ecs/ecs.config` when the container agent starts and configure the agent accordingly. Non-sensitive environment variables, such as `ECS_CLUSTER`, can be passed to the container instance at launch through Amazon EC2 user data and written to this file without consequence. However, other sensitive

information, such as your AWS credentials or the `ECS_ENGINE_AUTH_DATA` variable, should never be passed to an instance in user data or written to `/etc/ecs/ecs.config` in a way that would allow them to show up in a `.bash_history` file.

Storing configuration information in a private bucket in Amazon S3 and granting read-only access to your container instance IAM role is a secure and convenient way to allow container instance configuration at launch. You can store a copy of your `ecs.config` file in a private bucket. You can then use Amazon EC2 user data to install the AWS CLI and copy your configuration information to `/etc/ecs/ecs.config` when the instance launches.

### To store an `ecs.config` file in Amazon S3

1. You must grant the container instance role (`ecsInstanceRole`) permissions to have read only access to Amazon S3. You can do this by assigning the **AmazonS3ReadOnlyAccess** to the `ecsInstanceRole` role. For information about how to attach a policy to a role, see [Update permissions for a role](#) in the *AWS Identity and Access Management User Guide*
2. Create an `ecs.config` file with valid Amazon ECS agent configuration variables using the following format. This example configures private registry authentication. For more information, see [Using non-AWS container images in Amazon ECS](#).

```
ECS_ENGINE_AUTH_TYPE=dockercfg
ECS_ENGINE_AUTH_DATA={"https://index.docker.io/v1/":
{"auth":"zq212MzEXAMPLE7o6T25Dk0i","email":"email@example.com"}}
```

#### Note

For a full list of available Amazon ECS agent configuration variables, see [Amazon ECS Container Agent](#) on GitHub.

3. To store your configuration file, create a private bucket in Amazon S3. For more information, see [Creating a bucket](#) in the *Amazon Simple Storage Service User Guide*.
4. Upload the `ecs.config` file to your S3 bucket. For more information, see [Uploading objects](#) in the *Amazon Simple Storage Service User Guide*.

### To load an `ecs.config` file from Amazon S3 at launch

1. Complete the earlier procedures in this section to allow read-only Amazon S3 access to your container instances and store an `ecs.config` file in a private S3 bucket.

2. Launch new container instances and use the following example script in the EC2 User data. The script installs the AWS CLI and copies your configuration file to `/etc/ecs/ecs.config`. For more information, see [Launching an Amazon ECS Linux container instance](#).

```
#!/bin/bash
yum install -y aws-cli
aws s3 cp s3://your_bucket_name/ecs.config /etc/ecs/ecs.config
```

## Installing the Amazon ECS container agent

If you want to register an Amazon EC2 instance with your Amazon ECS cluster and that instance is not using an AMI based on the Amazon ECS-optimized AMI, you can install the Amazon ECS container agent manually using the following procedure. To do this, you can either download the agent from one of the regional Amazon S3 buckets or from Amazon Elastic Container Registry Public. If you download from one of the regional Amazon S3 buckets, you can optionally verify the validity of the container agent file using the PGP signature.

### Note

The systemd units for both Amazon ECS and Docker services have a directive to wait for `cloud-init` to finish before starting both services. The `cloud-init` process is not considered finished until your Amazon EC2 user data has finished running. Therefore, starting Amazon ECS or Docker via Amazon EC2 user data may cause a deadlock. To start the container agent using Amazon EC2 user data you can use `systemctl enable --now --no-block ecs.service`.

## Installing the Amazon ECS container agent on a non-Amazon Linux EC2 instance

To install the Amazon ECS container agent on an Amazon EC2 instance, you can download the agent from one of the regional Amazon S3 buckets and install it.

### Note

When using a non-Amazon Linux AMI, your Amazon EC2 instance requires `cgroupfs` support for the `cgroup` driver in order for the Amazon ECS agent to support task level resource limits. For more information, see [Amazon ECS agent on GitHub](#).

The latest Amazon ECS container agent files, by Region, for each system architecture are listed in the following table for reference.

| Region         | Region name              | Amazon ECS init deb files                     | Amazon ECS init rpm files                         |
|----------------|--------------------------|-----------------------------------------------|---------------------------------------------------|
| us-east-2      | US East (Ohio)           | <a href="#">Amazon ECS init amd64</a> (amd64) | <a href="#">Amazon ECS init x86_64</a> (x86_64)   |
|                |                          | <a href="#">Amazon ECS init arm64</a> (arm64) | <a href="#">Amazon ECS init aarch64</a> (aarch64) |
| us-east-1      | US East (N. Virginia)    | <a href="#">Amazon ECS init amd64</a> (amd64) | <a href="#">Amazon ECS init x86_64</a> (x86_64)   |
|                |                          | <a href="#">Amazon ECS init arm64</a> (arm64) | <a href="#">Amazon ECS init aarch64</a> (aarch64) |
| us-west-1      | US West (N. California)  | <a href="#">Amazon ECS init amd64</a> (amd64) | <a href="#">Amazon ECS init x86_64</a> (x86_64)   |
|                |                          | <a href="#">Amazon ECS init arm64</a> (arm64) | <a href="#">Amazon ECS init aarch64</a> (aarch64) |
| us-west-2      | US West (Oregon)         | <a href="#">Amazon ECS init amd64</a> (amd64) | <a href="#">Amazon ECS init x86_64</a> (x86_64)   |
|                |                          | <a href="#">Amazon ECS init arm64</a> (arm64) | <a href="#">Amazon ECS init aarch64</a> (aarch64) |
| ap-east-1      | Asia Pacific (Hong Kong) | <a href="#">Amazon ECS init amd64</a> (amd64) | <a href="#">Amazon ECS init x86_64</a> (x86_64)   |
|                |                          | <a href="#">Amazon ECS init arm64</a> (arm64) | <a href="#">Amazon ECS init aarch64</a> (aarch64) |
| ap-northeast-1 | Asia Pacific (Tokyo)     | <a href="#">Amazon ECS init amd64</a> (amd64) | <a href="#">Amazon ECS init x86_64</a> (x86_64)   |

| Region         | Region name              | Amazon ECS init deb files                     | Amazon ECS init rpm files                         |
|----------------|--------------------------|-----------------------------------------------|---------------------------------------------------|
|                |                          | <a href="#">Amazon ECS init arm64</a> (arm64) | <a href="#">Amazon ECS init aarch64</a> (aarch64) |
| ap-northeast-2 | Asia Pacific (Seoul)     | <a href="#">Amazon ECS init amd64</a> (amd64) | <a href="#">Amazon ECS init x86_64</a> (x86_64)   |

## To install the Amazon ECS container agent on an Amazon EC2 instance using a non-Amazon Linux AMI

1. Launch an Amazon EC2 instance with an IAM role that allows access to Amazon ECS. For more information, see [Amazon ECS container instance IAM role](#).
2. Connect to your instance.
3. Install a supported version of Docker on your instance. For more information, see [Docker Support](#).
4. Check your Docker version to verify that your system meets the minimum version requirement. For more information about Docker support, see [Amazon ECS EC2 Container Instances](#).

```
docker --version
```

5. Download the appropriate Amazon ECS agent file for your operating system and system architecture and install it.

For deb architectures:

```
ubuntu:~$ curl -O https://s3.us-west-2.amazonaws.com/amazon-ecs-agent-us-west-2/
amazon-ecs-init-latest.amd64.deb
ubuntu:~$ sudo dpkg -i amazon-ecs-init-latest.amd64.deb
```

For rpm architectures:

```
fedora:~$ curl -O https://s3.us-west-2.amazonaws.com/amazon-ecs-agent-us-west-2/
amazon-ecs-init-latest.x86_64.rpm
fedora:~$ sudo yum localinstall -y amazon-ecs-init-latest.x86_64.rpm
```

6. Edit the `/lib/systemd/system/ecs.service` file and add the following line at the end of the `[Unit]` section.

```
After=cloud-final.service
```

7. (Optional) To register the instance with a cluster other than the default cluster, edit the `/etc/ecs/ecs.config` file and add the following contents. The following example specifies the `MyCluster` cluster.

```
ECS_CLUSTER=MyCluster
```

For more information about these and other agent runtime options, see [Amazon ECS container agent configuration](#).

#### Note

You can optionally store your agent environment variables in Amazon S3 (which can be downloaded to your container instances at launch time using Amazon EC2 user data). We recommend this approach for sensitive information such as authentication credentials for private repositories. For more information, see [Storing Amazon ECS container instance configuration in Amazon S3](#) and [Using non-AWS container images in Amazon ECS](#).

8. Start the `ecs` service.

```
ubuntu:~$ sudo systemctl start ecs
```

## Running the Amazon ECS agent with host network mode

When running the Amazon ECS container agent, `ecs-init` will create the container agent container with the host network mode. This is the only supported network mode for the container agent container.

This allows you to block access to the [Amazon EC2 instance metadata service endpoint](#) (`http://169.254.169.254`) for the containers started by the container agent. This ensures that containers cannot access IAM role credentials from the container instance profile and enforces that tasks use only the IAM task role credentials. For more information, see [Amazon ECS task IAM role](#).

This also makes it so the container agent doesn't contend for connections and network traffic on the `docker0` bridge.

## Amazon ECS container agent log configuration parameters

The Amazon ECS container agent stores logs on your container instances.

For container agent version 1.36.0 and later, by default the logs are located at `/var/log/ecs/ecs-agent.log` on Linux instances and at `C:\ProgramData\Amazon\ECS\log\ecs-agent.log` on Windows instances.

For container agent version 1.35.0 and earlier, by default the logs are located at `/var/log/ecs/ecs-agent.log.timestamp` on Linux instances and at `C:\ProgramData\Amazon\ECS\log\ecs-agent.log.timestamp` on Windows instances.

By default, the agent logs are rotated hourly with a maximum of 24 logs being stored.

The following are the container agent configuration variables that can be used to change the default agent logging behavior. For detailed information about all available configuration parameters, see [Amazon ECS container agent configuration](#) or the [Amazon ECS Agent README](#) on GitHub.

For container agent version 1.36.0 and later, the following is an example log file when the `logfmt` format is used.

```
level=info time=2019-12-12T23:43:29Z msg="Loading configuration" module=agent.go
level=info time=2019-12-12T23:43:29Z msg="Image excluded from cleanup: amazon/amazon-ecs-agent:latest" module=parse.go
level=info time=2019-12-12T23:43:29Z msg="Image excluded from cleanup: amazon/amazon-ecs-pause:0.1.0" module=parse.go
level=info time=2019-12-12T23:43:29Z msg="Amazon ECS agent Version: 1.36.0, Commit: ca640387" module=agent.go
level=info time=2019-12-12T23:43:29Z msg="Creating root ecs cgroup: /ecs" module=init_linux.go

level=info time=2019-12-12T23:43:29Z msg="Event stream ContainerChange start listening..." module=eventstream.go
level=info time=2019-12-12T23:43:29Z msg="Restored cluster 'auto-robc'" module=agent.go
```

```
level=info time=2019-12-12T23:43:29Z msg="Restored from checkpoint file. I
am running as 'arn:aws:ecs:us-west-2:0123456789:container-instance/auto-
robc/3330a8a91d15464ea30662d5840164cd' in cluster 'auto-robc'" module=agent.go
```

The following is an example log file when the JSON format is used.

```
{"time": "2019-11-07T22:52:02Z", "level": "info", "msg": "Starting Amazon Elastic
Container Service Agent", "module": "engine.go"}
```

## Configuring Amazon ECS container instances for private Docker images

The Amazon ECS container agent can authenticate with private registries, using basic authentication. When you enable private registry authentication, you can use private Docker images in your task definitions. This feature is only supported by tasks using EC2.

Another method of enabling private registry authentication uses AWS Secrets Manager to store your private registry credentials securely and then reference them in your container definition. This allows your tasks to use images from private repositories. This method supports tasks using either EC2 or Fargate. For more information, see [Using non-AWS container images in Amazon ECS](#).

The Amazon ECS container agent looks for two environment variables when it launches:

- `ECS_ENGINE_AUTH_TYPE`, which specifies the type of authentication data that is being sent.
- `ECS_ENGINE_AUTH_DATA`, which contains the actual authentication credentials.

Linux variants of the Amazon ECS-optimized AMI scan the `/etc/ecs/ecs.config` file for these variables when the container instance launches, and each time the service is started (with the **sudo start ecs** command). AMIs that are not Amazon ECS-optimized should store these environment variables in a file and pass them with the `--env-file` *path\_to\_env\_file* option to the **docker run** command that starts the container agent.

### Important

We do not recommend that you inject these authentication environment variables at instance launch with Amazon EC2 user data or pass them with the `--env` option to the **docker run** command. These methods are not appropriate for sensitive data, such as authentication credentials. For information about safely adding authentication credentials

to your container instances, see [Storing Amazon ECS container instance configuration in Amazon S3](#).

## Authentication formats

There are two available formats for private registry authentication, `dockercfg` and `docker`.

### `dockercfg` authentication format

The `dockercfg` format uses the authentication information stored in the configuration file that is created when you run the **docker login** command. You can create this file by running **docker login** on your local system and entering your registry user name, password, and email address. You can also log in to a container instance and run the command there. Depending on your Docker version, this file is saved as either `~/.dockercfg` or `~/.docker/config.json`.

```
cat ~/.docker/config.json
```

Output:

```
{
  "auths": {
    "https://index.docker.io/v1/": {
      "auth": "zq212MzEXAMPLE7o6T25Dk0i"
    }
  }
}
```

### Important

Newer versions of Docker create a configuration file as shown in the preceding example with an outer `auths` object. The Amazon ECS agent only supports `dockercfg` authentication data that is in the following format, without the `auths` object. If you have the **jq** utility installed, you can extract this data with the following command: **cat ~/.docker/config.json | jq .auths**

```
cat ~/.docker/config.json | jq .auths
```

**Output:**

```
{
  "https://index.docker.io/v1/": {
    "auth": "zq212MzEXAMPLE7o6T25Dk0i",
    "email": "email@example.com"
  }
}
```

In the preceding example, the following environment variables should be added to the environment variable file (`/etc/ecs/ecs.config` for the Amazon ECS-optimized AMI) that the Amazon ECS container agent loads at runtime. If you are not using an Amazon ECS-optimized AMI and you are starting the agent manually with **docker run**, specify the environment variable file with the `--env-file path_to_env_file` option when you start the agent.

```
ECS_ENGINE_AUTH_TYPE=dockercfg
ECS_ENGINE_AUTH_DATA={"https://index.docker.io/v1/":
{"auth":"zq212MzEXAMPLE7o6T25Dk0i","email":"email@example.com"}}
```

You can configure multiple private registries with the following syntax:

```
ECS_ENGINE_AUTH_TYPE=dockercfg
ECS_ENGINE_AUTH_DATA={"repo.example-01.com":
{"auth":"zq212MzEXAMPLE7o6T25Dk0i","email":"email@example-01.com"}, "repo.example-02.com":
{"auth":"fQ172MzEXAMPLEoF7225DU0j","email":"email@example-02.com"}}
```

**docker authentication format**

The `docker` format uses a JSON representation of the registry server that the agent should authenticate with. It also includes the authentication parameters required by that registry (such as user name, password, and the email address for that account). For a Docker Hub account, the JSON representation looks like the following:

```
{
  "https://index.docker.io/v1/": {
    "username": "my_name",
    "password": "my_password",
    "email": "email@example.com"
  }
}
```

In this example, the following environment variables should be added to the environment variable file (`/etc/ecs/ecs.config` for the Amazon ECS-optimized AMI) that the Amazon ECS container agent loads at runtime. If you are not using an Amazon ECS-optimized AMI, and you are starting the agent manually with **docker run**, specify the environment variable file with the `--env-file path_to_env_file` option when you start the agent.

```
ECS_ENGINE_AUTH_TYPE=docker
ECS_ENGINE_AUTH_DATA={"https://index.docker.io/v1/":
{"username":"my_name","password":"my_password","email":"email@example.com"}}
```

You can configure multiple private registries with the following syntax:

```
ECS_ENGINE_AUTH_TYPE=docker
ECS_ENGINE_AUTH_DATA={"repo.example-01.com":
{"username":"my_name","password":"my_password","email":"email@example-01.com"},
"repo.example-02.com":
{"username":"another_name","password":"another_password","email":"email@example-02.com"}}
```

## Procedure

Use the following procedure to turn on private registries for your container instances.

### To enable private registries in the Amazon ECS-optimized AMI

1. Log in to your container instance using SSH.
2. Open the `/etc/ecs/ecs.config` file and add the `ECS_ENGINE_AUTH_TYPE` and `ECS_ENGINE_AUTH_DATA` values for your registry and account:

```
sudo vi /etc/ecs/ecs.config
```

This example authenticates a Docker Hub user account:

```
ECS_ENGINE_AUTH_TYPE=docker
ECS_ENGINE_AUTH_DATA={"https://index.docker.io/v1/":
{"username":"my_name","password":"my_password","email":"email@example.com"}}
```

3. Check to see if your agent uses the `ECS_DATADIR` environment variable to save its state:

```
docker inspect ecs-agent | grep ECS_DATADIR
```

Output:

```
"ECS_DATADIR=/data",
```

 **Important**

If the previous command does not return the ECS\_DATADIR environment variable, you must stop any tasks running on this container instance before stopping the agent. Newer agents with the ECS\_DATADIR environment variable save their state and you can stop and start them while tasks are running without issues. For more information, see [Updating the Amazon ECS container agent](#).

4. Stop the ecs service:

```
sudo stop ecs
```

Output:

```
ecs stop/waiting
```

5. Restart the ecs service.

- For the Amazon ECS-optimized Amazon Linux 2 AMI:

```
sudo systemctl restart ecs
```

- For the Amazon ECS-optimized Amazon Linux AMI:

```
sudo stop ecs && sudo start ecs
```

6. (Optional) You can verify that the agent is running and see some information about your new container instance by querying the agent introspection API operation. For more information, see [the section called "Container introspection"](#).

```
curl http://localhost:51678/v1/metadata
```

## Automatic Amazon ECS task and image cleanup

Each time a task is placed on a container instance, the Amazon ECS container agent checks to see if the images referenced in the task are the most recent of the specified tag in the repository. If not, the default behavior allows the agent to pull the images from their respective repositories. If you frequently update the images in your tasks and services, your container instance storage can quickly fill up with Docker images that you are no longer using and may never use again. For example, you may use a continuous integration and continuous deployment (CI/CD) pipeline.

### Note

The Amazon ECS agent image pull behavior can be customized using the `ECS_IMAGE_PULL_BEHAVIOR` parameter. For more information, see [Amazon ECS container agent configuration](#).

Likewise, containers that belong to stopped tasks can also consume container instance storage with log information, data volumes, and other artifacts. These artifacts are useful for debugging containers that have stopped unexpectedly, but most of this storage can be safely freed up after a period of time.

By default, the Amazon ECS container agent automatically cleans up stopped tasks and Docker images that are not being used by any tasks on your container instances.

### Note

The automated image cleanup feature requires at least version 1.13.0 of the Amazon ECS container agent. To update your agent to the latest version, see [Updating the Amazon ECS container agent](#).

The following agent configuration variables are available to tune your automated task and image cleanup experience. For more information about how to set these variables on your container instances, see [Amazon ECS container agent configuration](#).

## ECS\_ENGINE\_TASK\_CLEANUP\_WAIT\_DURATION

The default time to wait to delete containers for a stopped task. If the value is set to less than 1 second, the value is ignored. By default, this parameter is set to 3 hours, but you can reduce this period to as low as 1 second if you need to for your application.

### Note

The image cleanup process cannot delete an image as long as there is a container that references it. After containers are removed, any unreferenced images become candidates for cleanup based on the image cleanup configuration parameters.

## ECS\_DISABLE\_IMAGE\_CLEANUP

If you set this variable to `true`, then automated image cleanup is turned off on your container instance and no images are automatically removed.

## ECS\_IMAGE\_CLEANUP\_INTERVAL

This variable specifies how frequently the automated image cleanup process should check for images to delete. The default is every 30 minutes but you can reduce this period to as low as 10 minutes to remove images more frequently.

## ECS\_IMAGE\_MINIMUM\_CLEANUP\_AGE

This variable specifies the minimum amount of time between when an image was pulled and when it may become a candidate for removal. This is used to prevent cleaning up images that have just been pulled. The default is 1 hour.

## ECS\_NUM\_IMAGES\_DELETE\_PER\_CYCLE

This variable specifies how many images may be removed during a single cleanup cycle. The default is 5 and the minimum is 1.

When the Amazon ECS container agent is running and automated image cleanup is not turned off, the agent checks for Docker images that are not referenced by running or stopped containers at a frequency determined by the `ECS_IMAGE_CLEANUP_INTERVAL` variable. If unused images are found and they are older than the minimum cleanup time specified by the `ECS_IMAGE_MINIMUM_CLEANUP_AGE` variable, the agent removes up to the maximum number of images that are specified with the `ECS_NUM_IMAGES_DELETE_PER_CYCLE` variable. The least-

recently referenced images are deleted first. After the images are removed, the agent waits until the next interval and repeats the process again.

# Schedule your containers on Amazon ECS

Amazon Elastic Container Service (Amazon ECS) is a shared state, optimistic concurrency system that provides flexible scheduling capabilities for your containerized workloads. The Amazon ECS schedulers use the same cluster state information as the Amazon ECS API to make appropriate placement decisions.

Amazon ECS provides a service scheduler for long-running tasks and applications. It also provides the ability to run standalone tasks or scheduled tasks for batch jobs or single run tasks. You can specify the task placement strategies and constraints for running tasks that best meet your needs. For example, you can specify whether tasks run across multiple Availability Zones or within a single Availability Zone. And, optionally, you can integrate tasks with your own custom or third-party schedulers.

| Option  | When to use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | More information                    |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| Service | The <i>service scheduler</i> is suitable for long running stateless services and applications. The service scheduler optionally also makes sure that tasks are registered against an Elastic Load Balancing load balancer. You can update your services that are maintained by the service scheduler. This might include deploying a new task definition or changing the number of desired tasks that are running. By default, the service scheduler spreads tasks across multiple Availabil<br>ity Zones. However, you can use task placement strategies | <a href="#">Amazon ECS services</a> |

| Option          | When to use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | More information                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
|                 | and constraints to customize task placement decisions.                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                             |
| Standalone task | A standalone task is suitable for processes such as batch jobs that perform work and then stop. For example, you can have a process call <code>RunTask</code> when work comes into a queue. The task pulls work from the queue, performs the work, and then exits. Using <code>RunTask</code> , you can allow the default task placement strategy to distribute tasks randomly across your cluster. This minimizes the chances that a single instance gets a disproportionate number of tasks. | <a href="#">Amazon ECS standalone tasks</a> |

| Option          | When to use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | More information                                                                |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Scheduled tasks | A scheduled task is suitable when you have tasks to run at set intervals in your cluster, you can use EventBridge Scheduler to create a schedule. You can run tasks for a backup operation or a log scan. The EventBridge Scheduler schedule that you create can run one or more tasks in your cluster at specified times. Your scheduled event can be set to a specific interval (run every <i>N</i> minutes, hours, or days). Otherwise, for more complicated scheduling, you can use a <code>cron</code> expression. | <a href="#">Using Amazon EventBridge Scheduler to schedule Amazon ECS tasks</a> |

## Compute options

With Amazon ECS, you can specify the infrastructure your tasks or services run on. You can use a capacity provider strategy, or a launch type.

For Fargate, the capacity providers are Fargate and Fargate Spot. For EC2, the capacity provider is the Auto Scaling group with the registered container instances.

The capacity provider strategy distributes your tasks across the capacity providers associated with your cluster.

Only capacity providers that are both already associated with a cluster and have an `ACTIVE` or `UPDATING` status can be used in a capacity provider strategy. You can associate a capacity provider with a cluster when you create a cluster.

In a capacity provider strategy, the optional *base* value designates how many tasks, at a minimum, run on a specified capacity provider. Only one capacity provider in a capacity provider strategy can have a base defined.

The *weight* value determines the relative percentage of the total number of launched tasks that use the specified capacity provider. Consider the following example. You have a strategy that contains two capacity providers, and both have a weight of 1. When the base percentage is reached, the tasks are split evenly across the two capacity providers. Using that same logic, suppose that you specify a weight of 1 for *capacityProviderA* and a weight of 4 for *capacityProviderB*. Then, for every one task that's run using *capacityProviderA*, there are four tasks that use *capacityProviderB*.

The compute option launches your tasks directly on either Fargate or on the Amazon EC2 instances that you have manually registered to your clusters.

## Amazon ECS task lifecycle

When a task is started, either manually or as part of a service, it can pass through several states before it finishes on its own or is stopped manually. Some tasks are meant to run as batch jobs that naturally progress through from PENDING to RUNNING to STOPPED. Other tasks, which can be part of a service, are meant to continue running indefinitely, or to be scaled up and down as needed.

When task status changes are requested, such as stopping a task or updating the desired count of a service to scale it up or down, the Amazon ECS container agent tracks these changes as the last known status (*lastStatus*) of the task and the desired status (*desiredStatus*) of the task. Both the last known status and desired status of a task can be seen either in the console or by describing the task with the API or AWS CLI.

The flow chart below shows the task lifecycle flow.

## Lifecycle states

The following are descriptions of each of the task lifecycle states.

### PROVISIONING

Amazon ECS has to perform additional steps before the task is launched. For example, for tasks that use the `awsvpc` network mode, the elastic network interface needs to be provisioned.

### PENDING

This is a transition state where Amazon ECS is waiting on the container agent to take further action. A task stays in the pending state until there are available resources for the task.

## ACTIVATING

This is a transition state where Amazon ECS has to perform additional steps after the task is launched but before the task can transition to the RUNNING state. This is the state where Amazon ECS pulls the container images, creates the containers, configures the task networking, registers load balancer target groups, and configures service discovery.

## RUNNING

The task is successfully running.

## DEACTIVATING

This is a transition state where Amazon ECS has to perform additional steps before the task is stopped. For example, for tasks that are part of a service that's configured to use Elastic Load Balancing target groups, the target group deregistration occurs during this state.

## STOPPING

This is a transition state where Amazon ECS is waiting on the container agent to take further action.

For Linux containers, the container agent will send the stop signal defined in your container image to notify the application needs to finish and shut down using the STOPSIGNAL instruction. This is SIGTERM by default. Then it will send a SIGKILL after waiting the StopTimeout duration set in the task definition.

## DEPROVISIONING

Amazon ECS has to perform additional steps after the task has stopped but before the task transitions to the STOPPED state. For example, for tasks that use the awsvpc network mode, the elastic network interface needs to be detached and deleted.

## STOPPED

The task has been successfully stopped.

If your task stopped because of an error, see [Viewing Amazon ECS stopped task errors](#).

## DELETED

This is a transition state when a task stops. This state is not displayed in the console, but is displayed in `describe-tasks`.

# How Amazon ECS places tasks on container instances

You can use task placement to configure Amazon ECS to place your tasks on container instances that meet certain criteria, for example an Availability Zone or instance type.

The following are task placement components:

- Task placement strategy - The algorithm for selecting container instances for task placement or tasks for termination. For example, Amazon ECS can select container instances at random, or it can select container instances such that tasks are distributed evenly across a group of instances.
- Task group - A group of related tasks, for example database tasks.
- Task placement constraint - These are rules that must be met in order to place a task on a container instance. If the constraint is not met, the task is not placed and remains in the PENDING state. For example, you can use a constraint to place tasks only on a particular instance type.

Amazon ECS has different algorithms for the different capacity options.

## Amazon ECS Managed Instances

For tasks that run on Amazon ECS Managed Instances, Amazon ECS must determine where to place the task, and — when scaling down task count — which tasks to terminate. Amazon ECS makes this determination based on the instance requirements specified in the capacity provider launch template, requirements specified in the task definition such as CPU and memory, and task placement constraints.

### Note

Amazon ECS Managed Instances does not support task placement strategies. Amazon ECS will try its best to spread tasks across accessible Availability Zones.

When Amazon ECS places tasks, it uses the following process to select container instances:

1. Identify the container instances that satisfy the CPU, GPU, memory, and port requirements in the task definition.
2. Identify the container instances that satisfy the task placement constraints.

3. Identify the container instances that satisfy the instance requirements specified in the capacity provider launch template.
4. Select the container instances for task placement.

## EC2

For tasks that use the EC2 launch type, Amazon ECS must determine where to place the task based on the requirements specified in the task definition, such as CPU and memory. Similarly, when you scale down the task count, Amazon ECS must determine which tasks to terminate. You can apply task placement strategies and constraints to customize how Amazon ECS places and terminates tasks.

The default task placement strategies depend on whether you run tasks manually (standalone tasks) or within a service. For tasks running as part of an Amazon ECS service, the task placement strategy is spread using the `attribute:ecs.availability-zone`. There isn't a default task placement constraint for tasks not in services. For more information, see [Schedule your containers on Amazon ECS](#).

### Note

Task placement strategies are a best effort. Amazon ECS still attempts to place tasks even when the most optimal placement option is unavailable. However, task placement constraints are binding, and they can prevent task placement.

You can use task placement strategies and constraints together. For example, you can use a task placement strategy and a task placement constraint to distribute tasks across Availability Zones and bin pack tasks based on memory within each Availability Zone, but only for G2 instances.

When Amazon ECS places tasks, it uses the following process to select container instances:

1. Identify the container instances that satisfy the CPU, GPU, memory, and port requirements in the task definition.
2. Identify the container instances that satisfy the task placement constraints.
3. Identify the container instances that satisfy the task placement strategies.
4. Select the container instances for task placement.

## Fargate

Task placement strategies and constraints aren't supported for tasks using the Fargate. Fargate will try its best to spread tasks across accessible Availability Zones. If the capacity provider includes both Fargate and Fargate Spot, the spread behavior is independent for each capacity provider.

## Amazon ECS Managed Instances auto scaling and task placement

Amazon ECS Managed Instances use intelligent algorithms to automatically scale your cluster capacity and place tasks efficiently across your infrastructure. Understanding how these algorithms work helps you optimize your service configurations and troubleshoot placement behaviors.

### Task placement algorithm

Amazon ECS Managed Instances use a sophisticated placement algorithm that balances availability, resource utilization, and network requirements when scheduling tasks.

#### Availability Zone spread

By default, Amazon ECS Managed Instances prioritize availability by spreading tasks across multiple Availability Zones:

- For services with multiple tasks, Amazon ECS Managed Instances ensure distribution across at least 3 instances in different Availability Zones when possible
- This behavior provides fault tolerance but may result in lower resource utilization per instance
- Availability Zone spread takes precedence over bin packing optimization

#### Bin packing behavior

While Amazon ECS Managed Instances can perform bin packing to maximize resource utilization, this behavior is influenced by your network configuration:

- To achieve bin packing, configure your service to use a single subnet
- Multi-subnet configurations prioritize Availability Zone distribution over resource density
- Bin packing is more likely during initial service launch than during scaling events

## ENI density considerations

For services using the awsvpc network mode, Amazon ECS Managed Instances consider Elastic Network Interface (ENI) density when making placement decisions:

- Each task in awsvpc mode requires a dedicated ENI
- Instance types have different ENI limits that affect task density
- Amazon ECS Managed Instances account for ENI availability when selecting target instances

### Note

Improvements to ENI density calculations are continuously being made to optimize placement decisions.

## Capacity provider decision logic

Amazon ECS Managed Instances capacity providers make scaling and placement decisions based on multiple factors:

### Resource requirements

CPU, memory, and network requirements of pending tasks

### Instance availability

Current capacity and utilization across existing instances

### Network constraints

Subnet configuration and ENI availability

### Availability Zone distribution

Maintaining fault tolerance across multiple Availability Zones

## Configuration options

### Subnet selection strategy

Your subnet configuration significantly impacts task placement behavior:

## Multiple subnets (default)

Prioritizes Availability Zone spread for high availability

May result in lower resource utilization per instance

Recommended for production workloads requiring fault tolerance

## Single subnet

Enables bin packing for higher resource utilization

Reduces fault tolerance by concentrating tasks in one Availability Zone

Suitable for development or cost-optimized workloads

## Network mode considerations

The network mode you choose affects placement decisions:

- `awsvpc` mode – Each task requires a dedicated ENI, limiting task density per instance
- `host` mode – Tasks use the host's network directly, with placement primarily driven by resource availability

## CPU architecture considerations

The `cpuArchitecture` that you specify in your task definition is used for placing tasks on a specific architecture. If you don't specify a `cpuArchitecture`, Amazon ECS will try to place tasks on any available CPU architecture based on the capacity provider configuration. You can specify either `X86_64` or `ARM64`.

## Troubleshooting task placement

### Common placement patterns

Understanding expected placement patterns helps distinguish normal behavior from potential issues:

#### Spread distribution

Tasks distributed across multiple instances with partial utilization

Normal behavior when using multiple subnets

Indicates prioritization of availability over resource efficiency

Concentrated placement

Multiple tasks placed on fewer instances with higher utilization

Expected when using single subnet configuration

May occur during initial service launch

Uneven distribution

Some instances heavily utilized while others remain underutilized

May indicate ENI limits or resource constraints

Consider reviewing instance types and network configuration

## Optimizing placement behavior

To optimize task placement for your specific requirements:

1. Evaluate your availability requirements versus cost optimization needs
2. Choose appropriate subnet configuration based on your priorities
3. Select instance types with adequate ENI capacity for your network mode
4. Monitor placement patterns and adjust configuration as needed

## Best practices

- **For production workloads** – Use multiple subnets across different Availability Zones to ensure high availability, accepting the trade-off in resource utilization
- **For development or testing** – Consider single subnet configuration to maximize resource utilization and reduce costs
- **For awsvpc mode** – Choose instance types with sufficient ENI capacity to avoid placement constraints
- **For cost optimization** – Monitor utilization patterns and adjust service configuration to balance availability and efficiency
- **For troubleshooting** – Review subnet configuration and network mode when investigating unexpected placement patterns

## Use strategies to define Amazon ECS task placement

For tasks that use the EC2 launch type, Amazon ECS must determine where to place the task based on the requirements specified in the task definition, such as CPU and memory. Similarly, when you scale down the task count, Amazon ECS must determine which tasks to terminate. You can apply task placement strategies and constraints to customize how Amazon ECS places and terminates tasks.

The default task placement strategies depend on whether you run tasks manually (standalone tasks) or within a service. For tasks running as part of an Amazon ECS service, the task placement strategy is spread using the `attribute:ecs.availability-zone`. There isn't a default task placement constraint for tasks not in services. For more information, see [Schedule your containers on Amazon ECS](#).

### Note

Task placement strategies are a best effort. Amazon ECS still attempts to place tasks even when the most optimal placement option is unavailable. However, task placement constraints are binding, and they can prevent task placement.

You can use task placement strategies and constraints together. For example, you can use a task placement strategy and a task placement constraint to distribute tasks across Availability Zones and bin pack tasks based on memory within each Availability Zone, but only for G2 instances.

When Amazon ECS places tasks, it uses the following process to select container instances:

1. Identify the container instances that satisfy the CPU, GPU, memory, and port requirements in the task definition.
2. Identify the container instances that satisfy the task placement constraints.
3. Identify the container instances that satisfy the task placement strategies.
4. Select the container instances for task placement.

You specify task placement strategies in the service definition, or task definition using the `placementStrategy` parameter.

```
"placementStrategy": [
```

```
{
  "field": "The field to apply the placement strategy against",
  "type": "The placement strategy to use"
}
```

You can specify the strategies when you run a task ([RunTask](#)), create a new service ( [CreateService](#)), or update an existing service ([UpdateService](#)).

The following table describes the available types and fields.

| type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Valid field values                                                     |  |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|--|
| binpack<br><br>Tasks are placed on container instances so as to leave the least amount of unused CPU or memory. This strategy minimizes the number of container instances in use.<br><br>When this strategy is used and a scale-in action is taken, Amazon ECS terminates tasks. It does this based on the amount of resources that are left on the container instance after the task is terminated. The container instance that has the most available resources left after task termination has that task terminated. | <ul style="list-style-type: none"><li>• cpu</li><li>• memory</li></ul> |  |
| random<br><br>Tasks are placed randomly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Not used                                                               |  |

| type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Valid field values                                                                                                                                                                                                                                                  |  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <b>spread</b><br><br>Tasks are placed evenly based on the specified value. Service tasks are spread based on the tasks from that service. Standalone tasks are spread based on the tasks from the same task group. For more information about task groups, see <a href="#">Group related Amazon ECS tasks</a> .<br><br>When the spread strategy is used and a scale-in action is taken, Amazon ECS selects tasks to terminate that maintain a balance across Availability Zones. Within an Availability Zone, tasks are selected at random. | <ul style="list-style-type: none"><li>• <code>instanceId</code> (or <code>host</code>, which has the same effect)</li><li>• any platform or custom attribute that's applied to a container instance, such as <code>attribute:ecs.availability-zone</code></li></ul> |  |

The task placement strategies can be updated for existing services as well. For more information, see [How Amazon ECS places tasks on container instances](#).

You can create a task placement strategy that uses multiple strategies by creating arrays of strategies in the order that you want them performed. For example, if you want to spread tasks across Availability Zones and then bin pack tasks based on memory within each Availability Zone, specify the Availability Zone strategy followed by the memory strategy. For example strategies, see [Example Amazon ECS task placement strategies](#).

## Example Amazon ECS task placement strategies

You can specify task placement strategies with the following actions: [CreateService](#), [UpdateService](#), and [RunTask](#).

## Examples

- [Distribute tasks evenly across Availability Zones](#)
- [Distribute tasks evenly across all instances](#)
- [Bin pack tasks based on memory](#)
- [Place tasks randomly](#)
- [Distribute tasks evenly across Availability Zones and then distributes tasks evenly across the instances within each Availability Zone](#)
- [Distribute tasks evenly across Availability Zones and then bin pack tasks based on memory within each Availability Zone](#)
- [Distribute tasks evenly across instances and then bin pack tasks based on memory](#)

### Distribute tasks evenly across Availability Zones

The following strategy distributes tasks evenly across Availability Zones.

```
"placementStrategy": [  
  {  
    "field": "attribute:ecs.availability-zone",  
    "type": "spread"  
  }  
]
```

### Distribute tasks evenly across all instances

The following strategy distributes tasks evenly across all instances.

```
"placementStrategy": [  
  {  
    "field": "instanceId",  
    "type": "spread"  
  }  
]
```

### Bin pack tasks based on memory

The following strategy bin packs tasks based on memory.

```
"placementStrategy": [  
  {
```

```
        "field": "memory",
        "type": "binpack"
    }
]
```

## Place tasks randomly

The following strategy places tasks randomly.

```
"placementStrategy": [
  {
    "type": "random"
  }
]
```

## Distribute tasks evenly across Availability Zones and then distributes tasks evenly across the instances within each Availability Zone

The following strategy distributes tasks evenly across Availability Zones and then distributes tasks evenly across the instances within each Availability Zone.

```
"placementStrategy": [
  {
    "field": "attribute:ecs.availability-zone",
    "type": "spread"
  },
  {
    "field": "instanceId",
    "type": "spread"
  }
]
```

## Distribute tasks evenly across Availability Zones and then bin pack tasks based on memory within each Availability Zone

The following strategy distributes tasks evenly across Availability Zones and then bin packs tasks based on memory within each Availability Zone.

```
"placementStrategy": [
  {
    "field": "attribute:ecs.availability-zone",
    "type": "spread"
  }
]
```

```
    },  
    {  
      "field": "memory",  
      "type": "binpack"  
    }  
  ]  
}
```

### Distribute tasks evenly across instances and then bin pack tasks based on memory

The following strategy distributes tasks evenly across all instances and then bin packs tasks based on memory within each instance.

```
"placementStrategy": [  
  {  
    "field": "instanceId",  
    "type": "spread"  
  },  
  {  
    "field": "memory",  
    "type": "binpack"  
  }  
]
```

## Group related Amazon ECS tasks

You can identify a set of related tasks and place them in a task group. All tasks with the same task group name are considered as a set when using the spread task placement strategy. For example, suppose that you're running different applications in one cluster, such as databases and web servers. To ensure that your databases are balanced across Availability Zones, add them to a task group named databases and then use the spread task placement strategy. For more information, see [Use strategies to define Amazon ECS task placement](#).

Task groups can also be used as a task placement constraint. When you specify a task group in the `memberOf` constraint, tasks are only sent to container instances that run tasks in the specified task group. For an example, see [Example Amazon ECS task placement constraints](#).

By default, standalone tasks use the task definition family name (for example, `family:my-task-definition`) as the task group name if a custom task group name isn't specified. Tasks launched as part of a service use the service name as the task group name and can't be changed.

The following requirements for the task group apply.

- A task group name must be 255 or fewer characters.
- Each task can be in exactly one group.
- After launching a task, you can't modify its task group.

## Define which container instances Amazon ECS uses for tasks

A task placement constraint is a rule about a container instance that Amazon ECS uses to determine if the task is allowed to run on the instance. At least one container instance must match the constraint. If there are no instances that match the constraint, the task remains in a PENDING state. When you create a new service or update an existing one, you can specify task placement constraints for the service's tasks.

You can specify task placement constraints in the service definition, task definition, or task using the `placementConstraint` parameter.

```
"placementConstraints": [  
  {  
    "expression": "The expression that defines the task placement constraints",  
    "type": "The placement constraint type to use"  
  }  
]
```

The following table describes how to use the parameters.

| Constraint type                                                                                                                                                                                                                                                                                   | Can be specified when                                                                                                                                    |  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <code>distinctInstance</code><br><br>Place each active task on a different container instance.<br><br>Amazon ECS looks at the desired status of the tasks for the task placement. For example, if the desired status of the existing task is STOPPED, (but the last status isn't), a new incoming | <ul style="list-style-type: none"><li>• Running a task <a href="#">RunTask</a></li><li>• Creating a new service <a href="#">CreateService</a>,</li></ul> |  |

| Constraint type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Can be specified when |  |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|--|
| <p>task can be placed on the same instance despite the <code>distinctInstance</code> placement constraint. Therefore, you might see 2 tasks with last status of <code>RUNNING</code> on the same instance.</p> <div><div><div><div><div><div></div><div>Important</div></div></div><div><p>We recommend that customers looking for strong isolation for their tasks use Fargate. Fargate runs each task in a hardware virtualization environment. This ensures that these containerized workloads do not share network interfaces, Fargate ephemeral storage, CPU, or memory with other tasks.</p></div></div></div></div> |                       |  |

| Constraint type                                                                       | Can be specified when                                                                                                                                                                                                                                                                                                                                                                         |  |
|---------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <b>memberOf</b><br><br>Place tasks on container instances that satisfy an expression. | <ul style="list-style-type: none"> <li>Running a task <a href="#">RunTask</a></li> <li>Creating a new service <a href="#">CreateService</a>,</li> <li>Creating a new task definition <a href="#">RegisterTaskDefinition</a></li> <li>Creating a new revision of a task definition <a href="#">RegisterTaskDefinition</a></li> <li>Updating a service <a href="#">UpdateService</a></li> </ul> |  |

When you use the `memberOf` constraint type, you can create an expression using the cluster query language which defines the container instances where Amazon ECS can place tasks. The expression is a way for you to group your container instances by attributes. The expression goes in the `expression` parameter of `placementConstraint`.

## Amazon ECS container instance attributes

You can add custom metadata to your container instances, known as *attributes*. Each attribute has a name and an optional string value. You can use the built-in attributes provided by Amazon ECS or define custom attributes.

The following sections contain sample built-in, optional, and custom attributes.

### Built-in attributes

Amazon ECS automatically applies the following attributes to your container instances.

`ecs.ami-id`

The ID of the AMI used to launch the instance. An example value for this attribute is `ami-1234abcd`.

`ecs.availability-zone`

The Availability Zone for the instance. An example value for this attribute is `us-east-1a`.

## `ecs.instance-type`

The instance type for the instance. An example value for this attribute is `g2.2xlarge`.

## `ecs.os-type`

The operating system for the instance. The possible values for this attribute are `linux` and `windows`.

## `ecs.os-family`

The operating system version for the instance.

For Linux instances, the valid value is `LINUX`. For Windows instances, ECS sets the value in the `WINDOWS_SERVER_<OS_Release>_<FULL or CORE>` format. The valid values are `WINDOWS_SERVER_2022_FULL`, `WINDOWS_SERVER_2022_CORE`, `WINDOWS_SERVER_20H2_CORE`, `WINDOWS_SERVER_2019_FULL`, `WINDOWS_SERVER_2019_CORE`, and `WINDOWS_SERVER_2016_FULL`.

This is important for Windows containers and Windows containers on AWS Fargate because the OS version of every Windows container must match that of the host. If the Windows version of the container image is different than the host, the container doesn't start. For more information, see [Windows container version compatibility](#) on the Microsoft documentation website.

If your cluster runs multiple Windows versions, you can ensure that a task is placed on an EC2 instance running on the same version by using the placement constraint: `memberOf(attribute:ecs.os-family == WINDOWS_SERVER_<OS_Release>_<FULL or CORE>)`. For more information, see [the section called "Retrieving Amazon ECS-optimized Windows AMI metadata"](#).

## `ecs.cpu-architecture`

The CPU architecture for the instance. Example values for this attribute are `x86_64` and `arm64`.

## `ecs.vpc-id`

The VPC the instance was launched into. An example value for this attribute is `vpc-1234abcd`.

## `ecs.subnet-id`

The subnet the instance is using. An example value for this attribute is `subnet-1234abcd`.

**Note**

Amazon ECS Managed Instances supports the following subset of attributes:

- `ecs.subnet-id`
- `ecs.availability-zone`
- `ecs.instance-type`
- `ecs.cpu-architecture`

**Optional attributes**

Amazon ECS may add the following attributes to your container instances.

`ecs.awsvpc-trunk-id`

If this attribute exists, the instance has a trunk network interface. For more information, see [Increasing Amazon ECS Linux container instance network interfaces](#).

`ecs.outpost-arn`

If this attribute exists, it contains the Amazon Resource Name (ARN) of the Outpost. For more information, see [the section called "Amazon Elastic Container Service on AWS Outposts"](#).

`ecs.capability.external`

If this attribute exists, the instance is identified as an external instance. For more information, see [Amazon ECS clusters for external instances](#).

**Custom attributes**

You can apply custom attributes to your container instances. For example, you can define an attribute with the name "stack" and a value of "prod".

When specifying custom attributes, you must consider the following.

- The name must contain between 1 and 128 characters and name may contain letters (uppercase and lowercase), numbers, hyphens, underscores, forward slashes, back slashes, or periods.
- The value must contain between 1 and 128 characters and may contain letters (uppercase and lowercase), numbers, hyphens, underscores, periods, at signs (@), forward slashes, back slashes, colons, or spaces. The value can't contain any leading or trailing whitespace.

## Create expressions to define container instances for Amazon ECS tasks

Cluster queries are expressions that allow you to group objects. For example, you can group container instances by attributes such as Availability Zone, instance type, or custom metadata. For more information, see [Amazon ECS container instance attributes](#).

After you have defined a group of container instances, you can customize Amazon ECS to place tasks on container instances based on group. For more information, see [Running an application as an Amazon ECS task](#), and [Creating an Amazon ECS rolling update deployment](#). You can also apply a group filter when listing container instances.

### Expression syntax

Expressions have the following syntax:

```
subject operator [argument]
```

#### Subject

The attribute or field to be evaluated.

##### agentConnected

Select container instances by their Amazon ECS container agent connection status. You can use this filter to search for instances with container agents that are disconnected.

Valid operators: equals (==), not\_equals (!=), in, not\_in (!in), matches (=~), not\_matches (!~)

##### agentVersion

Select container instances by their Amazon ECS container agent version. You can use this filter to find instances that are running outdated versions of the Amazon ECS container agent.

Valid operators: equals (==), not\_equals (!=), greater\_than (>), greater\_than\_equal (>=), less\_than (<), less\_than\_equal (<=)

##### attribute:*attribute-name*

Select container instances by attribute. For more information, see [Amazon ECS container instance attributes](#).

##### ec2InstanceId

Select container instances by their Amazon EC2 instance ID.

Valid operators: equals (==), not\_equals (!=), in, not\_in (!in), matches (=~), not\_matches (!~)

#### registeredAt

Select container instances by their container instance registration date. You can use this filter to find newly registered instances or instances that are very old.

Valid operators: equals (==), not\_equals (!=), greater\_than (>), greater\_than\_equal (>=), less\_than (<), less\_than\_equal (<=)

Valid date formats: 2018-06-18T22:28:28+00:00, 2018-06-18T22:28:28Z, 2018-06-18T22:28:28, 2018-06-18

#### runningTasksCount

Select container instances by number of running tasks. You can use this filter to find instances that are empty or near empty (few tasks running on them).

Valid operators: equals (==), not\_equals (!=), greater\_than (>), greater\_than\_equal (>=), less\_than (<), less\_than\_equal (<=)

#### task:group

Select container instances by task group. For more information, see [Group related Amazon ECS tasks](#).

## Operator

The comparison operator. The following operators are supported.

| Operator               | Description              |
|------------------------|--------------------------|
| ==, equals             | String equality          |
| !=, not_equals         | String inequality        |
| >, greater_than        | Greater than             |
| >=, greater_than_equal | Greater than or equal to |
| <, less_than           | Less than                |

| Operator                                          | Description                |
|---------------------------------------------------|----------------------------|
| <code>&lt;=</code> , <code>less_than_equal</code> | Less than or equal to      |
| <code>exists</code>                               | Subject exists             |
| <code>!exists</code> , <code>not_exists</code>    | Subject doesn't exist      |
| <code>in</code>                                   | Value in argument list     |
| <code>!in</code> , <code>not_in</code>            | Value not in argument list |
| <code>=~</code> , <code>matches</code>            | Pattern match              |
| <code>!~</code> , <code>not_matches</code>        | Pattern mismatch           |

**Note**

A single expression can't contain parentheses. However, parentheses can be used to specify precedence in compound expressions.

## Argument

For many operators, the argument is a literal value.

The `in` and `not_in` operators expect an argument list as the argument. You specify an argument list as follows:

```
[argument1, argument2, ..., argumentN]
```

The `matches` and `not_matches` operators expect an argument that conforms to the Java regular expression syntax. For more information, see [java.util.regex.Pattern](https://docs.oracle.com/javase/8/docs/api/java/util/regex/Pattern.html).

## Compound expressions

You can combine expressions using the following Boolean operators:

- `&&`, and
- `||`, or

- `!`, not

You can specify precedence using parentheses:

```
(expression1 or expression2) and expression3
```

## Example expressions

The following are example expressions.

### Example: String Equality

The following expression selects instances with the specified instance type.

```
attribute:ecs.instance-type == t2.small
```

### Example: Argument List

The following expression selects instances in the us-east-1a or us-east-1b Availability Zone.

```
attribute:ecs.availability-zone in [us-east-1a, us-east-1b]
```

### Example: Compound Expression

The following expression selects G2 instances that aren't in the us-east-1d Availability Zone.

```
attribute:ecs.instance-type =~ g2.* and attribute:ecs.availability-zone != us-east-1d
```

### Example: Task Affinity

The following expression selects instances that are hosting tasks in the `service:production` group.

```
task:group == service:production
```

### Example: Task Anti-Affinity

The following expression selects instances that aren't hosting tasks in the database group.

```
not(task:group == database)
```

### Example: Running task count

The following expression selects instances that are only running one task.

```
runningTasksCount == 1
```

### Example: Amazon ECS container agent version

The following expression selects instances that are running a container agent version below 1.14.5.

```
agentVersion < 1.14.5
```

### Example: Instance registration time

The following expression selects instances that were registered before February 13, 2018.

```
registeredAt < 2018-02-13
```

### Example: Amazon EC2 instance ID

The following expression selects instances with the following Amazon EC2 instance IDs.

```
ec2InstanceId in ['i-abcd1234', 'i-wxyx7890']
```

### Example Amazon ECS task placement constraints

The following are task placement constraint examples.

This example uses the `memberOf` constraint to place tasks on t2 instances. It can be specified with the following actions: [CreateService](#), [UpdateService](#), [RegisterTaskDefinition](#), and [RunTask](#).

```
"placementConstraints": [  
  {  
    "expression": "attribute:ecs.instance-type =~ t2.*",  
    "type": "memberOf"  
  }  
]
```

```
]
```

The example uses the `memberOf` constraint to place replica tasks on instances with tasks in the daemon service `daemon-service` task group, respecting any task placement strategies that are also specified. This constraint ensures that the daemon service tasks get placed on the EC2 instance prior to the replica service tasks.

Replace `daemon-service` with the name of the daemon service.

```
"placementConstraints": [  
  {  
    "expression": "task:group == service:daemon-service",  
    "type": "memberOf"  
  }  
]
```

The example uses the `memberOf` constraint to place tasks on instances with other tasks in the databases task group, respecting any task placement strategies that are also specified. For more information about task groups, see [Group related Amazon ECS tasks](#). It can be specified with the following actions: [CreateService](#), [UpdateService](#), [RegisterTaskDefinition](#), and [RunTask](#).

```
"placementConstraints": [  
  {  
    "expression": "task:group == databases",  
    "type": "memberOf"  
  }  
]
```

The `distinctInstance` constraint places each task in the group on a different instance. It can be specified with the following actions: [CreateService](#), [UpdateService](#), and [RunTask](#).

Amazon ECS looks at the desired status of the tasks for the task placement. For example, if the desired status of the existing task is `STOPPED`, (but the last status isn't), a new incoming task can be placed on the same instance despite the `distinctInstance` placement constraint. Therefore, you might see 2 tasks with last status of `RUNNING` on the same instance.

```
"placementConstraints": [  
  {  
    "type": "distinctInstance"  
  }  
]
```

```
}  
]
```

## Amazon ECS standalone tasks

You can run your application as a task when you have an application that performs some work, and then stops, for example a batch process. If you want to run a task one time, you can use the console, AWS CLI, APIs, or SDKs.

If you need to run your application on a rate-based, cron-based, or one-time schedule, you can create schedule using EventBridge Scheduler.

### Task workflow

When you launch Amazon ECS tasks (standalone tasks or by Amazon ECS services), a task is created and initially moved to the PROVISIONING state. When a task is in the PROVISIONING state, neither the task nor the containers exist because Amazon ECS needs to find compute capacity for placing the task.

Amazon ECS selects the appropriate compute capacity for your task based on your launch type or capacity provider configuration. You can use capacity providers and capacity provider strategies with both the Fargate and EC2s. With Fargate, you don't have to think about provisioning, configuring, and scaling of your cluster capacity. Fargate takes care of all infrastructure management for your tasks. For EC2, you can either manage your cluster capacity by registering Amazon EC2 instances to your cluster, or you can use cluster auto scaling to simplify your compute capacity management. Cluster auto scaling takes care of dynamically scaling your cluster capacity, so that you can focus on running tasks. Amazon ECS determines where to place the task based on the requirements you specify in the task definition, such as CPU and memory, as well your placement constraints and strategies. For more information, see, [How Amazon ECS places tasks on container instances](#).

If you use a capacity provider with managed scaling enabled, tasks that can't be started due to a lack of compute capacity are moved to the PROVISIONING state rather than failing immediately. After finding the capacity for placing your task, Amazon ECS provisions the necessary attachments (for example, Elastic Network Interfaces (ENIs) for tasks in awsvpc mode). It uses the Amazon ECS container agent to pull your container images, and then start your containers. After the provisioning completes and the relevant containers have launched, Amazon ECS moves the task into RUNNING state. For information about the task states, see [Amazon ECS task lifecycle](#).

## Running an application as an Amazon ECS task

You can create a task for a one-time process using the AWS Management Console.

### To create a standalone task (AWS Management Console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. The Amazon ECS console allows you to create a standalone task from either your cluster detail page or from the task definition revision list. Use the following steps to create your standalone task depending on the resource page you choose.

| To start a service from           | Steps                                                                                                                                                                                                                                                                               |  |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| The cluster detail page           | <ol style="list-style-type: none"><li>a. On the <b>Clusters</b> page, select the cluster to create the service in.</li><li>b. From the <b>Tasks</b> tab, choose <b>Run task</b>.</li></ol>                                                                                          |  |
| The task definition revision page | <ol style="list-style-type: none"><li>a. On the <b>Task definitions</b> page, choose the task definition family to display the revisions for that family.</li><li>b. Select the revision you want to use.</li><li>c. From the <b>Deploy</b> menu, choose <b>Run task</b>.</li></ol> |  |

3. For **Existing cluster**, choose the cluster.

Choose **Create cluster** to run the task on a new cluster

4. Choose how your tasks are distributed across your cluster infrastructure. Under **Compute configuration**, choose your option. To use a capacity provider strategy, you must configure your capacity providers at the cluster level.

If you haven't configured your cluster to use a capacity provider, use a launch type instead.

If you want to run your workloads on Amazon ECS Managed Instances, you must use the Capacity provider strategy option.

| Distribution method        | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |

| Capacity provider strategy | <div><div><div>a. In the <b>Compute options</b> section, select <b>Capacity provider strategy</b>.</div><div>b. Choose a strategy:<ul style="list-style-type: none"><li>To use the cluster's default capacity provider strategy, choose <b>Use cluster default</b>.</li><li>If your cluster doesn't have a default capacity provider strategy, or to use a custom strategy, choose <b>Use custom, Add capacity provider strategy</b> and define your custom capacity provider strategy by specifying a <b>Base</b>, <b>Capacity provider</b>, and <b>Weight</b>.</li></ul></div></div><div><div><div><div><div></div><div>Note</div></div><div><div>To use a capacity provider in a strategy, the capacity provider must be associated with the cluster.</div></div></div></div></div></div> |  |

| Distribution method | Steps                                                                                                                                                                                                                                                                                                                                                              |  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Launch type         | <ol style="list-style-type: none"> <li>In the <b>Compute options</b> section, select <b>Launch type</b>.</li> <li>For <b>Launch type</b>, choose a launch type.</li> <li>(Optional) When you use Fargate, for <b>Platform version</b>, specify the platform version to use. If a platform version isn't specified, the LATEST platform version is used.</li> </ol> |  |

5. Under **Deployment configuration**, do the following:

- For **Task definition**, enter the task definition.

 **Important**

The console validates the selection to ensure that the selected task definition family and revision are compatible with the defined compute configuration.

- For **Desired tasks**, enter the number of tasks to launch.
- For **Task group**, enter the task group name.

6. If your task definition uses the awsvpc network mode, expand **Networking**. Use the following steps to specify a custom configuration.

- For **VPC**, select the VPC to use.
- For **Subnets**, select one or more subnets in the VPC that the task scheduler considers when placing your tasks.
- For **Security group**, you can either choose an existing security group or create a new one. To use an existing security group, choose the security group and move to the next step. To create a new security group, choose **Create a new security group**. You must specify a security group name, description, and then add one or more inbound rules for the security group.

- d. For **Public IP**, choose whether to auto-assign a public IP address to the elastic network interface (ENI) of the task.

AWS Fargate tasks can be assigned a public IP address when run in a public subnet so they have a route to the internet. EC2 tasks can't be assigned a public IP using this field. For more information, see [Amazon ECS task networking options for Fargate](#) and [Allocate a network interface for an Amazon ECS task..](#)

7. If your task uses a data volume that's compatible with configuration at deployment, you can configure the volume by expanding **Volume**.

The volume name and volume type are configured when creating a task definition revision and can't be changed when you run a standalone task. To update the volume name and type, you must create a new task definition revision and run a task by using the new revision.

| To configure this volume type | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Amazon EBS                    | <ol style="list-style-type: none"><li>a. For <b>EBS volume type</b>, choose the type of EBS volume that you want to attach to your task.</li><li>b. For <b>Size (GiB)</b>, enter a valid value for the volume size in gibibytes (GiB). You can specify a minimum of 1 GiB and a maximum of 16,384 GiB volume size. This value is required unless you provide a snapshot ID.</li><li>c. For <b>IOPS</b>, enter the maximum number of input/output operations (IOPS) that the volume should provide. By default, EBS volumes that are attached to tasks are deleted when the task is terminated.</p> <p>h. For <b>File system type</b>, choose the type of file system that will be used for data storage and retrieval on the volume. You can choose either the operating system default or a specific file system type. The default for Linux is XFS. For volumes created from a snapshot, you must specify the same filesystem type that the volume was using when the snapshot was created. If there is a filesystem type mismatch, the task will fail to start.</p> <p>i. For <b>Infrastructure role</b>, choose an IAM role with the necessary permissions that allow Amazon ECS to manage Amazon</p> |  |

| To configure this volume type | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |  |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                               | <p>EBS volumes for tasks. You can attach the <code>AmazonECSInfrastructureRolePolicyForVolumes</code> managed policy to the role, or you can use the policy as a guide to create and attach an your own policy with permissions that meet your specific needs. For more information about the necessary permissions, see <a href="#">Amazon ECS infrastructure IAM role</a>.</p> <p>j. For <b>Encryption</b>, choose <b>Default</b> if you want to use the Amazon EBS encryption by default settings. If your account has <a href="#">Encryption by default</a> configured, the volume will be encrypted with the AWS Key Management Service (AWS KMS) key that's specified in the setting. If you choose <b>Default</b> and Amazon EBS default encryption isn't turned on, the volume will be unencrypted.</p> |  |

| To configure this volume type | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                               | <p>If you choose <b>Custom</b>, you can specify an AWS KMS key of your choice for volume encryption.</p> <p>If you choose <b>None</b>, the volume will be unencrypted unless you have encryption by default configured, or if you create a volume from an encrypted snapshot.</p> <p>k. If you've chosen <b>Custom</b> for <b>Encryption</b>, you must specify the AWS KMS key that you want to use. For <b>KMS key</b>, choose an AWS KMS key or enter a key ARN. If you choose to encrypt your volume by using a symmetric customer managed key, make sure that you have the right permissions defined in your AWS KMS key policy. For more information, see <a href="#">Data encryption for Amazon EBS volumes</a>.</p> <p>l. (Optional) Under <b>Tags</b>, you can add tags to your Amazon EBS volume by either propagating tags</p> |  |

| To configure this volume type | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                               | <p>from the task definition or by providing your own tags.</p> <p>If you want to propagate tags from the task definition, choose <b>Task definition</b> for <b>Propagate tags from</b>. If you choose <b>Do not propagate</b>, or if you don't choose a value, the tags aren't propagated.</p> <p>If you want to provide your own tags, choose <b>Add tag</b> and then provide the key and value for each tag you add.</p> <p>For more information about tagging Amazon EBS volumes, see <a href="#">Tagging Amazon EBS volumes</a>.</p> |  |

8. (Optional) To use a task placement strategy other than the default, expand **Task Placement**, and then choose from the following options.

For more information, see [How Amazon ECS places tasks on container instances](#).

- **AZ Balanced Spread** – Distribute tasks across Availability Zones and across container instances in the Availability Zone.
- **AZ Balanced BinPack** – Distribute tasks across Availability Zones and across container instances with the least available memory.
- **BinPack** – Distribute tasks based on the least available amount of CPU or memory.

- **One Task Per Host** – Place, at most, one task from the service on each container instance.
- **Custom** – Define your own task placement strategy.

If you chose **Custom**, define the algorithm for placing tasks and the rules that are considered during task placement.

- Under **Strategy**, for **Type** and **Field**, choose the algorithm and the entity to use for the algorithm.

You can enter a maximum of 5 strategies.

- Under **Constraint**, for **Type** and **Expression**, choose the rule and attribute for the constraint.

For example, to set the constraint to place tasks on T2 instances, for the **Expression**, enter **attribute:ecs.instance-type =~ t2.\***.

You can enter a maximum of 10 constraints.

9. (Optional) To override the task IAM role, or task execution role that is defined in your task definition, expand **Task overrides**, and then complete the following steps:
  - a. For **Task role**, choose an IAM role for this task. For more information, see [Amazon ECS task IAM role](#).

Only roles with the `ecs-tasks.amazonaws.com` trust relationship are displayed. For instructions on how to create an IAM role for your tasks, see [Creating the task IAM role](#).
  - b. For **Task execution role**, choose a task execution role. For more information, see [Amazon ECS task execution IAM role](#).
10. (Optional) To override the container commands and environment variables, expand **Container Overrides**, and then expand the container.
  - To send a command to the container other than the task definition command, for **Command override**, enter the Docker command.
  - To add an environment variable, choose **Add Environment Variable**. For **Key**, enter the name of your environment variable. For **Value**, enter a string value for your environment value (without the surrounding double quotation marks (" ")).

AWS surrounds the strings with double quotation marks (" ") and passes the string to the container in the following format:

```
MY_ENV_VAR="This variable contains a string."
```

11. (Optional) To help identify your task, expand the **Tags** section, and then configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the task definition tags, select **Turn on Amazon ECS managed tags**, and then select **Task definitions**.

Add or remove a tag.

- [Add a tag] Choose **Add tag**, and then do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
- [Remove a tag] Next to the tag, choose **Remove tag**.

12. Choose **Create**.

## Using Amazon EventBridge Scheduler to schedule Amazon ECS tasks

EventBridge Scheduler is a serverless scheduler that allows you to create, run, and manage tasks from one central, managed service. It provides one-time and recurring scheduling functionality independent of event buses and rules. EventBridge Scheduler is highly customizable, and offers improved scalability over EventBridge scheduled rules, with a wider set of target API operations and AWS services. EventBridge Scheduler provides the following schedules which you can configure for your tasks in the EventBridge Scheduler console:

- Rate-based
- Cron-based

You can configure cron-based schedules in any time zone.

- One-time schedules

You can configure one-time schedules in any time zone.

You can schedule your Amazon ECS using Amazon EventBridge Scheduler.

Although you can create a scheduled task in the Amazon ECS console, currently the EventBridge Scheduler console provides more functionality.

Complete the following steps before you schedule a task:

1. Use the VPC console to get the subnet IDs where the tasks run and the security group IDs for the subnets. For more information, see [Subnets for your VPC](#), and [Control traffic to your AWS resources using security groups](#) in the *Amazon VPC User Guide*.
2. Configure the EventBridge Scheduler execution role. For more information, see [Set up the execution role](#) in the *Amazon EventBridge Scheduler User Guide*.
3. If you want to use a capacity provider strategy to run the task, you must have a capacity provider associated with the cluster.

To create a new schedule using the console

1. Open the Amazon EventBridge Scheduler console at <https://console.aws.amazon.com/scheduler/home>.
2. On the **Schedules** page, choose **Create schedule**.
3. On the **Specify schedule detail** page, in the **Schedule name and description** section, do the following:
  - a. For **Schedule name**, enter a name for your schedule. For example, **MyTestSchedule**.
  - b. (Optional) For **Description**, enter a description for your schedule. For example, **TestSchedule**.
  - c. For **Schedule group**, choose a schedule group. If you don't have a group, choose **default**. To create a schedule group, choose **create your own schedule**.

You use schedule groups to add tags to groups of schedules.

4. Choose your schedule options.

| Occurrence                                                                                                            | Do this...                                                                                                                                                                                   |  |
|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <b>One-time schedule</b><br><br>A one-time schedule invokes a target only once at the date and time that you specify. | For <b>Date and time</b> , do the following: <ul style="list-style-type: none"><li>• Enter a valid date in YYYY/MM/DD format.</li><li>• Enter a timestamp in 24-hour hh:mm format.</li></ul> |  |

For <b>Flexible time window</b>, choose <b>Off</b> to turn off the option, or choose one of the pre-defined time windows. For example, if you choose <b>15 minutes</b> and you set a recurring schedule to invoke its target once every hour, the schedule runs within</p> |  |

| Occurrence | Do this...                                |  |
|------------|-------------------------------------------|--|
|            | 15 minutes after the start of every hour. |  |

5. (Optional) If you chose **Recurring schedule** in the previous step, in the **Timeframe** section, do the following:
  - a. For **Timezone**, choose a timezone.
  - b. For **Start date and time**, enter a valid date in YYYY/MM/DD format, and then specify a timestamp in 24-hour hh:mm format.
  - c. For **End date and time**, enter a valid date in YYYY/MM/DD format, and then specify a timestamp in 24-hour hh:mm format.
6. Choose **Next**.
7. On the **Select target** page, do the following:
  - a. Choose **All APIs**, and then in the search box enter **ECS**.
  - b. Select **Amazon ECS**.
  - c. In the search box, enter **RunTask**, and then choose **RunTask**.
  - d. For **ECS cluster**, choose the cluster.
  - e. For **ECS task**, choose the task definition to use for the task.
  - f. Choose how your tasks are distributed across your cluster infrastructure. Expand **Compute options**, and then choose one of the following options

| Compute option             | Steps                                                                                                                                                                                                                                                                                                                                     |  |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Capacity provider strategy | <ol style="list-style-type: none"> <li>a. Choose <b>Capacity provider strategy</b>.</li> <li>b. Choose a strategy:               <ul style="list-style-type: none"> <li>• To use the default capacity provider strategy, choose <b>Use cluster default</b>.</li> <li>• To use a custom strategy, choose <b>Use</b></li> </ul> </li> </ol> |  |

| Compute option | Steps                                                                                                                                                                                                   |  |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                | <p><b>custom</b>. Then, enter the <b>Base</b>, <b>Capacity provider</b>, and <b>Weight</b>.</p> <p>For EC2, the Capacity provider is the Auto Scaling group.</p>                                        |  |
| Launch type    | <p>a. Choose <b>Launch type</b>.</p> <p>b. For <b>Launch type</b>, choose a launch type.</p> <p>c. When the Fargate is specified, for <b>Platform version</b>, specify the platform version to use.</p> |  |

- g. For **Subnets**, enter the subnet IDs to run the task in.
- h. For **Security groups**, enter the security group IDs for the subnet.
- i. (Optional) To use a task placement strategy other than the default, expand **Placement constraint**, and then enter the constraints.

For more information, see [How Amazon ECS places tasks on container instances](#).

- j. (Optional) To help identify your tasks, under **Tags** configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the task definition tags, select **Enable Amazon ECS managed tags**.

- 8. Choose **Next**.
- 9. On the **Settings** page, do the following:
  - a. To turn on the schedule, under **Schedule state**, toggle **Enable schedule**.
  - b. To configure a retry policy for your schedule, under **Retry policy and dead-letter queue (DLQ)**, do the following:
    - Toggle **Retry**.

- For **Maximum retention time of event**, enter the maximum **hour(s)** and **min(s)** that EventBridge Scheduler must keep an unprocessed event.
- The maximum time is 24 hours.
- For **Maximum retries**, enter the maximum number of times EventBridge Scheduler retries the schedule if the target returns an error.

The maximum value is 185 retries.

With retry policies, if a schedule fails to invoke its target, EventBridge Scheduler re-runs the schedule. If configured, you must set the maximum retention time and retries for the schedule.

- c. Choose where EventBridge Scheduler stores undelivered events.

| Dead-letter queue (DLQ) option                                                     | Do this...                                                                                                                                        |  |
|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Don't store                                                                        | Choose <b>None</b> .                                                                                                                              |  |
| Store the event in the same AWS account where you're creating the schedule         | a. Choose <b>Select an Amazon SQS queue in my AWS account as a DLQ</b> .<br>b. Choose the Amazon Resource Name (ARN) of the Amazon SQS queue.     |  |
| Store the event in a different AWS account from where you're creating the schedule | a. Choose <b>Specify an Amazon SQS queue in other AWS accounts as a DLQ</b> .<br>b. Enter the Amazon Resource Name (ARN) of the Amazon SQS queue. |  |

- d. To use a customer managed key to encrypt your target input, under **Encryption**, choose **Customize encryption settings (advanced)**.

If you choose this option, enter an existing KMS key ARN or choose **Create an AWS KMS key** to navigate to the AWS KMS console. For more information about how EventBridge Scheduler encrypts your data at rest, see [Encryption at rest](#) in the *Amazon EventBridge Scheduler User Guide*.

- e. For **Permissions**, choose **Use existing role**, then select the role.

To have EventBridge Scheduler create a new execution role for you, choose **Create new role for this schedule**. Then, enter a name for **Role name**. If you choose this option, EventBridge Scheduler attaches the required permissions necessary for your templated target to the role.

10. Choose **Next**.

11. In the **Review and create schedule** page, review the details of your schedule. In each section, choose **Edit** to go back to that step and edit its details.

12. Choose **Create schedule**.

You can view a list of your new and existing schedules on the **Schedules** page. Under the **Status** column, verify that your new schedule is **Enabled**.

## Next steps

You can use the EventBridge Scheduler console or the AWS CLI to manage the schedule. For more information, see [Managing a schedule](#) in the *Amazon EventBridge Scheduler User Guide*.

## Stopping an Amazon ECS task

If you no longer need to keep a standalone task running, you can stop the task. The Amazon ECS console makes it easy to stop one or more tasks.

You can't restart a standalone stopped task.

If you want to stop a service, see [Deleting an Amazon ECS service using the console](#).

### To stop a standalone task (AWS Management Console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster to navigate to the cluster details page.

4. On the cluster detail page, choose the **Tasks** tab.
5. You can filter tasks by launch type using the **Filter launch type** list.

| Tasks to stop | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |

## Amazon ECS services

You can use an Amazon ECS service to run and maintain a specified number of instances of a task definition simultaneously in an Amazon ECS cluster. If one of your tasks fails or stops, the Amazon ECS service scheduler launches another instance of your task definition to replace it. This helps maintain your desired number of tasks in the service.

You can also optionally run your service behind a load balancer. The load balancer distributes traffic across the tasks that are associated with the service.

We recommend that you use the service scheduler for long running stateless services and applications. The service scheduler ensures that the scheduling strategy that you specify is followed and reschedules tasks when a task fails. For example, if the underlying infrastructure fails, the service scheduler reschedules a task. You can use task placement strategies and constraints to customize how the scheduler places and terminates tasks. If a task in a service stops, the scheduler launches a new task to replace it. This process continues until your service reaches your desired number of tasks based on the scheduling strategy that the service uses.

The service scheduler also replaces tasks determined to be unhealthy after a container health check or a load balancer target group health check fails. This replacement depends on the `maximumPercent` and `desiredCount` service definition parameters. If a task is marked unhealthy, the service scheduler will first start a replacement task. Then, the following happens.

- If the replacement task has a health status of `HEALTHY`, the service scheduler stops the unhealthy task
- If the replacement task has a health status of `UNHEALTHY`, the scheduler will stop either the unhealthy replacement task or the existing unhealthy task to get the total task count to equal `desiredCount`.

If the `maximumPercent` parameter limits the scheduler from starting a replacement task first, the scheduler will stop an unhealthy task one at a time at random to free up capacity, and then start a replacement task. The start and stop process continues until all unhealthy tasks are replaced with healthy tasks. Once all unhealthy tasks have been replaced and only healthy tasks are running, if the total task count exceeds the `desiredCount`, healthy tasks are stopped at random until the total task count equals `desiredCount`. For more information about `maximumPercent` and `desiredCount`, see [Service definition parameters](#).

The service scheduler includes logic that throttles how often tasks are restarted if tasks repeatedly fail to start. If a task is stopped without having entered a RUNNING state, the service scheduler starts to slow down the launch attempts and sends out a service event message. This behavior prevents unnecessary resources from being used for failed tasks before you can resolve the issue. After the service is updated, the service scheduler resumes normal scheduling behavior. For more information, see [Amazon ECS service throttle logic](#) and [Viewing Amazon ECS service event messages](#).

## Infrastructure compute option

There are two compute options that distribute your tasks.

- A capacity provider strategy causes Amazon ECS to distribute your tasks in one or across multiple capacity providers.

If you want to run your workloads on Amazon ECS Managed Instances, you must use the Capacity provider strategy option.

For the **capacity provider strategy**, the console selects a compute option by default. The following describes the order that the console uses to select a default:

- If your cluster has a default capacity provider strategy defined, it is selected.
- If your cluster doesn't have a default capacity provider strategy defined but you have the Fargate capacity providers added to the cluster, a custom capacity provider strategy that uses the FARGATE capacity provider is selected.
- If your cluster doesn't have a default capacity provider strategy defined but you have one or more Auto Scaling group capacity providers added to the cluster, the **Use custom (Advanced)** option is selected and you need to manually define the strategy.
- If your cluster doesn't have a default capacity provider strategy defined and no capacity providers added to the cluster, the Fargate launch type is selected.
- A launch type causes Amazon ECS to launch our tasks directly on either Fargate or on the EC2 instances registered to your clusters.

If you want to run your workloads on Amazon ECS Managed Instances, you must use the Capacity provider strategy option.

By default the service starts in the subnets in your cluster VPC.

## Service auto scaling

Service auto scaling is the ability to increase or decrease the desired number of tasks in your Amazon ECS service automatically. Amazon ECS leverages the Application Auto Scaling service to provide this functionality.

For more information, see [Automatically scale your Amazon ECS service](#).

## Service load balancing

Amazon ECS services hosted on AWS Fargate support the Application Load Balancers, Network Load Balancers, and Gateway Load Balancers. Use the following table to learn about what type of load balancer to use.

| Load Balancer type        | Use in these cases                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Application Load Balancer | <div>Route HTTP/HTTPS (or layer 7) traffic.</div> <div>Application Load Balancers offer several features that make them attractive for use with Amazon ECS services:</div> <ul style="list-style-type: none"><li>• Each service can serve traffic from multiple load balancers and expose multiple load balanced ports by specifying multiple target groups.</li><li>• They are supported by tasks hosted on both Fargate and EC2 instances.</li><li>• Application Load Balancers allow containers to use dynamic host port mapping (so that multiple tasks from the same service</li></ul> |  |

| Load Balancer type    | Use in these cases                                                                                                                                                                                                                                                         |  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                       | <p>are allowed per container instance).</p> <ul style="list-style-type: none"> <li>• Application Load Balancers support path-based routing and priority rules (so that multiple services can use the same listener port on a single Application Load Balancer).</li> </ul> |  |
| Network Load Balancer | Route TCP or UDP (or layer 4) traffic.                                                                                                                                                                                                                                     |  |
| Gateway Load Balancer | <p>Route TCP or UDP (or layer 4) traffic.</p> <p>Use virtual appliances, such as firewalls, intrusion detection and prevention systems, and deep packet inspection systems.</p>                                                                                            |  |

For more information, see [Use load balancing to distribute Amazon ECS service traffic](#).

## Interconnecting services

If you need an application to connect to other applications that run as Amazon ECS services, Amazon ECS provides the following ways to do this without a load balancer:

- Service Connect - Allows for service-to-service communications with automatic discovery using short names and standard ports.
- Service discovery - Service discovery uses Route 53 to create a namespace for your service, which allows it to be discoverable through DNS.

- Amazon VPC Lattice - VPC Lattice is a fully managed application networking service to connect, secure, and monitor your services across multiple accounts and VPCs. There is a cost associated with it.

For more information, see [Interconnect Amazon ECS services](#).

## Amazon ECS service deployment controllers and strategies

Before you deploy your service, determine the options for deploying it, and the features the service uses.

### Scheduling strategy

There are two service scheduler strategies available:

- **REPLICA**—The replica scheduling strategy places and maintains the desired number of tasks across your cluster. By default, the service scheduler spreads tasks across Availability Zones. You can use task placement strategies and constraints to customize task placement decisions. For more information, see [Replica scheduling strategy](#).
- **DAEMON**—The daemon scheduling strategy deploys exactly one task on each active container instance that meets all of the task placement constraints that you specify in your cluster. When using this strategy, there is no need to specify a desired number of tasks, a task placement strategy, or use Service Auto Scaling policies. For more information, see [Daemon scheduling strategy](#).

#### Note

Fargate tasks do not support the DAEMON scheduling strategy.

### Replica scheduling strategy

The *replica* scheduling strategy places and maintains the desired number of tasks in your cluster.

For a service that runs tasks on Fargate, when the service scheduler launches new tasks or stops running tasks, the service scheduler uses a best attempt to maintain a balance across Availability Zones. You don't need to specify task placement strategies or constraints.

When you create a service that runs tasks on EC2 instances, you can optionally specify task placement strategies and constraints to customize task placement decisions. If no task placement strategies or constraints are specified, then by default the service scheduler spreads the tasks across Availability Zones. The service scheduler uses the following logic:

- Determines which of the container instances in your cluster can support your service's task definition (for example, required CPU, memory, ports, and container instance attributes).
- Determines which container instances satisfy any placement constraints that are defined for the service.
- When you have a replica service that depends on a daemon service (for example, a daemon log router task that needs to be running before tasks can use logging), create a task placement constraint that ensures that the daemon service tasks get placed on the EC2 instance prior to the replica service tasks. For more information, see [Example Amazon ECS task placement constraints](#).
- When there's a defined placement strategy, use that strategy to select an instance from the remaining candidates.
- When there's no defined placement strategy, use the following logic to balance tasks across the Availability Zones in your cluster:
  - Sorts the valid container instances. Gives priority to instances that have the fewest number of running tasks for this service in their respective Availability Zone. For example, if zone A has one running service task and zones B and C each have zero, valid container instances in either zone B or C are considered optimal for placement.
  - Places the new service task on a valid container instance in an optimal Availability Zone based on the previous steps. Favors container instances with the fewest number of running tasks for this service.

We recommend that you use the service rebalancing feature when you use the REPLICA strategy because it helps ensure high availability for your service.

## Daemon scheduling strategy

The *daemon* scheduling strategy deploys exactly one task on each active container instance that meets all of the task placement constraints specified in your cluster. The service scheduler evaluates the task placement constraints for running tasks, and stops tasks that don't meet the placement constraints. When you use this strategy, you don't need to specify a desired number of tasks, a task placement strategy, or use Service Auto Scaling policies.

Amazon ECS reserves container instance compute resources including CPU, memory, and network interfaces for the daemon tasks. When you launch a daemon service on a cluster with other replica services, Amazon ECS prioritizes the daemon task. This means that the daemon task is the first task to launch on the instances and the last task to stop after all replica tasks are stopped. This strategy ensures that resources aren't used by pending replica tasks and are available for the daemon tasks.

The daemon service scheduler doesn't place any tasks on instances that have a DRAINING status. If a container instance transitions to a DRAINING status, the daemon tasks on it are stopped. The service scheduler also monitors when new container instances are added to your cluster and adds the daemon tasks to them.

When you specify a deployment configuration, the value for the `maximumPercent` parameter must be 100 (specified as a percentage), which is the default value used if not set. The default value for the `minimumHealthyPercent` parameter is 0 (specified as a percentage).

You must restart the service when you change the placement constraints for the daemon service. Amazon ECS dynamically updates the resources that are reserved on qualifying instances for the daemon task. For existing instances, the scheduler tries to place the task on the instance.

A new deployment starts when there is a change to the task size or container resource reservation in the task definition. A new deployment also starts when updating a service or setting a different revision of the task definition. Amazon ECS picks up the updated CPU and memory reservations for the daemon, and then blocks that capacity for the daemon task.

If there are insufficient resources for either of the above cases, the following happens:

- The task placement fails.
- A CloudWatch event is generated.
- Amazon ECS continues to try and schedule the task on the instance by waiting for resources to become available.
- Amazon ECS frees up any reserved instances that no longer meet the placement constraint criteria and stops the corresponding daemon tasks.

The daemon scheduling strategy can be used in the following cases:

- Running application containers
- Running support containers for logging, monitoring and tracing tasks

Tasks using Fargate or the CODE\_DEPLOY or EXTERNAL deployment controller types don't support the daemon scheduling strategy.

When the service scheduler stops running tasks, it attempts to maintain balance across the Availability Zones in your cluster. The scheduler uses the following logic:

- If a placement strategy is defined, use that strategy to select which tasks to terminate. For example, if a service has an Availability Zone spread strategy defined, a task is selected that leaves the remaining tasks with the best spread.
- If no placement strategy is defined, use the following logic to maintain balance across the Availability Zones in your cluster:
  - Sort the valid container instances. Give priority to instances that have the largest number of running tasks for this service in their respective Availability Zone. For example, if zone A has one running service task and zones B and C each have two running service task, container instances in either zone B or C are considered optimal for termination.
  - Stop the task on a container instance in an optimal Availability Zone based on the previous steps. Favoring container instances with the largest number of running tasks for this service.

## Deployment controllers

The deployment controller is the mechanism that determines how tasks are deployed for your service. The valid options are:

- ECS

When you create a service which uses the ECS deployment controller, you can choose between the following deployment strategies:

- **ROLLING:** When you create a service which uses the *rolling update* (ROLLING) deployment strategy, the Amazon ECS service scheduler replaces the currently running tasks with new tasks. The number of tasks that Amazon ECS adds or removes from the service during a rolling update is controlled by the service deployment configuration.

Rolling update deployments are best suited for the following scenarios:

- **Gradual service updates:** You need to update your service incrementally without taking the entire service offline at once.
- **Limited resource requirements:** You want to avoid the additional resource costs of running two complete environments simultaneously (as required by blue/green deployments).

- Acceptable deployment time: Your application can tolerate a longer deployment process, as rolling updates replace tasks one by one.
- No need for instant roll back: Your service can tolerate a rollback process that takes minutes rather than seconds.
- Simple deployment process: You prefer a straightforward deployment approach without the complexity of managing multiple environments, target groups, and listeners.
- No load balancer, Service Connect, or VPC Lattice requirement: Your service doesn't use or require an Application Load Balancer, Network Load Balancer, Service Connect, or VPC Lattice (which are required for blue/green deployments).
- Stateful applications: Your application maintains state that makes it difficult to run two parallel environments.
- Cost sensitivity: You want to minimize deployment costs by not running duplicate environments during deployment.

Rolling updates are the default deployment strategy for services and provide a balance between deployment safety and resource efficiency for many common application scenarios.

- BLUE\_GREEN: A *blue/green* deployment strategy (BLUE\_GREEN) is a release methodology that reduces downtime and risk by running two identical production environments called blue and green. With Amazon ECS blue/green deployments, you can validate new service revisions before directing production traffic to them. This approach provides a safer way to deploy changes with the ability to quickly roll back if needed.

Amazon ECS blue/green deployments are best suited for the following scenarios:

- Service validation: When you need to validate new service revisions before directing production traffic to them
- Zero downtime: When your service requires zero-downtime deployments
- Instant roll back: When you need the ability to quickly roll back if issues are detected
- Load balancer, Service Connect, or VPC Lattice requirement: When your service uses Application Load Balancer, Network Load Balancer, Service Connect, or VPC Lattice
- LINEAR: A *linear* deployment strategy (LINEAR) gradually shifts traffic from the current production environment to a new environment in equal percentage increments over a specified time period. With Amazon ECS linear deployments, you can control the pace of traffic shifting and validate new service revisions with increasing amounts of production traffic.

Amazon ECS linear deployments are best suited for the following scenarios:

- **Gradual validation:** When you want to gradually validate your new service version with increasing traffic
- **Performance monitoring:** When you need time to monitor metrics and performance during the deployment
- **Risk minimization:** When you want to minimize risk by exposing the new version to production traffic incrementally
- **Load balancer, Service Connect, or VPC Lattice requirement:** When your service uses Application Load Balancer, Network Load Balancer, Service Connect, or VPC Lattice
- **CANARY:** A *canary* deployment strategy (CANARY) shifts a small percentage of traffic to the new service revision first, then shifts the remaining traffic all at once after a specified time period. This allows you to test the new version with a subset of users before full deployment.

Amazon ECS canary deployments are best suited for the following scenarios:

- **Feature testing:** When you want to test new features with a small subset of users before full rollout
- **Production validation:** When you need to validate performance and functionality with real production traffic
- **Blast radius control:** When you want to minimize blast radius if issues are discovered in the new version
- **Load balancer, Service Connect, or VPC Lattice requirement:** When your service uses Application Load Balancer, Network Load Balancer, Service Connect, or VPC Lattice
- **External**

Use a third-party deployment controller.

- **Blue/green deployment (powered by AWS CodeDeploy)**

CodeDeploy installs an updated version of the application as a new replacement task set and reroutes production traffic from the original application task set to the replacement task set. The original task set is terminated after a successful deployment. Use this deployment controller to verify a new deployment of a service before sending production traffic to it.

## Amazon ECS deployment failure detection

Amazon ECS provides two methods for detecting deployment failures:

- **Deployment Circuit Breaker**

- CloudWatch Alarms

You can configure both methods to automatically roll back failed deployments to the last known good state.

Consider the following:

- Both methods only support rolling update deployment and blue/green deployment types.
- When a service uses early success criteria, the deployment circuit breaker and CloudWatch alarm rollback apply until Amazon ECS completes the deployment. After the deployment completes, they no longer roll back the service. For more information, see [Complete Amazon ECS rolling deployments early with early success criteria](#).
- When both methods are used, either can trigger deployment failure.
- The rollback method requires a previous deployment in COMPLETED state.
- EventBridge events are generated for deployment state changes.

## How the Amazon ECS deployment circuit breaker detects failures

The deployment circuit breaker is the rolling update mechanism that determines if the tasks reach a steady state. The deployment circuit breaker has an option that will automatically roll back a failed deployment to the deployment that is in the COMPLETED state. You can customize how the circuit breaker counts failures and the threshold at which it triggers, so that rollback behavior matches your application's startup characteristics and your tolerance for task failures.

When a service deployment changes state, Amazon ECS sends a service deployment state change event to EventBridge. This provides a programmatic way to monitor the status of your service deployments. For more information, see [Amazon ECS service deployment state change events](#). We recommend that you create and monitor an EventBridge rule with an eventName of SERVICE\_DEPLOYMENT\_FAILED so that you can take manual action to start your deployment. For more information, see [Getting started with EventBridge](#) in the *Amazon EventBridge User Guide*.

When the deployment circuit breaker determines that a deployment failed, it looks for the most recent deployment that is in a COMPLETED state. This is the deployment that it uses as the rollback deployment. When the rollback starts, the deployment changes from a COMPLETED to IN\_PROGRESS. This means that the deployment is not eligible for another rollback until it reaches a COMPLETED state. When the deployment circuit breaker does not find a deployment that is in a COMPLETED state, the circuit breaker does not launch new tasks and the deployment is stalled.

When you create a service, the scheduler keeps track of the tasks that failed to launch in two stages.

- Stage 1 - The scheduler monitors the tasks to see if they transition into the RUNNING state.
  - Success - The deployment has a chance of transitioning to the COMPLETED state because there is more than one task that transitioned to the RUNNING state. The failure criteria is skipped and the circuit breaker moves to stage 2.
  - Failure - By default, consecutive tasks that do not transition to the RUNNING state count toward the failure threshold (`resetOnHealthyTask` is `true`). When `resetOnHealthyTask` is `false`, all task failures accumulate regardless of whether healthy tasks start between failures.
- Stage 2 - The deployment enters this stage when there is at least one task in the RUNNING state. The circuit breaker checks the health checks for the tasks in the current deployment being evaluated. The validated health checks are Elastic Load Balancing, AWS Cloud Map service health checks, and container health checks.
  - Success - There is at least one task in the running state with health checks that have passed.
  - Failure - The tasks that are replaced because of health check failures have reached the failure threshold.

Consider the following when you use the deployment circuit breaker method on a service. EventBridge generates the rule.

- The `DescribeServices` response provides insight into the state of a deployment, the `rolloutState` and `rolloutStateReason`. When a new deployment is started, the rollout state begins in an `IN_PROGRESS` state. When the service reaches a steady state, the rollout state transitions to `COMPLETED`. If the service fails to reach a steady state and circuit breaker is turned on, the deployment will transition to a `FAILED` state. A deployment in a `FAILED` state doesn't launch any new tasks.
- In addition to the service deployment state change events Amazon ECS sends for deployments that have started and have completed, Amazon ECS also sends an event when a deployment with circuit breaker turned on fails. These events provide details about why a deployment failed or if a deployment was started because of a rollback. For more information, see [Amazon ECS service deployment state change events](#).

- If a new deployment is started because a previous deployment failed and a rollback occurred, the reason field of the service deployment state change event indicates the deployment was started because of a rollback.
- The deployment circuit breaker is only supported for Amazon ECS services that use the rolling update (ECS) deployment controller.
- You must use the Amazon ECS console, or the AWS CLI when you use the deployment circuit breaker with the CloudWatch option. For more information, see [the section called “Create a service using defined parameters”](#) and [create-service](#) in the *AWS Command Line Interface Reference*.

The following create-service AWS CLI example shows how to create a Linux service when the deployment circuit breaker is used with the rollback option.

```
aws ecs create-service \
  --service-name MyService \
  --deployment-controller type=ECS \
  --desired-count 3 \
  --deployment-configuration "deploymentCircuitBreaker={enable=true,rollback=true}" \
  --task-definition sample-fargate:1 \
  --launch-type FARGATE \
  --platform-family LINUX \
  --platform-version 1.4.0 \
  --network-configuration
  "awsvpcConfiguration={subnets=[subnet-12344321],securityGroups=[sg-12344321],assignPublicIp=EN"
```

The following create-service AWS CLI example shows how to create a service with a custom deployment circuit breaker configuration that uses a fixed failure count of 5 and cumulative failure tracking.

```
aws ecs create-service \
  --service-name MyService \
  --deployment-controller type=ECS \
  --desired-count 10 \
  --deployment-configuration
  "deploymentCircuitBreaker={enable=true,rollback=true,resetOnHealthyTask=false,thresholdConfigu" \
  --task-definition sample-fargate:1 \
  --launch-type FARGATE \
  --platform-family LINUX \
```

```
--platform-version 1.4.0 \  
--network-configuration  
"awsVpcConfiguration={subnets=[subnet-12344321],securityGroups=[sg-12344321],assignPublicIp=EN
```

Example:

Deployment 1 is in a COMPLETED state.

Deployment 2 cannot start, so the circuit breaker rolls back to Deployment 1. Deployment 1 transitions to the IN\_PROGRESS state.

Deployment 3 starts and there is no deployment in the COMPLETED state, so Deployment 3 cannot roll back, or launch tasks.

## Failure threshold

The deployment circuit breaker uses a failure threshold to determine when to move the deployment to a FAILED state. You can configure both how failures are counted and the threshold value itself.

## Failure counting mode

The `resetOnHealthyTask` setting controls how the circuit breaker counts task failures during a deployment.

`true` (default)

The failure count resets to 0 each time a task reaches a healthy state. Only consecutive failures count toward the threshold. This mode is useful for applications that might experience intermittent startup failures before stabilizing.

`false`

Task failures accumulate throughout the deployment. The failure count never resets, even when healthy tasks start between failures. This mode provides faster detection when any pattern of failures indicates a problematic deployment.

## Threshold configuration

The `thresholdConfiguration` setting defines when the circuit breaker triggers. It contains a type that determines how the threshold is calculated and a value that specifies the percentage or count to use.

BOUNDED\_PERCENT (default)

Amazon ECS multiplies `value` by the latest service desired count to calculate the failure threshold. The result is clamped to a minimum of 3 and a maximum of 200. This is the default type with a default value of 50.

UNBOUNDED\_PERCENT

Amazon ECS multiplies `value` by the latest service desired count to calculate the failure threshold. There is no minimum or maximum bound on the result. Use this type for services with large desired counts that need a proportional threshold without the 200 cap.

COUNT

Amazon ECS uses `value` directly as the failure threshold. The threshold remains fixed regardless of the service desired count. Use this type when you want an exact number of tolerated failures, for example, a lower threshold for faster rollbacks in development environments.

For the percentage types (BOUNDED\_PERCENT and UNBOUNDED\_PERCENT), the valid range for `value` is 1–100. During a deployment, Amazon ECS continuously uses the latest service desired count in its calculation.

How BOUNDED\_PERCENT calculates the threshold

When you use the default BOUNDED\_PERCENT threshold type, the deployment circuit breaker calculates the threshold using the following formula.

Minimum threshold (3) <= (*value*/100) \* *desired task count* => Maximum threshold (200)

When the result of the calculation is less than 3, the threshold is set to 3. When the result is greater than 200, the threshold is set to 200. Otherwise, the threshold is set to the calculated value (rounded up).

The following table provides examples using the default value of 50.

| Desired task count | Calculation                          | Threshold                                         |
|--------------------|--------------------------------------|---------------------------------------------------|
| 1                  | <div>3 &lt;= 0.5 * 1 =&gt; 200</div> | 3 (the calculated value is less than the minimum) |

| Desired task count | Calculation                        | Threshold                                              |
|--------------------|------------------------------------|--------------------------------------------------------|
| 25                 | $3 \leq 0.5 * 25 \Rightarrow 200$  | 13 (the value is rounded up)                           |
| 400                | $3 \leq 0.5 * 400 \Rightarrow 200$ | 200 (the calculated value is greater than the maximum) |
| 800                | $3 \leq 0.5 * 800 \Rightarrow 200$ | 200 (the calculated value is greater than the maximum) |

With UNBOUNDED\_PERCENT, the same calculation applies but without the minimum and maximum bounds. For example, a service with a desired count of 800 and a value of 50 would have a threshold of 400.

There are two stages for the deployment status check.

1. The deployment circuit breaker monitors tasks that are part of the deployment and checks for tasks that are in the RUNNING state. The scheduler ignores the failure criteria when a task in the current deployment is in the RUNNING state and proceeds to the next stage. When tasks fail to reach the RUNNING state, the deployment circuit breaker increases the failure count by one. When the failure count equals the threshold, the deployment is marked as FAILED.
2. This stage is entered when there are one or more tasks in the RUNNING state. The deployment circuit breaker performs health checks on the following resources for the tasks in the current deployment:
  - Elastic Load Balancing load balancers
  - AWS Cloud Map service
  - Amazon ECS container health checks

When a health check fails for the task, the deployment circuit breaker increases the failure count by one. When the failure count equals the threshold, the deployment is marked as FAILED.

For example, when the threshold is 3, the circuit breaker starts with the failure count set at 0. When a task fails to reach the RUNNING state, the deployment circuit breaker increases the failure count by one. When the failure count equals 3, the deployment is marked as FAILED.

For additional examples about how to use the rollback option, see [Announcing Amazon ECS deployment circuit breaker](#).

## How CloudWatch alarms detect Amazon ECS deployment failures

You can configure Amazon ECS to set the deployment to failed when it detects that a specified CloudWatch alarm has gone into the ALARM state.

You can optionally set the configuration to roll back a failed deployment to the last completed deployment.

The following create-service AWS CLI example shows how to create a Linux service when the deployment alarms are used with the rollback option.

```
aws ecs create-service \
  --service-name MyService \
  --deployment-controller type=ECS \
  --desired-count 3 \
  --deployment-configuration
"alarms={alarmNames=[alarm1Name,alarm2Name],enable=true,rollback=true}" \
  --task-definition sample-fargate:1 \
  --launch-type FARGATE \
  --platform-family LINUX \
  --platform-version 1.4.0 \
  --network-configuration
"awsvpcConfiguration={subnets=[subnet-12344321],securityGroups=[sg-12344321],assignPublicIp=EN
```

Consider the following when you use the Amazon CloudWatch alarms method on a service.

- The duration when both blue and green service revisions are running simultaneously after the production traffic has shifted. Amazon ECS computes this time period based on the alarm configuration associated with the deployment. You can't set this value.
- The deploymentConfiguration request parameter now contains the alarms data type. You can specify the alarm names, whether to use the method, and whether to initiate a rollback when the alarms indicate a deployment failure. For more information, see [CreateService](#) in the *Amazon Elastic Container Service API Reference*.
- The DescribeServices response provides insight into the state of a deployment, the rolloutState and rolloutStateReason. When a new deployment starts, the rollout state begins in an IN\_PROGRESS state. When the service reaches a steady state and the bake time is

complete, the rollout state transitions to COMPLETED. If the service fails to reach a steady state and the alarm has gone into the ALARM state, the deployment will transition to a FAILED state. A deployment in a FAILED state won't launch any new tasks.

- In addition to the service deployment state change events Amazon ECS sends for deployments that have started and have completed, Amazon ECS also sends an event when a deployment that uses alarms fails. These events provide details about why a deployment failed or if a deployment was started because of a rollback. For more information, see [Amazon ECS service deployment state change events](#).
- If a new deployment is started because a previous deployment failed and rollback was turned on, the reason field of the service deployment state change event will indicate the deployment was started because of a rollback.
- If you use the deployment circuit breaker and the Amazon CloudWatch alarms to detect failures, either one can initiate a deployment failure as soon as the criteria for either method is met. A rollback occurs when you use the rollback option for the method that initiated the deployment failure.
- The Amazon CloudWatch alarms is only supported for Amazon ECS services that use the rolling update (ECS) deployment controller.
- You can configure this option by using the Amazon ECS console, or the AWS CLI. For more information, see [the section called "Create a service using defined parameters"](#) and [create-service](#) in the *AWS Command Line Interface Reference*.
- You might notice that the deployment status remains IN\_PROGRESS for a prolonged amount of time. The reason for this is that Amazon ECS does not change the status until it has deleted the active deployment, and this does not happen until after the bake time. Depending on your alarm configuration, the deployment might appear to take several minutes longer than it does when you don't use alarms (even though the new primary task set is scaled up and the old deployment is scaled down). If you use CloudFormation timeouts, consider increasing the timeouts. For more information, see [Creating wait conditions in a template](#) in the *AWS CloudFormation User Guide*.
- Amazon ECS calls DescribeAlarms to poll the alarms. The calls to DescribeAlarms count toward the CloudWatch service quotas associated with your account. If you have other AWS services that call DescribeAlarms, there might be an impact on Amazon ECS to poll the alarms. For example, if another service makes enough DescribeAlarms calls to reach the quota, that service is throttled and Amazon ECS is also throttled and unable to poll alarms. If an alarm is generated during the throttling period, Amazon ECS might miss the alarm and the roll back might not occur. There is no other impact on the deployment. For more information on CloudWatch service quotas, see [CloudWatch service quotas](#) in the *CloudWatch User Guide*.

- If an alarm is in the ALARM state at the beginning of a deployment, Amazon ECS will not monitor alarms for the duration of that deployment (Amazon ECS ignores the alarm configuration). This behavior addresses the case where you want to start a new deployment to fix an initial deployment failure.

## Recommended alarms

We recommend that you use the following alarm metrics:

- If you use an Application Load Balancer, use the `HTTPCode_ELB_5XX_Count` and `HTTPCode_ELB_4XX_Count` Application Load Balancer metrics. These metrics check for HTTP spikes. For more information about the Application Load Balancer metrics, see [CloudWatch metrics for your Application Load Balancer](#) in the *User Guide for Application Load Balancers*.
- If you have an existing application, use the `CPUUtilization` and `MemoryUtilization` metrics. These metrics check for the percentage of CPU and memory that the cluster or service uses. For more information, see [the section called “Considerations”](#).
- If you use Amazon Simple Queue Service queues in your tasks, use `ApproximateNumberOfMessagesNotVisible` Amazon SQS metric. This metric checks for number of messages in the queue that are delayed and not available for reading immediately. For more information about Amazon SQS metrics, see [Available CloudWatch metrics for Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*.

## Bake time

When you use the rollback option for your service deployments, Amazon ECS waits an additional amount of time after the target service revision has been deployed before it sends a CloudWatch alarm. This is referred to as the bake time. This time starts after:

- All tasks for a target service revision are running and in a healthy state
- Source service revisions are scaled down to 0%

The default bake time is less than 5 minutes. The service deployment is marked as complete after the bake time expires.

You can configure the bake time for a rolling deployment. When you use CloudWatch alarms to detect failure, if you change the bake time, and then decide you want the Amazon ECS default, you must manually set the bake time.

## Lifecycle hooks for Amazon ECS service deployments

When a deployment starts, it progresses through lifecycle stages. Each stage can be in a state such as `IN_PROGRESS` or `SUCCEEDED`. You can configure lifecycle hooks at specific stages to run custom logic or introduce decision points before the deployment proceeds. Amazon ECS supports two types of lifecycle hooks:

### Lambda hooks

Amazon ECS invokes a Lambda function at specific stages of a deployment. Your function contains your custom logic and must return a JSON object containing a `hookStatus` of `SUCCEEDED`, `FAILED`, or `IN_PROGRESS` to tell Amazon ECS how to proceed. You can use these hooks to run validation tests, enforce governance policies, or implement custom approval steps before the deployment proceeds. For more information, see [Lambda hooks for Amazon ECS service deployments](#).

### Pause hooks

Amazon ECS pauses the deployment at a configured lifecycle stage and waits for you to call the `ContinueServiceDeployment` API to continue or roll back. While paused, you can run your own workflows externally, such as manual approvals, integration tests with existing tools, operational readiness checks, or CI/CD pipeline steps. For more information, see [Pause hooks for Amazon ECS service deployments](#).

You can configure both Lambda hooks and pause hooks at the same lifecycle stage. Both hooks must complete before the deployment proceeds to the next stage.

### Lifecycle hook details

When hooks are active during a deployment, you can view their status by calling `DescribeServiceDeployments`. The response includes a `lifecycleHookDetails` array with the following fields for each active hook:

| Field                   | Description                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>hookId</code>     | The unique identifier for this hook execution. Use this value when calling <code>ContinueServiceDeployment</code> for pause hooks. |
| <code>targetType</code> | The hook type: <code>AWS_LAMBDA</code> or <code>PAUSE</code> .                                                                     |

| Field         | Description                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| targetArn     | The ARN of the hook target. For Lambda hooks, this is the Lambda function ARN. For pause hooks, this field is not set.                                               |
| status        | The current status of the hook: <code>AWAITING_ACTION</code> , <code>IN_PROGRESS</code> , <code>SUCCEEDED</code> , <code>FAILED</code> , or <code>TIMED_OUT</code> . |
| expiresAt     | The date and time when the hook expires. (Example: 2026-05-06T12:06:49-07:00)                                                                                        |
| timeoutAction | The action Amazon ECS takes when the hook times out: <code>ROLLBACK</code> or <code>CONTINUE</code> .                                                                |

## Lifecycle stage categories

Lifecycle stages fall into two categories:

- 1. Single invocation stages** - Amazon ECS invokes these stages only once during a service deployment:
  - `RECONCILE_SERVICE`
  - `PRE_SCALE_UP`
  - `POST_SCALE_UP`
  - `TEST_TRAFFIC_SHIFT`
  - `POST_TEST_TRAFFIC_SHIFT`
  - `POST_PRODUCTION_TRAFFIC_SHIFT`
- 2. Recurring invocation stages** - Amazon ECS can invoke these stages multiple times during a service deployment. For linear and canary deployments, these stages are invoked at each traffic shift step:
  - `PRE_PRODUCTION_TRAFFIC_SHIFT`
  - `PRODUCTION_TRAFFIC_SHIFT`

**Note**

Pause hooks cannot be configured at `TEST_TRAFFIC_SHIFT` or `PRODUCTION_TRAFFIC_SHIFT` because these stages are also invoked during rollback. Pausing during a rollback would require an additional `ContinueServiceDeployment` call to complete the rollback.

**Supported stages by hook type**

| Lifecycle stage               | Lambda hooks | Pause hooks |
|-------------------------------|--------------|-------------|
| RECONCILE_SERVICE             | Yes          | Yes         |
| PRE_SCALE_UP                  | Yes          | Yes         |
| POST_SCALE_UP                 | Yes          | Yes         |
| TEST_TRAFFIC_SHIFT            | Yes          | No          |
| POST_TEST_TRAFFIC_SHIFT       | Yes          | Yes         |
| PRE_PRODUCTION_TRAFFIC_SHIFT  | Yes          | Yes         |
| PRODUCTION_TRAFFIC_SHIFT      | Yes          | No          |
| POST_PRODUCTION_TRAFFIC_SHIFT | Yes          | Yes         |

**Lambda hooks for Amazon ECS service deployments**

Lambda hooks are Lambda functions that Amazon ECS invokes at specific stages of a deployment. You can use hooks to run validation tests, enforce governance policies, or implement custom logic before the deployment proceeds.

When Amazon ECS invokes your hook, your function must return a JSON object containing a `hookStatus` field. You can optionally include `callbackDelay` to control retry timing and `hookDetails` to pass data between invocations. If your function doesn't return a valid `hookStatus`, or if it fails, Amazon ECS rolls back the deployment.

## hookStatus values

The following are the valid hookStatus values:

- **SUCCEEDED** - The deployment continues to the next lifecycle stage.
- **FAILED** - Amazon ECS rolls back the deployment to the last successful service revision.
- **IN\_PROGRESS** - Amazon ECS invokes the function again after a delay. By default, the delay is 30 seconds. You can customize this value by returning a `callbackDelay` alongside the `hookStatus`.

The following example shows how to return a `hookStatus` with a custom callback delay. In this example, Amazon ECS retries the hook after 60 seconds instead of the default 30 seconds:

```
{
  "hookStatus": "IN_PROGRESS",
  "callbackDelay": 60
}
```

## Passing state with hookDetails

The `hookDetails` field is a dictionary that you can use to pass data into your lifecycle hook function. There are two ways to populate `hookDetails`:

- **At service creation or update** - Define `hookDetails` in the lifecycle hook configuration within your service definition. Amazon ECS passes this data to your function on every invocation. Use this to make your hooks reusable across multiple services by passing in service-specific configuration.
- **At runtime via IN\_PROGRESS responses** - Return `hookDetails` alongside the `IN_PROGRESS` hook status. Amazon ECS passes this data back to your function on the next invocation. Use this to maintain state between invocations without external storage.

The following example shows a lifecycle hook configuration in a service definition that passes an S3 bucket name to the function:

```
{
  "hookTargetArn": "arn:aws:lambda:us-west-2:123456789012:function:my-approval-hook",
  "roleArn": "arn:aws:iam::123456789012:role/ecs-lambda-invoke-role",
  "lifecycleStages": [
    "POST_TEST_TRAFFIC_SHIFT"
  ],
  "hookDetails": {
    "S3_BUCKET_NAME": "my-approval-bucket"
  }
}
```

When your function returns `IN_PROGRESS`, you can also include `hookDetails` in the response. Amazon ECS merges this data and passes it back on the next invocation. Common use cases include passing metric counters or ARNs of external resources between invocations.

```
{
  "hookStatus": "IN_PROGRESS",
  "callbackDelay": 30,
  "hookDetails": {
    "approvalChecked": true,
    "S3_BUCKET_NAME": "my-approval-bucket"
  }
}
```

On the next invocation, Amazon ECS includes the `hookDetails` in the event payload alongside `executionDetails`:

```
{
  "executionId": "e8d5a28f-eb01-4f3c-9454-a30ba6dc54bc",
  "lifecycleStage": "POST_TEST_TRAFFIC_SHIFT",
  "resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-service/EZe5RNVLH6PPzHXINuP28",
  "executionDetails": {
    "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
    "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-service/9313423515462893900",
    "testTrafficWeights": {},
    "productionTrafficWeights": {}
  }
}
```

```
},
"hookDetails": {
  "approvalChecked": true,
  "S3_BUCKET_NAME": "my-approval-bucket"
}
}
```

Your function can read event["hookDetails"] to access the configuration and state from previous invocations.

#### Note

Data added to hookDetails at runtime only persists between invocations of the same hook within a single deployment. Data doesn't carry over between different hooks within the same deployment or the same hook in different deployments.

## Timeout configuration

You can configure a timeout for Lambda hooks using `timeoutConfiguration`. If the Lambda function does not return `SUCCEEDED` or `FAILED` before the timeout expires, Amazon ECS takes the configured timeout action.

| Field                                              | Description                                                                                                                               |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>timeoutConfiguration.timeoutInMinutes</code> | How long to wait. Valid range: 1 to 1,440 (24 hours). Default: 1,440 minutes.                                                             |
| <code>timeoutConfiguration.action</code>           | The action to take if the timeout expires. Valid values: <code>ROLLBACK</code> , <code>CONTINUE</code> . Default: <code>ROLLBACK</code> . |

## Supported lifecycle stages

You can configure Lambda hooks at the following lifecycle stages:

- `RECONCILE_SERVICE`
- `PRE_SCALE_UP`

- POST\_SCALE\_UP
- TEST\_TRAFFIC\_SHIFT
- POST\_TEST\_TRAFFIC\_SHIFT
- PRE\_PRODUCTION\_TRAFFIC\_SHIFT
- PRODUCTION\_TRAFFIC\_SHIFT
- POST\_PRODUCTION\_TRAFFIC\_SHIFT

For linear and canary deployments, Lambda hooks configured at PRODUCTION\_TRAFFIC\_SHIFT or PRE\_PRODUCTION\_TRAFFIC\_SHIFT are invoked at each traffic shift step.

For more information about lifecycle stage categories, see [Lifecycle hooks for Amazon ECS service deployments](#).

## Lifecycle payloads

### Common payload structure

When Amazon ECS invokes your lifecycle hook Lambda function, the event payload contains the following top-level fields:

- `executionId` - The unique identifier for this hook execution.
- `lifecycleStage` - The current lifecycle stage (for example, PRODUCTION\_TRAFFIC\_SHIFT).
- `resourceArn` - The ARN of the resource associated with the deployment.
- `executionDetails` - An object containing the deployment-specific information described in the following list.

The `executionDetails` object contains the following fields:

- `serviceArn` - The Amazon Resource Name (ARN) of the service.
- `targetServiceRevisionArn` - The ARN of the target service revision being deployed.
- `testTrafficWeights` - A map of service revision ARNs to their corresponding test traffic weight percentages.
- `productionTrafficWeights` - A map of service revision ARNs to their corresponding production traffic weight percentages.

The following example shows the full event structure that your Lambda function receives:

```
{
  "executionId": "f4fcae0f-9bec-41c6-ba87-0eaa0cef8af5",
  "lifecycleStage": "PRODUCTION_TRAFFIC_SHIFT",
  "resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/EZe5RNVLH6PPzHXINuP28",
  "executionDetails": {
    "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
    "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
my-cluster/my-service/9313423515462893900",
    "testTrafficWeights": {},
    "productionTrafficWeights": {
      "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/9313423515462893900": 100,
      "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/1920498462936580504": 0
    }
  }
}
```

## Lifecycle stage payloads

The following sections show example payloads for each lifecycle stage. In these examples, the green service revision (9313423515462893900) is the new revision being deployed, and the blue service revision (1920498462936580504) is the existing production revision.

### PRE\_SCALE\_UP

This stage occurs before Amazon ECS launches the green service revision tasks. The green service revision has not started, and no traffic is being routed to it.

```
{
  "executionId": "e8d5a28f-eb01-4f3c-9454-a30ba6dc54bc",
  "lifecycleStage": "PRE_SCALE_UP",
  "resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/EZe5RNVLH6PPzHXINuP28",
  "executionDetails": {
    "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
```

```
    "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
my-cluster/my-service/9313423515462893900",
    "testTrafficWeights": {},
    "productionTrafficWeights": {}
  }
}
```

## POST\_SCALE\_UP

This stage occurs after Amazon ECS has launched the green service revision tasks and they are healthy. The green tasks are running but not yet receiving any traffic.

```
{
  "executionId": "8b095b05-7bb0-4c56-a223-a3f61f4f9295",
  "lifecycleStage": "POST_SCALE_UP",
  "resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/EZe5RNVLH6PPzHXINuP28",
  "executionDetails": {
    "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
    "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
my-cluster/my-service/9313423515462893900",
    "testTrafficWeights": {},
    "productionTrafficWeights": {}
  }
}
```

## TEST\_TRAFFIC\_SHIFT

This stage occurs when Amazon ECS shifts test traffic to the green service revision. The `testTrafficWeights` show the green revision receiving 100% of test traffic while the blue revision receives 0%. Production traffic continues to flow to the blue revision.

```
{
  "executionId": "779085de-ab47-42bc-84ad-41f9914a8643",
  "lifecycleStage": "TEST_TRAFFIC_SHIFT",
  "resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/EZe5RNVLH6PPzHXINuP28",
  "executionDetails": {
```

```

    "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
    "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
my-cluster/my-service/9313423515462893900",
    "testTrafficWeights": {
        "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/9313423515462893900": 100,
        "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/1920498462936580504": 0
    },
    "productionTrafficWeights": {}
}
}

```

## POST\_TEST\_TRAFFIC\_SHIFT

This stage occurs after Amazon ECS has completed the test traffic shift. The green service revision is handling 100% of test traffic.

```

{
    "executionId": "3a0345ba-b029-404b-890d-7da2a4b266aa",
    "lifecycleStage": "POST_TEST_TRAFFIC_SHIFT",
    "resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/EZe5RNVLH6PPzHXINuP28",
    "executionDetails": {
        "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
        "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
my-cluster/my-service/9313423515462893900",
        "testTrafficWeights": {},
        "productionTrafficWeights": {}
    }
}

```

## PRE\_PRODUCTION\_TRAFFIC\_SHIFT

This stage occurs before Amazon ECS shifts production traffic to the green service revision. For linear and canary deployments, this stage is invoked before each traffic shift step.

```

{

```

```

"executionId": "a2b3c4d5-e6f7-8901-abcd-ef1234567890",
"lifecycleStage": "PRE_PRODUCTION_TRAFFIC_SHIFT",
"resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/EZe5RNVLH6PPzHXINuP28",
"executionDetails": {
  "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
  "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
my-cluster/my-service/9313423515462893900",
  "testTrafficWeights": {},
  "productionTrafficWeights": {
    "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/9313423515462893900": 0,
    "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/1920498462936580504": 100
  }
}
}

```

## PRODUCTION\_TRAFFIC\_SHIFT

This stage occurs when Amazon ECS shifts production traffic to the green service revision. The `productionTrafficWeights` show the green revision receiving 100% of production traffic while the blue revision receives 0%.

```

{
  "executionId": "f4fcae0f-9bec-41c6-ba87-0eaa0cef8af5",
  "lifecycleStage": "PRODUCTION_TRAFFIC_SHIFT",
  "resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/EZe5RNVLH6PPzHXINuP28",
  "executionDetails": {
    "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
    "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
my-cluster/my-service/9313423515462893900",
    "testTrafficWeights": {},
    "productionTrafficWeights": {
      "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/9313423515462893900": 100,
      "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/1920498462936580504": 0
    }
  }
}

```

```
}
```

## POST\_PRODUCTION\_TRAFFIC\_SHIFT

This stage occurs after Amazon ECS has completed the production traffic shift. The green service revision is now handling all production traffic.

```
{
  "executionId": "5f40ed04-7e54-437d-b95d-98bc872fec49",
  "lifecycleStage": "POST_PRODUCTION_TRAFFIC_SHIFT",
  "resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/EZe5RNVLH6PPzHXINuP28",
  "executionDetails": {
    "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
    "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
my-cluster/my-service/9313423515462893900",
    "testTrafficWeights": {},
    "productionTrafficWeights": {}
  }
}
```

## Lifecycle hooks during rollback

There is no dedicated ROLLBACK lifecycle stage. When a rollback occurs, Amazon ECS re-invokes hooks registered at the PRODUCTION\_TRAFFIC\_SHIFT and TEST\_TRAFFIC\_SHIFT stages (the recurring invocation stages). During a rollback, the `productionTrafficWeights` in the payload show traffic shifting back to the blue revision.

The `targetServiceRevisionArn` remains the green revision ARN because it is still the target of the original deployment, even though traffic is shifting away from it.

The following example shows a PRODUCTION\_TRAFFIC\_SHIFT payload during a rollback. Notice that the blue revision (1920498462936580504) now receives 100% of production traffic, while the green revision (9313423515462893900) receives 0%:

```
{
  "executionId": "70073435-cb99-457f-b900-6ee1dcad05ec",
  "lifecycleStage": "PRODUCTION_TRAFFIC_SHIFT",
```

```

    "resourceArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/EZe5RNVLH6PPzHXINuP28",
    "executionDetails": {
        "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-service",
        "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
my-cluster/my-service/9313423515462893900",
        "testTrafficWeights": {},
        "productionTrafficWeights": {
            "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/9313423515462893900": 0,
            "arn:aws:ecs:us-west-2:123456789012:service-revision/my-cluster/my-
service/1920498462936580504": 100
        }
    }
}

```

To determine whether your hook is being invoked during a rollback, check the `productionTrafficWeights`. If the `targetServiceRevisionArn` (green revision) has a weight of 0% and the other revision has 100%, the deployment is rolling back.

## Pause hooks for Amazon ECS service deployments

Pause hooks pause an Amazon ECS service deployment at a specific lifecycle stage and wait for you to call `ContinueServiceDeployment` before the deployment proceeds. Use pause hooks when you need manual approval or external validation before a deployment continues.

### How pause hooks work

When a deployment reaches a lifecycle stage that has a pause hook configured, the following occurs:

1. Amazon ECS generates a unique `hookId` for the pause hook.
2. Amazon ECS emits an EventBridge event with the detail-type `ECS Hook State Change` and the event name `HOOK_AWAITING_ACTION`.
3. The deployment remains paused until you call `ContinueServiceDeployment` with the `hookId` and an action of `CONTINUE` or `ROLLBACK`, or until the configured timeout is reached.

You can retrieve the `hookId` by calling `DescribeServiceDeployments`. The response includes a `lifecycleHookDetails` array with the hook status:

```
{
  "serviceDeployments": [
    {
      "lifecycleHookDetails": [
        {
          "hookId": "ecs-pause-e7tK9G_WRJqNF_EOMjztDXfKenlJuEUVjsNStf4WLKw",
          "targetType": "PAUSE",
          "status": "AWAITING_ACTION",
          "expiresAt": "2024-01-15T12:00:00Z",
          "timeoutAction": "ROLLBACK"
        }
      ]
    }
  ]
}
```

## Configuring pause hooks

The following example shows a pause hook configuration in a service definition that pauses the deployment after the test traffic shift completes:

```
{
  "deploymentConfiguration": {
    "strategy": "BLUE_GREEN",
    "lifecycleHooks": [
      {
        "targetType": "PAUSE",
        "lifecycleStages": [
          "POST_TEST_TRAFFIC_SHIFT"
        ],
        "timeoutConfiguration": {
          "timeoutInMinutes": 10,
          "action": "ROLLBACK"
        }
      }
    ]
  }
}
```

## Configuration fields

| Field                                              | Description                                                                           | Valid values                                                                                                                                             | Required |
|----------------------------------------------------|---------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| <code>targetType</code>                            | The type of hook. Must be PAUSE for pause hooks.                                      | PAUSE                                                                                                                                                    | Yes      |
| <code>lifecycleStages</code>                       | The lifecycle stages at which the deployment pauses.                                  | RECONCILE_SERVICE ,<br>PRE_SCALE_UP ,<br>POST_SCALE_UP ,<br>POST_TEST_TRAFFIC_SHIFT ,<br>PRE_PRODUCTION_TRAFFIC_SHIFT ,<br>POST_PRODUCTION_TRAFFIC_SHIFT | Yes      |
| <code>timeoutConfiguration.timeoutInMinutes</code> | How long to wait before taking the timeout action. Default: 1,440 minutes (24 hours). | 1 - 20,160 (14 days)                                                                                                                                     | No       |
| <code>timeoutConfiguration.action</code>           | The action to take if the timeout expires.                                            | ROLLBACK (default),<br>CONTINUE                                                                                                                          | No       |

## Constraints

- You can configure a maximum of 10 pause hooks and 10 Lambda hooks per service.
- Pause hooks do not use `hookTargetArn` or `roleArn`. These fields are only for Lambda hooks.

- Pause hooks cannot be configured at the TEST\_TRAFFIC\_SHIFT or PRODUCTION\_TRAFFIC\_SHIFT stages.

## Continuing a paused deployment

When a deployment is paused (the pause hook status is `AWAITING_ACTION`), call `ContinueServiceDeployment` with the `hookId` and the action you want to take.

To continue the deployment:

```
aws ecs continue-service-deployment \  
  --hook-id ecs-pause-e7tK9G_WRJqNF_E0MjztDXfKen1JuEUVjsNStf4WLKw \  
  --action CONTINUE
```

To roll back the deployment:

```
aws ecs continue-service-deployment \  
  --hook-id ecs-pause-e7tK9G_WRJqNF_E0MjztDXfKen1JuEUVjsNStf4WLKw \  
  --action ROLLBACK
```

For more information, see [Continuing service deployments](#).

## Multiple hooks at the same stage

When multiple hooks are configured at the same lifecycle stage, the deployment stays paused until all hooks at that stage are continued. If any hook triggers a rollback, the entire deployment rolls back regardless of the status of other hooks at that stage.

This behavior applies when both Lambda hooks and pause hooks are configured at the same lifecycle stage. The deployment proceeds only when all hooks at that stage have completed successfully or been continued.

All hooks configured at the same lifecycle stage run in parallel.

## Timeout behavior

If you do not call `ContinueServiceDeployment` before the timeout expires, Amazon ECS takes the configured timeout action:

- **ROLLBACK (default)** - Amazon ECS rolls back the deployment to the previous service revision.
- **CONTINUE** - Amazon ECS continues the deployment to the next lifecycle stage.

Check the `expiresAt` field in the `lifecycleHookDetails` array of the `DescribeServiceDeployments` response to see when the timeout expires.

## Pause hooks with linear and canary deployments

For linear and canary deployments, pause hooks configured at `PRE_PRODUCTION_TRAFFIC_SHIFT` are invoked at each traffic shift step. Each invocation generates a unique `hookId`, and you must call `ContinueServiceDeployment` for each one.

For example, a linear deployment with 5 traffic shift steps and a pause hook at `PRE_PRODUCTION_TRAFFIC_SHIFT` pauses 5 times - once before each step. Each pause requires a separate call to `ContinueServiceDeployment` with the corresponding `hookId`.

## EventBridge events

Amazon ECS emits EventBridge events with the detail-type `ECS Hook State Change` as pause hooks progress through their lifecycle. The following table describes the event names:

| Event name                        | Description                                                                                                      |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>HOOK_AWAITING_ACTION</code> | The hook is waiting for you to call <code>ContinueServiceDeployment</code> .                                     |
| <code>HOOK_SUCCEEDED</code>       | The hook completed successfully (you called <code>ContinueServiceDeployment</code> with <code>CONTINUE</code> ). |
| <code>HOOK_FAILED</code>          | The hook failed (you called <code>ContinueServiceDeployment</code> with <code>ROLLBACK</code> ).                 |
| <code>HOOK_TIMED_OUT</code>       | The hook timed out before <code>ContinueServiceDeployment</code> was called.                                     |

The following example shows an EventBridge event emitted when a pause hook is awaiting action:

```
{
  "version": "0",
  "id": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
  "detail-type": "ECS Hook State Change",
  "source": "aws.ecs",
  "account": "123456789012",
  "time": "2024-01-15T10:00:00Z",
  "region": "us-west-2",
  "detail": {
    "eventType": "INFO",
    "eventName": "HOOK_AWAITING_ACTION",
    "hookId": "ecs-pause-e7tK9G_WRJqNF_E0MjztDXfKenlJuEUVjsNStf4WLKw",
    "hookType": "PAUSE",
    "expiresAt": "2024-01-15T12:00:00Z",
    "lifecycleStage": "POST_TEST_TRAFFIC_SHIFT",
    "clusterArn": "arn:aws:ecs:us-west-2:123456789012:cluster/my-cluster",
    "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-
service",
    "serviceDeploymentArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/
my-cluster/my-service/EZe5RNVLH6PPzHXINuP28",
    "updatedAt": "2024-01-15T10:00:00Z"
  }
}
```

## Continuing service deployments

When a pause lifecycle hook is configured for an Amazon ECS service deployment, the deployment pauses at the configured lifecycle stage and waits for an explicit action. Use the `ContinueServiceDeployment` API to either continue the deployment to the next lifecycle stage or roll back to the previous service revision.

The following action types are available:

- **CONTINUE** - This option continues the deployment to the next lifecycle stage.
- **ROLLBACK** - This option rolls back the service deployment to the previous service revision.

You can continue a deployment that has a pause hook in `AWAITING_ACTION` status. The deployment must be in the `IN_PROGRESS` state. For more information about service deployment states, see [View service history using Amazon ECS service deployments](#).

## Prerequisites

- The pause hook must be in `AWAITING_ACTION` status.
- You need the `hookId` from the `DescribeServiceDeployments` response.

## Procedure

### ECS Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. In the **Services** section, choose the service.
4. Choose the **Deployments** tab.
5. Verify that the pause hook status shows **Awaiting action**.
6. Choose **Take Action**, then choose **Continue** or **Roll back**.

### CLI

1. Get the `hookId` by calling `describe-service-deployments`:

```
aws ecs describe-service-deployments \
    --service-deployment-arn arn:aws:ecs:us-west-2:123456789012:service-
    deployment/my-cluster/my-service/EZe5RNVLH6PPzHXINuP28
```

2. Call `continue-service-deployment` with the `hookId` and the action:

To continue the deployment:

```
aws ecs continue-service-deployment \
    --hook-id ecs-pause-e7tK9G_WRJqNF_EOMjztDXfKenlJuEUVjsNStf4WLKw \
    --action CONTINUE
```

To roll back the deployment:

```
aws ecs continue-service-deployment \  
  --hook-id ecs-pause-e7tK9G_WRJqNF_E0MjztDXfKenlJuEUVjsNStf4WLKw \  
  --action ROLLBACK
```

The response includes the service deployment ARN:

```
{  
  "serviceDeploymentArn": "arn:aws:ecs:us-west-2:123456789012:service-  
deployment/my-cluster/my-service/EZe5RNVLH6PPzHXINuP28"  
}
```

## Next steps

- Monitor the deployment progress using `DescribeServiceDeployments` or the Amazon ECS console.
- If additional pause hooks are configured at later lifecycle stages, the deployment pauses again at those stages.

## Stopping Amazon ECS service deployments

You can manually stop a deployment when a failing deployment was not detected by the circuit breaker or CloudWatch alarms. The following stop types are available:

- **Rollback** - This option rolls back the service deployment to the previous service revision.

You can use this option even if you didn't configure the service deployment for the rollback option.

You can stop a deployment that is in any of the following states. For more information about service deployment states, see [View service history using Amazon ECS service deployments](#).

- **PENDING** - The service deployment moves to the `ROLLBACK_REQUESTED` state, and then the rollback operation starts.

- **IN\_PROGRESS** - The service deployment moves to the **ROLLBACK\_REQUESTED** state, and then the rollback operation starts.
- **STOP\_REQUESTED** - The service deployment continues to stop.
- **ROLLBACK\_REQUESTED** - The service deployment continues the rollback operation.
- **ROLLBACK\_IN\_PROGRESS** - The service deployment continues the rollback operation.

## Procedure

Before you begin, configure the required permissions for viewing service deployments. For more information, see [Permissions required for viewing Amazon ECS service deployments](#).

### Amazon ECS Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, choose the service.

The service details page displays.

4. On the service details page, choose **Deployments**.

The deployments page displays.

5. Under **Ongoing deployment**, choose **Roll back**. Then, in the confirmation window, choose **Roll back**.

### AWS CLI

1. Run `list-service-deployments` to retrieve the service deployment ARN.

Replace the *user-input* with your values.

```
aws ecs list-service-deployments --cluster cluster-name --service service-name
```

Note the `serviceDeploymentArn` for the deployment you want to stop.

```
{
  "serviceDeployments": [
    {
```

```

        "serviceDeploymentArn": "arn:aws:ecs:us-west-2:123456789012:service-
        deployment/cluster-name/service-name/NCWGC2ZR-taawPAYrIaU5",
        "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/cluster-
        name/service-name",
        "clusterArn": "arn:aws:ecs:us-west-2:123456789012:cluster/cluster-
        name",
        "targetServiceRevisionArn": "arn:aws:ecs:us-
        west-2:123456789012:service-revision/cluster-name/service-
        name/4980306466373577095",
        "status": "SUCCESSFUL"
    }
]
}

```

2. Run `stop-service-deployments`. Use the `serviceDeploymentArn` that was returned from `list-service-deployments`.

Replace the *user-input* with your values.

```

aws ecs stop-service-deployment --service-deployment-arn
arn:aws:ecs:region:123456789012:service-deployment/cluster-name/service-
name/NCWGC2ZR-taawPAYrIaU5 --stop-type ROLLBACK

```

## Next steps

Decide what changes need to be made to the service, and then update the service. For more information, see [Updating an Amazon ECS service](#).

## Deploy Amazon ECS services by replacing tasks

When you create a service which uses the *rolling update* (ECS) deployment type, the Amazon ECS service scheduler replaces the currently running tasks with new tasks. The number of tasks that Amazon ECS adds or removes from the service during a rolling update is controlled by the service deployment configuration.

Amazon ECS uses the following parameters to determine the number of tasks:

- The `minimumHealthyPercent` represents the lower limit on the number of tasks that should be running and healthy for a service during a rolling deployment or when a container instance is draining, as a percent of the desired number of tasks for the service. This value is rounded up. For example if the minimum healthy percent is 50 and the desired task count is four, then the

scheduler can stop two existing tasks before starting two new tasks. Likewise, if the minimum healthy percent is 75% and the desired task count is two, then the scheduler can't stop any tasks due to the resulting value also being two.

- The `maximumPercent` represents the upper limit on the number of tasks that should be running for a service during a rolling deployment or when a container instance is draining, as a percent of the desired number of tasks for a service. This value is rounded down. For example if the maximum percent is 200 and the desired task count is four, then the scheduler can start four new tasks before stopping four existing tasks. Likewise, if the maximum percent is 125 and the desired task count is three, the scheduler can't start any tasks due to the resulting value also being three.

During a rolling deployment, when tasks become unhealthy, Amazon ECS replaces them to maintain your service's `minimumHealthyPercent` and protect availability. Unhealthy tasks are replaced using the same service revision they belong to. This ensures that unhealthy task replacement in the source revision is independent from task failures in the target revision. When the `maximumPercent` setting allows, the scheduler launches replacement tasks before stopping unhealthy ones. If the `maximumPercent` parameter limits the scheduler from starting a replacement task first, the scheduler stops one unhealthy task at a time to free capacity before launching a replacement task.

### Important

When setting a minimum healthy percent or a maximum percent, you should ensure that the scheduler can stop or start at least one task when a deployment is initiated. If your service has a deployment that is stuck due to an invalid deployment configuration, a service event message will be sent. For more information, see [service \(\*service-name\*\) was unable to stop or start tasks during a deployment because of the service deployment configuration. Update the `minimumHealthyPercent` or `maximumPercent` value and try again..](#)

Rolling deployments have 2 methods which provide a way to quickly identify when a service deployment has failed:

- [the section called "How the deployment circuit breaker detects failures"](#)
- [the section called "How CloudWatch alarms detect deployment failures"](#)

The methods can be used separately or together. When both methods are used, the deployment is set to failed as soon as the failure criteria for either failure method is met.

Use the following guidelines to help determine which method to use:

- Circuit breaker - Use this method when you want to stop a deployment when the tasks can't start.
- CloudWatch alarms - Use this method when you want to stop a deployment based on application metrics.

Both methods support rolling back to the previous service revision.

You can configure early success criteria to have Amazon ECS complete a rolling deployment when a percentage of tasks that you define are healthy on the target service revision. For more information, see [Complete Amazon ECS rolling deployments early with early success criteria](#).

## Container image resolution

By default, Amazon ECS resolves container image tags specified in the task definition to container image digests. If you create a service that runs and maintains a single task, that task is used to establish image digests for the containers in the task. If you create a service that runs and maintains multiple tasks, the first task started by the service scheduler during deployment is used to establish the image digests for the containers in the tasks.

If three or more attempts at establishing the container image digests fail, the deployment continues without image digest resolution. If the deployment circuit breaker is enabled, the deployment is additionally failed and rolled back.

After the container image digests have been established, Amazon ECS uses the digests to start any other desired tasks, and for any future service updates. This leads to all tasks in a service always running identical container images, resulting in version consistency for your software.

You can configure this behavior for each container in your task by using the `versionConsistency` parameter in the container definition. For more information, see [versionConsistency](#).

### Note

- Amazon ECS Agent versions lower than 1.31.0 don't support image digest resolution. Agent versions 1.31.0 to 1.69.0 support image digest resolution only for images

pushed to Amazon ECR repositories. Agent versions 1.70.0 or higher support image digest resolution for all images.

- The minimum Fargate Linux platform version for image digest resolution is 1.3.0. The minimum Fargate Windows platform version for image digest resolution is 1.0.0.
- Amazon ECS doesn't capture digests of sidecar containers managed by Amazon ECS, such as the Amazon GuardDuty security agent or Service Connect proxy.
- To reduce potential latency associated with container image resolution in services with multiple tasks, run Amazon ECS agent version 1.83.0 or higher on EC2 container instances. To avoid potential latency, specify container image digests in your task definition.
- If you create a service with a desired task count of zero, Amazon ECS can't establish container digests until you trigger another deployment of the service with a desired task count greater than zero.
- To establish updated image digests, you can force a new deployment. The updated digests will be used to start new tasks and will not affect already running tasks. For more information about forcing new deployments, see [forceNewDeployment](#) in the *Amazon ECS API reference*.
- When using EC2 capacity providers, if there is insufficient capacity to start a task during the initial deployment, software version consistency may fail. To ensure version consistency is maintained even when capacity is limited, explicitly set `versionConsistency: "enabled"` in your task definition container configuration rather than relying on the default behavior. This causes Amazon ECS to wait until capacity becomes available before proceeding with the deployment.

## Best practices for Amazon ECS service parameters

To ensure that there's no application downtime, the deployment process is as follows:

1. Start the new application containers while keeping the existing containers running.
2. Check that the new containers are healthy.
3. Stop the old containers.

Depending on your deployment configuration and the amount of free, unreserved space in your cluster it may take multiple rounds of this to complete replace all old tasks with new tasks.

There are two service configuration options that you can use to modify the number:

- `minimumHealthyPercent`: 100% (default)

The lower limit on the number of tasks for your service that must remain in the `RUNNING` state during a deployment. This is a percentage of the `desiredCount` rounded up to the nearest integer. This parameter allows you to deploy without using additional cluster capacity.

- `maximumPercent`: 200% (default)

The upper limit on the number of tasks for your service that are allowed in the `RUNNING` or `PENDING` state during a deployment. This is a percentage of the `desiredCount` rounded down to the nearest integer.

### Example: Default configuration options

Consider the following service that has six tasks, deployed in a cluster that has room for eight tasks total. The default service configuration options don't allow the deployment to go below 100% of the six desired tasks.

The deployment process is as follows:

1. The goal is to replace the six tasks.
2. The scheduler starts two new tasks because the default settings require that there are six running tasks.

There are now six existing tasks and two new tasks.

3. The scheduler stops two of the existing tasks.

There are now four existing tasks and two new ones.

4. The scheduler starts two additional new tasks.

There are now four existing tasks and four new tasks.

5. The scheduler shuts down two of the existing tasks.

There are now two existing tasks and four new ones.

6. The scheduler starts two additional new tasks.

There are now two existing tasks and six new tasks

7. The scheduler shuts down the last two existing tasks.

There are now six new tasks.

In the preceding example, if you use the default values for the options, there is a 2.5 minute wait for each new task that starts. Additionally, the load balancer might have to wait 5 minutes for the old task to stop.

### **Example: Modify `minimumHealthyPercent`**

You can speed up the deployment by setting the `minimumHealthyPercent` value to 50%.

Consider the following service that has six tasks, deployed in a cluster that has room for eight tasks total. The deployment process is as follows:

1. The goal is to replace six tasks.
2. The scheduler stops three of the existing tasks.

There are still three existing tasks running which meets the `minimumHealthyPercent` value.

3. The scheduler starts five new tasks.

There are three existing task tasks and five new tasks.

4. The scheduler stops the remaining three existing tasks.

There are five new tasks

5. The scheduler starts the final new tasks.

There are six new tasks.

### **Example: Modify cluster free space**

You could also add additional free space so that you can run additional tasks.

Consider the following service that has six tasks, deployed in a cluster that has room for ten tasks total. The deployment process is as follows:

1. The goal is to replace the existing tasks.
2. The scheduler stops three of the existing tasks,

There are three existing tasks.

### 3. The scheduler starts six new tasks.

There are the existing tasks and six new tasks

### 4. The scheduler stops the three existing tasks.

There are six new tasks.

## Recommendations

Use the following values for the service configuration options when your tasks are idle for some time and don't have a high utilization rate.

- `minimumHealthyPercent`: 50%
- `maximumPercent`: 200%

## Creating an Amazon ECS rolling update deployment

Create a service to run and maintain a specified number of instances of a task definition simultaneously in a cluster. If one of your tasks fails or stops, the Amazon ECS service scheduler launches another instance of your task definition to replace it. This helps maintain your desired number of tasks in the service.

Decide on the following configuration parameters before you create a service:

- There are two compute options that distribute your tasks.
  - A **capacity provider strategy** causes Amazon ECS to distribute your tasks in one or across multiple capacity providers.

If you want to run your workloads on Amazon ECS Managed Instances, you must use the Capacity provider strategy option.

- A **launch type** causes Amazon ECS to launch our tasks directly on either Fargate or on the EC2 instances registered to your clusters.

If you want to run your workloads on Amazon ECS Managed Instances, you must use the Capacity provider strategy option.

- Task definitions that use the `awsvpc` network mode or services configured to use a load balancer must have a networking configuration. By default, the console selects the default Amazon VPC along with all subnets and the default security group within the default Amazon VPC.

- The placement strategy, The default task placement strategy distributes tasks evenly across Availability Zones.

We recommend that you use Availability Zone rebalancing to help ensure high availability for your service. For more information, see [Balancing an Amazon ECS service across Availability Zones](#).

- When you use the **Launch Type** for your service deployment, by default the service starts in the subnets in your cluster VPC.
- For the **capacity provider strategy**, the console selects a compute option by default. The following describes the order that the console uses to select a default:
  - If your cluster has a default capacity provider strategy defined, it is selected.
  - If your cluster doesn't have a default capacity provider strategy defined but you have the Fargate capacity providers added to the cluster, a custom capacity provider strategy that uses the FARGATE capacity provider is selected.
  - If your cluster doesn't have a default capacity provider strategy defined but you have one or more Auto Scaling group capacity providers added to the cluster, the **Use custom (Advanced)** option is selected and you need to manually define the strategy.
  - If your cluster doesn't have a default capacity provider strategy defined and no capacity providers added to the cluster, the Fargate launch type is selected.
- The default deployment failure detection default options are to use the **Amazon ECS deployment circuit breaker** option with the **Rollback on failures** option.

For more information, see [How the Amazon ECS deployment circuit breaker detects failures](#).

- Decide if you want Amazon ECS to increase or decrease the desired number of tasks in your service automatically. For information see, [Automatically scale your Amazon ECS service](#).
- If you need an application to connect to other applications that run in Amazon ECS, determine the option that fits your architecture. For more information, see [Interconnect Amazon ECS services](#).
- When you create a service that uses Amazon ECS circuit breaker, Amazon ECS creates a service deployment and a service revision. These resources allow you to view detailed information about the service history. For more information, see [View service history using Amazon ECS service deployments](#).

For information about how to create a service using the AWS CLI, see [create-service](#) in the *AWS Command Line Interface Reference*.

For information about how to create a service using AWS CloudFormation, see [AWS::ECS::Service](#) in the *AWS CloudFormation User Guide*.

## Create a service with the default options

You can use the console to quickly create and deploy a service. The service has the following configuration:

- Deploys in the VPC and subnets associated with your cluster
- Deploys one task
- Uses the rolling deployment
- Uses the capacity provider strategy with your default capacity provider
- Uses the deployment circuit breaker to detect failures and sets the option to automatically roll back the deployment on failure

To deploy a service using the default parameters follow these steps.

### To create a service (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation page, choose **Clusters**.
3. On the **Clusters** page, choose the cluster to create the service in.
4. From the **Services** tab, choose **Create**.

The **Create service** page appears.

5. Under **Service details**, do the following:
  - a. For **Task definition**, enter the task definition family and revision to use.
  - b. For **Service name**, enter a name for your service.
6. To use ECS Exec to debug the service, under **Troubleshooting configuration**, select **Turn on ECS Exec**.
7. Under **Deployment configuration**, do the following:
  - For **Desired tasks**, enter the number of tasks to launch and maintain in the service.

8. (Optional) To help identify your service and tasks, expand the **Tags** section, and then configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the task definition tags, select **Turn on Amazon ECS managed tags**, and then select **Task definitions**.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the service tags, select **Turn on Amazon ECS managed tags**, and then select **Service**.

Add or remove a tag.

- [Add a tag] Choose **Add tag**, and then do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
- [Remove a tag] Next to the tag, choose **Remove tag**.

## Create a service using defined parameters

To create a service by using defined parameters, follow these steps.

### To create a service (Amazon ECS console)

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. Determine the resource from where you launch the service.

| To start a service from | Steps                                                                                                                                                                                       |  |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Clusters                | <ol style="list-style-type: none"><li>a. On the <b>Clusters</b> page, select the cluster to create the service in.</li><li>b. From the <b>Services</b> tab, choose <b>Create</b>.</li></ol> |  |
| Task definition         | <ol style="list-style-type: none"><li>a. On the <b>Task definitions</b> page, select the option button next to the task definition.</li></ol>                                               |  |

| To start a service from | Steps                                                        |  |
|-------------------------|--------------------------------------------------------------|--|
|                         | b. On the <b>Deploy</b> menu, choose <b>Create service</b> . |  |

The **Create service** page appears.

3. Under Service details, do the following:
  - a. For **Task definition**, enter the task definition to use. Then, for **Revision**, choose the revision to use.
  - b. For **Service name**, enter a name for your service.
4. For **Existing cluster**, choose the cluster.

Choose **Create cluster** to run the task on a new cluster

5. Choose how your tasks are distributed across your cluster infrastructure. Under **Compute configuration**, choose your option.

| Compute option             | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |  |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Capacity provider strategy | <ol style="list-style-type: none"><li>a. Under <b>Compute options</b>, choose <b>Capacity provider strategy</b>.</li><li>b. Choose a strategy:<ul style="list-style-type: none"><li>• To use the cluster's default capacity provider strategy, choose <b>Use cluster default</b>.</li><li>• If your cluster doesn't have a default capacity provider strategy, or to use a custom strategy, choose <b>Use custom</b>, <b>Add capacity provider strategy</b>, and then</li></ul></li></ol> |  |

| Compute option | Steps                                                                                                                                                                                                                                                                                                                                                                                     |  |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                | <p>define your custom capacity provider strategy by specifying a <b>Base</b>, <b>Capacity provider</b>, and <b>Weight</b>.</p> <div data-bbox="634 510 1052 919"> <p> <b>Note</b></p> <p>To use a capacity provider in a strategy, the capacity provider must be associated with the cluster.</p> </div> |  |
| Launch type    | <ol style="list-style-type: none"> <li>In the <b>Compute options</b> section, select <b>Launch type</b>.</li> <li>For <b>Launch type</b>, choose a launch type.</li> <li>(Optional) When you use Fargate, for <b>Platform version</b>, specify the platform version to use. If a platform version isn't specified, the LATEST platform version is used.</li> </ol>                        |  |

- To use ECS Exec to debug the service, under **Troubleshooting configuration**, select **Turn on ECS Exec**.
- Under **Deployment configuration**, do the following:
  - For **Service type**, choose the service scheduling strategy.

- To have the scheduler deploy exactly one task on each active container instance that meets all of the task placement constraints, choose **Daemon**.
  - To have the scheduler place and maintain the desired number of tasks in your cluster, choose **Replica**.
- b. If you chose **Replica**, for **Desired tasks**, enter the number of tasks to launch and maintain in the service.
  - c. If you chose **Replica**, to have Amazon ECS monitor the distribution of tasks across Availability Zones, and redistribute them when there is an imbalance, under **Availability Zone service rebalancing**, select **Availability Zone service rebalancing**.
  - d. For **Health check grace period**, enter the amount of time (in seconds) that the service scheduler ignores unhealthy Elastic Load Balancing, VPC Lattice, and container health checks after a task has first started. If you do not specify a health check grace period value, the default value of 0 is used.
  - e. Determine the deployment type for your service. Expand **Deployment options**, and then specify the following parameters.

| Deployment type | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Rolling update  | <p>a. For <b>Min running tasks</b>, enter the lower limit on the number of tasks in the service that must remain in the RUNNING state during a deployment, as a percentage of the desired number of tasks (rounded up to the nearest integer). For more information, see <a href="#">Deployment configuration</a>.</p> <p>b. For <b>Max running tasks</b>, enter the upper limit on the number of tasks in the service that are allowed in the RUNNING or PENDING state during a deployment, as a percentage of the desired number of tasks (rounded down to the nearest integer).</p> |  |

- f. Under **Deployment configuration**, to complete the deployment before the target service revision reaches the full desired count, configure early success criteria. You can also choose when Amazon ECS cleans up the tasks on the source service revision.
  - i. Turn on **Early success criteria**.
  - ii. For **Healthy percent**, enter the percentage of tasks that must be running and healthy on the target service revision before Amazon ECS completes the deployment.
  - iii. For **Source service revision cleanup**, choose **Blocking** or **Deferred**.

- g. To configure how Amazon ECS detects and handles deployment failures, expand **Deployment failure detection**, and then choose your options.
  - i. To stop a deployment when the tasks cannot start, select **Use the Amazon ECS deployment circuit breaker**.

To have the software automatically roll back the deployment to the last completed deployment state when the deployment circuit breaker sets the deployment to a failed state, select **Rollback on failures**.

- ii. To stop a deployment based on application metrics, select **Use CloudWatch alarm(s)**. Then, from **CloudWatch alarm name**, choose the alarms. To create a new alarm, go to the CloudWatch console.

To have the software automatically roll back the deployment to the last completed deployment state when a CloudWatch alarm sets the deployment to a failed state, select **Rollback on failures**.

8. If your task definition uses the awsvpc network mode, you can specify a custom network configuration expand **Networking**, and then do the following:
  - a. For **VPC**, select the VPC to use.
  - b. For **Subnets**, select one or more subnets in the VPC that the task scheduler considers when placing your tasks.
  - c. For **Security group**, you can either select an existing security group or create a new one. To use an existing security group, select the security group and move to the next step. To create a new security group, choose **Create a new security group**. You must specify a security group name, description, and then add one or more inbound rules for the security group.
  - d. For **Public IP**, choose whether to auto-assign a public IP address to the elastic network interface (ENI) of the task.

AWS Fargate tasks can be assigned a public IP address when run in a public subnet so they have a route to the internet. EC2 tasks can't be assigned a public IP using this field. For more information, see [Amazon ECS task networking options for Fargate](#) and [Allocate a network interface for an Amazon ECS task](#).

9. (Optional) To interconnect your service using Service Connect, expand **Service Connect**, and then specify the following:

- a. Select **Turn on Service Connect**.
- b. Under **Service Connect configuration**, specify the client mode.
  - If your service runs a network client application that only needs to connect to other services in the namespace, choose **Client side only**.
  - If your service runs a network or web service application and needs to provide endpoints for this service, and connects to other services in the namespace, choose **Client and server**.
- c. To use a namespace that is not the default cluster namespace, for **Namespace**, choose the service namespace. This can be a namespace created separately in the same AWS Region in your AWS account or a namespace in the same Region that is shared with your account using AWS Resource Access Manager (AWS RAM). For more information about shared AWS Cloud Map namespaces, see [Cross-account AWS Cloud Map namespace sharing](#) in the *AWS Cloud Map Developer Guide*.
- d. (Optional) Specify a log configuration. Select **Use log collection**. The default option sends container logs to CloudWatch Logs. The other log driver options are configured using AWS FireLens. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

The following describes each container log destination in more detail.

- **Amazon CloudWatch** – Configure the task to send container logs to CloudWatch Logs. The default log driver options are provided, which create a CloudWatch log group on your behalf. To specify a different log group name, change the driver option values.
- **Amazon Data Firehose** – Configure the task to send container logs to Firehose. The default log driver options are provided, which send logs to a Firehose delivery stream. To specify a different delivery stream name, change the driver option values.
- **Amazon Kinesis Data Streams** – Configure the task to send container logs to Kinesis Data Streams. The default log driver options are provided, which send logs to an Kinesis Data Streams stream. To specify a different stream name, change the driver option values.
- **Amazon OpenSearch Service** – Configure the task to send container logs to an OpenSearch Service domain. The log driver options must be provided.

- **Amazon S3** – Configure the task to send container logs to an Amazon S3 bucket. The default log driver options are set by default, but you must specify a valid Amazon S3 bucket name.
- e. (Optional) To enable access logs, follow these steps:
- i. Expand **Access log configuration**. For **Format**, choose either **JSON** or **TEXT**.
  - ii. To include query parameters in access logs, select **Include query parameters**.
10. (Optional) To interconnect your service using Service Discovery, expand **Service discovery**, and then do the following.
- a. Select **Use service discovery**.
  - b. To use a new namespace, choose **Create a new namespace** under **Configure namespace**, and then provide a namespace name and description. To use an existing namespace, choose **Select an existing namespace** and then choose the namespace that you want to use.
  - c. Provide Service Discovery service information such as the service's name and description.
  - d. To have Amazon ECS perform periodic container-level health checks, select **Enable Amazon ECS task health propagation**.
  - e. For **DNS record type**, select the DNS record type to create for your service. Amazon ECS service discovery only supports **A** and **SRV** records, depending on the network mode that your task definition specifies. For more information about these record types, see [Supported DNS Record Types](#) in the *Amazon Route 53 Developer Guide*.
- If the task definition that your service task specifies uses the `bridge` or `host` network mode, only type **SRV** records are supported. Choose a container name and port combination to associate with the record.
  - If the task definition that your service task specifies uses the `awsvpc` network mode, select either the **A** or **SRV** record type. If you choose **A**, skip to the next step. If you choose **SRV**, specify either the port that the service can be found on or a container name and port combination to associate with the record.
- For **TTL**, enter the time in seconds how long a record set is cached by DNS resolvers and by web browsers.
11. (Optional) To interconnect your service using VPC Lattice, expand **VPC Lattice**, and then do the following:

- a. Select **Turn on VPC Lattice**
- b. For **Infrastructure role**, choose the infrastructure role.

If you haven't created a role, choose **Create infrastructure role**.

- c. Under **Target Groups** choose the target group or groups. You need to choose at least one target group and can have a maximum of five. Choose **Add target group** to add additional target groups. Choose the **Port name**, **Protocol**, and **Port** for each target group you chose.

To delete a target group, choose **Remove**.

 **Note**

- If you want to add existing target groups, you need use the AWS CLI. For instructions on how to add target groups using the AWS CLI, see [register-targets](#) in the *AWS Command Line Interface Reference*.
- While a VPC Lattice service can have multiple target groups, each target group can only be added to one service.

- d. To complete the VPC Lattice configuration, by including your new target groups in the listener default action or in the rules of an existing VPC Lattice service in the VPC Lattice console. For more information, see [Listener rules for your VPC Lattice service](#).

12. (Optional) To configure a load balancer for your service, expand **Load balancing**.

Choose the load balancer.

| To use this load balancer | Do this                                                                                                                                                                                                                                                                       |  |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Application Load Balancer | <ul style="list-style-type: none"><li>a. For <b>Load balancer type</b>, select <b>Application Load Balancer</b>.</li><li>b. Choose <b>Create a new load balancer</b> to create a new Application Load Balancer or <b>Use an existing load balancer</b> to select an</li></ul> |  |

13. (Optional) To configure service Auto Scaling, expand **Service auto scaling**, and then specify the following parameters. To use predictive auto scaling, which looks at past load data from traffic flows, configure it after you create the service. For more information, see [Use historical patterns to scale Amazon ECS services with predictive scaling](#).

- a. To use service auto scaling, select **Service auto scaling**.
- b. For **Minimum number of tasks**, enter the lower limit of the number of tasks for service auto scaling to use. The desired count will not go below this count.
- c. For **Maximum number of tasks**, enter the upper limit of the number of tasks for service auto scaling to use. The desired count will not go above this count.
- d. Choose the policy type. Under **Scaling policy type**, choose one of the following options.

| To use this policy type | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |

|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                         | <p>the lower bound is negative (-) infinity.</p> <ul style="list-style-type: none"><li>• (Optional) Add additional scaling options. Choose <b>Add new scaling action</b>, and then repeat the <b>Scaling actions</b> steps.</li><li>• For <b>Cooldown period</b>, enter the amount of time, in seconds, to wait for a previous scaling activity to take effect. For an add policy, this is the time after a scale-out activity that the scaling policy blocks scale-in activities and limits how many tasks can be scale out at a time. For a remove policy, this is the time after a scale-in activity that must pass before another scale-in activity can start.</li></ul> |  |

14. (Optional) To use a task placement strategy other than the default, expand **Task Placement**, and then choose from the following options.

For more information, see [How Amazon ECS places tasks on container instances](#).

- **AZ Balanced Spread** – Distribute tasks across Availability Zones and across container instances in the Availability Zone.
- **AZ Balanced BinPack** – Distribute tasks across Availability Zones and across container instances with the least available memory.
- **BinPack** – Distribute tasks based on the least available amount of CPU or memory.
- **One Task Per Host** – Place, at most, one task from the service on each container instance.
- **Custom** – Define your own task placement strategy.

If you chose **Custom**, define the algorithm for placing tasks and the rules that are considered during task placement.

- Under **Strategy**, for **Type** and **Field**, choose the algorithm and the entity to use for the algorithm.

You can enter a maximum of 5 strategies.

- Under **Constraint**, for **Type** and **Expression**, choose the rule and attribute for the constraint.

For example, to set the constraint to place tasks on T2 instances, for the **Expression**, enter **attribute:ecs.instance-type =~ t2.\***.

You can enter a maximum of 10 constraints.

15. If your task uses a data volume that's compatible with configuration at deployment, you can configure the volume by expanding **Volume**.

The volume name and volume type are configured when you create a task definition revision and can't be changed when creating a service. To update the volume name and type, you must create a new task definition revision and create a service by using the new revision.

| To configure this volume type | Do this                                                                                             |  |
|-------------------------------|-----------------------------------------------------------------------------------------------------|--|
| Amazon EBS                    | a. For <b>EBS volume type</b> , choose the type of EBS volume that you want to attach to your task. |  |

| To configure this volume type | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |  |

If you choose</p> |  |

| To configure this volume type | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |  |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                               | <p><b>Default</b> and Amazon EBS default encryption isn't turned on, the volume will be unencrypted.</p> <p>If you choose <b>Custom</b>, you can specify an AWS KMS key of your choice for volume encryption.</p> <p>If you choose <b>None</b>, the volume will be unencrypted unless you have encryption by default configured, or if you create a volume from an encrypted snapshot.</p> <p>j. If you've chosen <b>Custom</b> for <b>Encryption</b>, you must specify the AWS KMS key that you want to use. For <b>KMS key</b>, choose an AWS KMS key or enter a key ARN. If you choose to encrypt your volume by using a symmetric customer managed key, make sure that you have the right permissions defined in your AWS KMS key policy. For more information, see <a href="#">Data encryption for Amazon EBS volumes</a>.</p> |  |

| To configure this volume type | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                               | <p>k. (Optional) Under <b>Tags</b>, you can add tags to your Amazon EBS volume by either propagating tags from the task definition or service, or by providing your own tags.</p> <p>If you want to propagate tags from the task definition, choose <b>Task definition</b> for <b>Propagate tags from</b>. If you want to propagate tags from the service, choose <b>Service</b> for <b>Propagate tags from</b>. If you choose <b>Do not propagate</b>, or if you don't choose a value, the tags aren't propagated.</p> <p>If you want to provide your own tags, choose <b>Add tag</b> and then provide the key and value for each tag you add.</p> <p>For more information about tagging Amazon EBS volumes, see <a href="#">Tagging Amazon EBS volumes</a>.</p> |  |

16. To use ECS Exec to debug the service, under **Troubleshooting configuration**, select **Turn on ECS Exec**.

17. (Optional) To help identify your service and tasks, expand the **Tags** section, and then configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the task definition tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Task definitions**.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the service tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Service**.

Add or remove a tag.

- [Add a tag] Choose **Add tag**, and then do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
- [Remove a tag] Next to the tag, choose **Remove tag**.

18. Choose **Create**.

## Next steps

The following are additional actions after you create a service.

- Configure predictive auto scaling, which looks at past load data from traffic flows. For more information, see [Use historical patterns to scale Amazon ECS services with predictive scaling](#).
- Track your deployment and view your service history for services that Amazon ECS circuit breaker. For more information, see [View service history using Amazon ECS service deployments](#).

## Complete Amazon ECS rolling deployments early with early success criteria

When you update a service that uses the rolling deployment strategy, Amazon ECS starts a deployment that replaces the tasks on the source service revision with new tasks on the target service revision. Amazon ECS completes the deployment after all of the following are true:

- The target service revision reaches 100 percent of the desired count, and all of its tasks are running and healthy.
- The deployment circuit breaker or a CloudWatch alarm does not trigger a rollback.

- If you use alarm-based rollback, the bake time elapses.
- The tasks on the source service revision are cleaned up.

With early success criteria, you configure when Amazon ECS completes a deployment, based on the confidence and operational needs of your workload.

You can use early success criteria in the following scenarios:

- You are confident that a percentage of healthy tasks on the target service revision is enough to complete the deployment, and you want to complete it sooner so that subsequent deployments, CI/CD pipelines, and other dependent operations can proceed.
- Your service runs on specialized or constrained capacity, such as GPU-accelerated inference workloads, where some tasks take longer to launch because of hardware availability.
- Your service has tasks on the source service revision that are slow to drain and would otherwise hold the deployment open, such as tasks with long-lived connections.
- You want the deployment circuit breaker or CloudWatch alarm rollback to protect the deployment until the target service revision reaches a health level that you define, and you do not want a rollback after that point.

You define the criteria by using the following settings in the deployment configuration.

### Healthy percent

The `earlySuccessCriteria.healthyPercent` represents the number of tasks that must be running and healthy on the target service revision before Amazon ECS completes the deployment, as a percent of the desired number of tasks for the service. This value is rounded up. For example, if the healthy percent is 90 and the desired count is 100, Amazon ECS completes the deployment after 90 tasks are healthy. If the healthy percent is 50 and the desired count is 3, Amazon ECS completes the deployment after 2 tasks are healthy.

A task is healthy when it passes the health checks that you configure for the service.

Amazon ECS launches any remaining tasks on the target service revision outside of the deployment, through regular service scaling. After Amazon ECS completes the deployment, the deployment circuit breaker and CloudWatch alarm rollback no longer apply.

The healthy percent must be between the service `minimumHealthyPercent` and 100.

## Source service revision cleanup

The `earlySuccessCriteria.sourceServiceRevisionCleanup` determines when Amazon ECS cleans up the tasks from the source service revision. It has two values, `BLOCKING` and `DEFERRED`.

With `BLOCKING`, the deployment proceeds in the following order:

1. The healthy percent of tasks are running and healthy on the target service revision.
2. If you use alarm-based rollback, the bake time elapses.
3. Amazon ECS cleans up the tasks on the source service revision.
4. Amazon ECS completes the deployment.

With `DEFERRED`, the deployment proceeds in the following order:

1. The healthy percent of tasks are running and healthy on the target service revision.
2. If you use alarm-based rollback, the bake time elapses.
3. Amazon ECS completes the deployment.
4. Amazon ECS cleans up the tasks on the source service revision, outside of the deployment.

With `DEFERRED`, Amazon ECS tries to clean up the tasks on the source service revision for up to two weeks.

Use `DEFERRED` for services with long-lived connections or task scale-in protection, where tasks from the source service revision might need to keep running without holding the deployment open. This is useful when draining the source service revision is a long-tail operation and your CI/CD tooling has time limits. Amazon ECS completes the deployment when the healthy percent is met, and the tasks on the source service revision drain outside of the deployment.

## How Amazon ECS evaluates early success criteria

Amazon ECS completes a deployment that uses early success criteria after all of the following are true:

- The number of running and healthy tasks on the target service revision is at least the healthy percent of the desired count, rounded up.
- The deployment circuit breaker or a CloudWatch alarm does not trigger a rollback.

- If you use alarm-based rollback, the bake time elapses.
- If source service revision cleanup is BLOCKING, the tasks on the source service revision are cleaned up.

Amazon ECS launches at least one task on the target service revision and waits for it to become healthy before it evaluates the healthy percent.

### Example healthy task counts

| Desired count | Healthy percent | Required healthy tasks (rounded up) |
|---------------|-----------------|-------------------------------------|
| 2             | 50              | 1                                   |
| 3             | 50              | 2                                   |
| 10            | 80              | 8                                   |
| 100           | 90              | 90                                  |
| 10            | 100             | 10                                  |

### Configure early success criteria

You can configure early success criteria for a new or existing service by using the console or the AWS CLI.

#### Console

In the create service or update service flow, under Deployment configuration, turn on early success criteria. Enter a value for Healthy percent, and choose a Source service revision cleanup option, either Blocking or Deferred.

#### AWS CLI

Set the `earlySuccessCriteria` values in the `--deployment-configuration` parameter when you create or update a service.

```
aws ecs update-service \  
  --cluster MyCluster \  
  --service MyService \  
  --deployment-configuration '{  
    "earlySuccessCriteria": {  
      "healthyPercent": 50,  
      "sourceServiceRevisionCleanup": "Blocking"  
    }  
  }'
```

```
--deployment-configuration '{
  "strategy": "ROLLING",
  "earlySuccessCriteria": {
    "enable": true,
    "healthyPercent": 90,
    "sourceServiceRevisionCleanup": "BLOCKING"
  }
}'
```

## What you observe

- `DescribeServiceDeployments` returns the deployment status and the configured early success criteria. While the deployment is in progress, the task counts are live. After the deployment completes, the task counts are a snapshot from when the deployment completed. This applies to both `BLOCKING` and `DEFERRED`.
- To view live task counts for a service, use `DescribeServices`.
- Deployments that complete early are included when you filter `ListServiceDeployments` by a status of `SUCCESSFUL`.
- Deployment state-change events and AWS CloudTrail records show the standard `IN_PROGRESS` to `SUCCESSFUL` lifecycle. Early success criteria does not add a new deployment status.

## Considerations

Review the following considerations before you use early success criteria.

### Rollback monitoring applies during the deployment

The deployment circuit breaker and CloudWatch alarm rollback are failure-detection mechanisms for the deployment. They can roll back the deployment while it is in progress. After Amazon ECS completes the deployment, these mechanisms no longer roll back the service, including while Amazon ECS launches any remaining tasks through regular service scaling. You can't stop a deployment after it completes. Set the healthy percent to a percentage at which you are confident that the target service revision is healthy.

### DEFERRED cleanup

With `DEFERRED`, Amazon ECS cleans up the tasks on the source service revision after it completes the deployment. If the tasks on the source service revision are protected, by task scale-in protection or another mechanism, for more than two weeks after the deployment,

Amazon ECS can't clean them up. Use `DescribeServices` to monitor the tasks on the source service revision.

## Amazon ECS blue/green deployments

A blue/green deployment is a release methodology that reduces downtime and risk by running two identical production environments called blue and green. With Amazon ECS blue/green deployments, you can validate new service revisions before directing production traffic to them. This approach provides a safer way to deploy changes with the ability to quickly roll back if needed.

### Benefits

The following are benefits of using blue/green deployments:

- Reduces risk through testing with production traffic before switching production. You can validate the new deployment with test traffic before directing production traffic to it.
- Zero downtime deployments. The production environment remains available throughout the deployment process, ensuring continuous service availability.
- Easy rollback if issues are detected. If problems arise with the green deployment, you can quickly revert to the blue deployment without extended service disruption.
- Controlled testing environment. The green environment provides an isolated space to test new features with real traffic patterns before full deployment.
- Predictable deployment process. The structured approach with defined lifecycle stages makes deployments more consistent and reliable.
- Automated validation through lifecycle hooks. You can implement automated tests at various stages of the deployment to verify functionality.

### Terminology

The following are Amazon ECS blue/green deployment terms:

- Bake time - The duration when both blue and green service revisions are running simultaneously after the production traffic has shifted.
- Blue deployment - The current production service revision that you want to replace.
- Green deployment - The new service revision that you want to deploy.
- Lifecycle stages - A series of events in the deployment operation, such as "after production traffic shift".

- **Lifecycle hook** - A Lambda function or pause point at a specific lifecycle stage. Lambda hooks invoke Lambda functions that you have defined to run custom code. Pause hooks pause the deployment and wait for you to call `ContinueServiceDeployment` to proceed.
- **Listener** - An Elastic Load Balancing or VPC Lattice resource that checks for connection requests using the protocol and port that you configure. The rules that you define for a listener determine how Amazon ECS routes requests to its registered targets.
- **Rule** - An Elastic Load Balancing or VPC Lattice resource associated with a listener. A rule defines how requests are routed and consists of an action, condition, and priority.
- **Target group** - An Elastic Load Balancing or VPC Lattice resource used to route requests to one or more registered targets (for example, EC2 instances). When you create a listener, you specify a target group for its default action. Traffic is forwarded to the target group specified in the listener rule.
- **Traffic shift** - The process Amazon ECS uses to shift traffic from the blue deployment to the green deployment. For services with a load balancer, Service Connect, or VPC Lattice, Amazon ECS manages the traffic shift automatically. For headless services, Amazon ECS replaces the blue tasks with green tasks but doesn't manage traffic shifting.

## Considerations

Consider the following when choosing a deployment type:

- **Resource usage:** Blue/green deployments temporarily run both the blue and green service revisions simultaneously, which may double your resource usage during deployments.
- **Deployment monitoring:** Blue/green deployments provide more detailed deployment status information, allowing you to monitor each stage of the deployment process.
- **Rollback:** Blue/green deployments make it easier to roll back to the previous version if issues are detected, as the blue revision is kept running until the bake time expires.
- **Network Load Balancer lifecycle hooks:** If you use a Network Load Balancer for blue/green deployments, there is an additional 10 minutes for the `TEST_TRAFFIC_SHIFT` and `PRODUCTION_TRAFFIC_SHIFT` lifecycle stages. This is because Amazon ECS makes sure that it is safe to shift traffic.

## Amazon ECS blue/green service deployments workflow

The Amazon ECS blue/green deployment process follows a structured approach with six distinct phases that ensure safe and reliable application updates. Each phase serves a specific purpose in

validating and transitioning your application from the current version (blue) to the new version (green).

1. **Preparation Phase:** Create the green environment alongside the existing blue environment. This includes provisioning new service revisions, and preparing target groups.
2. **Deployment Phase:** Deploy the new service revision to the green environment. Amazon ECS launches new tasks using the updated service revision while the blue environment continues serving production traffic.
3. **Testing Phase:** Validate the green environment using test traffic routing. The Application Load Balancer directs test requests to the green environment while production traffic remains on blue.
4. **Traffic Shifting Phase:** Shift production traffic from blue to green based on your configured deployment strategy. This phase includes monitoring and validation checkpoints.
5. **Monitoring Phase:** Monitor application health, performance metrics, and alarm states during the bake time period. A rollback operation is initiated when issues are detected.
6. **Completion Phase:** Finalize the deployment by terminating the blue environment or maintaining it for potential rollback scenarios, depending on your configuration.

## Workflow

The following diagram illustrates the comprehensive blue/green deployment workflow, showing the interaction between Amazon ECS, and the Application Load Balancer:

The enhanced deployment workflow includes the following detailed steps:

- 1. Initial State:** The blue service (current production) handles 100% of production traffic. The Application Load Balancer has a single listener with rules that route all requests to the blue target group containing healthy blue tasks.
- 2. Green Environment Provisioning:** Amazon ECS creates new tasks using the updated task definition. These tasks are registered with a new green target group but receive no traffic initially.
- 3. Health Check Validation:** The Application Load Balancer performs health checks on green tasks. Only when green tasks pass health checks does the deployment proceed to the next phase.
- 4. Test Traffic Routing:** If configured, the Application Load Balancer's listener rules route specific traffic patterns (such as requests with test headers) to the green environment for validation while production traffic remains on blue. This is controlled by the same listener that handles production traffic, using different rules based on request attributes.
- 5. Production Traffic Shift:** Based on the deployment configuration, traffic shifts from blue to green. In ECS blue/green deployments, this is an immediate (all-at-once) shift where 100% of

the traffic is moved from the blue to the green environment. The Application Load Balancer uses a single listener with listener rules that control traffic distribution between the blue and green target groups based on weights.

6. **Monitoring and Validation:** Throughout the traffic shift, Amazon ECS monitors CloudWatch metrics, alarm states, and deployment health. Automatic rollback triggers activate if issues are detected.
7. **Bake Time Period:** The duration when both blue and green service revisions are running simultaneously after the production traffic has shifted.
8. **Blue Environment Termination:** After successful traffic shift and validation, the blue environment is terminated to free up cluster resources, or maintained for rapid rollback capability.
9. **Final State:** The green environment becomes the new production environment, handling 100% of traffic. The deployment is marked as successful.

## Deployment lifecycle stages

The blue/green deployment process progresses through distinct lifecycle stages (a series of events in the deployment operation, such as "after production traffic shift"), each with specific responsibilities and validation checkpoints. Understanding these stages helps you monitor deployment progress and troubleshoot issues effectively.

Each lifecycle stage can last up to 24 hours. We recommend that the value remains below the 24-hour mark. This is because asynchronous processes need time to trigger the hooks. The system times out, fails the deployment, and then initiates a rollback after a stage reaches 24 hours. CloudFormation deployments have additional timeout restrictions. While the 24-hour stage limit remains in effect, CloudFormation enforces a 36-hour limit on the entire deployment. CloudFormation fails the deployment, and then initiates a rollback if the process doesn't complete within 36 hours.

For pause hooks, you can configure the timeout up to 20,160 minutes (14 days). The overall deployment timeout is 30 days.

| Lifecycle stages  | Description                                                               | Use this stage for lifecycle hook? |
|-------------------|---------------------------------------------------------------------------|------------------------------------|
| RECONCILE_SERVICE | This stage only happens when you start a new service deployment with more | Yes                                |

| Lifecycle stages             | Description                                                                                                                                                                                  | Use this stage for lifecycle hook? |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
|                              | than 1 service revision in an ACTIVE state.                                                                                                                                                  |                                    |
| PRE_SCALE_UP                 | The green service revision has not started. The blue service revision is handling 100% of the production traffic. There is no test traffic.                                                  | Yes                                |
| SCALE_UP                     | The time when the green service revision scales up to 100% and launches new tasks. The green service revision is not serving any traffic at this point.                                      | No                                 |
| POST_SCALE_UP                | The green service revision has started. The blue service revision is handling 100% of the production traffic. There is no test traffic.                                                      | Yes                                |
| TEST_TRAFFIC_SHIFT           | The blue and green service revisions are running. The blue service revision handles 100% of the production traffic. The green service revision is migrating from 0% to 100% of test traffic. | Yes (Lambda only)                  |
| POST_TEST_TRAFFIC_SHIFT      | The test traffic shift is complete. The green service revision handles 100% of the test traffic.                                                                                             | Yes                                |
| PRE_PRODUCTION_TRAFFIC_SHIFT | Occurs before the production traffic shift. For blue/green deployments, this stage is invoked once.                                                                                          | Yes                                |
| PRODUCTION_TRAFFIC_SHIFT     | Production traffic is shifting to the green service revision. The green service revision is migrating from 0% to 100% of production traffic.                                                 | Yes (Lambda only)                  |

| Lifecycle stages              | Description                                                                                                                                                     | Use this stage for lifecycle hook? |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| POST_PRODUCTION_TRAFFIC_SHIFT | The production traffic shift is complete.                                                                                                                       | Yes                                |
| BAKE_TIME                     | The duration when both blue and green service revisions are running simultaneously.                                                                             | No                                 |
| CLEAN_UP                      | The blue service revision has completely scaled down to 0 running tasks.<br>The green service revision is now the production service revision after this stage. | No                                 |

Each lifecycle stage includes built-in validation checkpoints that must pass before proceeding to the next stage. If any validation fails, the deployment can be automatically rolled back to maintain service availability and reliability.

When you use a Lambda function, the function must complete the work, or return `IN_PROGRESS` within 15 minutes. You can use the `callbackDelaySeconds` to delay the call to Lambda. For more information, see [app.py function](#) in the `sample-amazon-ecs-blue-green-deployment-patterns` on GitHub.

### Required resources for Amazon ECS blue/green deployments

You can use Amazon ECS blue/green deployments with or without managed traffic shifting. When your service uses Elastic Load Balancing, Service Connect, or VPC Lattice, Amazon ECS manages the traffic shift between the blue and green service revisions for you. If your service doesn't use a load balancer, Service Connect, or VPC Lattice (headless service), you can still use blue/green deployments for controlled rollouts, but Amazon ECS doesn't manage the traffic shift automatically.

For managed traffic shifting, configure one of the following:

- Elastic Load Balancing
- Service Connect

- VPC Lattice

The following list provides a high-level overview of what you need to configure for Amazon ECS blue/green deployments:

- If your service uses an Application Load Balancer, Network Load Balancer, Service Connect, or VPC Lattice, configure the appropriate resources for managed traffic shifting.
  - Application Load Balancer - For more information, see [Application Load Balancer resources for blue/green, linear, and canary deployments](#).
  - Network Load Balancer - For more information, see [Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments](#).
  - Service Connect - For more information, see [Service Connect resources for Amazon ECS blue/green, linear, and canary deployments](#).
  - VPC Lattice - For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).

If your service is headless (no load balancer, Service Connect, or VPC Lattice), you don't need to configure additional traffic shifting resources.

- Set the service deployment controller to ECS.
- Configure the deployment strategy as blue/green in your service definition.
- Optionally, configure additional parameters such as:
  - Bake time for the new deployment
  - CloudWatch alarms for automatic rollback
  - Deployment lifecycle hooks (Lambda functions or pause hooks that run at specified deployment stages)

## Best practices

Follow these best practices for successful Amazon ECS blue/green deployments:

- Configure appropriate health checks that accurately reflect your application's health.
- Set a bake time that allows sufficient testing of the green deployment.
- Implement CloudWatch alarms to automatically detect issues and trigger rollbacks.
- Use lifecycle hooks to perform automated testing at each deployment stage.

- Ensure your application can handle both blue and green service revisions running simultaneously.
- Plan for sufficient cluster capacity to handle both service revisions during deployment.
- Test your rollback procedures before implementing them in production.

## Application Load Balancer resources for blue/green, linear, and canary deployments

To use Application Load Balancers with Amazon ECS blue/green deployments, you need to configure specific resources that allow traffic routing between the blue and green service revisions.

### Target groups

For blue/green deployments with Elastic Load Balancing, you need to create two target groups:

- A primary target group for the blue service revision (current production traffic)
- An alternate target group for the green service revision (new version)

Both target groups should be configured with the following settings:

- Target type: IP (for Fargate or EC2 with awsvpc network mode)
- Protocol: HTTP (or the protocol your application uses)
- Port: The port your application listens on (typically 80 for HTTP)
- VPC: The same VPC as your Amazon ECS tasks
- Health check settings: Configured to properly check your application's health

During a blue/green deployment, Amazon ECS automatically registers tasks with the appropriate target group based on the deployment stage.

### Example Creating target groups for an Application Load Balancer

The following CLI commands create two target groups for use with an Application Load Balancer in a blue/green deployment:

```
aws elbv2 create-target-group \  
  --name blue-target-group \  
  --protocol HTTP \  
  --port 80 \  
  --vpc-id vpc-abcd1234 \  
  --health-check-path /health
```

```
--target-type ip \  
--health-check-path / \  
--health-check-protocol HTTP \  
--health-check-interval-seconds 30 \  
--health-check-timeout-seconds 5 \  
--healthy-threshold-count 2 \  
--unhealthy-threshold-count 2  
  
aws elbv2 create-target-group \  
  --name green-target-group \  
  --protocol HTTP \  
  --port 80 \  
  --vpc-id vpc-abcd1234 \  
  --target-type ip \  
  --health-check-path / \  
  --health-check-protocol HTTP \  
  --health-check-interval-seconds 30 \  
  --health-check-timeout-seconds 5 \  
  --healthy-threshold-count 2 \  
  --unhealthy-threshold-count 2
```

## Application Load Balancer

You need to create an Application Load Balancer with the following configuration:

- Scheme: Internet-facing or internal, depending on your requirements
- IP address type: IPv4
- VPC: The same VPC as your Amazon ECS tasks
- Subnets: At least two subnets in different Availability Zones
- Security groups: A security group that allows traffic on the listener ports

The security group attached to the Application Load Balancer must have an outbound rule that allows traffic to the security group attached to your Amazon ECS tasks.

### Example Creating an Application Load Balancer

The following CLI command creates an Application Load Balancer for use in a blue/green deployment:

```
aws elbv2 create-load-balancer \  
  --name my-application-load-balancer \  
  --
```

```
--type application \  
--security-groups sg-abcd1234 \  
--subnets subnet-12345678 subnet-87654321
```

## Listeners and rules

For blue/green deployments, you need to configure listeners on your Application Load Balancer:

- Production listener: Handles production traffic (typically on port 80 or 443)
  - Initially forwards traffic to the primary target group (blue service revision)
  - After deployment, forwards traffic to the alternate target group (green service revision)
- Test listener (optional): Handles test traffic to validate the green service revision before shifting production traffic
  - Can be configured on a different port (for example, 8080 or 8443)
  - Forwards traffic to the alternate target group (green service revision) during testing

During a blue/green deployment, Amazon ECS automatically updates the listener rules to route traffic to the appropriate target group based on the deployment stage.

### Example Creating a production listener

The following CLI command creates a production listener on port 80 that forwards traffic to the primary (blue) target group:

```
aws elbv2 create-listener \  
  --load-balancer-arn arn:aws:elasticloadbalancing:region:123456789012:loadbalancer/app/my-application-load-balancer/abcdef123456 \  
  --protocol HTTP \  
  --port 80 \  
  --default-actions  
    Type=forward,TargetGroupArn=arn:aws:elasticloadbalancing:region:123456789012:targetgroup/blue-target-group/abcdef123456
```

### Example Creating a test listener

The following CLI command creates a test listener on port 8080 that forwards traffic to the alternate (green) target group:

```
aws elbv2 create-listener \  
  --load-balancer-arn arn:aws:elasticloadbalancing:region:123456789012:loadbalancer/app/my-application-load-balancer/abcdef123456 \  
  --protocol HTTP \  
  --port 8080 \  
  --default-actions  
    Type=forward,TargetGroupArn=arn:aws:elasticloadbalancing:region:123456789012:targetgroup/green-target-group/abcdef123456
```

```
--load-balancer-arn arn:aws:elasticloadbalancing:region:123456789012:loadbalancer/
app/my-application-load-balancer/abcdef123456 \
--protocol HTTP \
--port 8080 \
--default-actions
Type=forward,TargetGroupArn=arn:aws:elasticloadbalancing:region:123456789012:targetgroup/
green-target-group/ghijkl789012
```

## Example Creating a listener rule for path-based routing

The following CLI command creates a rule that forwards traffic for a specific path to the green target group for testing:

```
aws elbv2 create-rule \
--listener-arn arn:aws:elasticloadbalancing:region:123456789012:listener/app/my-
application-load-balancer/abcdef123456/ghijkl789012 \
--priority 10 \
--conditions Field=path-pattern,Values='/test/*' \
--actions
Type=forward,TargetGroupArn=arn:aws:elasticloadbalancing:region:123456789012:targetgroup/
green-target-group/ghijkl789012
```

## Example Creating a listener rule for header-based routing

The following CLI command creates a rule that forwards traffic with a specific header to the green target group for testing:

```
aws elbv2 create-rule \
--listener-arn arn:aws:elasticloadbalancing:region:123456789012:listener/app/my-
application-load-balancer/abcdef123456/ghijkl789012 \
--priority 20 \
--conditions Field=http-header,HttpHeaderConfig='{Name=X-
Environment,Values=[test]}' \
--actions
Type=forward,TargetGroupArn=arn:aws:elasticloadbalancing:region:123456789012:targetgroup/
green-target-group/ghijkl789012
```

## Service configuration

You must have permissions to allow Amazon ECS to manage load balancer resources in your clusters on your behalf. For more information, see [Amazon ECS infrastructure IAM role for load balancers](#).

When creating or updating an Amazon ECS service for blue/green deployments with Elastic Load Balancing, you need to specify the following configuration.

Replace the *user-input* with your values.

The key components in this configuration are:

- `targetGroupArn`: The ARN of the primary target group (blue service revision).
- `alternateTargetGroupArn`: The ARN of the alternate target group (green service revision).
- `productionListenerRule`: The ARN of the listener rule for production traffic.
- `roleArn`: The ARN of the role that allows Amazon ECS to manage Elastic Load Balancing resources.
- `strategy`: Set to `BLUE_GREEN` to enable blue/green deployments.
- `bakeTimeInMinutes`: The duration when both blue and green service revisions are running simultaneously after the production traffic has shifted.
- `TestListenerRule`: The ARN of the listener rule for test traffic. This is an optional parameter.

```
{
  "loadBalancers": [
    {
      "targetGroupArn":
        "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/primary-target-group/
        abcdef123456",
      "containerName": "container-name",
      "containerPort": 80,
      "advancedConfiguration": {
        "alternateTargetGroupArn":
          "arn:aws:elasticloadbalancing:region:account-id:targetgroup/alternate-target-group/
          ghijkl789012",
        "productionListenerRule": "arn:aws:elasticloadbalancing:region:account-
        id:listener-rule/app/load-balancer-name/abcdef123456/listener/ghijkl789012/rule/
        mnopqr345678",
        "roleArn": "arn:aws:iam::123456789012:role/ecs-elb-role"
      }
    }
  ],
  "deploymentConfiguration": {
    "strategy": "BLUE_GREEN",
    "maximumPercent": 200,
  }
}
```

```
        "minimumHealthyPercent": 100,  
        "bakeTimeInMinutes": 5  
    }  
}
```

## Traffic flow during deployment

During a blue/green deployment with Elastic Load Balancing, traffic flows through the system as follows:

1. *Initial state*: All production traffic is routed to the primary target group (blue service revision).
2. *Green service revision deployment*: Amazon ECS deploys the new tasks and registers them with the alternate target group.
3. *Test traffic*: If a test listener is configured, test traffic is routed to the alternate target group to validate the green service revision.
4. *Production traffic shift*: Amazon ECS updates the production listener rule to route traffic to the alternate target group (green service revision).
5. *Bake time*: The duration when both blue and green service revisions are running simultaneously after the production traffic has shifted.
6. *Completion*: After a successful deployment, the blue service revision is terminated.

If issues are detected during the deployment, Amazon ECS can automatically roll back by routing traffic back to the primary target group (blue service revision).

## Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments

To use a Network Load Balancer with Amazon ECS blue/green deployments, you need to configure specific resources that enable traffic routing between the blue and green service revisions. This section explains the required components and their configuration.

When your configuration includes a Network Load Balancer, Amazon ECS adds a 10 minute delay to the following lifecycle stages:

- TEST\_TRAFFIC\_SHIFT
- PRODUCTION\_TRAFFIC\_SHIFT

This delay accounts for Network Load Balancer timing issues that can cause a mismatch between the configured traffic weights and the actual traffic routing in the data plane.

## Target groups

For blue/green deployments with a Network Load Balancer, you need to create two target groups:

- A primary target group for the blue service revision (current production traffic)
- An alternate target group for the green service revision (new service revision)

Both target groups should be configured with the following settings:

- Target type: `ip` (for Fargate or EC2 with `awsvpc` network mode)
- Protocol: TCP (or the protocol your application uses)
- Port: The port your application listens on (typically 80 for HTTP)
- VPC: The same VPC as your Amazon ECS tasks
- Health check settings: Configured to properly check your application's health

For TCP health checks, the Network Load Balancer establishes a TCP connection with the target. If the connection is successful, the target is considered healthy.

For HTTP/HTTPS health checks, the Network Load Balancer sends an HTTP/HTTPS request to the target and verifies the response.

During a blue/green deployment, Amazon ECS automatically registers tasks with the appropriate target group based on the deployment stage.

### Example Creating target groups for a Network Load Balancer

The following AWS CLI commands create two target groups for use with a Network Load Balancer in a blue/green deployment:

```
aws elbv2 create-target-group \  
  --name blue-target-group \  
  --protocol TCP \  
  --port 80 \  
  --vpc-id vpc-abcd1234 \  
  --target-type ip \  
  --health-check-protocol TCP  
  
aws elbv2 create-target-group \  
  --name green-target-group \  
  --protocol TCP \  
  --port 80 \  
  --vpc-id vpc-abcd1234 \  
  --target-type ip \  
  --health-check-protocol TCP
```

```
--protocol TCP \  
--port 80 \  
--vpc-id vpc-abcd1234 \  
--target-type ip \  
--health-check-protocol TCP
```

## Network Load Balancer

You need to create a Network Load Balancer with the following configuration:

- Scheme: Internet-facing or internal, depending on your requirements
- IP address type: IPv4
- VPC: The same VPC as your Amazon ECS tasks
- Subnets: At least two subnets in different Availability Zones

Unlike Application Load Balancers, Network Load Balancers operate at the transport layer (Layer 4) and do not use security groups. Instead, you need to ensure that the security groups associated with your Amazon ECS tasks allow traffic from the Network Load Balancer on the listener ports.

### Example Creating a Network Load Balancer

The following AWS CLI command creates a Network Load Balancer for use in a blue/green deployment:

```
aws elbv2 create-load-balancer \  
  --name my-network-load-balancer \  
  --type network \  
  --subnets subnet-12345678 subnet-87654321
```

## Considerations for using NLB with blue/green deployments

When using a Network Load Balancer for blue/green deployments, consider the following:

- **Layer 4 operation:** Network Load Balancers operate at the transport layer (Layer 4) and do not inspect application layer (Layer 7) content. This means you cannot use HTTP headers or paths for routing decisions.
- **Health checks:** Network Load Balancer health checks are limited to TCP, HTTP, or HTTPS protocols. For TCP health checks, the Network Load Balancer only verifies that the connection can be established.

- **Connection preservation:** Network Load Balancers preserve the source IP address of the client, which can be useful for security and logging purposes.
- **Static IP addresses:** Network Load Balancers provide static IP addresses for each subnet, which can be useful for whitelisting or when clients need to connect to a fixed IP address.
- **Test traffic:** Since Network Load Balancers do not support content-based routing, test traffic must be sent to a different port than production traffic.

## Listeners and rules

For blue/green deployments with a Network Load Balancer, you need to configure listeners:

- Production listener: Handles production traffic (typically on port 80 or 443)
  - Initially forwards traffic to the primary target group (blue service revision)
  - After deployment, forwards traffic to the alternate target group (green service revision)
- Test listener (optional): Handles test traffic to validate the green service revision before shifting production traffic
  - Can be configured on a different port (e.g., 8080 or 8443)
  - Forwards traffic to the alternate target group (green service revision) during testing

Unlike Application Load Balancers, Network Load Balancers do not support content-based routing rules. Instead, traffic is routed based on the listener port and protocol.

The following AWS CLI commands create production and test listeners for a Network Load Balancer:

Replace the *user-input* with your values.

```
aws elbv2 create-listener \  
  --load-balancer-arn arn:aws:elasticloadbalancing:region:123456789012:loadbalancer/net/my-network-lb/1234567890123456 \  
  --protocol TCP \  
  --port 80 \  
  --default-actions Type=forward,  
  TargetGroupArn=arn:aws:elasticloadbalancing:region:123456789012:targetgroup/blue-target-group/1234567890123456  
  
aws elbv2 create-listener \  

```

```
--load-balancer-arn arn:aws:elasticloadbalancing:region:123456789012:loadbalancer/  
net/my-network-lb/1234567890123456 \  
--protocol TCP \  
--port 8080 \  
--default-actions Type=forward,  
TargetGroupArn=arn:aws:elasticloadbalancing:region:123456789012:targetgroup/green-  
target-group/1234567890123456
```

## Service configuration

You must have permissions to allow Amazon ECS to manage load balancer resources in your clusters on your behalf. For more information, see [Amazon ECS infrastructure IAM role for load balancers](#).

When creating or updating an Amazon ECS service for blue/green deployments with a Network Load Balancer, you need to specify the following configuration:

Replace the *user-input* with your values.

The key components in this configuration are:

- `targetGroupArn`: The ARN of the primary target group (blue service revision)
- `alternateTargetGroupArn`: The ARN of the alternate target group (green service revision)
- `productionListenerRule`: The ARN of the listener for production traffic
- `testListenerRule`: (Optional) The ARN of the listener for test traffic
- `roleArn`: The ARN of the role that allows Amazon ECS to manage Network Load Balancer resources
- `strategy`: Set to `BLUE_GREEN` to enable blue/green deployments
- `bakeTimeInMinutes`: The duration when both blue and green service revisions are running simultaneously after the production traffic has shifted

```
{  
  "loadBalancers": [  
    {  
      "targetGroupArn":  
        "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/blue-target-  
group/1234567890123456",  
      "containerName": "container-name",
```

```

        "containerPort": 80,
        "advancedConfiguration": {
            "alternateTargetGroupArn":
                "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/green-target-
                group/1234567890123456",
            "productionListenerRule":
                "arn:aws:elasticloadbalancing:region:123456789012:listener/net/my-network-
                lb/1234567890123456/1234567890123456",
            "testListenerRule":
                "arn:aws:elasticloadbalancing:region:123456789012:listener/net/my-network-
                lb/1234567890123456/2345678901234567",
            "roleArn": "arn:aws:iam::123456789012:role/ecs-nlb-role"
        }
    },
    "deploymentConfiguration": {
        "strategy": "BLUE_GREEN",
        "maximumPercent": 200,
        "minimumHealthyPercent": 100,
        "bakeTimeInMinutes": 5
    }
}

```

## Traffic flow during deployment

During a blue/green deployment with a Network Load Balancer, traffic flows through the system as follows:

1. *Initial state:* All production traffic is routed to the primary target group (blue service revision).
2. *Green service revision deployment:* Amazon ECS deploys the new tasks and registers them with the alternate target group.
3. *Test traffic:* If a test listener is configured, test traffic is routed to the alternate target group to validate the green service revision.
4. *Production traffic shift:* Amazon ECS updates the production listener to route traffic to the alternate target group (green service revision).
5. *Bake time:* The duration when both blue and green service revisions are running simultaneously after the production traffic has shifted.
6. *Completion:* After a successful deployment, the blue service revision is terminated.

If issues are detected during the deployment, Amazon ECS can automatically roll back by routing traffic back to the primary target group (blue service revision).

## Service Connect resources for Amazon ECS blue/green, linear, and canary deployments

When using Service Connect with blue/green deployments, you need to configure specific components to enable proper traffic routing between the blue and green service revisions. This section explains the required components and their configuration.

### Architecture overview

Service Connect builds both service discovery and service mesh capabilities through a managed sidecar proxy that's automatically injected into your Amazon ECS tasks. These proxies handle routing decisions, retries, and metrics collection, while AWS Cloud Map provides the service registry backend. When you deploy a service with Service Connect enabled, the service registers itself in AWS Cloud Map, and client services discover it through the namespace.

In a standard Service Connect implementation, client services connect to logical service names, and the sidecar proxy handles routing to the actual service instances. With blue/green deployments, this model is extended to include test traffic routing through the `testTrafficRules` configuration.

During a blue/green deployment, the following key components work together:

- **Service Connect Proxy:** All traffic between services passes through the Service Connect proxy, which makes routing decisions based on the configuration.
- **AWS Cloud Map Registration:** Both blue and green deployments register with AWS Cloud Map, but the green deployment initially registers as a "test" endpoint.
- **Test Traffic Routing:** The `testTrafficRules` in the Service Connect configuration determine how to identify and route test traffic to the green deployment. This is accomplished through **header-based routing**, where specific HTTP headers in the requests direct traffic to the test revision. By default, Service Connect recognizes the `x-amzn-ecs-blue-green-test` header for HTTP-based protocols when no custom rules are specified.
- **Client Configuration:** All clients in the namespace automatically receive both production and test routes, but only requests matching test rules will go to the green deployment.

What makes this approach powerful is that it handles the complexity of service discovery during transitions. As traffic shifts from the blue to green deployment, all connectivity and discovery

mechanisms update automatically. There's no need to update DNS records, reconfigure load balancers, or deploy service discovery changes separately since the service mesh handles it all.

## Traffic routing and testing

Service Connect provides advanced traffic routing capabilities for blue/green deployments, including header-based routing and client alias configuration for testing scenarios.

### Test traffic header rules

During blue/green deployments, you can configure test traffic header rules to route specific requests to the green (new) service revision for testing purposes. This allows you to validate the new version with controlled traffic before completing the deployment.

Service Connect uses **header-based routing** to identify test traffic. By default, Service Connect recognizes the `x-amzn-ecs-blue-green-test` header for HTTP-based protocols when no custom rules are specified. When this header is present in a request, the Service Connect proxy automatically routes the request to the green deployment for testing.

Test traffic header rules enable you to:

- Route requests with specific headers to the green service revision
- Test new functionality with a subset of traffic
- Validate service behavior before full traffic cutover
- Implement canary testing strategies
- Perform integration testing in a production-like environment

The header-based routing mechanism works seamlessly with your existing application architecture. Client services don't need to be aware of the blue/green deployment process - they simply include the appropriate headers when sending test requests, and the Service Connect proxy handles the routing logic automatically.

#### Important

Test traffic header rules require that the Service Connect service port mapping has `appProtocol` set to `http`, `http2`, or `grpc`. If your service uses plain TCP without an application-layer protocol (that is, `appProtocol` is not set), you cannot use header-based

`testTrafficRules` for blue/green deployments. In this case, use port-based test traffic routing instead.

For more information about configuring test traffic header rules, see [ServiceConnectTestTrafficHeaderRules](#) in the *Amazon Elastic Container Service API Reference*.

## Header matching rules

Header matching rules define the criteria for routing test traffic during blue/green deployments. You can configure multiple matching conditions to precisely control which requests are routed to the green service revision.

Header matching supports:

- Exact header value matching
- Header presence checking
- Pattern-based matching
- Multiple header combinations

Example use cases include routing requests with specific user agent strings, API versions, or feature flags to the green service for testing.

For more information about header matching configuration, see [ServiceConnectTestTrafficHeaderMatchRules](#) in the *Amazon Elastic Container Service API Reference*.

## Client aliases for blue/green deployments

Client aliases provide stable DNS endpoints for services during blue/green deployments. They enable seamless traffic routing between blue and green service revisions without requiring client applications to change their connection endpoints.

During a blue/green deployment, client aliases:

- Maintain consistent DNS names for client connections
- Enable automatic traffic switching between service revisions
- Support gradual traffic migration strategies
- Provide rollback capabilities by redirecting traffic to the blue revision

You can configure multiple client aliases for different ports or protocols, allowing complex service architectures to maintain connectivity during deployments.

For more information about client alias configuration, see [ServiceConnectClientAlias](#) in the *Amazon Elastic Container Service API Reference*.

## Best practices for traffic routing

When implementing traffic routing for blue/green deployments with Service Connect, consider the following best practices:

- **Start with header-based testing:** Use test traffic header rules to validate the green service with controlled traffic before switching all traffic.
- **Configure health checks:** Ensure both blue and green services have appropriate health checks configured to prevent routing traffic to unhealthy instances.
- **Monitor service metrics:** Track key performance indicators for both service revisions during the deployment to identify issues early.
- **Plan rollback strategy:** Configure client aliases and routing rules to enable quick rollback to the blue service if issues are detected.
- **Test header matching logic:** Validate your header matching rules in a non-production environment before applying them to production deployments.

## Service Connect blue/green deployment workflow

Understanding how Service Connect manages the blue/green deployment process helps you implement and troubleshoot your deployments effectively. The following workflow shows how the different components interact during each phase of the deployment.

### Deployment phases

A Service Connect blue/green deployment progresses through several distinct phases:

1. **Initial State:** The blue service handles 100% of production traffic. All client services in the namespace connect to the blue service through the logical service name configured in Service Connect.
2. **Green Service Registration:** When the green deployment starts, it registers with AWS Cloud Map as a "test" endpoint. The Service Connect proxy in client services automatically receives both production and test route configurations.

3. **Test Traffic Routing:** Requests containing the test traffic headers (such as `x-amzn-ecs-blue-green-test`) are automatically routed to the green service by the Service Connect proxy. Production traffic continues to flow to the blue service.
4. **Traffic Shift Preparation:** After successful testing, the deployment process prepares for production traffic shift. Both blue and green services remain registered and healthy.
5. **Production Traffic Shift:** The Service Connect configuration updates to route production traffic to the green service. This happens automatically without requiring client service updates or DNS changes.
6. **Bake Time Period:** The duration when both blue and green service revisions are running simultaneously after the production traffic has shifted.
7. **Blue Service Deregistration:** After successful traffic shift and validation, the blue service is deregistered from AWS Cloud Map and terminated, completing the deployment.

## Service Connect proxy behavior

The Service Connect proxy plays a crucial role in managing traffic during blue/green deployments. Understanding its behavior helps you design effective testing and deployment strategies.

Key proxy behaviors during blue/green deployments:

- **Automatic Route Discovery:** The proxy automatically discovers both production and test routes from AWS Cloud Map without requiring application restarts or configuration changes.
- **Header-Based Routing:** The proxy examines incoming request headers and routes traffic to the appropriate service revision based on the configured test traffic rules.
- **Health Check Integration:** The proxy only routes traffic to healthy service instances, automatically excluding unhealthy tasks from the routing pool.
- **Retry and Circuit Breaking:** The proxy provides built-in retry logic and circuit breaking capabilities, improving resilience during deployments.
- **Metrics Collection:** The proxy collects detailed metrics for both blue and green services, enabling comprehensive monitoring during deployments.

## Service discovery updates

One of the key advantages of using Service Connect for blue/green deployments is the automatic handling of service discovery updates. Traditional blue/green deployments often require complex

DNS updates or load balancer reconfiguration, but Service Connect manages these changes transparently.

During a deployment, Service Connect handles:

- **Namespace Updates:** The Service Connect namespace automatically includes both blue and green service endpoints, with appropriate routing rules.
- **Client Configuration:** All client services in the namespace automatically receive updated routing information without requiring restarts or redeployment.
- **Gradual Transition:** Service discovery updates happen gradually and safely, ensuring no disruption to ongoing requests.
- **Rollback Support:** If a rollback is needed, Service Connect can quickly revert service discovery configurations to route traffic back to the blue service.

### VPC Lattice resources for blue/green, linear, and canary deployments

To use Amazon VPC Lattice with Amazon ECS blue/green, linear, and canary deployments, you configure the following resources:

- A pair of VPC Lattice target groups.
- A VPC Lattice service with a listener.
- The listener rules that route traffic to the target groups. A production listener rule is required, and a test listener rule is optional.

When your service uses VPC Lattice, Amazon ECS waits at the following deployment lifecycle stages so that target registration and traffic-weight changes can propagate to the VPC Lattice data plane:

- `POST_SCALE_UP` – approximately 3 minutes, so that the new tasks are healthy before Amazon ECS shifts traffic to them.
- `TEST_TRAFFIC_SHIFT`, `PRODUCTION_TRAFFIC_SHIFT`, and `RECONCILE_SERVICE` – approximately 90 seconds after each weight change. Canary deployments change weights twice; linear deployments change weights once per step.

## Target groups

For blue/green, linear, and canary deployments with VPC Lattice, you need to create two target groups:

- A primary target group for the blue service revision (the version currently serving production traffic)
- An alternate target group for the green service revision (new version)

Configure both target groups with the following settings:

- Target type: IP (required for Amazon ECS tasks)
- Protocol: HTTP (or the protocol your application uses)
- Port: The port your application listens on (typically 80 for HTTP)
- IP address type: IPV4 or IPV6 (match your tasks)
- VPC: The same VPC as your Amazon ECS tasks
- Health check settings: Configured to properly check your application's health

The two target groups swap roles on every deployment. Amazon ECS registers the new service revision's tasks with whichever target group isn't serving production traffic.

Both target groups must be in the ACTIVE state.

### Example Creating target groups for VPC Lattice

The following CLI commands create two target groups for a blue/green deployment:

```
aws vpc-lattice create-target-group \  
  --name blue-target-group \  
  --type IP \  
  --config '{  
    "port": 80,  
    "protocol": "HTTP",  
    "ipAddressType": "IPV4",  
    "vpcIdentifier": "vpc-abcd1234",  
    "healthCheck": {  
      "enabled": true,  
      "protocol": "HTTP",  
      "path": "/",
```

```

        "healthCheckIntervalSeconds": 30,
        "healthCheckTimeoutSeconds": 5,
        "healthyThresholdCount": 2,
        "unhealthyThresholdCount": 2
    }
}'

aws vpc-lattice create-target-group \
  --name green-target-group \
  --type IP \
  --config '{
    "port": 80,
    "protocol": "HTTP",
    "ipAddressType": "IPv4",
    "vpcIdentifier": "vpc-abcd1234",
    "healthCheck": {
      "enabled": true,
      "protocol": "HTTP",
      "path": "/",
      "healthCheckIntervalSeconds": 30,
      "healthCheckTimeoutSeconds": 5,
      "healthyThresholdCount": 2,
      "unhealthyThresholdCount": 2
    }
  }'

```

## VPC Lattice service

You need a VPC Lattice service with a listener that carries the rules described in the next section. Clients reach the VPC Lattice service through a service network, or through a VPC association, in the same way as for an Amazon ECS service that doesn't use blue/green deployments. To learn more about these VPC Lattice resources, see the [Amazon VPC Lattice User Guide](#).

The security group attached to your Amazon ECS tasks must allow inbound traffic on the container port from the VPC Lattice managed prefix list (`com.amazonaws.region.vpc-lattice`, or `com.amazonaws.region.ipv6.vpc-lattice` for IPv6). A managed prefix list is an AWS-managed set of CIDR blocks for VPC Lattice that you reference in a security group rule. For more information, see [Control traffic to your VPC Lattice services using security groups](#).

## Example Creating a VPC Lattice service and a listener

The following CLI commands create a VPC Lattice service and an HTTP listener. The listener's default action returns a fixed 404 response, so only the listener rules route traffic to the target groups:

```
aws vpc-lattice create-service \  
  --name my-service  
  
aws vpc-lattice create-listener \  
  --service-identifier svc-0123456789abcdef0 \  
  --name my-listener \  
  --protocol HTTP \  
  --port 80 \  
  --default-action '{  
    "fixedResponse": {  
      "statusCode": 404  
    }  
  }'
```

Associate the VPC Lattice service with a service network so that your clients can reach it. The service network must already exist and be associated with the VPC that your clients run in.

## Example Associating the service with a service network

The following CLI command associates the VPC Lattice service with a service network:

```
aws vpc-lattice create-service-network-service-association \  
  --service-identifier svc-0123456789abcdef0 \  
  --service-network-identifier sn-0123456789abcdef0
```

## Listeners and rules

You configure the following listener rules on your VPC Lattice service:

- Production listener rule (required): Routes production traffic.
  - Initially forwards all traffic to one of the two target groups.
  - After a successful deployment, forwards all traffic to the other target group.
- Test listener rule (optional): Routes test traffic, so you can validate the new service revision before production traffic moves to it.

- Must match a different set of requests than the production listener rule matches, and must be evaluated first. For example, match on a specific header or path, and give the test rule a lower priority number than the production rule, because VPC Lattice evaluates lower priority numbers first.
- Amazon ECS points the test listener rule at the new service revision during the TEST\_TRAFFIC\_SHIFT stage, before any production traffic moves.
- If you don't configure a test listener rule, Amazon ECS skips test traffic routing.

Both rules must meet the following requirements:

- The action is forward. Amazon ECS rejects a rule with a `fixedResponse` action.
- The rule must forward to both target groups, with weight 100 on the target group that currently serves that traffic and weight 0 on the other. Both target groups are required.
- The test listener rule is on the same VPC Lattice service as the production listener rule, and it is a different rule.
- Each listener rule can be used by only one VPC Lattice configuration on the Amazon ECS service.

#### Note

The production listener rule can also be the listener's default rule. In that case, Amazon ECS updates the listener's default action instead of a named rule, so specify the listener ARN in place of a rule ARN. Use this approach for listeners that don't support rules, such as TLS\_PASSTHROUGH listeners. For test traffic on such a service, use the default rule of a second listener on a different port.

Amazon ECS shifts traffic by rewriting the forward action of these rules while a deployment is in progress.

### Example Creating a production listener rule

The following CLI command creates a production listener rule that matches all paths and forwards all traffic to the blue target group:

```
aws vpc-lattice create-rule \  
  --service-identifier svc-0123456789abcdef0 \  
  --
```

```

--listener-identifier listener-0123456789abcdef0 \
--name production \
--priority 100 \
--match '{
    "httpMatch": {
        "pathMatch": {
            "match": {
                "prefix": "/"
            }
        }
    }
}' \
--action '{
    "forward": {
        "targetGroups": [
            {
                "targetGroupIdentifier": "tg-0123456789abcdef0",
                "weight": 100
            },
            {
                "targetGroupIdentifier": "tg-0fedcba9876543210",
                "weight": 0
            }
        ]
    }
}'

```

### Example Creating a test listener rule for header-based routing

The following CLI command creates a test listener rule that matches requests with an X-Environment: test header. It has a lower priority number than the production listener rule, so VPC Lattice evaluates it first:

```

aws vpc-lattice create-rule \
--service-identifier svc-0123456789abcdef0 \
--listener-identifier listener-0123456789abcdef0 \
--name test \
--priority 10 \
--match '{
    "httpMatch": {
        "headerMatches": [
            {
                "name": "X-Environment",

```

```

        "match": {
            "exact": "test"
        }
    ]
}
}' \
--action '{
    "forward": {
        "targetGroups": [
            {
                "targetGroupIdentifier": "tg-0123456789abcdef0",
                "weight": 100
            },
            {
                "targetGroupIdentifier": "tg-0fedcba9876543210",
                "weight": 0
            }
        ]
    }
}'

```

## Service configuration

You must have permissions to allow Amazon ECS to manage VPC Lattice resources on your behalf. For more information, see [Amazon ECS infrastructure IAM role](#).

When you create or update an Amazon ECS service for blue/green, linear, or canary deployments with VPC Lattice, specify the following configuration.

Replace the *user-input* with your values.

The key components in this configuration are:

- **roleArn**: The ARN of the infrastructure role that allows Amazon ECS to manage VPC Lattice resources.
- **targetGroupArn**: The ARN of one target group of the pair.
- **portName**: The name of the port mapping in your task definition that receives the traffic.
- **alternateTargetGroupArn**: The ARN of the other target group of the pair.
- **productionListenerRule**: The ARN of the listener rule for production traffic.
- **testListenerRule**: The ARN of the listener rule for test traffic. This is an optional parameter.

- **strategy:** Set to BLUE\_GREEN, LINEAR, or CANARY.
- **bakeTimeInMinutes:** The duration when both service revisions are running simultaneously after production traffic has shifted.

```
{
  "vpcLatticeConfigurations": [
    {
      "roleArn": "arn:aws:iam::111122223333:role/ecsInfrastructureRoleVpcLattice",
      "targetGroupArn": "arn:aws:vpc-lattice:region:111122223333:targetgroup/tg-0123456789abcdef0",
      "portName": "web",
      "advancedConfiguration": {
        "alternateTargetGroupArn": "arn:aws:vpc-lattice:region:111122223333:targetgroup/tg-0fedcba9876543210",

For more information about creating an Amazon ECS service that uses VPC Lattice, see [Create a service that uses VPC Lattice](#).

## Traffic flow during deployment

During a deployment with VPC Lattice, traffic flows through the system as follows:

1. *Initial state:* The production listener rule forwards all production traffic to the target group of the current (blue) service revision.
2. *Green service revision deployment:* Amazon ECS registers the new tasks with the target group that isn't serving production traffic (the green target group), at weight 0.
3. *Target propagation:* Amazon ECS waits for the new targets to become healthy.
4. *Test traffic:* If a test listener rule is configured, test traffic is routed to the green target group to validate the green service revision.
5. *Production traffic shift:* Amazon ECS updates the production listener rule's weights. A blue/green deployment moves all traffic at once. A linear or canary deployment moves traffic incrementally.
6. *Bake time:* The duration when both service revisions are running simultaneously after production traffic has shifted.
7. *Completion:* After a successful deployment, Amazon ECS deregisters and stops the blue tasks. Both target groups remain attached to the listener rules, with the blue target group at weight 0, ready for the next deployment.

## Considerations

- **Don't modify forward actions:** After the initial setup, don't modify the forward actions of the production and test listener rules outside of Amazon ECS. If a listener rule is modified externally, for example if a rule forwards to both target groups or to neither of them when a deployment starts, the deployment would fail.
- **Rollback behavior:** When a deployment rolls back, whether triggered by Amazon CloudWatch alarms, the deployment circuit breaker, or a manual rollback, Amazon ECS reverts the listener rule weights to route all traffic back to the previous service revision and stops the new tasks.
- **Switching from a rolling deployment:** To switch an Amazon ECS service that uses VPC Lattice from a rolling deployment to a blue/green, linear, or canary deployment, add the `advancedConfiguration` block to provide the alternate target group and listener rules. You can do this in the same update that changes the strategy, or in an earlier update. The first progressive deployment shifts traffic to the other target group.
- **Multiple configurations:** Each VPC Lattice configuration on the service needs its own pair of target groups and its own production listener rule. Amazon ECS shifts each configuration's rules independently.
- **Accounts:** The VPC Lattice target groups, service, and listener rules must be in the same account as the Amazon ECS service.

## Creating an Amazon ECS blue/green deployment

By using Amazon ECS blue/green deployments, you can make and test service changes before implementing them in a production environment.

### Prerequisites

Perform the following operations before you start a blue/green deployment.

1. Configure the appropriate permissions.
  - For information about Elastic Load Balancing permissions, see [Amazon ECS infrastructure IAM role for load balancers](#).
  - If you're using VPC Lattice, for information about VPC Lattice permissions, see [AmazonECSInfrastructureRolePolicyForVpcLattice](#).
  - For information about Lambda permissions, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#)
2. (Optional) For managed traffic shifting, configure one of the following resources. If your service is headless (no load balancer, Service Connect, or VPC Lattice), you can skip this step. Amazon ECS doesn't manage the traffic shift automatically for headless services.
  - Application Load Balancer - For more information, see [Application Load Balancer resources for blue/green, linear, and canary deployments](#).
  - Network Load Balancer - For more information, see [Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments](#).
  - Service Connect - For more information, see [Service Connect resources for Amazon ECS blue/green, linear, and canary deployments](#).
  - VPC Lattice - For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).
3. Decide if you want to run Lambda functions for the lifecycle stages.
  - PRE\_SCALE\_UP
  - POST\_SCALE\_UP
  - TEST\_TRAFFIC\_SHIFT
  - POST\_TEST\_TRAFFIC\_SHIFT
  - PRODUCTION\_TRAFFIC\_SHIFT
  - POST\_PRODUCTION\_TRAFFIC\_SHIFT

For more information, see [Create a Lambda function with the console](#) in the *AWS Lambda Developer Guide*.

Procedure

You can use the console or the AWS CLI to create an Amazon ECS blue/green service.

Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. Determine the resource from where you launch the service.

| To start a service from | Steps                                                                                                                                                                                                          |  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Clusters                | <div><div>a. On the <b>Clusters</b> page, select the cluster to create the service in.</div><div>The cluster details page displays.</div><div>b. On the <b>Services</b> tab, choose <b>Create</b>.</div></div> |  |
| Task definition         | <div><div>a. On the <b>Task definitions</b> page, select the task definition.</div><div>b. From the <b>Deploy</b> menu, choose <b>Create service</b>.</div></div>                                              |  |

The **Create service** page displays.

3. Under **Service details**, do the following:
  - a. For **Task definition family**, choose the task definition to use. Then, for **Task definition revision**, enter the revision to use.
  - b. For **Service name**, enter a name for your service.

4. To run the service in an existing cluster, for **Existing cluster**, choose the cluster. To run the service in a new cluster, choose **Create cluster**
5. Choose how your tasks are distributed across your cluster infrastructure. Under **Compute configuration**, choose your option.

| Compute option             | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Capacity provider strategy | <div><div>a. Under <b>Compute options</b>, choose <b>Capacity provider strategy</b>.</div><div>b. Choose a strategy:<ul style="list-style-type: none"><li>To use the cluster's default capacity provider strategy, choose <b>Use cluster default</b>.</li><li>If your cluster doesn't have a default capacity provider strategy, or to use a custom strategy, choose <b>Use custom</b>, <b>Add capacity provider strategy</b>, and then define your custom capacity provider strategy by specifying a <b>Base</b>, <b>Capacity provider</b>, and <b>Weight</b>.</li></ul></div></div> <div><div><div><div></div><div>Note</div></div><div>To use a capacity provider in a</div></div></div> |  |

| Compute option | Steps                                                                                                                                                                                                                                                                                                                                                                       |  |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                | <p>strategy, the capacity provider must be associated with the cluster.</p>                                                                                                                                                                                                                                                                                                 |  |
| Launch type    | <ol style="list-style-type: none"> <li>In the <b>Compute options</b> section, select <b>Launch type</b>.</li> <li>For <b>Launch type</b>, choose a launch type.</li> <li>(Optional) When the Fargate is specified, for <b>Platform version</b>, specify the platform version to use. If a platform version isn't specified, the LATEST platform version is used.</li> </ol> |  |

6. Under **Deployment configuration**, do the following:
  - For **Service type**, choose **Replica**.
  - For **Desired tasks**, enter the number of tasks to launch and maintain in the service.
  - To have Amazon ECS monitor the distribution of tasks across Availability Zones, and redistribute them when there is an imbalance, under **Availability Zone service rebalancing**, select **Availability Zone service rebalancing**.
  - For **Health check grace period**, enter the amount of time (in seconds) that the service scheduler ignores unhealthy Elastic Load Balancing, VPC Lattice, and container health checks after a task has first started. If you do not specify a health check grace period value, the default value of 0 is used.
7. a. For **Bake time**, enter the number of minutes that both the blue and green service revisions will run simultaneously before the blue revision is terminated. This allows time for verification and testing.

- b. (Optional) Configure lifecycle hooks to run at specific stages of the deployment. Under **Deployment lifecycle hooks**, choose **Add**.

For Lambda hooks:

- For **Target type**, choose **Lambda**.
- For **Lambda function**, enter the function name or ARN.
- For **Role**, select the IAM role that has permission to invoke the Lambda function.
- For **Lifecycle stages**, select the stages when the Lambda function should run.

For pause hooks:

- For **Target type**, choose **Pause**.
- For **Lifecycle stages**, select the stages where the deployment should pause.
- (Optional) For **Timeout**, configure the timeout duration and action.

8. To configure how Amazon ECS detects and handles deployment failures, expand **Deployment failure detection**, and then choose your options.

- a. To stop a deployment when the tasks cannot start, select **Use the Amazon ECS deployment circuit breaker**.

To have the software automatically roll back the deployment to the last completed deployment state when the deployment circuit breaker sets the deployment to a failed state, select **Rollback on failures**.

- b. To stop a deployment based on application metrics, select **Use CloudWatch alarm(s)**. Then, from **CloudWatch alarm name**, choose the alarms. To create a new alarm, go to the CloudWatch console.

To have the software automatically roll back the deployment to the last completed deployment state when a CloudWatch alarm sets the deployment to a failed state, select **Rollback on failures**.

9. (Optional) To interconnect your service using Service Connect, expand **Service Connect**, and then specify the following:

- a. Select **Turn on Service Connect**.
- b. Under **Service Connect configuration**, specify the client mode.

- If your service runs a network client application that only needs to connect to other services in the namespace, choose **Client side only**.
  - If your service runs a network or web service application and needs to provide endpoints for this service, and connects to other services in the namespace, choose **Client and server**.
- c. To use a namespace that is not the default cluster namespace, for **Namespace**, choose the service namespace. This can be a namespace created separately in the same AWS Region in your AWS account or a namespace in the same Region that is shared with your account using AWS Resource Access Manager (AWS RAM). For more information about shared AWS Cloud Map namespaces, see [Cross-account AWS Cloud Map namespace sharing](#) in the *AWS Cloud Map Developer Guide*.
- d. (Optional) Configure test traffic header rules for blue/green deployments. Under **Test traffic routing**, specify the following:
- i. Select **Enable test traffic header rules** to route specific requests to the green service revision during testing.
  - ii. For **Header matching rules**, configure the criteria for routing test traffic:
    - **Header name:** Enter the name of the HTTP header to match (for example, X-Test-Version or User-Agent).
    - **Match type:** Choose the matching criteria:
      - **Exact match:** Route requests where the header value exactly matches the specified value
      - **Header present:** Route requests that contain the specified header, regardless of value
      - **Pattern match:** Route requests where the header value matches a specified pattern
    - **Header value** (if using exact match or pattern match): Enter the value or pattern to match against.

You can add multiple header matching rules to create complex routing logic. Requests matching any of the configured rules will be routed to the green service revision for testing.

- iii. Choose **Add header rule** to configure additional header matching conditions.

**Note**

Test traffic header rules enable you to validate new functionality with controlled traffic before completing the full deployment. This allows you to test the green service revision with specific requests (such as those from internal testing tools or beta users) while maintaining normal traffic flow to the blue service revision.

- e. (Optional) Specify a log configuration. Select **Use log collection**. The default option sends container logs to CloudWatch Logs. The other log driver options are configured using AWS FireLens. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

The following describes each container log destination in more detail.

- **Amazon CloudWatch** – Configure the task to send container logs to CloudWatch Logs. The default log driver options are provided, which create a CloudWatch log group on your behalf. To specify a different log group name, change the driver option values.
- **Amazon Data Firehose** – Configure the task to send container logs to Firehose. The default log driver options are provided, which send logs to a Firehose delivery stream. To specify a different delivery stream name, change the driver option values.
- **Amazon Kinesis Data Streams** – Configure the task to send container logs to Kinesis Data Streams. The default log driver options are provided, which send logs to an Kinesis Data Streams stream. To specify a different stream name, change the driver option values.
- **Amazon OpenSearch Service** – Configure the task to send container logs to an OpenSearch Service domain. The log driver options must be provided.
- **Amazon S3** – Configure the task to send container logs to an Amazon S3 bucket. The default log driver options are set by default, but you must specify a valid Amazon S3 bucket name.

10. (Optional) Configure **Load balancing** for blue/green deployment.

| Elastic Load Balancing type | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|

|                             | <p>that the Network Load Balancer routes requests to.</p> <ul style="list-style-type: none"><li>• For <b>Protocol</b>, choose the protocol for the target group that the Network Load Balancer routes requests to. By default, the target group routes requests to the first container defined in your task definition.</li><li>• For <b>Deregistration delay</b>, enter the number of seconds for the load balancer to change the target state to UNUSED. The default is 300 seconds.</li><li>• For <b>Health check path</b>, enter an existing path within your container where the Application Load Balancer periodically sends requests to verify the connection health between the Application Load Balancer and the container. The default</li></ul> |  |

| Elastic Load Balancing type | Steps                                                                                                                                                                                                  |  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                             | <p>is the root directory (/).</p> <ul style="list-style-type: none"> <li>For <b>Alternate group name</b>, enter the group name for the target group for your test (green) service revision.</li> </ul> |  |

11. (Optional) To use VPC Lattice for managed traffic shifting during blue/green deployments, expand **VPC Lattice - optional** and select **Use VPC Lattice**, then do the following:
  - a. For **VPC**, choose the VPC for your VPC Lattice resources. This must be the same VPC as your Fargate service.
  - b. For **Infrastructure role**, choose the Amazon ECS infrastructure IAM role that Amazon ECS uses to manage your VPC Lattice resources, or choose **Create a new infrastructure role**.
  - c. For **Container port name**, choose the port name from the task definition that maps to the container port that receives traffic from VPC Lattice.
  - d. For **VPC Lattice service**, choose **Create a new service** or **Use an existing service**. For **Service name**, enter a unique name for the service.
  - e. For **Listener**, choose **Create new listener** or **Use an existing listener**. For **Port**, enter a port from 1 to 65535. For **Protocol**, choose the protocol (for example, **HTTP**).
  - f. Under **Production listener rule**, enter a **Name**, a **Priority** from 1 to 100, and a **Path pattern** (maximum 200 characters). Amazon ECS uses this rule to route production traffic.
  - g. (Optional, recommended) Under **Test listener rule**, enter a **Name**, a **Priority** from 1 to 100, and a **Path pattern**. Amazon ECS uses this rule to route test traffic to the green service revision.
  - h. For **Target groups**, choose **Create two new target groups**, **Create green target group**, or **Use two existing target groups**. For a new target group, enter a **Target group name**, choose a **Protocol**, enter a **Port** from 1 to 65535, choose a **Health check**

**protocol**, and enter a **Health check path**. For **Green target group name**, enter a name; the green target group uses the same configuration as the blue target group.

12. (Optional) To help identify your service and tasks, expand the **Tags** section, and then configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the task definition tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Task definitions**.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the service tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Service**.

Add or remove a tag.

- [Add a tag] Choose **Add tag**, and then do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
- [Remove a tag] Next to the tag, choose **Remove tag**.

13. Choose **Create**.

## AWS CLI

1. Create a file named `service-definition.json` with the following content.

Replace the *user-input* with your values.

```
{
  "serviceName": "myBlueGreenService",
  "cluster": "arn:aws:ecs:us-west-2:123456789012:cluster/sample-fargate-
cluster",
  "taskDefinition": "sample-fargate:1",
  "desiredCount": 5,
  "launchType": "FARGATE",
  "networkConfiguration": {
    "awsvpcConfiguration": {
      "subnets": [
        "subnet-09ce6e74c116a2299",
        "subnet-00bb3bd7a73526788",
```

```

        "subnet-0048a611aaec65477"
    ],
    "securityGroups": [
        "sg-09d45005497daa123"
    ],
    "assignPublicIp": "ENABLED"
  }
},
"deploymentController": {
  "type": "ECS"
},
"deploymentConfiguration": {
  "strategy": "BLUE_GREEN",
  "maximumPercent": 200,
  "minimumHealthyPercent": 100,
  "bakeTimeInMinutes": 2,
  "alarms": {
    "alarmNames": [
      "myAlarm"
    ],
    "rollback": true,
    "enable": true
  },
  "lifecycleHooks": [
    {
      "hookTargetArn": "arn:aws:lambda:us-
west-2:7123456789012:function:checkExample",
      "roleArn": "arn:aws:iam::123456789012:role/ECSLifecycleHookInvoke",
      "lifecycleStages": [
        "PRE_SCALE_UP"
      ],
      "hookDetails": {
        "MY_CONFIG_KEY": "my-config-value"
      }
    }
  ]
},
"loadBalancers": [
  {
    "targetGroupArn": "arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/blue-target-group/54402ff563af1197",
    "containerName": "fargate-app",
    "containerPort": 80,
    "advancedConfiguration": {

```

```

        "alternateTargetGroupArn": "arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/green-target-group/cad10a56f5843199",
        "productionListenerRule": "arn:aws:elasticloadbalancing:us-
west-2:123456789012:listener-rule/app/my-blue-green-
demo/32e0e4f946c3c05b/9cfa8c482e204f7d/831dbaf72edb911",
        "roleArn": "arn:aws:iam::123456789012:role/LoadBalancerManagementforECS"
    }
}
]
}

```

## 2. Run create-service.

Replace the *user-input* with your values.

```
aws ecs create-service --cli-input-json file://service-definition.json
```

Alternatively, you can use the following example which creates a blue/green deployment service with a load balancer configuration:

```

aws ecs create-service \
  --cluster "arn:aws:ecs:us-west-2:123456789012:cluster/MyCluster" \
  --service-name "blue-green-example-service" \
  --task-definition "nginxServer:1" \
  --launch-type "FARGATE" \
  --network-configuration
  "awsvpcConfiguration={subnets=[subnet-12345,subnet-67890,subnet-abcdef,subnet-
fedcba],securityGroups=[sg-12345],assignPublicIp=ENABLED}" \
  --desired-count 3 \
  --deployment-controller "type=ECS" \
  --deployment-configuration
  "strategy=BLUE_GREEN,maximumPercent=200,minimumHealthyPercent=100,bakeTimeInMinutes=0" \
  --load-balancers "targetGroupArn=arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/MyBGtg1/
abcdef1234567890,containerName=nginx,containerPort=80,advancedConfiguration={alternateTa
west-2:123456789012:targetgroup/
MyBGtg2/0987654321fedcba,productionListenerRule=arn:aws:elasticloadbalancing:us-
west-2:123456789012:listener-rule/app/
MyLB/1234567890abcdef/1234567890abcdef,roleArn=arn:aws:iam::123456789012:role/
ELBManagementRole}"

```

Alternatively, you can use the following example which creates a blue/green deployment service with a VPC Lattice configuration:

```
aws ecs create-service \
  --cluster "arn:aws:ecs:us-west-2:123456789012:cluster/MyCluster" \
  --service-name "blue-green-example-service" \
  --task-definition "nginxServer:1" \
  --launch-type "FARGATE" \
  --network-configuration
  "awsvpcConfiguration={subnets=[subnet-12345,subnet-67890,subnet-abcdef,subnet-
  fedcba],securityGroups=[sg-12345],assignPublicIp=ENABLED}" \
  --desired-count 3 \
  --deployment-controller "type=ECS" \
  --deployment-configuration
  "strategy=BLUE_GREEN,maximumPercent=200,minimumHealthyPercent=100,bakeTimeInMinutes=0" \
  --vpc-lattice-configurations
  "portName=web,roleArn=arn:aws:iam::111122223333:role/ecs-
  vpc-lattice-role,targetGroupArn=arn:aws:vpc-lattice:us-
  west-2:111122223333:targetgroup/primary-target-group/
  abcdef123456,advancedConfiguration={alternateTargetGroupArn=arn:aws:vpc-
  lattice:us-west-2:111122223333:targetgroup/alternate-target-
  group/ghijkl789012,productionListenerRule=arn:aws:vpc-lattice:us-
  west-2:111122223333:service/svc-0123456789abcdef0/listener/
  listener-0123456789abcdef0/rule/
  rule-0123456789abcdef0,testListenerRule=arn:aws:vpc-lattice:us-
  west-2:111122223333:service/svc-0123456789abcdef0/listener/
  listener-0123456789abcdef0/rule/rule-abcdef01234567890}"
```

## Next steps

- Update the service to start the deployment. For more information, see [Updating an Amazon ECS service](#).
- Monitor the deployment process to ensure it follows the blue/green pattern:
  - The green service revision is created and scaled up
  - Test traffic is routed to the green revision (if configured)
  - Production traffic is shifted to the green revision
  - After the bake time, the blue revision is terminated

## Troubleshooting Amazon ECS blue/green deployments

This following provides solutions for common issues you might encounter when using blue/green deployments with Amazon ECS. Blue/green deployment errors can occur during the following phases:

- *Synchronous path*: Errors that appear immediately in response to `CreateService` or `UpdateService` API calls.
- *Asynchronous path*: Errors that appear in the `statusReason` field of `DescribeServiceDeployments` and cause a deployment rollback

### Tip

You can use the [Amazon ECS MCP server](#) with AI assistants to monitor deployments and troubleshoot deployment issues using natural language.

## Load balancer configuration issues

Load balancer configuration is a critical component of blue/green deployments in Amazon ECS. Proper configuration of listener rules, target groups, and load balancer types is essential for successful deployments. This section covers common load balancer configuration issues that can cause blue/green deployments to fail.

When troubleshooting load balancer issues, it's important to understand the relationship between listener rules and target groups. In a blue/green deployment:

- The production listener rule directs traffic to the currently active (blue) service revision
- The test listener rule can be used to validate the new (green) service revision before shifting production traffic
- Target groups are used to register the container instances from each service revision
- During deployment, traffic is gradually shifted from the blue service revision to the green service revision by adjusting the weights of the target groups in the listener rules

## Listener rule configuration errors

The following issues relate to incorrect listener rule configuration for blue/green deployments.

## Using an Application Load Balancer listener ARN instead of a listener rule ARN

*Error message:* productionListenerRule has an invalid ARN format. Must be RuleArn for ALB or ListenerArn for NLB. Got: arn:aws:elasticloadbalancing:us-west-2:123456789012:listener/app/my-alb/abc123/def456

*Solution:* When using an Application Load Balancer, you must specify a listener rule ARN for productionListenerRule and testListenerRule, not a listener ARN. For Network Load Balancers, you must use the listener ARN.

For information about how to find the listener ARN, see [Listeners for your Application Load Balancers](#) in the *Application Load Balancer User Guide*. The ARN for a rule has the format *arn:aws:elasticloadbalancing:region:account-id:listener-rule/app/...*

## Using the same rule for both production and test listeners

*Error message:* The following rules cannot be used as both production and test listener rules: arn:aws:elasticloadbalancing:us-west-2:123456789012:listener-rule/app/my-alb/abc123/def456/ghi789

*Solution:* You must use different listener rules for production and test traffic. Create a separate listener rule for test traffic that routes to your test target group.

## Target group not associated with listener rules

*Error message:* Service deployment rolled back because of invalid networking configuration: Target group arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/myAlternateTG/abc123 is not associated with either productionListenerRule or testListenerRule.

*Solution:* Both the primary target group and alternate target group must be associated with either the production listener rule or the test listener rule. Update your load balancer configuration to ensure both target groups are properly associated with your listener rules.

## Missing test listener rule with an Application Load Balancer

*Error message:* For Application LoadBalancer, testListenerRule is required when productionListenerRule is not associated with both targetGroup and alternateTargetGroup

*Solution:* When you use an Application Load Balancer, if both target groups are not associated with the production listener rule, you must specify a test listener rule. Add a

`testListenerRule` to your configuration and ensure both target groups are associated with either the production or test listener rule. For more information, see [Listeners for your Application Load Balancers](#) in the *Application Load Balancer User Guide*.

## Target group configuration errors

The following issues relate to incorrect target group configuration for blue/green deployments.

### Multiple target groups with traffic in listener rule

*Error message:* Service deployment rolled back because of invalid networking configuration. `productionListenerRule` `arn:aws:elasticloadbalancing:us-west-2:123456789012:listener-rule/app/my-alb/abc123/def456/ghi789` should have exactly one target group serving traffic but found 2 target groups which are serving traffic

*Solution:* Before starting a blue/green deployment, ensure that only one target group is receiving traffic (has a non-zero weight) in your listener rule. Update your listener rule configuration to set the weight to zero for any target group that should not be receiving traffic.

### Duplicate target groups across load balancer entries

*Error message:* Duplicate `targetGroupArn` found:  
`arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/myecs-targetgroup/abc123`

*Solution:* Each target group ARN must be unique across all load balancer entries in your service definition. Review your configuration and ensure you're using different target groups for each load balancer entry.

### Unexpected target group in production listener rule

*Error message:* Service deployment rolled back because of invalid networking configuration. Production listener rule is forwarding traffic to unexpected target group `arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/random-nlb-tg/abc123`.

Expected traffic to be forwarded to either `targetGroupArn: arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/nlb-targetgroup/def456` or `alternateTargetGroupArn: arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/nlb-tg-alternate/ghi789`

*Solution:* The production listener rule is forwarding traffic to a target group that is not specified in your service definition. Ensure that the listener rule is configured to forward traffic only to the target groups specified in your service definition.

For more information, see [forward actions](#) in the *Application Load Balancer User Guide*.

## Load balancer type configuration errors

The following issues relate to incorrect load balancer type configuration for blue/green deployments.

Mixing Classic Load Balancer and Application Load Balancer or Network Load Balancer configurations

*Error message:* All loadBalancers must be strictly either ELBv1 (defining loadBalancerName) or ELBv2 (defining targetGroupArn)

### Note

Classic Load Balancers are the previous generation of load balancers from Elastic Load Balancing. We recommend that you migrate to a current generation load balancer. For more information, see [Migrate your Classic Load Balancer](#).

*Solution:* . Use either all Classic Load Balancers or all Application Load Balancers and Network Load Balancers.

For Application Load Balancers and Network Load Balancers, specify only the targetGroupArn field.

Using advanced configuration with a Classic Load Balancer

*Error message:* advancedConfiguration field is not allowed with ELBv1 loadBalancers

*Solution:* Advanced configuration for blue/green deployments is only supported with Application Load Balancers and Network Load Balancers. If you use a Classic Load Balancer (specified with loadBalancerName), you cannot use the advancedConfiguration field. Either switch to an Application Load Balancer, or remove the advancedConfiguration field.

## Inconsistent advanced configuration across load balancers

*Error message:* Either all or none of the provided loadBalancers must have advancedConfiguration defined

*Solution:* If you're using multiple load balancers, you must either define advancedConfiguration for all of them or for none of them. Update your configuration to ensure consistency across all load balancer entries.

## Missing advanced configuration with blue/green deployment

*Error message:* advancedConfiguration field is required for all loadBalancers when using a non-ROLLING deployment strategy

*Solution:* When using a blue/green deployment strategy with Application Load Balancers, you must specify the advancedConfiguration field for all load balancer entries. Add the required advancedConfiguration to your load balancer configuration.

## Permission issues

The following issues relate to insufficient permissions for blue/green deployments.

### Missing trust policy on infrastructure role

*Error message:* Service deployment rolled back because of invalid networking configuration. ECS was unable to manage the ELB resources due to missing permissions on ECS Infrastructure Role 'arn:aws:iam::123456789012:role/Admin'.

*Solution:* The IAM role specified for managing load balancer resources does not have the correct trust policy. Update the role's trust policy to allow the service to assume the role. The trust policy must include:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
```

```
        "Service": "ecs.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

### Missing read permissions on load balancer role

*Error message:* service myService failed to describe target health on target-group myTargetGroup with (error User: arn:aws:sts::123456789012:assumed-role/myELBRole/ecs-service-scheduler is not authorized to perform: elasticloadbalancing:DescribeTargetHealth because no identity-based policy allows the elasticloadbalancing:DescribeTargetHealth action)

*Solution:* The IAM role used for managing load balancer resources does not have permission to read target health information. Add the elasticloadbalancing:DescribeTargetHealth permission to the role's policy. For information about Elastic Load Balancing permissions, see [Amazon ECS infrastructure IAM role for load balancers](#).

### Missing write permissions on load balancer role

*Error message:* service myService failed to register targets in target-group myTargetGroup with (error User: arn:aws:sts::123456789012:assumed-role/myELBRole/ecs-service-scheduler is not authorized to perform: elasticloadbalancing:RegisterTargets on resource: arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/myTargetGroup/abc123 because no identity-based policy allows the elasticloadbalancing:RegisterTargets action)

*Solution:* The IAM role used for managing load balancer resources does not have permission to register targets. Add the elasticloadbalancing:RegisterTargets permission to the role's policy. For information about Elastic Load Balancing permissions, see [Amazon ECS infrastructure IAM role for load balancers](#).

### Missing permission to modify listener rules

*Error message:* Service deployment rolled back because TEST\_TRAFFIC\_SHIFT lifecycle hook(s) failed. User: arn:aws:sts::123456789012:assumed-role/myELBRole/ECSNetworkingWithELB is not authorized to perform: elasticloadbalancing:ModifyListener on resource:

arn:aws:elasticloadbalancing:us-west-2:123456789012:listener/app/my-alb/abc123/def456 because no identity-based policy allows the elasticloadbalancing:ModifyListener action

*Solution:* The IAM role used for managing load balancer resources does not have permission to modify listeners. Add the elasticloadbalancing:ModifyListener permission to the role's policy. For information about Elastic Load Balancing permissions, see [Amazon ECS infrastructure IAM role for load balancers](#).

For blue/green deployments, we recommend attaching the AmazonECS-ServiceLinkedRolePolicy managed policy to your infrastructure role, which includes all the necessary permissions for managing load balancer resources.

## Lifecycle hook issues

The following issues relate to lifecycle hooks in blue/green deployments.

### Incorrect trust policy on Lambda hook role

*Error message:* Service deployment rolled back because TEST\_TRAFFIC\_SHIFT lifecycle hook(s) failed. ECS was unable to assume role arn:aws:iam::123456789012:role/Admin

*Solution:* The IAM role specified for the Lambda lifecycle hook does not have the correct trust policy. Update the role's trust policy to allow the service to assume the role. The trust policy must include:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "ecs.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

## Lambda hook returns FAILED status

*Error message:* Service deployment rolled back because TEST\_TRAFFIC\_SHIFT lifecycle hook(s) failed. Lifecycle hook target arn:aws:lambda:us-west-2:123456789012:function:myHook returned FAILED status.

*Solution:* The Lambda function specified as a lifecycle hook returned a FAILED status. Check the Lambda function logs in Amazon CloudWatch logs to determine the failure reason, and update the function to handle the deployment event correctly.

## Missing permission to invoke Lambda function

*Error message:* Service deployment rolled back because TEST\_TRAFFIC\_SHIFT lifecycle hook(s) failed. ECS was unable to invoke hook target arn:aws:lambda:us-west-2:123456789012:function:myHook due to User: arn:aws:sts::123456789012:assumed-role/myLambdaRole/ECS-Lambda-Execution is not authorized to perform: lambda:InvokeFunction on resource: arn:aws:lambda:us-west-2:123456789012:function:myHook because no identity-based policy allows the lambda:InvokeFunction action

*Solution:* The IAM role used for the Lambda lifecycle hook does not have permission to invoke the Lambda function. Add the `lambda:InvokeFunction` permission to the role's policy for the specific Lambda function ARN. For information about Lambda permissions, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#).

## Lambda function timeout or invalid response

*Error message:* Service deployment rolled back because TEST\_TRAFFIC\_SHIFT lifecycle hook(s) failed. ECS was unable to parse the response from arn:aws:lambda:us-west-2:123456789012:function:myHook due to HookStatus must not be null

*Solution:* The Lambda function either timed out or returned an invalid response. Ensure that your Lambda function returns a valid response with a `hookStatus` field set to either `SUCCEEDED` or `FAILED`. Also, check that the Lambda function timeout is set appropriately for your validation logic. For more information, see [Lifecycle hooks for Amazon ECS service deployments](#).

Example of a valid Lambda response:

```
{
```

```
"hookStatus": "SUCCEEDED",  
"reason": "Validation passed"  
}
```

### Invalid targetType for lifecycle hook

*Error message:* Invalid targetType. Valid values are: AWS\_LAMBDA, PAUSE

*Solution:* Check the targetType field in your lifecycle hook configuration. Valid values are AWS\_LAMBDA and PAUSE.

### Invalid lifecycle stage for pause hook

*Error message:* Invalid lifecycle stage provided for Pause Hook

*Solution:* Pause hooks can only be configured at PRE\_SCALE\_UP, POST\_SCALE\_UP, POST\_TEST\_TRAFFIC\_SHIFT, PRE\_PRODUCTION\_TRAFFIC\_SHIFT, or POST\_PRODUCTION\_TRAFFIC\_SHIFT. You cannot use TEST\_TRAFFIC\_SHIFT or PRODUCTION\_TRAFFIC\_SHIFT for pause hooks.

### Pause hook timed out

*Error message:* Service deployment rolled back because POST\_TEST\_TRAFFIC\_SHIFT pause hook timed out.

*Solution:* The pause hook timed out before a ContinueServiceDeployment call was received. Verify that your automation or approval workflow is calling ContinueServiceDeployment before the configured timeout expires. Check the expiresAt field in DescribeServiceDeployments to see when the hook was set to expire. If you need more time, increase the timeoutInMinutes value in the pause hook configuration (maximum 20,160 minutes / 14 days). If you want the deployment to continue automatically on timeout instead of rolling back, set the timeoutConfiguration.action to CONTINUE.

### Invalid hookId format

*Error message:* Invalid hookId: hookId must follow the format: ecs-{hookType}-{id}

*Solution:* The hookId provided to ContinueServiceDeployment does not match the expected format. Retrieve the correct hookId by calling DescribeServiceDeployments and checking the lifecycleHookDetails array. Do not construct hookIds manually.

## hookId not found or expired

*Error message:* Provided hookId is either completed, unavailable, or not associated with the given Resource ARN

*Solution:* The hookId is no longer valid. This can happen if the hook already timed out, was already continued or rolled back, a new deployment was triggered (invalidating previous hookIds), or the hookId belongs to a different service deployment ARN. Retrieve the current hookId by calling `DescribeServiceDeployments` on the active deployment.

## Deployment in terminal state

*Error message:* Continuing a service deployment is not allowed for service deployment in terminal states.

*Solution:* The deployment has already completed, rolled back, or stopped. You can only call `ContinueServiceDeployment` on a deployment that is `IN_PROGRESS` with a pause hook in `AWAITING_ACTION` status. Use `DescribeServiceDeployments` to check the current deployment status.

## Service deployment not found

*Error message:* The service deployment does not exist.

*Solution:* The `serviceDeploymentArn` provided does not match any existing service deployment. Use `ListServiceDeployments` to find the correct ARN.

## Amazon ECS linear deployments

Linear deployments gradually shift traffic from the old service revision to the new one in equal increments over time, allowing you to monitor each step before proceeding to the next. With Amazon ECS linear deployments, control the pace of traffic shifting and validate new service revisions with increasing amounts of production traffic. This approach provides a controlled way to deploy changes with the ability to monitor performance at each increment.

### Resources involved in a linear deployment

The following are resources involved in Amazon ECS linear deployments:

- **Traffic shift** - The process Amazon ECS uses to shift production traffic. For Amazon ECS linear deployments, traffic is shifted in equal percentage increments with configurable wait times between each increment.

- **Step percent** - The percentage of traffic to shift in each increment during a linear deployment. This field takes Double for value, and valid values are from 3.0 to 100.0.
- **Step bake time** - The duration to wait between each traffic shift increment during a linear deployment. Valid values are from 0 - 1440 minutes.
- **Deployment bake time** - The time, in minutes, Amazon ECS waits after shifting all production traffic to the new service revision, before it terminates the old service revision. This is the duration when both blue and green service revisions are running simultaneously after the production traffic has shifted.
- **Lifecycle stages** - A series of events in the deployment operation, such as "after production traffic shift".
- **Lifecycle hook** - A Lambda function or pause point at a specific lifecycle stage. Lambda hooks invoke Lambda functions that you have defined to run custom code. Pause hooks pause the deployment and wait for you to call `ContinueServiceDeployment` to proceed. Hooks configured for `PRODUCTION_TRAFFIC_SHIFT` or `PRE_PRODUCTION_TRAFFIC_SHIFT` are invoked at every production traffic shift step.
- **Target group** - An Elastic Load Balancing or VPC Lattice resource used to route requests to one or more registered targets (for example, EC2 instances). When you create a listener, you specify a target group for its default action. Traffic is forwarded to the target group specified in the listener rule.
- **Listener** - An Elastic Load Balancing or VPC Lattice resource that checks for connection requests using the protocol and port that you configure. The rules that you define for a listener determine how Amazon ECS routes requests to its registered targets.
- **Rule** - An Elastic Load Balancing or VPC Lattice resource associated with a listener. A rule defines how requests are routed and consists of an action, condition, and priority.

## Considerations

Consider the following when choosing a deployment type:

- **Resource usage:** Linear deployments temporarily run both the blue and green service revisions simultaneously, which may double your resource usage during deployments.
- **Deployment monitoring:** Linear deployments provide detailed deployment status information, allowing you to monitor each stage of the deployment process and each traffic shift increment.
- **Rollback:** Linear deployments make it easier to roll back to the previous version if issues are detected, as the blue revision is kept running until the bake time expires.

- **Gradual validation:** Linear deployments allow you to validate the new revision with increasing amounts of production traffic, providing more confidence in the deployment.
- **Deployment duration:** Linear deployments take longer to complete than all-at-once deployments due to the incremental traffic shifting and wait times between steps.

## How Linear deployment works

The Amazon ECS Linear deployment process follows a structured approach with six distinct phases that ensure safe and reliable application updates. Each phase serves a specific purpose in validating and transitioning your application from the current version (blue) to the new version (green).

1. **Preparation Phase:** Create the green environment alongside the existing blue environment.
2. **Deployment Phase:** Deploy the new service revision to the green environment. Amazon ECS launches new tasks using the updated service revision while the blue environment continues serving production traffic.
3. **Testing Phase:** Validate the green environment using test traffic routing. Your traffic-shifting resource (an Application Load Balancer, Network Load Balancer, Service Connect, or VPC Lattice) directs test requests to the green environment while production traffic remains on blue.
4. **Linear Traffic Shifting Phase:** Gradually shift production traffic from blue to green in equal percentage increments based on your configured deployment strategy.
5. **Monitoring Phase:** Monitor application health, performance metrics, and alarm states during the bake time period. A rollback operation is initiated when issues are detected.
6. **Completion Phase:** Finalize the deployment by terminating the blue environment.

The linear traffic shift phase follows these steps:

- **Initial** - The deployment begins with 100% of traffic routed to the blue (current) service revision. The green (new) service revision receives test traffic but no production traffic initially.
- **Incremental traffic shifting** - Traffic is gradually shifted from blue to green in equal percentage increments. For example, with a 10.0% step configuration, traffic shifts occur as follows:
  - Step 1: 10.0% to green, 90.0% to blue
  - Step 2: 20.0% to green, 80.0% to blue
  - Step 3: 30.0% to green, 70.0% to blue
  - And so on until 100% reaches green

- **Step bake time** - Between each traffic shift increment, the deployment waits for a configurable duration (step bake time) to allow monitoring and validation of the new revision's performance with the increased traffic load. Note, that last step bake time is skipped once traffic is shifted 100.0%.
- **Lifecycle hooks** - Optional Lambda functions or pause hooks can be configured at various lifecycle stages during the deployment to perform automated validation, monitoring, or custom logic. Hooks configured for `PRODUCTION_TRAFFIC_SHIFT` or `PRE_PRODUCTION_TRAFFIC_SHIFT` are invoked at every production traffic shift step.

## Deployment lifecycle stages

The Linear deployment process progresses through distinct lifecycle stages, each with specific responsibilities and validation checkpoints. Understanding these stages helps you monitor deployment progress and troubleshoot issues effectively.

Each lifecycle stage can last up to 24 hours and in addition each traffic shift step in `PRODUCTION_TRAFFIC_SHIFT` can last upto 24 hours. We recommend that the value remains below the 24-hour mark. This is because asynchronous processes need time to trigger the hooks. The system times out, fails the deployment, and then initiates a rollback after a stage reaches 24 hours.

CloudFormation deployments have additional timeout restrictions. While the 24-hour stage limit remains in effect, CloudFormation enforces a 36-hour limit on the entire deployment. CloudFormation fails the deployment, and then initiates a rollback if the process doesn't complete within 36 hours.

For pause hooks, you can configure the timeout up to 20,160 minutes (14 days). The overall deployment timeout is 30 days.

| Lifecycle stages  | Description                                                                                                           | Lifecycle hook support |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|------------------------|
| RECONCILE_SERVICE | This stage only happens when you start a new service deployment with more than 1 service revision in an ACTIVE state. | Yes                    |

| Lifecycle stages              | Description                                                                                                                                                                                  | Lifecycle hook support |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| PRE_SCALE_UP                  | The green service revision has not started. The blue service revision is handling 100% of the production traffic. There is no test traffic.                                                  | Yes                    |
| SCALE_UP                      | The time when the green service revision scales up to 100% and launches new tasks. The green service revision is not serving any traffic at this point.                                      | No                     |
| POST_SCALE_UP                 | The green service revision has started. The blue service revision is handling 100% of the production traffic. There is no test traffic.                                                      | Yes                    |
| TEST_TRAFFIC_SHIFT            | The blue and green service revisions are running. The blue service revision handles 100% of the production traffic. The green service revision is migrating from 0% to 100% of test traffic. | Yes (Lambda only)      |
| POST_TEST_TRAFFIC_SHIFT       | The test traffic shift is complete. The green service revision handles 100% of the test traffic.                                                                                             | Yes                    |
| PRE_PRODUCTION_TRAFFIC_SHIFT  | Occurs before each production traffic shift increment. Lifecycle hooks configured for this stage are invoked at every traffic shift step.                                                    | Yes                    |
| PRODUCTION_TRAFFIC_SHIFT      | Traffic is gradually shifted from blue to green in equal percentage increments until green receives 100% of traffic. Each traffic shift invokes lifecycle hook with 24 hours timeout.        | Yes (Lambda only)      |
| POST_PRODUCTION_TRAFFIC_SHIFT | The production traffic shift is complete.                                                                                                                                                    | Yes                    |

| Lifecycle stages | Description                                                                                                                                                  | Lifecycle hook support |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| BAKE_TIME        | The duration when both blue and green service revisions are running simultaneously.                                                                          | No                     |
| CLEAN_UP         | The blue service revision has completely scaled down to 0 running tasks. The green service revision is now the production service revision after this stage. | No                     |

## Required resources for Amazon ECS linear deployments

To use a linear deployment with managed traffic shifting, your service must use one of the following features:

- Elastic Load Balancing
- Service Connect
- VPC Lattice

The following list provides a high-level overview of what you need to configure for Amazon ECS linear deployments:

- Your service uses an Application Load Balancer, Network Load Balancer, Service Connect, or VPC Lattice. Configure the appropriate resources.
  - Application Load Balancer - For more information, see [Application Load Balancer resources for blue/green, linear, and canary deployments](#).
  - Network Load Balancer - For more information, see [Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments](#).
  - Service Connect - For more information, see [Service Connect resources for Amazon ECS blue/green, linear, and canary deployments](#).
  - VPC Lattice - For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).
- Set the service deployment controller to ECS.
- Configure the deployment strategy as `linear` in your service definition.

- Optionally, configure additional parameters such as:
  - Bake time for the new deployment
  - The percentage of traffic to shift in each increment.
  - The duration in minutes to wait between each traffic shift increment.
  - CloudWatch alarms for automatic rollback
  - Deployment lifecycle hooks (Lambda functions or pause hooks that run at specified deployment stages)

## Best practices

Follow these best practices for successful Amazon ECS linear deployments:

- **Ensure your application can handle both service revisions running simultaneously.**
- **Plan for sufficient cluster capacity to handle both service revisions during deployment.**
- **Test your rollback procedures before implementing them in production.**
- Configure appropriate health checks that accurately reflect your application's health.
- Set a bake time that allows sufficient testing of the new service revision.
- Implement CloudWatch alarms to automatically detect issues and trigger rollbacks.
- Choose step percentages and bake times that balance deployment speed with validation needs.
- Use smaller step percentages (5-10%) for critical applications to minimize risk exposure.
- Set longer step bake times for applications that need time to warm up or stabilize.
- Implement CloudWatch alarms to automatically detect issues and trigger rollbacks at any traffic increment.
- Monitor application metrics closely during each traffic shift to detect performance degradation early.
- Ensure your application can handle both service revisions running simultaneously.
- Test your rollback procedures at different traffic percentages before implementing them in production.

## Creating an Amazon ECS linear deployment

By using Amazon ECS linear deployments, you can gradually shift traffic in equal increments over specified time intervals. This provides controlled validation at each step of the deployment process.

Prerequisites

Perform the following operations before you start a linear deployment.

1. Configure the appropriate permissions.
  - For information about Elastic Load Balancing permissions, see [Amazon ECS infrastructure IAM role for load balancers](#).
  - If you're using VPC Lattice, for information about VPC Lattice permissions, see [AmazonECSInfrastructureRolePolicyForVpcLattice](#).
  - For information about Lambda permissions, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#).
2. Amazon ECS linear deployments require that your service to use one of the following features: Configure the appropriate resources.
  - Application Load Balancer - For more information, see [Application Load Balancer resources for blue/green, linear, and canary deployments](#).
  - Network Load Balancer - For more information, see [Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments](#).
  - Service Connect - For more information, see [Service Connect resources for Amazon ECS blue/green, linear, and canary deployments](#).
  - VPC Lattice - For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).

Procedure

You can use the console or the AWS CLI to create an Amazon ECS linear deployment service.

Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. Determine the resource from where you launch the service.

| To start a service from | Steps                                                                        |  |
|-------------------------|------------------------------------------------------------------------------|--|
| Clusters                | a. On the <b>Clusters</b> page, select the cluster to create the service in. |  |

| To start a service from | Steps                                                                                                                                           |  |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                         | <p>The cluster details page displays.</p> <p>b. On the <b>Services</b> tab, choose <b>Create</b>.</p>                                           |  |
| Task definition         | <p>a. On the <b>Task definitions</b> page, select the task definition.</p> <p>b. From the <b>Deploy</b> menu, choose <b>Create service</b>.</p> |  |

The **Create service** page displays.

3. Under **Service details**, do the following:
  - a. For **Task definition family**, choose the task definition to use. Then, for **Task definition revision**, enter the revision to use.
  - b. For **Service name**, enter a name for your service.
4. To run the service in an existing cluster, for **Existing cluster**, choose the cluster. To run the service in a new cluster, choose **Create cluster**
5. Choose how your tasks are distributed across your cluster infrastructure. Under **Compute configuration**, choose your option.

| Compute option             | Steps                                                                                                                                                                                                                       |  |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Capacity provider strategy | <p>a. Under <b>Compute options</b>, choose <b>Capacity provider strategy</b>.</p> <p>b. Choose a strategy:</p> <ul style="list-style-type: none"> <li>• To use the cluster's default capacity provider strategy,</li> </ul> |  |

| Compute option | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                | <div><p>choose <b>Use cluster default</b>.</p><ul style="list-style-type: none"><li>• If your cluster doesn't have a default capacity provider strategy, or to use a custom strategy, choose <b>Use custom, Add capacity provider strategy</b>, and then define your custom capacity provider strategy by specifying a <b>Base, Capacity provider</b>, and <b>Weight</b>.</li></ul></div> <div><div><div> <b>Note</b></div><div><p>To use a capacity provider in a strategy, the capacity provider must be associated with the cluster.</p></div></div></div> |  |

| Compute option | Steps                                                                                                                                                                                                                                                                                                                                                                       |  |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Launch type    | <ol style="list-style-type: none"> <li>In the <b>Compute options</b> section, select <b>Launch type</b>.</li> <li>For <b>Launch type</b>, choose a launch type.</li> <li>(Optional) When the Fargate is specified, for <b>Platform version</b>, specify the platform version to use. If a platform version isn't specified, the LATEST platform version is used.</li> </ol> |  |

6. Under **Deployment configuration**, do the following:
  - For **Service type**, choose **Replica**.
  - For **Desired tasks**, enter the number of tasks to launch and maintain in the service.
  - To have Amazon ECS monitor the distribution of tasks across Availability Zones, and redistribute them when there is an imbalance, under **Availability Zone service rebalancing**, select **Availability Zone service rebalancing**.
  - For **Health check grace period**, enter the amount of time (in seconds) that the service scheduler ignores unhealthy Elastic Load Balancing, VPC Lattice, and container health checks after a task has first started. If you do not specify a health check grace period value, the default value of 0 is used.
7. Under **Deployment configuration**, configure the linear deployment settings:
  - For **Deployment strategy**, choose **Linear**.
  - For **Traffic increment percentage**, enter the percentage of traffic to shift in each increment (for example, 10% to shift traffic in 10% increments).
  - For **Interval between increments**, enter the time in minutes to wait between each traffic shift increment.

- d. For **Bake time**, enter the number of minutes that both the blue and green service revisions will run simultaneously after the final traffic shift before the blue revision is terminated.
- e. (Optional) Configure lifecycle hooks to run at specific stages of the deployment. Under **Deployment lifecycle hooks**, choose **Add**.

For Lambda hooks:

- For **Target type**, choose **Lambda**.
- For **Lambda function**, enter the function name or ARN.
- For **Role**, select the IAM role that has permission to invoke the Lambda function.
- For **Lifecycle stages**, select the stages when the Lambda function should run.

For pause hooks:

- For **Target type**, choose **Pause**.
- For **Lifecycle stages**, select the stages where the deployment should pause.
- (Optional) For **Timeout**, configure the timeout duration and action.

8. To configure how Amazon ECS detects and handles deployment failures, expand **Deployment failure detection**, and then choose your options.
  - a. To stop a deployment when the tasks cannot start, select **Use the Amazon ECS deployment circuit breaker**.

To have the software automatically roll back the deployment to the last completed deployment state when the deployment circuit breaker sets the deployment to a failed state, select **Rollback on failures**.

- b. To stop a deployment based on application metrics, select **Use CloudWatch alarm(s)**. Then, from **CloudWatch alarm name**, choose the alarms. To create a new alarm, go to the CloudWatch console.

To have the software automatically roll back the deployment to the last completed deployment state when a CloudWatch alarm sets the deployment to a failed state, select **Rollback on failures**.

9. (Optional) To interconnect your service using Service Connect, expand **Service Connect**, and then specify the following:

- a. Select **Turn on Service Connect**.
- b. Under **Service Connect configuration**, specify the client mode.
  - If your service runs a network client application that only needs to connect to other services in the namespace, choose **Client side only**.
  - If your service runs a network or web service application and needs to provide endpoints for this service, and connects to other services in the namespace, choose **Client and server**.
- c. To use a namespace that is not the default cluster namespace, for **Namespace**, choose the service namespace. This can be a namespace created separately in the same AWS Region in your AWS account or a namespace in the same Region that is shared with your account using AWS Resource Access Manager (AWS RAM). For more information about shared AWS Cloud Map namespaces, see [Cross-account AWS Cloud Map namespace sharing](#) in the *AWS Cloud Map Developer Guide*.
- d. (Optional) Configure test traffic header rules for linear deployments. Under **Test traffic routing**, specify the following:
  - i. Select **Enable test traffic header rules** to route specific requests to the green service revision during testing.
  - ii. For **Header matching rules**, configure the criteria for routing test traffic:
    - **Header name**: Enter the name of the HTTP header to match (for example, X-Test-Version or User-Agent).
    - **Match type**: Choose the matching criteria:
      - **Exact match**: Route requests where the header value exactly matches the specified value
      - **Header present**: Route requests that contain the specified header, regardless of value
      - **Pattern match**: Route requests where the header value matches a specified pattern
    - **Header value** (if using exact match or pattern match): Enter the value or pattern to match against.

You can add multiple header matching rules to create complex routing logic. Requests matching any of the configured rules will be routed to the green service revision for testing.

- iii. Choose **Add header rule** to configure additional header matching conditions.

 **Note**

Test traffic header rules enable you to validate new functionality with controlled traffic before completing the full deployment. This allows you to test the green service revision with specific requests (such as those from internal testing tools or beta users) while maintaining normal traffic flow to the blue service revision.

- e. (Optional) Specify a log configuration. Select **Use log collection**. The default option sends container logs to CloudWatch Logs. The other log driver options are configured using AWS FireLens. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

The following describes each container log destination in more detail.

- **Amazon CloudWatch** – Configure the task to send container logs to CloudWatch Logs. The default log driver options are provided, which create a CloudWatch log group on your behalf. To specify a different log group name, change the driver option values.
- **Amazon Data Firehose** – Configure the task to send container logs to Firehose. The default log driver options are provided, which send logs to a Firehose delivery stream. To specify a different delivery stream name, change the driver option values.
- **Amazon Kinesis Data Streams** – Configure the task to send container logs to Kinesis Data Streams. The default log driver options are provided, which send logs to an Kinesis Data Streams stream. To specify a different stream name, change the driver option values.
- **Amazon OpenSearch Service** – Configure the task to send container logs to an OpenSearch Service domain. The log driver options must be provided.

- **Amazon S3** – Configure the task to send container logs to an Amazon S3 bucket. The default log driver options are set by default, but you must specify a valid Amazon S3 bucket name.

10. (Optional) Configure **Load balancing** for linear deployment.

| Elastic Load Balancing type | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |

| Elastic Load Balancing type | Steps                                                                                                                                                                                                  |  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                             | <p>is the root directory (/).</p> <ul style="list-style-type: none"> <li>For <b>Alternate group name</b>, enter the group name for the target group for your test (green) service revision.</li> </ul> |  |

11. (Optional) To use VPC Lattice for managed traffic shifting during linear deployments, expand **VPC Lattice - optional** and select **Use VPC Lattice**, then do the following:
  - a. For **VPC**, choose the VPC for your VPC Lattice resources. This must be the same VPC as your Fargate service.
  - b. For **Infrastructure role**, choose the Amazon ECS infrastructure IAM role that Amazon ECS uses to manage your VPC Lattice resources, or choose **Create a new infrastructure role**.
  - c. For **Container port name**, choose the port name from the task definition that maps to the container port that receives traffic from VPC Lattice.
  - d. For **VPC Lattice service**, choose **Create a new service** or **Use an existing service**. For **Service name**, enter a unique name for the service.
  - e. For **Listener**, choose **Create new listener** or **Use an existing listener**. For **Port**, enter a port from 1 to 65535. For **Protocol**, choose the protocol (for example, **HTTP**).
  - f. Under **Production listener rule**, enter a **Name**, a **Priority** from 1 to 100, and a **Path pattern** (maximum 200 characters). Amazon ECS uses this rule to route production traffic.
  - g. (Optional, recommended) Under **Test listener rule**, enter a **Name**, a **Priority** from 1 to 100, and a **Path pattern**. Amazon ECS uses this rule to route test traffic to the green service revision.
  - h. For **Target groups**, choose **Create two new target groups**, **Create green target group**, or **Use two existing target groups**. For a new target group, enter a **Target group name**, choose a **Protocol**, enter a **Port** from 1 to 65535, choose a **Health check**

**protocol**, and enter a **Health check path**. For **Green target group name**, enter a name; the green target group uses the same configuration as the blue target group.

12. (Optional) To help identify your service and tasks, expand the **Tags** section, and then configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the task definition tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Task definitions**.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the service tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Service**.

Add or remove a tag.

- [Add a tag] Choose **Add tag**, and then do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
- [Remove a tag] Next to the tag, choose **Remove tag**.

13. Choose **Create**.

## AWS CLI

1. Create a file named `linear-service-definition.json` with the following content.

Replace the *user-input* with your values.

```
{
  "serviceName": "myLinearService",
  "cluster": "arn:aws:ecs:us-west-2:123456789012:cluster/sample-fargate-cluster",
  "taskDefinition": "sample-fargate:1",
  "desiredCount": 5,
  "launchType": "FARGATE",
  "networkConfiguration": {
    "awsvpcConfiguration": {
      "subnets": [
        "subnet-09ce6e74c116a2299",
        "subnet-00bb3bd7a73526788",
```

```

        "subnet-0048a611aaec65477"
    ],
    "securityGroups": [
        "sg-09d45005497daa123"
    ],
    "assignPublicIp": "ENABLED"
  }
},
"deploymentController": {
    "type": "ECS"
},

        "containerName": "fargate-app",
        "containerPort": 80,
        "advancedConfiguration": {
            "alternateTargetGroupArn": "arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/green-target-group/cad10a56f5843199",
            "productionListenerRule": "arn:aws:elasticloadbalancing:us-
west-2:123456789012:listener-rule/app/my-linear-
demo/32e0e4f946c3c05b/9cfa8c482e204f7d/831dbaf72edb911",
            "roleArn": "arn:aws:iam::123456789012:role/LoadBalancerManagementforECS"
        }
    }
]

```

```
}
```

## 2. Run create-service.

```
aws ecs create-service --cli-input-json file://linear-service-definition.json
```

### Next steps

- Update the service to start the deployment. For more information, see [Updating an Amazon ECS service](#).
- Monitor the deployment process to ensure it follows the linear pattern:
  - The green service revision is created and scaled up
  - Traffic is shifted incrementally at the specified intervals
  - Each increment waits for the specified interval before the next shift
  - After all traffic is shifted, the bake time begins
  - After the bake time, the blue revision is terminated

## Amazon ECS canary deployments

Canary deployments first route a small percentage of traffic to the new revision for initial testing, then shift all remaining traffic at once after the canary phase completes successfully. With Amazon ECS canary deployments, validate new service revisions with real user traffic while minimizing risk exposure. This approach provides a controlled way to deploy changes with the ability to monitor performance and roll back quickly if issues are detected.

### Resources involved in a canary deployment

The following are resources involved in Amazon ECS canary deployments:

- Traffic shift - The process Amazon ECS uses to shift production traffic. For Amazon ECS canary deployments, traffic is shifted in two phases: first to the canary percentage, then to complete the deployment.
- Canary percentage - The percentage of traffic routed to the new version during the evaluation period.
- Canary bake time - The duration to monitor the canary version before proceeding with full deployment.

- **Deployment bake time** - The time, in minutes, Amazon ECS waits after shifting all production traffic to the new service revision, before it terminates the old service revision. This is the duration when both blue and green service revisions are running simultaneously after the production traffic has shifted.
- **Lifecycle stages** - A series of events in the deployment operation, such as "after production traffic shift".
- **Lifecycle hook** - A Lambda function or pause point at a specific lifecycle stage. Lambda hooks invoke Lambda functions that you have defined to run custom code. Pause hooks pause the deployment and wait for you to call `ContinueServiceDeployment` to proceed.
- **Target group** - An Elastic Load Balancing or VPC Lattice resource used to route requests to one or more registered targets (for example, EC2 instances). When you create a listener, you specify a target group for its default action. Traffic is forwarded to the target group specified in the listener rule.
- **Listener** - An Elastic Load Balancing or VPC Lattice resource that checks for connection requests using the protocol and port that you configure. The rules that you define for a listener determine how Amazon ECS routes requests to its registered targets.
- **Rule** - An Elastic Load Balancing or VPC Lattice resource associated with a listener. A rule defines how requests are routed and consists of an action, condition, and priority.

## Considerations

Consider the following when choosing a deployment type:

- **Resource usage:** Canary deployments run both original and canary task sets simultaneously during the evaluation period, increasing resource usage.
- **Traffic volume:** Ensure the canary percentage generates sufficient traffic for meaningful validation of the new version.
- **Monitoring complexity:** Canary deployments require monitoring and comparing metrics between two different versions simultaneously.
- **Rollback speed:** Canary deployments enable quick rollback by shifting traffic back to the original task set.
- **Risk mitigation:** Canary deployments provide excellent risk mitigation by limiting exposure to a small percentage of users.
- **Deployment duration:** Canary deployments include evaluation periods that extend the overall deployment time but provide validation opportunities.

## How canary deployments work

The Amazon ECS Canary deployment process follows a structured approach with six distinct phases that ensure safe and reliable application updates. Each phase serves a specific purpose in validating and transitioning your application from the current version (blue) to the new version (green).

1. **Preparation Phase:** Create the green environment alongside the existing blue environment.
2. **Deployment Phase:** Deploy the new service revision to the green environment. Amazon ECS launches new tasks using the updated service revision while the blue environment continues serving production traffic.
3. **Testing Phase:** Validate the green environment using test traffic routing. The Application Load Balancer directs test requests to the green environment while production traffic remains on blue.
4. **Canary Traffic Shifting Phase:** Shift configured percentage of traffic to the new green service revision during the canary phase, followed by shifting 100.0% of traffic to Green service revision.
5. **Monitoring Phase:** Monitor application health, performance metrics, and alarm states during the bake time period. A rollback operation is initiated when issues are detected.
6. **Completion Phase:** Finalize the deployment by terminating the blue environment.

The canary traffic shift phase follows these steps:

- **Initial** - The deployment begins with 100% of traffic routed to the blue (current) service revision. The green (new) service revision receives test traffic but no production traffic initially.
- **Canary traffic shifting** - This is a two step traffic shift strategy.
  - Step 1: 10.0% to green, 90.0% to blue
  - Step 2: 100.0% to green, 0.0% to blue
- **Canary bake time** - Waits for a configurable duration (canary bake time) after canary traffic shift to allow monitoring and validation of the new revision's performance with the increased traffic load.
- **Lifecycle hooks** - Optional Lambda functions or pause hooks can be configured at various lifecycle stages during the deployment to perform automated validation, monitoring, or custom logic. Hooks configured for `PRODUCTION_TRAFFIC_SHIFT` or `PRE_PRODUCTION_TRAFFIC_SHIFT` are invoked at every production traffic shift step.

## Deployment lifecycle stages

The canary deployment process progresses through distinct lifecycle stages, each with specific responsibilities and validation checkpoints. Understanding these stages helps you monitor deployment progress and troubleshoot issues effectively.

Each lifecycle stage can last up to 24 hours and in addition each traffic shift step in `PRODUCTION_TRAFFIC_SHIFT` can last upto 24 hours. We recommend that the value remains below the 24-hour mark. This is because asynchronous processes need time to trigger the hooks. The system times out, fails the deployment, and then initiates a rollback after a stage reaches 24 hours.

CloudFormation deployments have additional timeout restrictions. While the 24-hour stage limit remains in effect, CloudFormation enforces a 36-hour limit on the entire deployment. CloudFormation fails the deployment, and then initiates a rollback if the process doesn't complete within 36 hours.

For pause hooks, you can configure the timeout up to 20,160 minutes (14 days). The overall deployment timeout is 30 days.

### Lifecycle stages

| Lifecycle stages  | Description                                                                                                                                             | Lifecycle hook support |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| RECONCILE_SERVICE | This stage only happens when you start a new service deployment with more than 1 service revision in an ACTIVE state.                                   | Yes                    |
| PRE_SCALE_UP      | The green service revision has not started. The blue service revision is handling 100% of the production traffic. There is no test traffic.             | Yes                    |
| SCALE_UP          | The time when the green service revision scales up to 100% and launches new tasks. The green service revision is not serving any traffic at this point. | No                     |

| Lifecycle stages              | Description                                                                                                                                                                                  | Lifecycle hook support |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| POST_SCALE_UP                 | The green service revision has started. The blue service revision is handling 100% of the production traffic. There is no test traffic.                                                      | Yes                    |
| TEST_TRAFFIC_SHIFT            | The blue and green service revisions are running. The blue service revision handles 100% of the production traffic. The green service revision is migrating from 0% to 100% of test traffic. | Yes (Lambda only)      |
| POST_TEST_TRAFFIC_SHIFT       | The test traffic shift is complete. The green service revision handles 100% of the test traffic.                                                                                             | Yes                    |
| PRE_PRODUCTION_TRAFFIC_SHIFT  | Occurs before each production traffic shift step. For canary, this occurs before the canary traffic shift and before the remaining traffic shift.                                            | Yes                    |
| PRODUCTION_TRAFFIC_SHIFT      | Canary production traffic is routed to green revision and lifecycle hook is invoked with 24 hours timeout. The second step shifts remaining production traffic to green revision.            | Yes (Lambda only)      |
| POST_PRODUCTION_TRAFFIC_SHIFT | The production traffic shift is complete.                                                                                                                                                    | Yes                    |
| BAKE_TIME                     | The duration when both blue and green service revisions are running simultaneously.                                                                                                          | No                     |
| CLEAN_UP                      | The blue service revision has completely scaled down to 0 running tasks. The green service revision is now the production service revision after this stage.                                 | No                     |

## Configuration parameters

Canary deployments require the following configuration parameters:

- **Canary percentage** - The percentage of traffic to route to the new service revision during the canary phase. This allows testing with a controlled subset of production traffic.
- **Canary bake time** - The duration to wait during the canary phase before shifting the remaining traffic to the new service revision. This provides time to monitor and validate the new version.

## Traffic management

Canary deployments use load balancer target groups to manage traffic distribution:

- **Original target group** - Contains tasks from the current stable version and receives the majority of traffic.
- **Canary target group** - Contains tasks from the new version and receives a small percentage of traffic for testing.
- **Weighted routing** - The load balancer uses weighted routing rules to distribute traffic between the target groups based on the configured canary percentage.

## Monitoring and validation

Effective canary deployments rely on comprehensive monitoring:

- **Health checks** - Both task sets must pass health checks before receiving traffic.
- **Metrics comparison** - Compare key performance indicators between the original and canary versions, such as response time, error rate, and throughput.
- **Automated rollback** - Configure CloudWatch alarms to automatically trigger rollback if the canary version shows degraded performance.
- **Manual validation** - Use the evaluation period to manually review logs, metrics, and user feedback before proceeding.

## Best practices for canary deployments

Follow these best practices to ensure successful canary deployments with services.

## Choose appropriate traffic percentages

Consider these factors when selecting canary traffic percentages:

- Start small - Begin with 5-10% of traffic to minimize impact if issues occur.
- Consider application criticality - Use smaller percentages for mission-critical applications and larger percentages for less critical services.
- Account for traffic volume - Ensure the canary percentage generates sufficient traffic for meaningful validation.

## Set appropriate evaluation periods

Configure evaluation periods based on these considerations:

- Allow sufficient time - Set evaluation periods long enough to capture meaningful performance data, typically 10-30 minutes.
- Consider traffic patterns - Account for your application's traffic patterns and peak usage times.
- Balance speed and safety - Longer evaluation periods provide more data but slow deployment velocity.

## Implement comprehensive monitoring

Set up monitoring to track canary deployment performance:

- Key metrics - Monitor response time, error rate, throughput, and resource utilization for both task sets.
- Alarm-based rollback - Configure CloudWatch alarms to automatically trigger rollback when metrics exceed thresholds.
- Comparative analysis - Set up dashboards to compare metrics between original and canary versions side-by-side.
- Business metrics - Include business-specific metrics like conversion rates or user engagement alongside technical metrics.

## Plan rollback strategies

Prepare for potential rollback scenarios with these strategies:

- Automated rollback - Configure automatic rollback triggers based on health checks and performance metrics.
- Manual rollback procedures - Document clear procedures for manual rollback when automated triggers don't capture all issues.
- Rollback testing - Regularly test rollback procedures to ensure they work correctly when needed.

## **Validate thoroughly before deployment**

Ensure thorough validation before proceeding with canary deployments:

- Pre-deployment testing - Thoroughly test changes in staging environments before canary deployment.
- Health check configuration - Ensure health checks accurately reflect application readiness and functionality.
- Dependency validation - Verify that new versions are compatible with downstream and upstream services.
- Data consistency - Ensure database schema changes and data migrations are backward compatible.

## **Coordinate team involvement**

Ensure effective team coordination during canary deployments:

- Deployment windows - Schedule canary deployments during business hours when teams are available to monitor and respond.
- Communication channels - Establish clear communication channels for deployment status and issue escalation.
- Role assignments - Define roles and responsibilities for monitoring, decision-making, and rollback execution.

## **Required resources for Amazon ECS canary deployments**

To use a canary deployment with managed traffic shifting, your service must use one of the following features:

- Elastic Load Balancing

- Service Connect
- VPC Lattice

The following list provides a high-level overview of what you need to configure for Amazon ECS canary deployments:

- Your service uses an Application Load Balancer, Network Load Balancer, Service Connect, or VPC Lattice. Configure the appropriate resources.
  - Application Load Balancer - For more information, see [Application Load Balancer resources for blue/green, linear, and canary deployments](#).
  - Network Load Balancer - For more information, see [Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments](#).
  - Service Connect - For more information, see [Service Connect resources for Amazon ECS blue/green, linear, and canary deployments](#).
  - VPC Lattice - For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).
- Set the service deployment controller to ECS.
- Configure the deployment strategy as canary in your service definition.
- Optionally, configure additional parameters such as:
  - Bake time for the new deployment
  - The percentage of traffic to route to the new service revision during the canary phase.
  - The duration to wait during the canary phase before shifting the remaining traffic to the new service revision.
  - CloudWatch alarms for automatic rollback
  - Deployment lifecycle hooks (Lambda functions or pause hooks that run at specified deployment stages)

## Best practices

Follow these best practices for successful Amazon ECS canary deployments:

- **Ensure your application can handle both service revisions running simultaneously.**
- **Plan for sufficient cluster capacity to handle both service revisions during deployment.**
- **Test your rollback procedures before implementing them in production.**

- Configure appropriate health checks that accurately reflect your application's health.
- Set a bake time that allows sufficient testing of the green deployment.
- Implement CloudWatch alarms to automatically detect issues and trigger rollbacks.
- Use lifecycle hooks to perform automated testing at each deployment stage.
- Start with small canary percentages (5-10%) to minimize impact if issues occur.
- Set appropriate evaluation periods that allow sufficient time for meaningful performance data collection.
- Implement comprehensive monitoring with CloudWatch alarms for automated rollback triggers.
- Configure health checks that accurately reflect your application's readiness and functionality.
- Monitor both technical metrics (response time, error rate) and business metrics during evaluation.
- Ensure your application can handle traffic splitting without session or state issues.
- Plan rollback procedures and test them regularly to ensure they work when needed.
- Schedule canary deployments during business hours when teams can monitor and respond.
- Validate changes thoroughly in staging environments before canary deployment.
- Document clear procedures for manual intervention and rollback decisions.

## Creating an Amazon ECS canary deployment

By using Amazon ECS canary deployments, you can shift a small percentage of traffic to your new service revision (the "canary"). Validate the deployment, and then shift the remaining traffic all at once after a specified interval. This approach allows you to test new functionality with minimal risk before full deployment.

### Prerequisites

Perform the following operations before you start a canary deployment.

1. Configure the appropriate permissions.
  - For information about Elastic Load Balancing permissions, see [Amazon ECS infrastructure IAM role for load balancers](#).
  - If you're using VPC Lattice, for information about VPC Lattice permissions, see [AmazonECSInfrastructureRolePolicyForVpcLattice](#).
  - For information about Lambda permissions, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#).

2. Amazon ECS canary deployments require that your service to use one of the following features:  
Configure the appropriate resources.
- Application Load Balancer - For more information, see [Application Load Balancer resources for blue/green, linear, and canary deployments](#).
  - Network Load Balancer - For more information, see [Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments](#).
  - Service Connect - For more information, see [Service Connect resources for Amazon ECS blue/green, linear, and canary deployments](#).
  - VPC Lattice - For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).

Procedure

You can use the console or the AWS CLI to create an Amazon ECS canary deployment service.

Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. Determine the resource from where you launch the service.

| To start a service from | Steps                                                                                                                                                                                                          |  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Clusters                | <div><div>a. On the <b>Clusters</b> page, select the cluster to create the service in.</div><div>The cluster details page displays.</div><div>b. On the <b>Services</b> tab, choose <b>Create</b>.</div></div> |  |
| Task definition         | <div><div>a. On the <b>Task definitions</b> page, select the task definition.</div><div>b. From the <b>Deploy</b> menu, choose <b>Create service</b>.</div></div>                                              |  |

The **Create service** page displays.

- Under **Service details**, do the following:
  - For **Task definition family**, choose the task definition to use. Then, for **Task definition revision**, enter the revision to use.
  - For **Service name**, enter a name for your service.
- To run the service in an existing cluster, for **Existing cluster**, choose the cluster. To run the service in a new cluster, choose **Create cluster**
- Choose how your tasks are distributed across your cluster infrastructure. Under **Compute configuration**, choose your option.

| Compute option             | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Capacity provider strategy | <div><div><div>a. Under <b>Compute options</b>, choose <b>Capacity provider strategy</b>.</div><div>b. Choose a strategy:<ul style="list-style-type: none"><li>To use the cluster's default capacity provider strategy, choose <b>Use cluster default</b>.</li><li>If your cluster doesn't have a default capacity provider strategy, or to use a custom strategy, choose <b>Use custom, Add capacity provider strategy</b>, and then define your custom capacity provider strategy by specifyin</li></ul></div></div></div> |  |

| Compute option | Steps                                                                                                                                                                                                                                                                                                                                                                       |  |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                | <p>g a <b>Base</b>, <b>Capacity provider</b>, and <b>Weight</b>.</p> <div data-bbox="665 367 1068 777"> <p> <b>Note</b></p> <p>To use a capacity provider in a strategy, the capacity provider must be associated with the cluster.</p> </div>                                             |  |
| Launch type    | <ol style="list-style-type: none"> <li>In the <b>Compute options</b> section, select <b>Launch type</b>.</li> <li>For <b>Launch type</b>, choose a launch type.</li> <li>(Optional) When the Fargate is specified, for <b>Platform version</b>, specify the platform version to use. If a platform version isn't specified, the LATEST platform version is used.</li> </ol> |  |

6. Under **Deployment configuration**, do the following:
  - For **Service type**, choose **Replica**.
  - For **Desired tasks**, enter the number of tasks to launch and maintain in the service.
  - To have Amazon ECS monitor the distribution of tasks across Availability Zones, and redistribute them when there is an imbalance, under **Availability Zone service rebalancing**, select **Availability Zone service rebalancing**.

- d. For **Health check grace period**, enter the amount of time (in seconds) that the service scheduler ignores unhealthy Elastic Load Balancing, VPC Lattice, and container health checks after a task has first started. If you do not specify a health check grace period value, the default value of 0 is used.
7. Under **Deployment configuration**, configure the canary deployment settings:
  - a. For **Deployment strategy**, choose **Canary**.
  - b. For **Canary percentage**, enter the percentage of traffic to shift to the green service revision in the first stage (for example, 10% for the initial canary traffic).
  - c. For **Canary bake time**, enter the time in minutes to wait before shifting the remaining traffic to the green service revision.
  - d. For **Bake time**, enter the number of minutes that both the blue and green service revisions will run simultaneously after the final traffic shift before the blue revision is terminated.
  - e. (Optional) Configure lifecycle hooks to run at specific stages of the deployment. Under **Deployment lifecycle hooks**, choose **Add**.

For Lambda hooks:

- For **Target type**, choose **Lambda**.
- For **Lambda function**, enter the function name or ARN.
- For **Role**, select the IAM role that has permission to invoke the Lambda function.
- For **Lifecycle stages**, select the stages when the Lambda function should run.

For pause hooks:

- For **Target type**, choose **Pause**.
- For **Lifecycle stages**, select the stages where the deployment should pause.
- (Optional) For **Timeout**, configure the timeout duration and action.

8. To configure how Amazon ECS detects and handles deployment failures, expand **Deployment failure detection**, and then choose your options.
  - a. To stop a deployment when the tasks cannot start, select **Use the Amazon ECS deployment circuit breaker**.

To have the software automatically roll back the deployment to the last completed deployment state when the deployment circuit breaker sets the deployment to a failed state, select **Rollback on failures**.

- b. To stop a deployment based on application metrics, select **Use CloudWatch alarm(s)**. Then, from **CloudWatch alarm name**, choose the alarms. To create a new alarm, go to the CloudWatch console.

To have the software automatically roll back the deployment to the last completed deployment state when a CloudWatch alarm sets the deployment to a failed state, select **Rollback on failures**.

9. (Optional) To interconnect your service using Service Connect, expand **Service Connect**, and then specify the following:
  - a. Select **Turn on Service Connect**.
  - b. Under **Service Connect configuration**, specify the client mode.
    - If your service runs a network client application that only needs to connect to other services in the namespace, choose **Client side only**.
    - If your service runs a network or web service application and needs to provide endpoints for this service, and connects to other services in the namespace, choose **Client and server**.
  - c. To use a namespace that is not the default cluster namespace, for **Namespace**, choose the service namespace. This can be a namespace created separately in the same AWS Region in your AWS account or a namespace in the same Region that is shared with your account using AWS Resource Access Manager (AWS RAM). For more information about shared AWS Cloud Map namespaces, see [Cross-account AWS Cloud Map namespace sharing](#) in the *AWS Cloud Map Developer Guide*.
  - d. (Optional) Configure test traffic header rules for canary deployments. Under **Test traffic routing**, specify the following:
    - i. Select **Enable test traffic header rules** to route specific requests to the green service revision during testing.
    - ii. For **Header matching rules**, configure the criteria for routing test traffic:
      - **Header name:** Enter the name of the HTTP header to match (for example, X-Test-Version or User-Agent).

- **Match type:** Choose the matching criteria:
  - **Exact match:** Route requests where the header value exactly matches the specified value
  - **Header present:** Route requests that contain the specified header, regardless of value
  - **Pattern match:** Route requests where the header value matches a specified pattern
- **Header value** (if using exact match or pattern match): Enter the value or pattern to match against.

You can add multiple header matching rules to create complex routing logic. Requests matching any of the configured rules will be routed to the green service revision for testing.

- iii. Choose **Add header rule** to configure additional header matching conditions.

 **Note**

Test traffic header rules enable you to validate new functionality with controlled traffic before completing the full deployment. This allows you to test the green service revision with specific requests (such as those from internal testing tools or beta users) while maintaining normal traffic flow to the blue service revision.

- e. (Optional) Specify a log configuration. Select **Use log collection**. The default option sends container logs to CloudWatch Logs. The other log driver options are configured using AWS FireLens. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

The following describes each container log destination in more detail.

- **Amazon CloudWatch** – Configure the task to send container logs to CloudWatch Logs. The default log driver options are provided, which create a CloudWatch log group on your behalf. To specify a different log group name, change the driver option values.

- **Amazon Data Firehose** – Configure the task to send container logs to Firehose. The default log driver options are provided, which send logs to a Firehose delivery stream. To specify a different delivery stream name, change the driver option values.
- **Amazon Kinesis Data Streams** – Configure the task to send container logs to Kinesis Data Streams. The default log driver options are provided, which send logs to an Kinesis Data Streams stream. To specify a different stream name, change the driver option values.
- **Amazon OpenSearch Service** – Configure the task to send container logs to an OpenSearch Service domain. The log driver options must be provided.
- **Amazon S3** – Configure the task to send container logs to an Amazon S3 bucket. The default log driver options are set by default, but you must specify a valid Amazon S3 bucket name.

10. (Optional) Configure **Load balancing** for canary deployment.

| Elastic Load Balancing type | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                   |  |

| Elastic Load Balancing type | Steps                                                                                                                                                                                                  |  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                             | <p>is the root directory (/).</p> <ul style="list-style-type: none"> <li>For <b>Alternate group name</b>, enter the group name for the target group for your test (green) service revision.</li> </ul> |  |

11. (Optional) To use VPC Lattice for managed traffic shifting during canary deployments, expand **VPC Lattice - optional** and select **Use VPC Lattice**, then do the following:
  - a. For **VPC**, choose the VPC for your VPC Lattice resources. This must be the same VPC as your Fargate service.
  - b. For **Infrastructure role**, choose the Amazon ECS infrastructure IAM role that Amazon ECS uses to manage your VPC Lattice resources, or choose **Create a new infrastructure role**.
  - c. For **Container port name**, choose the port name from the task definition that maps to the container port that receives traffic from VPC Lattice.
  - d. For **VPC Lattice service**, choose **Create a new service** or **Use an existing service**. For **Service name**, enter a unique name for the service.
  - e. For **Listener**, choose **Create new listener** or **Use an existing listener**. For **Port**, enter a port from 1 to 65535. For **Protocol**, choose the protocol (for example, **HTTP**).
  - f. Under **Production listener rule**, enter a **Name**, a **Priority** from 1 to 100, and a **Path pattern** (maximum 200 characters). Amazon ECS uses this rule to route production traffic.
  - g. (Optional, recommended) Under **Test listener rule**, enter a **Name**, a **Priority** from 1 to 100, and a **Path pattern**. Amazon ECS uses this rule to route test traffic to the green service revision.
  - h. For **Target groups**, choose **Create two new target groups**, **Create green target group**, or **Use two existing target groups**. For a new target group, enter a **Target group name**, choose a **Protocol**, enter a **Port** from 1 to 65535, choose a **Health check**

**protocol**, and enter a **Health check path**. For **Green target group name**, enter a name; the green target group uses the same configuration as the blue target group.

12. (Optional) To help identify your service and tasks, expand the **Tags** section, and then configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the task definition tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Task definitions**.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the service tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Service**.

Add or remove a tag.

- [Add a tag] Choose **Add tag**, and then do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
- [Remove a tag] Next to the tag, choose **Remove tag**.

13. Choose **Create**.

## AWS CLI

1. Create a file named `canary-service-definition.json` with the following content.

Replace the *user-input* with your values.

```
{
  "serviceName": "myCanaryService",
  "cluster": "arn:aws:ecs:us-west-2:123456789012:cluster/sample-fargate-cluster",
  "taskDefinition": "sample-fargate:1",
  "desiredCount": 5,
  "launchType": "FARGATE",
  "networkConfiguration": {
    "awsvpcConfiguration": {
      "subnets": [
        "subnet-09ce6e74c116a2299",
        "subnet-00bb3bd7a73526788",
```

```

        "subnet-0048a611aaec65477"
    ],
    "securityGroups": [
        "sg-09d45005497daa123"
    ],
    "assignPublicIp": "ENABLED"
  }
},
"deploymentController": {
    "type": "ECS"
},
"deploymentConfiguration": {
    "strategy": "CANARY",
    "maximumPercent": 200,
    "minimumHealthyPercent": 100,
    "canaryConfiguration" : {
        "canaryPercent" : 5.0,
        "canaryBakeTime" : 10
    },
    "bakeTimeInMinutes": 10,
    "alarms": {
        "alarmNames": [
            "myAlarm"
        ],
        "rollback": true,
        "enable": true
    }
},
"loadBalancers": [
    {
        "targetGroupArn": "arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/blue-target-group/54402ff563af1197",
        "containerName": "fargate-app",
        "containerPort": 80,
        "advancedConfiguration": {
            "alternateTargetGroupArn": "arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/green-target-group/cad10a56f5843199",
            "productionListenerRule": "arn:aws:elasticloadbalancing:us-
west-2:123456789012:listener-rule/app/my-canary-
demo/32e0e4f946c3c05b/9cfa8c482e204f7d/831dbaf72edb911",
            "roleArn": "arn:aws:iam::123456789012:role/LoadBalancerManagementforECS"
        }
    }
]

```

```
}
```

## 2. Run `create-service`.

```
aws ecs create-service --cli-input-json file://canary-service-definition.json
```

## Next steps

After configuring your canary deployment, complete these steps:

- Update the service to start the deployment. For more information, see [Updating an Amazon ECS service](#).
- Monitor the deployment process to ensure it follows the canary pattern:
  - The green service revision is created and scaled up
  - A small percentage of traffic (canary) is shifted to the green revision
  - The system waits for the specified canary interval
  - The remaining traffic is shifted all at once to the green revision
  - After the bake time, the blue revision is terminated

## Deployment terminology

The following terms are used throughout the Amazon ECS deployment documentation:

### Blue-green deployment

A deployment strategy that creates a new environment (green) alongside the existing environment (blue), then switches traffic from blue to green after validation.

### Canary deployment

A deployment strategy that routes a small percentage of traffic to a new version while maintaining the majority on the stable version for validation.

### Linear deployment

A deployment strategy that gradually shifts traffic from the old version to the new version in equal increments over time.

## Rolling deployment

A deployment strategy that replaces instances of the old version with instances of the new version one at a time.

## Task set

A collection of tasks that run the same task definition within a service during a deployment.

## Target group

A logical grouping of targets that receive traffic from a load balancer during deployments.

## Deployment controller

The method used to deploy new versions of your service, such as Amazon ECS, CodeDeploy, or external controllers.

## Rollback

The process of reverting to a previous version of your application when issues are detected during deployment.

## Deploy Amazon ECS services using a third-party controller

The *external* deployment type allows you to use any third-party deployment controller for full control over the deployment process for an Amazon ECS service. The details for your service are managed by either the service management API actions (`CreateService`, `UpdateService`, and `DeleteService`) or the task set management API actions (`CreateTaskSet`, `UpdateTaskSet`, `UpdateServicePrimaryTaskSet`, and `DeleteTaskSet`). Each API action manages a subset of the service definition parameters.

The `UpdateService` API action updates the desired count and health check grace period parameters for a service. If the compute option, platform version, load balancer details, network configuration, or task definition need to be updated, you must create a new task set.

The `UpdateTaskSet` API action updates only the scale parameter for a task set.

The `UpdateServicePrimaryTaskSet` API action modifies which task set in a service is the primary task set. When you call the `DescribeServices` API action, it returns all fields specified for a primary task set. If the primary task set for a service is updated, any task set parameter values

that exist on the new primary task set that differ from the old primary task set in a service are updated to the new value when a new primary task set is defined. If no primary task set is defined for a service, when describing the service, the task set fields are null.

## External deployment considerations

Consider the following when using the external deployment type:

- The supported load balancer types are either an Application Load Balancer or a Network Load Balancer.
- The Fargate or EXTERNAL deployment controller types don't support the DAEMON scheduling strategy.
- Application AutoScaling integration with Amazon ECS only supports Amazon ECS service as a target. The supported scalable dimension for Amazon ECS is `ecs:service:DesiredCount` - the task count of an Amazon ECS service. There is no direct integration between Application AutoScaling and Amazon ECS task sets. Amazon ECS task sets calculate the `ComputedDesiredCount` based on the Amazon ECS service `DesiredCount`.

## External deployment workflow

The following is the basic workflow for managing an external deployment on Amazon ECS.

### To manage an Amazon ECS service using an external deployment controller

1. Create an Amazon ECS service. The only required parameter is the service name. You can specify the following parameters when creating a service using an external deployment controller. All other service parameters are specified when creating a task set within the service.

`serviceName`

Type: String

Required: Yes

The name of your service. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed. Service names must be unique within a cluster, but you can have similarly named services in multiple clusters within a Region or across multiple Regions.

## desiredCount

The number of instantiations of the specified task set task definition to place and keep running within the service.

## deploymentConfiguration

Optional deployment parameters that control how many tasks run during a deployment and the ordering of stopping and starting tasks.

## tags

Type: Array of objects

Required: No

The metadata that you apply to the service to help you categorize and organize them. Each tag consists of a key and an optional value, both of which you define. When a service is deleted, the tags are deleted as well. A maximum of 50 tags can be applied to the service. For more information, see [Tagging Amazon ECS resources](#).

When you update a service, this parameter doesn't trigger a new service deployment.

## key

Type: String

Length Constraints: Minimum length of 1. Maximum length of 128.

Required: No

One part of a key-value pair that make up a tag. A key is a general label that acts like a category for more specific tag values.

## value

Type: String

Length Constraints: Minimum length of 0. Maximum length of 256.

Required: No

The optional part of a key-value pair that make up a tag. A value acts as a descriptor **within a tag category (key)**.

## enableECSTags

Specifies whether to use Amazon ECS managed tags for the tasks within the service. For more information, see [Use tags for billing](#).

## propagateTags

Type: String

Valid values: TASK\_DEFINITION | SERVICE

Required: No

Specifies whether to copy the tags from the task definition or the service to the tasks in the service. If no value is specified, the tags are not copied. Tags can only be copied to the tasks within the service during service creation. To add tags to a task after service creation or task creation, use the TagResource API action.

When you update a service, this parameter doesn't trigger a new service deployment.

## schedulingStrategy

The scheduling strategy to use. Services using an external deployment controller support only the REPLICA scheduling strategy.

## placementConstraints

An array of placement constraint objects to use for tasks in your service. You can specify a maximum of 10 constraints per task (this limit includes constraints in the task definition and those specified at run time). If you are using Fargate, task placement constraints aren't supported.

## placementStrategy

The placement strategy objects to use for tasks in your service. You can specify a maximum of four strategy rules per service.

The following is an example service definition for creating a service using an external deployment controller.

```
{
  "cluster": "",
  "serviceName": ""
```

```
"desiredCount": 0,
"role": "",
"deploymentConfiguration": {
  "maximumPercent": 0,
  "minimumHealthyPercent": 0
},
"placementConstraints": [
  {
    "type": "distinctInstance",
    "expression": ""
  }
],
"placementStrategy": [
  {
    "type": "binpack",
    "field": ""
  }
],
"schedulingStrategy": "REPLICA",
"deploymentController": {
  "type": "EXTERNAL"
},
"tags": [
  {
    "key": "",
    "value": ""
  }
],
"enableECSTags": true,
"propagateTags": "TASK_DEFINITION"
}
```

2. Create an initial task set. The task set contains the following details about your service:

#### taskDefinition

The task definition for the tasks in the task set to use.

#### launchType

Type: String

Valid values: EC2 | FARGATE | EXTERNAL

Required: No

The launch type on which to run your service. If a launch type is not specified, the default `capacityProviderStrategy` is used by default.

When you update a service, this parameter triggers a new service deployment.

If a `launchType` is specified, the `capacityProviderStrategy` parameter must be omitted.

## `platformVersion`

Type: String

Required: No

The platform version on which your tasks in the service are running. A platform version is only specified for tasks using the Fargate launch type. If one is not specified, the latest version (LATEST) is used by default.

When you update a service, this parameter triggers a new service deployment.

AWS Fargate platform versions are used to refer to a specific runtime environment for the Fargate task infrastructure. When specifying the LATEST platform version when running a task or creating a service, you get the most current platform version available for your tasks. When you scale up your service, those tasks receive the platform version that was specified on the service's current deployment. For more information, see [Fargate platform versions for Amazon ECS](#).

### Note

Platform versions are not specified for tasks using the EC2 launch type.

## `loadBalancers`

A load balancer object representing the load balancer to use with your service. When using an external deployment controller, only Application Load Balancers and Network Load Balancers are supported. If you're using an Application Load Balancer, only one Application Load Balancer target group is allowed per task set.

The following snippet shows an example `loadBalancer` object to use.

```
"loadBalancers": [  
  {  
    "targetGroupArn": "",  
    "containerName": "",  
    "containerPort": 0  
  }  
]
```

 **Note**

When specifying a `loadBalancer` object, you must specify a `targetGroupArn` and omit the `loadBalancerName` parameters.

## `networkConfiguration`

The network configuration for the service. This parameter is required for task definitions that use the `awsvpc` network mode to receive their own elastic network interface, and it's not supported for other network modes. For more information about networking for the Fargate, see [Amazon ECS task networking options for Fargate](#).

## `serviceRegistries`

The details of the service discovery registries to assign to this service. For more information, see [Use service discovery to connect Amazon ECS services with DNS names](#).

## `scale`

A floating-point percentage of the desired number of tasks to place and keep running in the task set. The value is specified as a percent total of a service's `desiredCount`. Accepted values are numbers between 0 and 100.

The following is a JSON example for creating a task set for an external deployment controller.

```
{  
  "service": "",  
  "cluster": "",  
  "externalId": "",
```

```
"taskDefinition": "",
"networkConfiguration": {
  "awsvpcConfiguration": {
    "subnets": [
      ""
    ],
    "securityGroups": [
      ""
    ],
    "assignPublicIp": "DISABLED"
  }
},
"loadBalancers": [
  {
    "targetGroupArn": "",
    "containerName": "",
    "containerPort": 0
  }
],
"serviceRegistries": [
  {
    "registryArn": "",
    "port": 0,
    "containerName": "",
    "containerPort": 0
  }
],
"launchType": "EC2",
"capacityProviderStrategy": [
  {
    "capacityProvider": "",
    "weight": 0,
    "base": 0
  }
],
"platformVersion": "",
"scale": {
  "value": null,
  "unit": "PERCENT"
},
"clientToken": ""
}
```

3. When service changes are needed, use the `UpdateService`, `UpdateTaskSet`, or `CreateTaskSet` API action depending on which parameters you're updating. If you created a task set, use the `scale` parameter for each task set in a service to determine how many tasks to keep running in the service. For example, if you have a service that contains `tasksetA` and you create a `tasksetB`, you might test the validity of `tasksetB` before wanting to transition production traffic to it. You could set the `scale` for both task sets to 100, and when you were ready to transition all production traffic to `tasksetB`, you could update the `scale` for `tasksetA` to 0 to scale it down.

## CodeDeploy blue/green deployments for Amazon ECS

We recommend that you use the Amazon ECS blue/green deployment. For more information, see [Creating an Amazon ECS blue/green deployment](#).

The *blue/green* deployment type uses the blue/green deployment model controlled by CodeDeploy. Use this deployment type to verify a new deployment of a service before sending production traffic to it. For more information, see [What Is CodeDeploy](#) in the *AWS CodeDeploy User Guide*. Validate the state of an Amazon ECS service before deployment

There are three ways traffic can shift during a blue/green deployment:

- **Canary** — Traffic is shifted in two increments. You can choose from predefined canary options that specify the percentage of traffic shifted to your updated task set in the first increment and the interval, in minutes, before the remaining traffic is shifted in the second increment.
- **Linear** — Traffic is shifted in equal increments with an equal number of minutes between each increment. You can choose from predefined linear options that specify the percentage of traffic shifted in each increment and the number of minutes between each increment.
- **All-at-once** — All traffic is shifted from the original task set to the updated task set all at once.

The following are components of CodeDeploy that Amazon ECS uses when a service uses the blue/green deployment type:

### CodeDeploy application

A collection of CodeDeploy resources. This consists of one or more deployment groups.

### CodeDeploy deployment group

The deployment settings. This consists of the following:

- Amazon ECS cluster and service
- Load balancer target group and listener information
- Deployment roll back strategy
- Traffic rerouting settings
- Original revision termination settings
- Deployment configuration
- CloudWatch alarms configuration that can be set up to stop deployments
- SNS or CloudWatch Events settings for notifications

For more information, see [Working with Deployment Groups](#) in the *AWS CodeDeploy User Guide*.

## CodeDeploy deployment configuration

Specifies how CodeDeploy routes production traffic to your replacement task set during a deployment. The following pre-defined linear and canary deployment configuration are available. You can also create custom defined linear and canary deployments as well. For more information, see [Working with Deployment Configurations](#) in the *AWS CodeDeploy User Guide*.

- **CodeDeployDefault.ECSAllAtOnce:** Shifts all traffic to the updated Amazon ECS container at once
- **CodeDeployDefault.ECSLinear10PercentEvery1Minutes:** Shifts 10 percent of traffic every minute until all traffic is shifted.
- **CodeDeployDefault.ECSLinear10PercentEvery3Minutes:** Shifts 10 percent of traffic every 3 minutes until all traffic is shifted.
- **CodeDeployDefault.ECSCanary10Percent5Minutes:** Shifts 10 percent of traffic in the first increment. The remaining 90 percent is deployed five minutes later.
- **CodeDeployDefault.ECSCanary10Percent15Minutes:** Shifts 10 percent of traffic in the first increment. The remaining 90 percent is deployed 15 minutes later.

## Revision

A revision is the CodeDeploy application specification file (AppSpec file). In the AppSpec file, you specify the full ARN of the task definition and the container and port of your replacement task set where traffic is to be routed when a new deployment is created. The container name must be one of the container names referenced in your task definition. If the network configuration or platform version has been updated in the service definition, you must also specify those details in the AppSpec file. You can also specify the Lambda functions to run

during the deployment lifecycle events. The Lambda functions allow you to run tests and return metrics during the deployment. For more information, see [AppSpec File Reference](#) in the *AWS CodeDeploy User Guide*.

## Considerations

Consider the following when using the blue/green deployment type:

- When an Amazon ECS service using the blue/green deployment type is initially created, an Amazon ECS task set is created.
- You must configure the service to use either an Application Load Balancer or Network Load Balancer. The following are the load balancer requirements:
  - You must add a production listener to the load balancer, which is used to route production traffic.
  - An optional test listener can be added to the load balancer, which is used to route test traffic. If you specify a test listener, CodeDeploy routes your test traffic to the replacement task set during a deployment.
  - Both the production and test listeners must belong to the same load balancer.
  - You must define a target group for the load balancer. The target group routes traffic to the original task set in a service through the production listener.
  - When a Network Load Balancer is used, only the `CodeDeployDefault.ECSAllAtOnce` deployment configuration is supported.
- For services configured to use service auto scaling and the blue/green deployment type, auto scaling is not blocked during a deployment but the deployment may fail under some circumstances. The following describes this behavior in more detail.
  - If a service is scaling and a deployment starts, the green task set is created and CodeDeploy will wait up to an hour for the green task set to reach steady state and won't shift any traffic until it does.
  - If a service is in the process of a blue/green deployment and a scaling event occurs, traffic will continue to shift for 5 minutes. If the service doesn't reach steady state within 5 minutes, CodeDeploy will stop the deployment and mark it as failed.
- Tasks using Fargate or the `CODE_DEPLOY` deployment controller types don't support the `DAEMON` scheduling strategy.
- When you initially create a CodeDeploy application and deployment group, you must specify the following:

- You must define two target groups for the load balancer. One target group should be the initial target group defined for the load balancer when the Amazon ECS service was created. The second target group's only requirement is that it can't be associated with a different load balancer than the one the service uses.
- When you create a CodeDeploy deployment for an Amazon ECS service, CodeDeploy creates a *replacement task set* (or *green task set*) in the deployment. If you added a test listener to the load balancer, CodeDeploy routes your test traffic to the replacement task set. This is when you can run any validation tests. Then CodeDeploy reroutes the production traffic from the original task set to the replacement task set according to the traffic rerouting settings for the deployment group.

## Required IAM permissions

Blue/green deployments are made possible by a combination of the Amazon ECS and CodeDeploy APIs. Users must have the appropriate permissions for these services before they can use Amazon ECS blue/green deployments in the AWS Management Console or with the AWS CLI or SDKs.

In addition to the standard IAM permissions for creating and updating services, Amazon ECS requires the following permissions. These permissions have been added to the AmazonECS\_FullAccess IAM policy. For more information, see [AmazonECS\\_FullAccess](#).

- `codedeploy:CreateApplication`
- `codedeploy:CreateDeployment`
- `codedeploy:CreateDeploymentGroup`
- `codedeploy:GetApplication`
- `codedeploy:GetDeployment`
- `codedeploy:GetDeploymentGroup`
- `codedeploy:ListApplications`
- `codedeploy:ListDeploymentGroups`
- `codedeploy:ListDeployments`
- `codedeploy:StopDeployment`
- `codedeploy:GetDeploymentTarget`
- `codedeploy:ListDeploymentTargets`
- `codedeploy:GetDeploymentConfig`

- `codedeploy:GetApplicationRevision`
- `codedeploy:RegisterApplicationRevision`
- `codedeploy:BatchGetApplicationRevisions`
- `codedeploy:BatchGetDeploymentGroups`
- `codedeploy:BatchGetDeployments`
- `codedeploy:BatchGetApplications`
- `codedeploy:ListApplicationRevisions`
- `codedeploy:ListDeploymentConfigs`
- `codedeploy:ContinueDeployment`
- `sns:ListTopics`
- `cloudwatch:DescribeAlarms`
- `lambda:ListFunctions`

#### Note

In addition to the standard Amazon ECS permissions required to run tasks and services, users also require `iam:PassRole` permissions to use IAM roles for tasks.

CodeDeploy needs permissions to call Amazon ECS APIs, modify your Elastic Load Balancing, invoke Lambda functions, and describe CloudWatch alarms, as well as permissions to modify your service's desired count on your behalf. Before creating an Amazon ECS service that uses the blue/green deployment type, you must create an IAM role (`ecsCodeDeployRole`). For more information, see [Amazon ECS CodeDeploy IAM Role](#).

## Migrate CodeDeploy blue/green deployments to Amazon ECS blue/green deployments

CodeDeploy blue/green and Amazon ECS blue/green deployments provide similar functionality, but they differ in how you configure and manage them.

### CodeDeploy blue/green deployment overview

When creating an Amazon ECS service using CodeDeploy, you:

1. Create a load balancer with a production listener and (optionally) a test listener. Each listener is configured with a single (default) rule that routes all traffic to a single target group (the primary target group).
2. Create an Amazon ECS service, configured to use the listener and target group, with `deploymentController` type set to `CODE_DEPLOY`. Service creation results in the creation of a (blue) task set registered with the specified target group.
3. Create a CodeDeploy deployment group (as part of a CodeDeploy application), and configure it with details of the Amazon ECS cluster, service name, load balancer listeners, two target groups (the primary target group used in the production listener rule, and a secondary target group to be used for replacement tasks), a service role (to grant CodeDeploy permissions to manipulate Amazon ECS and Elastic Load Balancing resources) and various parameters that control the deployment behavior.

With CodeDeploy, new versions of a service are deployed using `CreateDeployment()`, specifying the CodeDeploy application name, deployment group name, and an AppSpec file which provides details of the new revision and optional lifecycle hooks. The CodeDeploy deployment creates a replacement (green) task set and registers its tasks with the secondary target group. When this becomes healthy, it is available for testing (optional) and for production. In both cases, re-routing is achieved by changing the respective listener rule to point at the secondary target group associated with the green task set. Rollback is achieved by changing the production listener rule back to the primary target group.

## Amazon ECS blue/green deployment overview

With Amazon ECS blue/green deployments, The deployment configuration is part of the Amazon ECS service itself:

1. You must pre-configure the load balancer production listener with a rule that includes two target groups with weights of 1 and 0.
2. You need to specify the following resources, or update the service resources:
  - The ARN of this listener rule
  - The two target groups
  - An IAM role to grant Amazon ECS permission to call the Elastic Load Balancing APIs
  - An optional IAM role to run Lambda functions

- Set `deploymentController` type to ECS and `deploymentConfiguration.strategy` to `BLUE_GREEN`. This results in the creation of a (blue) service deployment whose tasks are registered with the primary target group.

With Amazon ECS blue/green, a new service revision is created by calling Amazon ECS `UpdateService()`, passing details of the new revision. The service deployment creates new (green) service revision tasks and registers them with the secondary target group. Amazon ECS handles re-routing and rollback operations by switching the weights on the listener rule.

## Key implementation differences

While both approaches result in the creation of an initial set of tasks, the underlying implementation differs:

- CodeDeploy uses a task set, whereas Amazon ECS uses a service revision. Amazon ECS task sets are an older construct which have been superseded by Amazon ECS service revisions and deployments. The latter offer greater visibility into the deployment process, as well as the service deployment and service revision history.
- With CodeDeploy, lifecycle hooks are specified as part of the AppSpec file that is supplied to `CreateDeployment()`. This means that the hooks can be changed from one deployment to the next. With Amazon ECS blue/green, the hooks are specified as part of the service configuration, and any updates would require an `UpdateService()` call.
- Both CodeDeploy and Amazon ECS blue/green use Lambda for hook implementation, but the expected inputs and outputs differ.

With CodeDeploy, the function must call `PutLifecycleEventHookExecutionStatus()` to return the hook status, which can either be `SUCCEEDED` or `FAILED`. With Amazon ECS, the Lambda response is used to indicate the hook status.

- CodeDeploy invokes each hook as a one-off call, and expects a final execution status to be returned within one hour. Amazon ECS hooks are more flexible in that they can return an `IN_PROGRESS` indicator, which signals that the hook must be re-invoked repeatedly until it results in `SUCCEEDED` or `FAILED`. For more information, see [Lifecycle hooks for Amazon ECS service deployments](#).

## Migration approaches

There are three main approaches to migrating from CodeDeploy blue/green to Amazon ECS blue/green deployments. Each approach has different characteristics in terms of complexity, risk, rollback capability, and potential downtime.

### Reuse the same Elastic Load Balancing resources used for CodeDeploy

You update the existing Amazon ECS service to use the Amazon ECS deployment controller with blue/green deployment strategy instead of CodeDeploy deployment controller. Consider the following when using this approach:

- The migration procedure is simpler because you are updating the existing Amazon ECS service deployment controller and deployment strategy.
- There is no downtime when correctly configured and migrated.
- A rollback requires that you revert the service revision.
- The risk is high because there is no parallel blue/green configuration.

You use the same load balancer listener and target groups that are used for CodeDeploy. If you are using CloudFormation, see [Migrating an CloudFormation CodeDeploy blue/green deployment template to an Amazon ECS blue/green CloudFormation template](#).

1. Modify the default rule of the production/test listeners to include the alternate target group and set the weight of the primary target group to 1 and the alternate target group to 0.

For CodeDeploy, the listeners of the load balancer attached to the service are configured with a single (default) rule that routes all traffic to a single target group. For Amazon ECS blue/green, the load balancer listeners must be pre-configured with a rule that includes the two target groups with weights. The primary target group must be weighted to 1 and the alternate target group must be weighted to 0.

2. Update the existing Amazon ECS service by calling the `UpdateService` API and setting the parameter `deploymentController` to `ECS`, and the parameter `deploymentStrategy` to `BLUE_GREEN`. Specify the ARNs of the target group, the alternative target group, the production listener, and an optional test listener.
3. Verify that the service works as expected.
4. Delete the CodeDeploy setup for this Amazon ECS service as you are now using Amazon ECS blue/green.

## New service with existing load balancer

This approach uses the blue/green strategy for the migration.

Consider the following when using this approach:

- There is minimal disruption. It occurs only during the Elastic Load Balancing port swap.
  - A rollback requires that you revert the Elastic Load Balancing port swap.
  - The risk is low because there are parallel configurations. Therefore you can test before the traffic shift.
1. Leave the listeners, the target groups, and the Amazon ECS service for the CodeDeploy setup intact so you can easily rollback to this setup if needed.
  2. Create new target groups and new listeners (with different ports from the original listeners) under the existing load balancer. Then, create a new Amazon ECS service that matches the existing Amazon ECS service except that you use ECS as deployment controller, BLUE\_GREEN as a deployment strategy, and pass the ARNs for the new target groups and the new listeners rules.
  3. Verify the new setup by manually sending HTTP traffic to the service. If everything goes well, swap the ports of the original listeners and the new listeners to route the traffic to the new setup.
  4. Verify the new setup, and if everything continues to work as expected, delete the CodeDeploy setup.

## New service with a new load balancer

Like the previous approach, this approach uses the blue/green strategy for the migration. The key difference is that the switch from the CodeDeploy setup to the Amazon ECS blue/green setup happens at a reverse proxy layer above the load balancer. Sample implementations for the reverse proxy layer are Route 53 and CloudFront.

This approach is suitable for customers who already have this reverse proxy layer, and if all the communication with the service is happening through it (for example, no direct communication at the load balancer level).

Consider the following when using this approach:

- This requires a reverse proxy layer.

- The migration procedure is more complex because you need to update the existing Amazon ECS service deployment controller and deployment strategy.
  - There is minimal disruption. It occurs only during the Elastic Load Balancing port swap.
  - A rollback requires that you reverse the proxy configuration changes.
  - The risk is low because there are parallel configurations. Therefore you can test before the traffic shift.
1. Do not modify the existing CodeDeploy setup intact (load balancer, listeners, target groups, Amazon ECS service, and CodeDeploy deployment group).
  2. Create a new load balancer, target groups, and listeners configured for Amazon ECS blue/green deployments.

Configure the appropriate resources.

- Application Load Balancer - For more information, see [Application Load Balancer resources for blue/green, linear, and canary deployments](#).
  - Network Load Balancer - For more information, see [Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments](#).
  - VPC Lattice - For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).
3. Create a new service with ECS as deployment controller and BLUE\_GREEN as deployment strategy, pointing to the new load balancer resources.
  4. Verify the new setup by testing it through the new load balancer.
  5. Update the reverse proxy configuration to route traffic to the new load balancer.
  6. Observe the new service revision, and if everything continues to work as expected, delete the CodeDeploy setup.

## Next steps

After migrating to Amazon ECS blue/green deployments:

- Update your deployment scripts and CI/CD pipelines to use the Amazon ECS UpdateService API instead of the CodeDeploy CreateDeployment API.
- Update your monitoring and alerting to track Amazon ECS service deployments instead of CodeDeploy deployments.

- Consider implementing automated testing of your new deployment process to ensure it works as expected.

## Migrating from a CodeDeploy blue/green to an Amazon ECS blue/green service deployment

By using Amazon ECS blue/green deployments, you can make and test service changes before implementing them in a production environment.

You must create new lifecycle hooks for your Amazon ECS blue/green deployment.

### Prerequisites

Perform the following operations before you start a blue/green deployment.

1. Replace the Amazon ECS CodeDeploy IAM role with the following permissions.
  - For information about Elastic Load Balancing permissions, see [Amazon ECS infrastructure IAM role for load balancers](#).
  - For information about Lambda permissions, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#).
2. Turn off CodeDeploy automation. For more information, see [Working with deployment groups in CodeDeploy](#) in the *CodeDeploy User Guide*.
3. Make sure that you have the following information from your CodeDeploy blue/green deployment. You can reuse this information for the Amazon ECS blue/green deployment:
  - The production target group
  - The production listener
  - The production rule
  - The test target group

This is the target group for the green service revision,

4. Ensure that your Application Load Balancer target groups are properly associated with listener rules:
  - If you are not using test listeners, both target groups (production and test) must be associated with production listener rules.
  - If you are using test listeners, one target group must be linked to production listener rules and the other target group must be linked to test listener rules.

If this requirement is not met, the service deployment will fail with the following error: Service deployment rolled back because of invalid networking configuration. Both `targetGroup` and `alternateTargetGroup` must be associated with the `productionListenerRule` or `testListenerRule`.

5. Verify that there are no ongoing service deployments for the service. For more information, see [View service history using Amazon ECS service deployments](#).
6. Amazon ECS blue/green deployments require your service to use one of the following features: Configure the appropriate resources.
  - Application Load Balancer - For more information, see [Application Load Balancer resources for blue/green, linear, and canary deployments](#).
  - Network Load Balancer - For more information, see [Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments](#).
  - Service Connect - For more information, see [Service Connect resources for Amazon ECS blue/green, linear, and canary deployments](#).
  - VPC Lattice - For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).
7. Decide if you want to run Lambda functions for the lifecycle stages for the stages in the Amazon ECS blue/green deployment.
  - Pre scale up
  - After scale up
  - Test traffic shift
  - After test traffic shift
  - Production traffic shift
  - After production traffic shift

Create Lambda functions for each lifecycle stage. For more information, see [Create a Lambda function with the console](#) in the *AWS Lambda Developer Guide*.

For more information about updating a service's deployment controller, see [Update Amazon ECS service parameters](#).

## Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.

2. On the **Clusters** page, choose the cluster.

The cluster details page displays.

3. From the **Services** tab, choose the service.

The service details page displays.

4. In the banner, choose **Update deployment controller type**.

The **Migrate deployment controller type** page displays.

5. Expand **New**, and then specify the following parameters.

- a. For **Deployment controller type**, choose **ECS**.
- b. For **Deployment strategy**, choose **Blue/green**.
- c. For **Bake time**, enter the time that both the blue and green service revisions run.
- d. To run Lambda functions for a lifecycle stage, under **Deployment lifecycle hooks** do the following for each unique Lambda function:

- i. Choose **Add**.

Repeat for every unique function you want to run.

- ii. For **Lambda function**, enter the function name.
- iii. For **Role**, choose the role that you created in the prerequisites with the blue/green permissions.

For more information, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#).

- iv. For **Lifecycle stages**, select the stages the Lambda function runs.
- v. (Optional) For **Hook details**, enter a key-value pair that provides information about the hook.

6. Expand **Load Balancing**, and then configure the following:

- a. For **Role**, choose the role that you created in the prerequisites with the blue/green permissions.

For more information, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#).

- b. For **Listener**, choose the production listener from your CodeDeploy blue/green deployment.
  - c. For **Production rule**, choose the production rule from your CodeDeploy blue/green deployment.
  - d. For **Test rule**, choose the test rule from your CodeDeploy blue/green deployment.
  - e. For **Target group**, choose the production target group from your CodeDeploy blue/green deployment.
  - f. For **Alternate target group**, choose the test target group from your CodeDeploy blue/green deployment.
7. Choose **Update**.

## Next steps

- Update the service to start the deployment. For more information, see [Updating an Amazon ECS service](#).
- Monitor the deployment process to ensure it follows the blue/green pattern:
  - The green service revision is created and scaled up
  - Test traffic is routed to the green revision (if configured)
  - Production traffic is shifted to the green revision
  - After the bake time, the blue revision is terminated

## Migrating an CloudFormation CodeDeploy blue/green deployment template to an Amazon ECS blue/green CloudFormation template

Migrate a CloudFormation template that uses CodeDeploy blue/green deployments for Amazon ECS services to one that uses the native Amazon ECS blue/green deployment strategy. The migration follows the "Reuse the same Elastic Load Balancing resources used for CodeDeploy" approach. For more information, see [the section called "Migrate CodeDeploy blue/green deployments to Amazon ECS blue/green deployments"](#).

## Source template

This template uses the `AWS::CodeDeployBlueGreen` transform and `AWS::CodeDeploy::BlueGreen` hook to implement blue/green deployments for an Amazon ECS service.

## Source

This is the complete CloudFormation template using CodeDeploy blue/green deployment. For more information, see [Blue/green deployment template example](#) in the *AWS CloudFormation User Guide*:

    "Cluster": {"Ref": "ECSDemoCluster"},
    "Service": {"Ref": "ECSDemoService"},
    "TaskSetId": {"Fn::GetAtt": ["BlueTaskSet", "Id"]}
  }
}
}
}
}

```

## Migration steps

### Remove CodeDeploy-specific resources

You no longer need the following properties:

- The `AWS::CodeDeployBlueGreen` transform
- The `CodeDeployBlueGreenHook` hook
- The `GreenTaskDefinition` and `GreenTaskSet` resources (these will be managed by Amazon ECS)
- The `PrimaryTaskSet` resource (Amazon ECS will manage task sets internally)

### Reconfigure the load balancer listener

Modify the `ALBListenerProdTraffic` resource to use a forward action with two target groups:

```

{
  "DefaultActions": [
    {
      "Type": "forward",
      "ForwardConfig": {
        "TargetGroups": [
          {
            "TargetGroupArn": {"Ref": "ALBTargetGroupBlue"},
            "Weight": 1
          },
          {

```

```

        "TargetGroupArn": {"Ref": "ALBTargetGroupGreen"},
        "Weight": 0
    }
]
}
}
]
}

```

## Update the deployment properties

Update and add the following:

- Change the `DeploymentController` property from `EXTERNAL` to `ECS`.
- Add the `Strategy` property and set it to `BLUE_GREEN`.
- Add the `BakeTimeInMinutes` property.

```

{
  "DeploymentConfiguration": {
    "MaximumPercent": 200,
    "MinimumHealthyPercent": 100,
    "DeploymentCircuitBreaker": {
      "Enable": true,
      "Rollback": true
    },
    "BakeTimeInMinutes": 5,
    "Strategy": "BLUE_GREEN"
  }
}

```

- Add the load balancer configuration to the service:

```

{
  "LoadBalancers": [
    {
      "ContainerName": "DemoApp",
      "ContainerPort": 80,
      "TargetGroupArn": {"Ref": "ALBTargetGroupBlue"},
      "AdvancedConfiguration": {
        "AlternateTargetGroupArn": {"Ref": "ALBTargetGroupGreen"},
        "ProductionListenerRule": {"Ref": "ALBListenerProdRule"},
        "RoleArn": {"Fn::GetAtt": ["ECSInfrastructureRoleForLoadBalancers", "Arn"]}
      }
    }
  ]
}

```

```

    }
  }
]
}

```

- Add the task definition reference to the service:

```

{
  "TaskDefinition": {"Ref": "BlueTaskDefinition"}
}

```

## Create the AmazonECSInfrastructureRolePolicyForLoadBalancers role

Add a new IAM role that allows Amazon ECS to manage load balancer resources. For more information, see [the section called “Infrastructure IAM role for load balancers”](#)

## Testing recommendations

1. Deploy the migrated template to a non-production environment.
2. Verify that the service deploys correctly with the initial configuration.
3. Test a deployment by updating the task definition and observing the blue/green deployment process.
4. Verify that traffic shifts correctly between the blue and green deployments.
5. Test rollback functionality by forcing a deployment failure.

## Template after migration

### Final template

This is the complete CloudFormation template using an Amazon ECS blue/green deployment:

```

{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Parameters": {
    "Vpc": {
      "Type": "AWS::EC2::VPC::Id"
    },
    "Subnet1": {
      "Type": "AWS::EC2::Subnet::Id"
    },

```

```

    "Subnet2": {
      "Type": "AWS::EC2::Subnet::Id"
    }
  },
  "Resources": {
    "ExampleSecurityGroup": {
      "Type": "AWS::EC2::SecurityGroup",
      "Properties": {
        "GroupDescription": "Security group for ec2 access",
        "VpcId": {"Ref": "Vpc"},
        "SecurityGroupIngress": [
          {
            "IpProtocol": "tcp",
            "FromPort": 80,
            "ToPort": 80,
            "CidrIp": "0.0.0.0/0"
          },
          {
            "IpProtocol": "tcp",
            "FromPort": 8080,
            "ToPort": 8080,
            "CidrIp": "0.0.0.0/0"
          },
          {
            "IpProtocol": "tcp",
            "FromPort": 22,
            "ToPort": 22,
            "CidrIp": "0.0.0.0/0"
          }
        ]
      }
    },
    "ALBTargetGroupBlue": {
      "Type": "AWS::ElasticLoadBalancingV2::TargetGroup",
      "Properties": {
        "HealthCheckIntervalSeconds": 5,
        "HealthCheckPath": "/",
        "HealthCheckPort": "80",
        "HealthCheckProtocol": "HTTP",
        "HealthCheckTimeoutSeconds": 2,
        "HealthyThresholdCount": 2,
        "Matcher": {
          "HttpCode": "200"
        }
      }
    },

```

```

    "Port": 80,
    "Protocol": "HTTP",
    "Tags": [
      {
        "Key": "Group",
        "Value": "Example"
      }

## Migrating from a CodeDeploy blue/green to an Amazon ECS rolling update service deployment

You can migrate your service deployments from an CodeDeploy blue/green deployment to an Amazon ECS rolling update deployment. This moves you away from CodeDeploy dependency to using an integrated deployment.

The Amazon ECS service scheduler replaces the currently running tasks with new tasks. The number of tasks that Amazon ECS adds or removes from the service during a rolling update is controlled by the service deployment configuration.

### Prerequisites

Perform the following operations before you start a blue/green deployment.

1. You no longer need the Amazon ECS CodeDeploy IAM role.
2. Turn off CodeDeploy automation. For more information, see [Working with deployment groups in CodeDeploy](#) in the *CodeDeploy User Guide*.
3. Verify that there are no ongoing service deployments for the service. For more information, see [View service history using Amazon ECS service deployments](#).

For more information about updating a service's deployment controller, see [Update Amazon ECS service parameters](#).

## Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.

The cluster details page displays.

3. From the **Services** tab, choose the service.

The service details page displays.

4. In the banner, choose **Migrate**.

The **Update deployment configuration** page displays.

5. Expand **Deployment options**, and then specify the following parameters.
  - a. For **Deployment controller type**, choose **ECS**.
  - b. For **Deployment strategy**, choose **Rolling update**.
  - c. For **Min running tasks**, enter the lower limit on the number of tasks in the service that must remain in the RUNNING state during a deployment, as a percentage of the desired number of tasks (rounded up to the nearest integer). For more information, see [Deployment configuration](#).
  - d. For **Max running tasks**, enter the upper limit on the number of tasks in the service that are allowed in the RUNNING or PENDING state during a deployment, as a percentage of the desired number of tasks (rounded down to the nearest integer).
6. Expand **Load Balancing**, and then configure the following:

- a. For **Role**, choose the role that you created in the prerequisites with the blue/green permissions.

For more information, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#).

- b. For **Listener**, choose the production listener from your CodeDeploy blue/green deployment.
- c. For **Target group**, choose the production target group from your CodeDeploy blue/green deployment.

## 7. Choose **Update**.

### Next steps

You must update the service for the change to take effect. For more information, see [Updating an Amazon ECS service](#).

## Update the Amazon ECS deployment strategy

Amazon ECS supports multiple deployment strategies for updating your services. You can migrate between these strategies based on your application requirements. This topic explains how to migrate between rolling deployments and blue/green deployments.

### Understanding Amazon ECS deployment strategies

Before migrating between deployment strategies, it's important to understand how each strategy works and their key differences:

#### Rolling deployments

In a rolling deployment, Amazon ECS replaces the current running version of your application with a new version. The service scheduler uses the minimum and maximum healthy percentage parameters to determine the deployment strategy.

Rolling deployments are simpler to set up but provide less control over the deployment process and traffic routing.

#### Blue/green deployments

In a blue/green deployment, Amazon ECS creates a new version of your service (green) alongside the existing version (blue). This allows you to verify the new version before routing production traffic to it.

Blue/green deployments provide more control over the deployment process, including traffic shifting, testing, and rollback capabilities.

### Best practices

Follow these best practices when migrating between deployment strategies:

- **Test in a non-production environment:** Always test the update in a non-production environment before applying changes to production services.

- **Plan for rollback:** Have a rollback plan in case the update doesn't work as expected.
- **Monitor during transition:** Closely monitor your service during and after the migration to ensure it continues to operate correctly.
- **Update documentation:** Update your deployment documentation to reflect the new deployment strategy.
- **Consider traffic impact:** Understand how the update might impact traffic to your service and plan accordingly.

## Updating the deployment strategy from rolling update to Amazon ECS blue/green

You can migrate from a rolling update deployment to an Amazon ECS blue/green deployment when you want to make and test service changes before implementing them in a production environment.

### Prerequisites

Before migrating your service from rolling to blue/green deployments, ensure you have the following:

- Wait for any current deployments to complete.
- An existing Amazon ECS service using the rolling deployment strategy.
- If you have multiple service revisions serving traffic, Amazon ECS attempts to consolidate traffic to a single revision during migration. If this fails, you might need to manually update your service to use a single revision before migrating.
- Configure the appropriate permissions.
  - For information about Elastic Load Balancing permissions, see [Amazon ECS infrastructure IAM role for load balancers](#).
  - For information about Lambda permissions, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#).
- Depending on configuration, you need to perform one of the following:
  - If your service uses Elastic Load Balancing, update your service with the new `advancedConfiguration`` and start a rolling deployment.
  - If your service uses Service Connect, update your service and start a rolling deployment.
  - If your service uses both Elastic Load Balancing and Service Connect, perform both preceding steps (you can use a single `UpdateService` request).

- If your service uses none of these, then no additional operation is needed.
- Amazon ECS blue/green deployments require that your service uses one of the following features. Configure the appropriate resources.
  - Application Load Balancer - For more information, see [Application Load Balancer resources for blue/green, linear, and canary deployments](#).
  - Network Load Balancer - For more information, see [Network Load Balancer resources for Amazon ECS blue/green, linear and canary deployments](#).
  - Service Connect - For more information, see [Service Connect resources for Amazon ECS blue/green, linear, and canary deployments](#).
  - VPC Lattice - For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).

## Procedure

1. Open the Amazon ECS console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster that contains the service you want to migrate.

The Cluster details page is displayed.

4. On the **Cluster details** page, choose the **Services** tab.
5. Choose the service, and then choose **Update**.

The Update service page is displayed

6. Expand **Deployment options**, and then do the following:
7. For **Deployment strategy**, choose **Blue/green**.
8. Configure the blue/green deployment settings:
  - a. For **Bake time**, enter the number of minutes that both the blue and green service revisions will run simultaneously before the blue revision is terminated.

This allows time for verification and testing.

- b. (Optional) Configure Lambda functions to run at specific stages of the deployment. Under **Deployment lifecycle hooks**, configure Lambda functions for the following stages:
  - **Pre scale up:** Runs before scaling up the green service revision

- **Post scale up:** Runs after scaling up the green service revision
- **Test traffic shift:** Runs during test traffic routing to the green service revision
- **Post test traffic shift:** Runs after test traffic is routed to the green service revision
- **Production traffic shift:** Runs during production traffic routing to the green service revision
- **Post production traffic shift:** Runs after production traffic is routed to the green service revision

To add a lifecycle hook:

- a. Choose **Add**.
- b. For **Lambda function**, enter the function name or ARN.
- c. For **Role**, choose the IAM role that has permission to invoke the Lambda function.
- d. For **Lifecycle stages**, select the stages when the Lambda function should run.
- e. Optional: For **Hook details**, enter key-value pairs to provide additional information to the hook.

9. Configure the load balancer settings:

- a. Under **Load balancing**, verify that your service is configured to use a load balancer.
- b. For **Target group**, choose the primary target group for your production (blue) environment.
- c. For **Alternate target group**, choose the target group for your test (green) environment.
- d. For **Production listener rule**, choose the listener rule for routing production traffic.
- e. Optional: For **Test listener rule**, choose a listener rule for routing test traffic to your green environment.
- f. For **Role**, choose the IAM role that allows Amazon ECS to manage your load balancer.

10. Review your configuration changes, and then choose **Update**.

## Next steps

- Update the service to start the deployment. For more information, see [Updating an Amazon ECS service](#).
- Monitor the deployment process to ensure it follows the blue/green pattern:

- The green service revision is created and scaled up
- Test traffic is routed to the green revision (if configured)
- Production traffic is shifted to the green revision
- After the bake time, the blue revision is terminated

## Updating the deployment strategy from Amazon ECS blue/green to rolling update

You can migrate a blue/green deployment to a rolling update deployment.

Keep the following considerations in mind when migrating to rolling deployments:

- **Traffic handling:** With rolling deployments, new tasks start receiving traffic as soon as they pass health checks. There is no separate testing phase as with blue/green deployments.
- **Resource efficiency:** Rolling deployments typically use fewer resources than blue/green deployments because they replace tasks incrementally rather than creating a complete duplicate environment.
- **Rollback complexity:** Rolling deployments make rollbacks more complex compared to blue/green deployments. If you need to roll back, you must initiate a new deployment with the previous task definition.
- **Deployment speed:** Rolling deployments may take longer to complete than blue/green deployments, especially for services with many tasks.
- **Load balancer configuration:** Your existing load balancer configuration will continue to work with rolling deployments, but the traffic shifting behavior will be different.

## Prerequisites

Before migrating your service from blue/green to rolling deployments, ensure you have the following:

- An existing Amazon ECS service using the blue/green deployment strategy
- No ongoing deployments for the service (wait for any current deployments to complete)
- A clear understanding of how your service will behave with rolling deployments

**Note**

You cannot migrate a service to rolling deployment if it has an ongoing deployment. Wait for any current deployments to complete before proceeding.

**Migration procedure**

Follow these steps to migrate your Amazon ECS service from blue/green to rolling deployments:

1. Open the Amazon ECS console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster that contains the service you want to migrate.
4. On the **Cluster details** page, choose the **Services** tab.
5. Select the service you want to migrate, and then choose **Update**.
6. On the **Update service** page, navigate to the **Deployment options** section and expand it if necessary.
7. For **Deployment strategy**, choose **Rolling update**.
8. Configure the rolling deployment settings:
  - a. For **Minimum healthy percent**, enter the minimum percentage of tasks that must remain in the RUNNING state during a deployment. This value is specified as a percentage of the desired number of tasks for the service.
  - b. For **Maximum percent**, enter the maximum percentage of tasks that are allowed in the RUNNING or PENDING state during a deployment. This value is specified as a percentage of the desired number of tasks for the service.
9. Optional: Under **Deployment failure detection**, configure how Amazon ECS detects and handles deployment failures:
  - a. To enable the deployment circuit breaker, choose **Use the deployment circuit breaker**.
  - b. To automatically roll back failed deployments, choose **Rollback on failure**.
10. Review your configuration changes, and then choose **Update** to save your changes and migrate the service to rolling deployment.

Amazon ECS will update your service configuration to use the rolling deployment strategy. The next time you update your service, it will use the rolling deployment process.

**Note**

When you migrate from blue/green to rolling deployment, Amazon ECS handles the transition by:

1. Identifying the current active service revision that is serving traffic.
2. Maintaining the existing load balancer configuration but changing how new deployments are handled.
3. Preparing the service for future rolling deployments.

**Next steps**

- Update the service to start the deployment. For more information, see [Updating an Amazon ECS service](#).

**Troubleshooting Amazon ECS deployment strategy updates**

This section provides solutions for common issues you might encounter when migrating deployment strategies.

**Multiple service revisions or tasks sets**

The following issues relate to having multiple service revisions for a deployment.

**Multiple task sets when updating ECS deployment controller**

*Error message:* Updating the deployment controller is not supported when there are multiple tasksets in the service. Please ensure your service has only one taskset and try again.

*Solution:* This error occurs when attempting to change the deployment controller type of a service with multiple active task sets. To resolve this issue for the CODE\_DEPLOY or EXTERNAL deployment controller:

1. Check current task sets:

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name --query "services[0].taskSets"
```

2. Wait for any in-progress deployments to complete.
3. Force a new deployment to clean up task sets:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name
--force-new-deployment
```

4. If necessary, delete extra task sets manually:

```
aws ecs delete-task-set --cluster your-cluster-name --service your-service-name
--task-set task-set-id
```

5. After only one task set remains, retry updating the deployment controller.

For more information, see [the section called “Service deployment controllers and strategies”](#).

### Missing primary task set when updating ECS deployment controller

*Error message:* Updating the deployment controller requires a primary taskset in the service. Please ensure your service has a primary taskset and try again.

*Solution:* This error occurs when attempting to change the deployment controller type of a service that doesn't have a primary task set. To resolve this issue:

1. Verify the service status and task sets. ). If a task set exists in the service, it should be marked as ACTIVE.

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name
--query "services[0].taskSets[*].[status,id]"
```

If there are no task sets in the ACTIVE state, migrate the deployment. For more information, see [Migration approaches](#).

2. If the service has no running tasks, deploy at least one task by updating the service:

```
aws ecs update-service-primary-task-set --cluster your-cluster-name --
service your-service-name --primary-task-set your-taskset-id
```

This will mark the (previously ACTIVE) task set in the service as PRIMARY status.

3. Wait for the task to reach a stable running state. You can check the status with:

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name --query "services[0].deployments"
```

4. After the service has a primary task set with running tasks, retry updating the deployment controller.

For more information, see [the section called “Service deployment controllers and strategies”](#).

## Mismatch between the deployment failure detection type and deployment controller

The following issues relate to a mismatch between the deployment failure detection type and deployment controller.

### Deployment circuit breaker with non-ECS controller

*Error message:* Deployment circuit breaker feature is only supported with ECS deployment controller. Update to ECS deployment controller and try again.

*Solution:* This error occurs when attempting to enable the deployment circuit breaker feature on a service that is not using the ECS deployment controller. The deployment circuit breaker is only compatible with the ECS deployment controller.

1. Check your service's current deployment controller:

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name --query "services[0].deploymentController"
```

2. Update your service to use the ECS deployment controller:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name --deployment-controller type=ECS
```

3. After the service is using the ECS deployment controller, enable the deployment circuit breaker:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name --deployment-configuration "deploymentCircuitBreaker={enable=true,rollback=true}"
```

For more information, see [the section called “How the deployment circuit breaker detects failures”](#).

### Alarm-based rollback with non-ECS controller

*Error message:* Alarm based rollback feature is only supported with ECS deployment controller. Update to ECS deployment controller and try again.

*Solution:* This error occurs when attempting to configure alarm-based rollback on a service that is not using the ECS deployment controller. The alarm-based rollback feature is only compatible with the ECS deployment controller.

1. Check your service's current deployment controller:

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name --query "services[0].deploymentController"
```

2. Update your service to use the ECS deployment controller:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name --deployment-controller type=ECS
```

3. After the service is using the ECS deployment controller, configure alarm-based rollback:

```
aws ecs update-service --cluster your-cluster-name --services your-service-name --deployment-configuration "alarms={alarmNames=[your-alarm-name],enable=true,rollback=true}"
```

For more information, see [the section called “How CloudWatch alarms detect deployment failures”](#).

### Mismatch between Service Connect and the deployment controller

The following issues relate to a mismatch between Service Connect and the deployment controller.

#### EXTERNAL controller with Service Connect

*Error message:* The EXTERNAL deployment controller type is not supported for services using Service Connect.

**Solution:** This error occurs when attempting to use the EXTERNAL deployment controller with an service that has Service Connect enabled. The EXTERNAL controller is not compatible with Service Connect.

1. Check if your service has Service Connect enabled:

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name --query "services[0].serviceConnectConfiguration"
```

2. If you need to use the EXTERNAL deployment controller, disable Service Connect by updating your service:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name --service-connect-configuration "{}"
```

3. Alternatively, if you must use Service Connect, use the ECS deployment controller instead:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name --deployment-controller type=ECS
```

For more information, see [the section called “Service deployment controllers and strategies”](#).

## Service Connect with non-ECS controller

**Error message:** Service Connect feature is only supported with ECS (rolling update) deployment controller. Update to ECS deployment controller and try again.

**Solution:** This error occurs when attempting to enable Service Connect on a that is not using the ECS deployment controller. The Service Connect feature is only compatible with the ECS deployment controller.

1. Check your service's current deployment controller:

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name --query "services[0].deploymentController"
```

2. Update your service to use the ECS deployment controller:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name
--deployment-controller type=ECS
```

3. Once the service is using the ECS deployment controller, enable Service Connect:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name
--service-connect-configuration "enabled=true,namespace=your-namespace"
```

For more information, see [the section called “Service deployment controllers and strategies”](#).

## Mismatch between controller type and scheduling strategy

The following issues relate to a mismatch between controller type and scheduling strategy.

### CODE\_DEPLOY controller with DAEMON scheduling strategy

*Error message:* The CODE\_DEPLOY deployment controller type is not supported for services using the DAEMON scheduling strategy.

*Solution:* This error occurs when attempting to use the CODE\_DEPLOY deployment controller with a service that uses the DAEMON scheduling strategy. The CODE\_DEPLOY controller is only compatible with the REPLICA scheduling strategy.

1. Check your service's current scheduling strategy:

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name
--query "services[0].schedulingStrategy"
```

2. If you need blue/green deployments, change your service to use the REPLICA scheduling strategy:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name
--scheduling-strategy REPLICA
```

3. Alternatively, if you must use the DAEMON scheduling strategy, use the ECS deployment controller instead:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name
--deployment-controller type=ECS
```

For more information, see [the section called “Service deployment controllers and strategies”](#).

## EXTERNAL controller with DAEMON scheduling strategy

*Error message:* The EXTERNAL deployment controller type is not supported for services using the DAEMON scheduling strategy.

*Solution:* This error occurs when attempting to use the EXTERNAL deployment controller with an ECS service that uses the DAEMON scheduling strategy. The EXTERNAL controller is only compatible with the REPLICA scheduling strategy.

1. Check your service's current scheduling strategy:

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name
--query "services[0].schedulingStrategy"
```

2. If you need to use the EXTERNAL deployment controller, change your service to use the REPLICA scheduling strategy:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name
--scheduling-strategy REPLICA
```

3. Alternatively, if you must use the DAEMON scheduling strategy, use the ECS deployment controller instead:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name
--deployment-controller type=ECS
```

For more information, see [the section called “Service deployment controllers and strategies”](#).

## Service registries with external launch type

*Error message:* Service registries are not supported for external launch type.

**Solution:** This error occurs when attempting to configure service discovery (service registries) for a service that uses the EXTERNAL launch type. Service discovery is not compatible with the EXTERNAL launch type.

1. Check your service's current launch type:

```
aws ecs describe-services --cluster your-cluster-name --services your-service-name --query "services[0].launchType"
```

2. If you need service discovery, change your service to use either the EC2 or FARGATE launch type:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name --launch-type FARGATE
```

3. Alternatively, if you must use the EXTERNAL launch type, remove the service registry configuration:

```
aws ecs update-service --cluster your-cluster-name --service your-service-name --service-registries "[]"
```

For more information, see [the section called “Service deployment controllers and strategies”](#).

## Revert a deployment controller update

If you decide that you want to return to the previous deployment controller, you can do one of the following:

- If you used CloudFormation, you can use the previous template to create a new stack. For more information, see [Create a stack from](#) in the *CloudFormation User Guide*.
- If you used the Amazon ECS console, or the AWS CLI, you can update the service. For more information, see [the section called “Updating a service”](#).

If you use the update-service command, use the `--deployment-controller` option and set it to the previous deployment controller.

## View service history using Amazon ECS service deployments

Service deployments provide a comprehensive view of your deployments. Service deployments provide the following information about the service:

- The currently deployed workload configuration (the source service revision)
- The workload configuration being deployed (the target service revision)
- The deployment status
- The number of failed tasks the circuit break detected
- The CloudWatch alarms that are in alarm
- When the service deployment started and completed
- The details of a rollback if one occurred

For information about the service deployment properties, see [Properties included in an Amazon ECS service deployment](#).

Service deployments are read-only and each have a unique ID.

There are three service deployment stages:

| Stage     | Definition                                                         | Associated states                                                                                                                                  |
|-----------|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Pending   | A service deployment has been created, but has not started         | PENDING                                                                                                                                            |
| Ongoing   | A service deployment is in-progress                                | <ul style="list-style-type: none"><li>• IN_PROGRESS</li><li>• STOP_REQUESTED</li><li>• ROLLBACK_REQUESTED</li><li>• ROLLBACK_IN_PROGRESS</li></ul> |
| Completed | A service deployment has finished (successfully or unsuccessfully) | <ul style="list-style-type: none"><li>• SUCCESSFUL</li><li>• STOPPED</li><li>• ROLLBACK_SUCCESSFUL</li><li>• ROLLBACK_FAILED</li></ul>             |

You use service deployments to understand the lifecycle of your service and to determine if there are any actions you need to take. For example, if a rollback happened, you might need to investigate the service deployment and looking at service events.

You can view the most recent 90-day history for deployments created on or after October 25, 2024 by using the console, API, and the AWS CLI.

You can stop a deployment that has not completed. For more information, see [Stopping Amazon ECS service deployments](#).

If a deployment uses early success criteria, `DescribeServiceDeployments` returns the configured early success criteria, and the running task counts that it reports are a snapshot from when the deployment completed rather than live counts. Deployments that complete early are included when you filter `ListServiceDeployments` by a status of `SUCCESSFUL`. For more information, see [Complete Amazon ECS rolling deployments early with early success criteria](#).

## Service deployment lifecycle

Amazon ECS creates a new service deployment automatically when any of the following actions happen:

- A user creates a service.
- A user updates the service and uses the force new deployment option.
- A user updates one or more service properties that require a deployment.

While a deployment is ongoing, Amazon ECS updates the following service deployment properties to reflect the service deployment's progress:

- The state
- The number of running tasks

The number of running tasks indicated in the service revision might not equal the actual number of running task. This number represents the number of tasks running when the deployment completed. For example, if you launched tasks independent of the service deployment, those tasks are not included in the running task count for the service revision.

- Circuit breaker failure detection:
  - The number of tasks that have failed to start

- CloudWatch alarm failure detection
  - The alarms that are active
- Rollback information:
  - The start time
  - The reason for the rollback
  - The ARN of the service revision used for the rollback
- The status reason

Amazon ECS deletes the service deployment when you delete a service.

## Service deployment states

A service deployment starts in PENDING state.

The following illustration shows the service deployment states that can happen after the PENDING state: IN\_PROGRESS, ROLLBACK\_REQUESTED, SUCCESSFUL, STOP\_REQUESTED, ROLLBACK\_IN\_PROGRESS, ROLLBACK\_FAILED, ROLLBACK\_SUCCESSFUL, and STOPPED.

The following information provides details about service deployment states:

- **PENDING** - The service deployment has been created, but has not started.

The state can move to **IN\_PROGRESS**, **ROLLBACK\_REQUESTED**, **STOP\_REQUESTED**, or **STOPPED**.

- **IN\_PROGRESS** - The service deployment is ongoing.

The state can move to **SUCCESSFUL**, **STOP\_REQUESTED**, **ROLLBACK\_REQUESTED**, **ROLLBACK\_IN\_PROGRESS**, and **STOPPED**.

- **STOP\_REQUESTED** - The service deployment state moves to **STOP\_REQUESTED** when any of the following happen:
  - A user starts a new service deployment.
  - The rollback option is not in use for the failure detection mechanism (the circuit breaker or alarm-based) and the service does not reach the **SUCCESSFUL** state.

The state moves to **STOPPED**.

- **ROLLBACK\_REQUESTED** - The service deployment state moves to **ROLLBACK\_REQUESTED** when a user request a rollback through the console, API, or CLI.

The state can move to **SUCCESSFUL**, **ROLLBACK\_IN\_PROGRESS**, and **STOPPED**.

- **SUCCESSFUL** - The service deployment state moves to **SUCCESSFUL** when the service deployment successfully completes.
- **ROLLBACK\_IN\_PROGRESS** - The service deployment state moves to **ROLLBACK\_IN\_PROGRESS** when the rollback option is in use for the failure detection mechanism (the circuit breaker or alarm-based) and the service fails.

The state moves to **ROLLBACK\_SUCCESSFUL**, or **ROLLBACK\_FAILED**.

## Properties included in an Amazon ECS service deployment

The following properties are included in a service deployment.

| Property               | Description                                         |  |
|------------------------|-----------------------------------------------------|--|
| Service deployment ARN | The ARN of the service deployment.                  |  |
| Service ARN            | The ARN of the service for this service deployment. |  |

| Property                         | Description                                                                                                                                                                      |  |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Cluster ARN                      | The ARN for the cluster that hosts the service.                                                                                                                                  |  |
| Service deployment creation time | The time the service deployment was created.                                                                                                                                     |  |
| Service deployment start time    | The time the service deployment started.                                                                                                                                         |  |
| Service deployment finish time   | The time the service deployment finished.                                                                                                                                        |  |
| Service deployment stopped time  | The time the service deployment stopped.                                                                                                                                         |  |
| Service deployment update time   | The time that the service deployment was last updated.                                                                                                                           |  |
| Source service revisions         | <p>The currently running service revisions.</p> <p>For information about the included properties, see <a href="#">Properties included in an Amazon ECS service revision</a>.</p> |  |

| Property                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Deployment configuration | <p>The deployment parameters including the circuit breaker configuration, the alarms that determine.</p> <ul style="list-style-type: none"><li>• The lower limit on the number of tasks that should be running for a service during a deployment or when a container instance is draining, as a percent of the desired number of tasks for the service.</li><li>• The upper limit on the number of tasks that should be running for a service during a deployment or when a container instance is draining, as a percent of the desired number of tasks for the service.</li><li>• The circuit breaker configuration.</li><li>• The alarms used for failure detection.</li></ul> |  |
| Target service revision  | <p>The service revision to deploy.</p> <p>After the deployment completes successfully, the target service revision is the running service revision.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |

| Property                                     | Description                                                                                                                                                                                            |  |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Service deployment status                    | The service deployment state.<br><br>The valid values are PENDING, SUCCESSFUL, STOPPED, STOP_REQUESTED, STOP_IN_PROGRESS, IN_PROGRESS, ROLLBACK_IN_PROGRESS, ROLLBACK_SUCCESSFUL, and ROLLBACK_FAILED. |  |
| Service deployment status information        | Information about why the service deployment is in the current status. For example, the circuit breaker detected a failure.                                                                            |  |
| Rollback information                         | The rollback options the service deployment uses when the deployment fails.                                                                                                                            |  |
| Service deployment circuit breaker options   | The circuit breaker that determines a service deployment failed.                                                                                                                                       |  |
| CloudWatch alarms for the service deployment | The CloudWatch alarms that determine when a service deployment fails.                                                                                                                                  |  |

## Permissions required for viewing Amazon ECS service deployments

When you follow the best practice of granting least privilege, you need to add additional permissions in order to view service deployments in the console.

You need access to the following actions:

- ListServiceDeployments
- DescribeServiceDeployments
- DescribeServiceRevisions

You need access to the following resources:

- Service
- Service deployment
- Service revision

The following example policy contains the required permissions, and limits the actions to a specified service.

Replace the account, cluster-name, and service-name with your values.

JSON

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:ListServiceDeployments",
        "ecs:DescribeServiceDeployments",
        "ecs:DescribeServiceRevisions"
      ],
      "Resource": [
        "arn:aws:ecs:us-east-1:123456789012:service/cluster-name/service-name",
        "arn:aws:ecs:us-east-1:123456789012:service-deployment/cluster-name/service-name/*",
        "arn:aws:ecs:us-east-1:123456789012:service-revision/cluster-name/service-name/*"
      ]
    }
  ]
}
```

## Viewing Amazon ECS service deployments

You can see the most recent 90-day history for deployments created on or after October 25, 2024. The service deployments can be in any of the following states:

- In-progress
- Pending
- Completed

You can use this information to determine if you need to update how the service is being deployed, or the service revision. For information about the included properties, see [Properties included in an Amazon ECS service deployment](#).

Before you begin, configure the required permissions for viewing service deployments. For more information, see [Permissions required for viewing Amazon ECS service deployments](#).

### Amazon ECS Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, choose the service.

The service details page displays.

4. On the service details page, choose **Deployments**.
5. Choose the service deployment to view.

| To view service deployments for this deployment type | Do this                                                              |  |
|------------------------------------------------------|----------------------------------------------------------------------|--|
| Ongoing deployment                                   | Under <b>Ongoing deployments</b> , choose the <b>Deployment ID</b> . |  |
| Last deployment                                      | Under <b>Last deployment</b> , choose the <b>Deployment ID</b> .     |  |

| To view service deployments for this deployment type | Do this                                                              |  |
|------------------------------------------------------|----------------------------------------------------------------------|--|
| Completed deployments                                | Under <b>Service deployments</b> , choose the <b>Deployment ID</b> . |  |

The service deployment details page appears.

6. (Optional) Compare service revisions to view the differences.

Under **Service revisions**, choose **Compare revisions**, and then select 2 revisions to compare.

The service revisions are displayed side-by-side with the differences highlighted.

## AWS CLI

1. Run `list-service-deployments` to retrieve the service deployment ARN.

Replace the variables with your values.

```
aws ecs list-service-deployments --cluster cluster-name --service service-name
```

Note the `serviceDeploymentArn` for the deployment you want to view.

```
{
  "serviceDeployments": [
    {
      "serviceDeploymentArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/example/sd-example/NCWGC2ZR-taawPAYrIaU5",
      "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/example/sd-example",
      "clusterArn": "arn:aws:ecs:us-west-2:123456789012:cluster/example",
      "targetServiceRevisionArn": "arn:aws:ecs:us-west-2:123456789012:service-revision/example/sd-example/4980306466373577095",
      "status": "SUCCESSFUL"
    }
  ]
}
```

```
}
```

2. Run `describe-service-deployments`. Use the `serviceDeploymentArn` that was returned from `list-service-deployments`.

Replace the variables with your values.

```
aws ecs describe-service-deployments --service-deployment-arns
arn:aws:ecs:region:123456789012:service-deployment/cluster-name/service-
name/NCWGC2ZR-taawPAYrIaU5
```

## Next steps

You can view the details for service revisions in the deployment. For more information, see [Viewing Amazon ECS service revision details](#)

## Amazon ECS service revisions

A service revision contains a record of the workload configuration Amazon ECS is attempting to deploy. Whenever you create or deploy a service, Amazon ECS automatically creates and captures the configuration that you're trying to deploy in the service revision.

Service revisions are read-only and have unique identifiers. For information about the included properties, see [Properties included in an Amazon ECS service revision](#).

Service revisions provide the following benefits:

- During a service deployment, you can compare the currently deployed service revision (source) with the one being deployed (target).
- When you use the rollback option for a service deployment, Amazon ECS automatically rolls back the service deployment to the last successfully deployed service revision.
- Service revisions contain the record of the workload configuration in one resource.

## Service revision lifecycle

Amazon ECS automatically creates a new service revision when you create a service, or update a service property that starts a deployment.

Amazon ECS doesn't create a new service revision for a rollback operation. Amazon ECS uses the last successful service revision for the rollback.

A service revision is immutable.

Amazon ECS deletes the service revision when you delete a service.

You can view service revisions created on or after October 25, 2024 by using the console, API, and the CLI.

Properties included in an Amazon ECS service revision

The following properties are included in a service revision.

| Resource            | Description                                                                                                                                                                                                                                                                                                                                                                               |  |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Service ARN         | The ARN that identifies the service.                                                                                                                                                                                                                                                                                                                                                      |  |
| Cluster ARN         | The ARN for the cluster that hosts the service.                                                                                                                                                                                                                                                                                                                                           |  |
| Task definition ARN | The ARN of the task definition used for the service tasks.                                                                                                                                                                                                                                                                                                                                |  |
| Service registries  | <div>The details for the service registries used for service discovery.<ul style="list-style-type: none"><li>The container name<div>The container name value to be used for your service discovery service.</div></li><li>The container port<div>The port value to be used for your service discovery service. This value is also specified in the task definition.</div></li></ul></div> |  |

## Viewing Amazon ECS service revision details

You can view information about the following service revision types that were created on or after October 25, 2024:

- Source -The currently deployed workload configuration
- Target - The workload configuration being deployed

### Amazon ECS Console

- Open the console at <https://console.aws.amazon.com/ecs/v2>.
- On the **Clusters** page, choose the cluster.
- On the cluster details page, in the **Services** section, choose the service.

The service details page displays.

- On the service details page, choose **Deployments**.

## 5. Choose the service revision to view.

| To view service revisions for this deployment type | Do this                                                                                                                                                                                                                                                                                                                                                                                                 |  |

| Completed deployments                              | <p>Under <b>Service deployments</b>, do the following:</p> <ul style="list-style-type: none"> <li>Under <b>Target service revision</b>, choose the ID.</li> </ul>                                                                                                                                                                                                                                       |  |

## AWS CLI

1. Run `describe-service-deployments` to retrieve the service revision ARN.

Replace the variables with your values.

```
aws ecs describe-service-deployments --service-deployment-arns
arn:aws:ecs:region:account-id:service/cluster-name/service-name/NCWGC2ZR-
taawPAYrIaU5
```

Note the arn for the `sourceServiceRevisions` or the `targetServiceRevisions`.

```
{
  "serviceDeployments": [
    {
      "serviceDeploymentArn": "arn:aws:ecs:us-west-2:123456789012:service-
deployment/example/sd-example/NCWGC2ZR-taawPAYrIaU5",
      "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/example/
sd-example",
      "clusterArn": "arn:aws:ecs:us-west-2:123456789012:cluster/example",
      "updatedAt": "2024-09-10T16:49:35.572000+00:00",
      "sourceServiceRevision": {
        "arn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
example/sd-example/4980306466373578954",
        "requestedTaskCount": 0,
        "runningTaskCount": 0,
        "pendingTaskCount": 0
      },
      "targetServiceRevision": {
        "arn": "arn:aws:ecs:us-west-2:123456789012:service-revision/
example/sd-example/4980306466373577095",
        "requestedTaskCount": 0,
        "runningTaskCount": 0,
        "pendingTaskCount": 0
      },
      "status": "IN_PROGRESS",
      "deploymentConfiguration": {
        "deploymentCircuitBreaker": {
          "enable": false,
          "rollback": false
        },
        "maximumPercent": 200,
        "minimumHealthyPercent": 100
      }
    }
  ],
  "failures": []
}
```

```
}
```

2. Run `describe-service-revisions`. Use the arn that was returned from `describe-service-deployments`.

Replace the variables with your values.

```
aws ecs describe-service-revisions --service-revision-arns
arn:aws:ecs:region:123456789012:service-revision/cluster-name/service-
name/4980306466373577095
```

## Balancing an Amazon ECS service across Availability Zones

Starting September 5, 2025, Amazon ECS enables Availability Zone rebalancing for all services that are eligible for the feature. A service is eligible when Availability Zone spread is the first task placement strategy, or when there is no placement strategy.

To help your applications achieve high availability, we recommend configuring your multi-task services to run across multiple Availability Zones. For services that specify their first placement strategy to be Availability Zone spread, AWS makes a best effort to evenly distribute service tasks across the available Availability Zones.

However, there might be times when the number of tasks running in one Availability Zone is not the same as in other Availability Zones, such as after an Availability Zone disruption. To address this task imbalance, you can enable the Availability Zone rebalancing feature.

With Availability Zone rebalancing, Amazon ECS continuously monitors the distribution of tasks across Availability Zones for each of your services. When Amazon ECS detects an uneven task distribution, it automatically takes action to rebalance the workload across Availability Zones. This involves launching new tasks in the Availability Zones with the fewest tasks and terminating tasks in the overloaded Availability Zones.

This redistribution ensures no single Availability Zone becomes a point of failure, helping maintain the overall availability of your containerized applications. The automated rebalancing process eliminates the need for manual intervention, speeding the time to recovery after an event.

The following is an overview of the Availability Zone rebalancing process:

1. Amazon ECS starts monitoring a service after it reaches the steady state, and looks at the number of tasks running in each Availability Zone.

2. Amazon ECS performs the following operations when it detects an imbalance in the number of tasks running in each Availability Zone:
  - Sends a service event indicating that Availability Zone rebalancing is starting.
  - Starts tasks in Availability Zones with the fewest number of running tasks
  - Stops the tasks in Availability Zones with the largest number of running tasks.
  - The scheduler waits for the newly started tasks to be `HEALTHY` and `RUNNING` before stopping the tasks in the over-scaled Availability Zone.
  - Sends a service event with the Availability Zone rebalancing outcome.

## How Amazon ECS detects uneven task distribution

Amazon ECS determines an imbalance in the number of tasks running in each Availability Zone by dividing the service's desired task count by the number of configured Availability Zones. If the desired task count doesn't divide evenly, Amazon ECS distributes the remainder of tasks evenly across the configured Availability Zones. Each Availability Zone must have at least one task.

For example, consider an Amazon ECS service with a desired count of two tasks configured for two Availability Zones. In this scenario, the desired task count divides evenly. A balanced distribution would be one task per Availability Zone. If there are two tasks in Availability Zone 1 and zero tasks in Availability Zone 2, Amazon ECS would initiate rebalancing by starting a task in Availability Zone 2 before stopping a task in Availability Zone 1.

Now, consider an Amazon ECS service with a desired count of three tasks configured for two Availability Zones. In this scenario, the desired task count does not divide evenly. A balanced distribution would be one task in Availability Zone 1 and two tasks in Availability Zone 2 because each Availability Zone has at least one task and the remainder task is placed in Availability Zone 2.

Consider an Amazon ECS service that has a desired count of five tasks configured for three Availability Zones. In this scenario, the desired task count does not divide evenly. A balanced distribution would be one task in Availability Zone 1 and two tasks each in Availability Zones 2 and 3. After accounting for every Availability Zone having one task each, the two remainder tasks are distributed evenly across the Availability Zones.

## Considerations for configuring Availability Zone rebalancing

Consider the following when you want to configure Availability Zone rebalancing:

- Availability Zone rebalancing supports Fargate and EC2 capacity providers, and is supported on Amazon ECS Managed Instances. For Fargate, Amazon ECS will automatically redistribute tasks across available Availability Zones to maintain balance. For EC2 capacity providers, Amazon ECS rebalances tasks across existing container instances on a best-effort basis, respecting your defined placement strategies and constraints. However, Amazon ECS can't launch new instances in underutilized Availability Zones as part of the rebalancing process, limiting the rebalancing to existing container instances.
- Availability Zone rebalancing works in the following configurations:
  - Services that use the `Replica` strategy
  - Services that specify Availability Zone spread as the first task placement strategy, or do not specify a placement strategy.
- You can't use Availability Zone rebalancing with services that meet any of the following criteria:
  - Uses the `Daemon` strategy
  - Uses the `EXTERNAL` launch type (ECS Anywhere)
  - Uses 100% for the `maximumPercent` value
  - Uses a Classic Load Balancer
  - Uses the `attribute:ecs.availability-zone` as a task placement constraint

## Placement strategies and placement constraints with Availability Zone rebalancing

Placement strategies determine how Amazon ECS selects container instances and Availability Zones for task placement termination. Task placement constraints are rules that determine whether a task is allowed to run on a specific container instance.

For EC2, you can use placement strategies and placement constraints in conjunction with Availability Zone rebalancing. However, for Availability Zone rebalancing to work, the Availability Zone spread placement strategy must be the first strategy specified.

Availability Zone rebalancing is compatible with various placement strategy combinations. For example, you can create a strategy that first distributes tasks evenly across Availability Zones, and then bin packs tasks based on memory within each Availability Zone. In this case, Availability Zone rebalancing works because the Availability Zone spread strategy is specified first.

It's important to note that Availability Zone rebalancing won't work if the first strategy in the placement strategy array is not an Availability Zone spread component. This requirement ensures

that the primary focus of task distribution is maintaining balance across Availability Zones, which is crucial for high availability.

For more information about task placement strategies and constraints, see [How Amazon ECS places tasks on container instances](#).

Task placement strategies and constraints aren't supported for tasks using Fargate. Fargate will try its best to spread tasks across accessible Availability Zones. If the capacity provider includes both Fargate and Fargate Spot, the spread behavior is independent for each capacity provider.

The following example strategy distributes tasks evenly across Availability Zones, and then bin packs tasks based on memory within each Availability Zone. Availability Zone rebalancing is compatible with the service because the spread strategy is first.

```
"placementStrategy": [
  {
    "field": "attribute:ecs.availability-zone",
    "type": "spread"
  },
  {
    "field": "memory",
    "type": "binpack"
  }
]
```

## Turn on Availability Zone rebalancing

You need to enable Availability Zone rebalancing for new and existing services.

You can enable and disable Availability Zone rebalancing using the console, APIs, AWS CLI, and CloudFormation.

The default behavior of `AvailabilityZoneRebalancing` differs between create and update requests:

- For create service requests, when no value is specified for `AvailabilityZoneRebalancing`, Amazon ECS defaults the value to `ENABLED`.
- For update service requests, when no value is specified for `AvailabilityZoneRebalancing`, Amazon ECS defaults to the existing service's `AvailabilityZoneRebalancing` value. If the service never had an `AvailabilityZoneRebalancing` value set, Amazon ECS treats this as `DISABLED`.

| Service type | API                           | Console                                                          | CLI                            |
|--------------|-------------------------------|------------------------------------------------------------------|--------------------------------|
| Existing     | <a href="#">UpdateService</a> | <a href="#">Updating an Amazon ECS service</a>                   | <a href="#">update-service</a> |
| New          | <a href="#">CreateService</a> | <a href="#">Creating an Amazon ECS rolling update deployment</a> | <a href="#">create-service</a> |

The following example shows how to enable service rebalancing when creating a new service:

```
aws ecs create-service \
  --cluster my-cluster \
  --service-name my-service \
  --task-definition my-task-definition:1 \
  --desired-count 6 \
  --availability-zone-rebalancing ENABLED
```

## Track Amazon ECS Availability Zone rebalancing

You can verify if Availability Zone rebalancing is enabled for a service in the console or by calling `describe-services`. The following example can be used to see the status with the CLI.

The response will be either `ENABLED` or `DISABLED`.

```
aws ecs describe-services \
  --services service-name \
  --cluster cluster-name \
  --query services[0].availabilityZoneRebalancing
```

## Service events

Amazon ECS sends service action events to help you understand the Availability Zone rebalancing lifecycle.

| Event                         | Scenario                                                                                    | Type | Learn more                                                                                                                                                                                                                      |
|-------------------------------|---------------------------------------------------------------------------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SERVICE_REBALANCING_STARTED   | Amazon ECS starts an Availability Zone rebalancing operation                                | INFO | <a href="#">service (service-name) is not AZ balanced with number-tasks tasks in Availability Zone 1, number-tasks tasks in Availability Zone 2, and number-tasks tasks in Availability Zone 3. AZ Rebalancing in progress.</a> |
| SERVICE_REBALANCING_COMPLETED | The Availability Zone rebalancing operation completes                                       | INFO | <a href="#">service (service-name) is AZ balanced with number-tasks tasks in Availability Zone 1, number-tasks tasks in Availability Zone 2, and number-tasks tasks in Availability Zone 3.</a>                                 |
| TASKS_STARTED                 | Amazon ECS successfully starts tasks as part of the Availability Zone rebalancing operation | INFO | <a href="#">service-name has started number-tasks tasks in Availability Zone to AZ</a>                                                                                                                                          |

| TASKS_STOPPED                               | Amazon ECS successfully stops tasks as part of the Availability Zone rebalancing operation | INFO  | <a href="#">service-name has stopped <i>number-tasks</i> running tasks in Availability Zone due to AZ rebalancing: <i>task-id</i>.</a>                                                                                                                                                                |
| SERVICE_TASK_PLACEMENT_FAILURE              | Amazon ECS failed to start a task as part of the Availability Zone rebalancing operation   | ERROR | <p>For EC2, see <a href="#">service (<i>service-name</i>) is unable to place a task in Availability Zone because no container instance met all of its requirements.</a></p> <p>For the Fargate, see <a href="#">service (<i>service-name</i>) is unable to place a task in Availability Zone.</a></p> |
| TASKSET_SCALE_IN_FAILURE_BY_TASK_PROTECTION | The Availability Zone rebalancing operation is blocked because task protection is in use.  | INFO  | <a href="#">service (<i>service-name</i>) was unable to AZ Rebalance because <i>task-set-name</i> was unable to scale in due to <i>reason</i>.</a>                                                                                                                                                    |

| Event                       | Scenario                                                                                                                | Type | Learn more                                                            |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------|------|-----------------------------------------------------------------------|
| SERVICE_REBALANCING_STOPPED | The Availability Zone rebalancing operation stopped. Amazon ECS sends additional events which provide more information. | INFO | <a href="#">service (<i>service-name</i>) stopped AZ Rebalancing.</a> |

## Task state change events

Amazon ECS sends a task state change event (START) for each task that it starts as part of the rebalancing process.

Amazon ECS sends a task state change event (STOPPED) event for each task that it stops as part of the rebalancing process. The reason is set to Availability-zone rebalancing initiated by (deployment ecs-svc/*deployment-id*).

For more information about the events, see [Amazon ECS task state change events](#).

## Troubleshooting service rebalancing

If you encounter issues with service rebalancing, consider the following troubleshooting steps:

### Rebalancing doesn't start

Verify that:

- Service rebalancing is enabled for your service
- Your service uses a supported configuration (see [the section called "Considerations for configuring Availability Zone rebalancing"](#))
- Your service has reached a steady state

### Task placement failures during rebalancing

If you see SERVICE\_TASK\_PLACEMENT\_FAILURE events:

- For EC2: Check if you have container instances available in the target Availability Zone
- For Fargate: Check if there are resource constraints or service quotas limiting task placement

- Review your task placement constraints to ensure they're not preventing proper task distribution

### Rebalancing stops unexpectedly

If you see `SERVICE_REBALANCING_STOPPED` events:

- Check for task protection that might be blocking the operation
- Look for concurrent service deployments that could interrupt rebalancing
- Review service events for additional information about why rebalancing stopped

## Best practices for service rebalancing

Follow these best practices to get the most out of service rebalancing:

- **Monitor rebalancing operations** - Set up CloudWatch alarms to monitor service events related to rebalancing to quickly identify any issues.
- **Consider performance impact** - Be aware that rebalancing operations may temporarily increase resource usage as new tasks are started before old ones are stopped.
- **Use task protection strategically** - If you have critical tasks that shouldn't be terminated during rebalancing, consider using task protection.
- **Plan for EC2 capacity** - For EC2, ensure you have sufficient container instances across all Availability Zones to support effective rebalancing.
- **Test rebalancing behavior** - Before relying on rebalancing in production, test how your services behave during rebalancing operations in a non-production environment.

## Use load balancing to distribute Amazon ECS service traffic

Your service can optionally be configured to use Elastic Load Balancing to distribute traffic evenly across the tasks in your service.

### Note

When you use tasks sets, all the tasks in the set must all be configured to use Elastic Load Balancing or to not use Elastic Load Balancing.

Amazon ECS services hosted on AWS Fargate support the Application Load Balancers, Network Load Balancers, and Gateway Load Balancers. Use the following table to learn about what type of load balancer to use.

| Load Balancer type        | Use in these cases                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |

| Gateway Load Balancer | Route TCP or UDP (or layer 4) traffic.<br><br>Use virtual appliances, such as firewalls, intrusion detection and prevention systems, and deep packet inspection systems. |  |

We recommend that you use Application Load Balancers for your Amazon ECS services so that you can take advantage of these latest features, unless your service requires a feature that is only available with Network Load Balancers or Gateway Load Balancers. For more information about Elastic Load Balancing and the differences between the load balancer types, see the [Elastic Load Balancing User Guide](#).

With your load balancer, you pay only for what you use. For more information, see [Elastic Load Balancing pricing](#).

## Optimize load balancer health check parameters for Amazon ECS

Load balancers route requests only to the healthy targets in the Availability Zones for the load balancer. Each target is registered to a target group. The load balancer checks the health of each target, using the target group health check settings. After you register the target, it must pass one health check to be considered healthy. Amazon ECS monitors the load balancer. The load balancer periodically sends health checks to the Amazon ECS container. The Amazon ECS agent monitors, and waits for the load balancer to report on the container health. It does this before it considers the container to be in a healthy status.

Two Elastic Load Balancing health check parameters affect deployment speed:

- **Health check interval:** Determines the approximate amount of time, in seconds, between health checks of an individual container. By default, the load balancer checks every 30 seconds.

This parameter is named:

- `HealthCheckIntervalSeconds` in the Elastic Load Balancing API
- **Interval** on the Amazon EC2 console
- **Healthy threshold count:** Determines the number of consecutive health check successes required before considering an unhealthy container healthy. By default, the load balancer requires five passing health checks before it reports that the target container is healthy.

This parameter is named:

- `HealthyThresholdCount` in the Elastic Load Balancing API
- **Healthy threshold** on the Amazon EC2 console

**Important:** For newly registered targets, only a single successful health check is required to consider the target healthy, regardless of the healthy threshold count setting. The healthy threshold count only applies when a target is transitioning from an unhealthy state back to a healthy state.

With the default settings, if a target becomes unhealthy and then recovers, the total time to determine the health of a container is two minutes and 30 seconds ( $30 \text{ seconds} * 5 = 150 \text{ seconds}$ ).

You can speed up the health-check process if your service starts up and stabilizes in under 10 seconds. To speed up the process, reduce the health check interval and the healthy threshold count.

- `HealthCheckIntervalSeconds` (Elastic Load Balancing API name) or **Interval** (Amazon EC2 console name): 5
- `HealthyThresholdCount` (Elastic Load Balancing API name) or **Healthy threshold** (Amazon EC2 console name): 2

With this setting, the health-check process takes 10 seconds compared to the default of two minutes and 30 seconds.

For more information about the Elastic Load Balancing health check parameters, see [Health checks for your target groups](#) in the *Elastic Load Balancing User Guide*.

## Optimize load balancer connection draining parameters for Amazon ECS

To allow for optimization, clients maintain a keep alive connection to the container service. This allows subsequent requests from that client to reuse the existing connection. When you want to stop traffic to a container, you notify the load balancer. The load balancer periodically checks to see if the client closed the keep alive connection. Amazon ECS monitors the load balancer, and waits for the load balancer to report that the keep alive connection is closed (the target is in an UNUSED state).

The amount of time that the load balancer waits to move the target to the UNUSED state is the deregistration delay. You can configure the following load balancer parameter to speed up your deployments.

- `deregistration_delay.timeout_seconds`: 300 (default)

When you have a service with a response time that's under 1 second, set the parameter to the following value to have the load balancer only wait 5 seconds before it breaks the connection between the client and the back-end service:

- `deregistration_delay.timeout_seconds`: 5

### Note

Do not set the value to 5 seconds when you have a service with long-lived requests, such as slow file uploads or streaming connections.

## SIGTERM responsiveness

Amazon ECS first sends a stop signal to the task to notify the application needs to finish and shut down. This signal can be defined in your container image with the `STOPSIGNAL` instruction and will default to `SIGTERM`. Then, Amazon ECS sends a `SIGKILL` message. When applications ignore the `SIGTERM`, the Amazon ECS service must wait to send the `SIGKILL` signal to terminate the process.

The amount of time that Amazon ECS waits to send the `SIGKILL` message is determined by the following Amazon ECS agent option:

- `ECS_CONTAINER_STOP_TIMEOUT`: 30 (default)

For more information about the container agent parameter, see [Amazon ECS Container Agent](#) on GitHub.

To speed up the waiting period, set the Amazon ECS agent parameter to the following value:

- `ECS_CONTAINER_STOP_TIMEOUT: 2`

If your application takes more than 1 second, multiply the value by 2 and use that number as the value.

In this case, the Amazon ECS waits 2 seconds for the container to shut down, and then Amazon ECS sends a SIGKILL message when the application didn't stop.

You can also modify the application code to trap the SIGTERM signal and react to it. The following is example in JavaScript:

```
process.on('SIGTERM', function() {  
  server.close();  
})
```

This code causes the HTTP server to stop listening for any new requests, finish answering any in-flight requests, and then the Node.js process terminates because the event loop has nothing to do. Given this, if it takes the process only 500 ms to finish its in-flight requests, it terminates early without having to wait out the stop timeout and get sent a SIGKILL.

## Use an Application Load Balancer for Amazon ECS

An Application Load Balancer makes routing decisions at the application layer (HTTP/HTTPS), supports path-based routing, and can route requests to one or more ports on each container instance in your cluster. Application Load Balancers support dynamic host port mapping. For example, if your task's container definition specifies port 80 for an NGINX container port, and port 0 for the host port, then the host port is dynamically chosen from the ephemeral port range of the container instance (such as 32768 to 61000 on the latest Amazon ECS-optimized AMI). When the task launches, the NGINX container is registered with the Application Load Balancer as an instance ID and port combination, and traffic is distributed to the instance ID and port corresponding to that container. This dynamic mapping allows you to have multiple tasks from a single service on the same container instance. For more information, see the [User Guide for Application Load Balancers](#).

For information about the best practices for setting parameters to speed up you deployments see:

- [Optimize load balancer health check parameters for Amazon ECS](#)
- [Optimize load balancer connection draining parameters for Amazon ECS](#)

Consider the following when using Application Load Balancers with Amazon ECS:

- Amazon ECS requires the service-linked IAM role which provides the permissions needed to register and deregister targets with your load balancer when tasks are created and stopped. For more information, see [Using service-linked roles for Amazon ECS](#).
- For services in an IPv6-only configuration, you must set the target group IP address type of the Application Load Balancer to `dualstack` or `dualstack-without-public-ipv4`.
- For services with tasks using the `awsvpc` network mode, when you create a target group for your service, you must choose `ip` as the target type, not `instance`. This is because tasks that use the `awsvpc` network mode are associated with an elastic network interface, not an Amazon EC2 instance.
- If your service requires access to multiple load balanced ports, such as port 80 and port 443 for an HTTP/HTTPS service, you can configure two listeners. One listener is responsible for HTTPS that forwards the request to the service, and another listener that is responsible for redirecting HTTP requests to the appropriate HTTPS port. For more information, see [Create a listener to your Application Load Balancer](#) in the *User Guide for Application Load Balancers*.
- Your load balancer subnet configuration must include all Availability Zones that your container instances reside in.
- After you create a service, the load balancer configuration can't be changed from the AWS Management Console. You can use the AWS Copilot, AWS CloudFormation, AWS CLI or SDK to modify the load balancer configuration for the ECS rolling deployment controller only, not AWS CodeDeploy blue/green or external. When you add, update, or remove a load balancer configuration, Amazon ECS starts a new deployment with the updated Elastic Load Balancing configuration. This causes tasks to register to and deregister from load balancers. We recommend that you verify this on a test environment before you update the Elastic Load Balancing configuration. For information about how to modify the configuration, see [UpdateService](#) in the *Amazon Elastic Container Service API Reference*.
- If a service task fails the load balancer health check criteria, the task is stopped and restarted. This process continues until your service reaches the number of desired running tasks.

- If you are experiencing problems with your load balancer-enabled services, see [Troubleshooting service load balancers in Amazon ECS](#).
- When using instance target type, your tasks and load balancer must be in the same VPC. When using ip target type, cross-VPC connectivity is supported.
- Use a unique target group for each service.

Using the same target group for multiple services might lead to issues during service deployments.

- You must specify target groups that are associated with an Application Load Balancer.

For information about how to create an Application Load Balancer, see [Create an Application Load Balancer](#) in *Application Load Balancers*

## Use a Network Load Balancer for Amazon ECS

A Network Load Balancer makes routing decisions at the transport layer (TCP/SSL). It can handle millions of requests per second. After the load balancer receives a connection, it selects a target from the target group for the default rule using a flow hash routing algorithm. It attempts to open a TCP connection to the selected target on the port specified in the listener configuration. It forwards the request without modifying the headers. Network Load Balancers support dynamic host port mapping. For example, if your task's container definition specifies port 80 for an NGINX container port, and port 0 for the host port, then the host port is dynamically chosen from the ephemeral port range of the container instance (such as 32768 to 61000 on the latest Amazon ECS-optimized AMI). When the task is launched, the NGINX container is registered with the Network Load Balancer as an instance ID and port combination, and traffic is distributed to the instance ID and port corresponding to that container. This dynamic mapping allows you to have multiple tasks from a single service on the same container instance. For more information, see the [User Guide for Network Load Balancers](#).

For information about the best practices for setting parameters to speed up you deployments see:

- [Optimize load balancer health check parameters for Amazon ECS](#)
- [Optimize load balancer connection draining parameters for Amazon ECS](#)

Consider the following when using Network Load Balancers with Amazon ECS:

- Amazon ECS requires the service-linked IAM role which provides the permissions needed to register and deregister targets with your load balancer when tasks are created and stopped. For more information, see [Using service-linked roles for Amazon ECS](#).
- You cannot attach more than five target groups to a service.
- For services in an IPv6-only configuration, you must set the target group IP address type of the Network Load Balancer to `dualstack`.
- For services with tasks using the `awsvpc` network mode, when you create a target group for your service, you must choose `ip` as the target type, not `instance`. This is because tasks that use the `awsvpc` network mode are associated with an elastic network interface, not an Amazon EC2 instance.
- Your load balancer subnet configuration must include all Availability Zones that your container instances reside in.
- After you create a service, the load balancer configuration can't be changed from the AWS Management Console. You can use the AWS Copilot, AWS CloudFormation, AWS CLI or SDK to modify the load balancer configuration for the ECS rolling deployment controller only, not AWS CodeDeploy blue/green or external. When you add, update, or remove a load balancer configuration, Amazon ECS starts a new deployment with the updated Elastic Load Balancing configuration. This causes tasks to register to and deregister from load balancers. We recommend that you verify this on a test environment before you update the Elastic Load Balancing configuration. For information about how to modify the configuration, see [UpdateService](#) in the *Amazon Elastic Container Service API Reference*.
- If a service task fails the load balancer health check criteria, the task is stopped and restarted. This process continues until your service reaches the number of desired running tasks.
- When you use a Gateway Load Balancer configured with IP addresses as targets and Client IP Preservation off, requests are seen as coming from the Gateway Load Balancers private IP address. This means that services behind an Gateway Load Balancer are effectively open to the world as soon as you allow incoming requests and health checks in the target security group.
- For Fargate tasks, you must use platform version `1.4.0` (Linux) or `1.0.0` (Windows).
- If you are experiencing problems with your load balancer-enabled services, see [Troubleshooting service load balancers in Amazon ECS](#).
- When using `instance` target type, your tasks and load balancer must be in the same VPC. When using `ip` target type, cross-VPC connectivity is supported.
- The Network Load Balancer client IP address preservation is compatible with Fargate targets.
- Use a unique target group for each service.

Using the same target group for multiple services might lead to issues during service deployments.

- You must specify target groups that are associated with a Network Load Balancer.

For information about how to create a Network Load Balancer, see [Create a Network Load Balancer](#) in *Network Load Balancers*

### Important

If your service's task definition uses the `awsvpc` network mode (which is required for Fargate), you must choose `ip` as the target type, not `instance`. This is because tasks that use the `awsvpc` network mode are associated with an elastic network interface, not an Amazon EC2 instance.

You cannot register instances by instance ID if they have the following instance types: C1, CC1, CC2, CG1, CG2, CR1, G1, G2, HI1, HS1, M1, M2, M3, and T1. You can register instances of these types by IP address.

## Use a Gateway Load Balancer for Amazon ECS

A Gateway Load Balancer operates at the third layer of the Open Systems Interconnection (OSI) model, the network layer. It listens for all IP packets across all ports and forwards traffic to the target group that's specified in the listener rule. It maintains stickiness of flows to a specific target appliance using 5-tuple (for TCP/UDP flows) or 3-tuple (for non-TCP/UDP flows). For example, if your task's container definition specifies port 80 for an NGINX container port, and port 0 for the host port, then the host port is dynamically chosen from the ephemeral port range of the container instance (such as 32768 to 61000 on the latest Amazon ECS-optimized AMI). When the task is launched, the NGINX container is registered with the Gateway Load Balancer as an instance ID and port combination, and traffic is distributed to the instance ID and port corresponding to that container. This dynamic mapping allows you to have multiple tasks from a single service on the same container instance. For more information, see [What is a Gateway Load Balancer](#) in *Gateway Load Balancers*.

For information about the best practices for setting parameters to speed up you deployments see:

- [Optimize load balancer health check parameters for Amazon ECS](#)
- [Optimize load balancer connection draining parameters for Amazon ECS](#)

Consider the following when using Gateway Load Balancers with Amazon ECS:

- Amazon ECS requires the service-linked IAM role which provides the permissions needed to register and deregister targets with your load balancer when tasks are created and stopped. For more information, see [Using service-linked roles for Amazon ECS](#).
- For services in an IPv6-only configuration, you must set the target group IP address type of the Gateway Load Balancer to `dualstack`.
- For services with tasks that use a network mode other than `awsvpc`, Gateway Load Balancers are not supported.
- Your load balancer subnet configuration must include all Availability Zones that your container instances reside in.
- After you create a service, the load balancer configuration can't be changed from the AWS Management Console. You can use the AWS Copilot, AWS CloudFormation, AWS CLI or SDK to modify the load balancer configuration for the ECS rolling deployment controller only, not AWS CodeDeploy blue/green or external. When you add, update, or remove a load balancer configuration, Amazon ECS starts a new deployment with the updated Elastic Load Balancing configuration. This causes tasks to register to and deregister from load balancers. We recommend that you verify this on a test environment before you update the Elastic Load Balancing configuration. For information about how to modify the configuration, see [UpdateService](#) in the *Amazon Elastic Container Service API Reference*.
- If a service task fails the load balancer health check criteria, the task is stopped and restarted. This process continues until your service reaches the number of desired running tasks.
- When you use a Gateway Load Balancer configured with IP addresses as targets, requests are seen as coming from the Gateway Load Balancers private IP address. This means that services behind an Gateway Load Balancer are effectively open to the world as soon as you allow incoming requests and health checks in the target security group.
- For Fargate tasks, you must use platform version `1.4.0` (Linux) or `1.0.0` (Windows).
- If you are experiencing problems with your load balancer-enabled services, see [Troubleshooting service load balancers in Amazon ECS](#).
- When using `instance` target type, your tasks and load balancer must be in the same VPC. When using `ip` target type, cross-VPC connectivity is supported.
- Use a unique target group for each service.

Using the same target group for multiple services might lead to issues during service deployments.

- You must specify target groups that are associated with a Gateway Load Balancer.

For information about how to create a Gateway Load Balancer, see [Getting started with Gateway Load Balancers](#) in *Gateway Load Balancers*

### Important

If your service's task definition uses the awsvpc network mode (which is required for Fargate), you must choose `ip` as the target type, not `instance`. This is because tasks that use the awsvpc network mode are associated with an elastic network interface, not an Amazon EC2 instance.

You cannot register instances by instance ID if they have the following instance types: C1, CC1, CC2, CG1, CG2, CR1, G1, G2, HI1, HS1, M1, M2, M3, and T1. You can register instances of these types by IP address.

## Registering multiple target groups with an Amazon ECS service

Your Amazon ECS service can serve traffic from multiple load balancers and expose multiple load balanced ports when you specify multiple target groups in a service definition.

To create a service specifying multiple target groups, you must create the service using the Amazon ECS API, SDK, AWS CLI, or an CloudFormation template. After the service is created, you can view the service and the target groups registered to it with the AWS Management Console. You must use [UpdateService](#) to modify the load balancer configuration of an existing service.

Multiple target groups can be specified in a service definition using the following format. For the full syntax of a service definition, see [Service definition template](#).

```
"loadBalancers":[
  {
    "targetGroupArn":"arn:aws:elasticloadbalancing:region:123456789012:targetgroup/target_group_name_1/1234567890123456",
    "containerName":"container_name",
    "containerPort":container_port
  },
  {
```

```
"targetGroupArn":"arn:aws:elasticloadbalancing:region:123456789012:targetgroup/  
target_group_name_2/6543210987654321",  
  "containerName":"container_name",  
  "containerPort":container_port  
}  
]
```

## Considerations

The following should be considered when you specify multiple target groups in a service definition.

- For services that use an Application Load Balancer or Network Load Balancer, you cannot attach more than five target groups to a service.
- Specifying multiple target groups in a service definition is only supported under the following conditions:
  - The service must use either an Application Load Balancer or Network Load Balancer.
  - The service must use the (ECS) deployment controller type. This can be either the Amazon ECS native/blue green deployment, or the rolling update deployment.
- Specifying multiple target groups is supported for services containing tasks using both the Fargate and EC2 launch types.
- When creating a service that specifies multiple target groups, the Amazon ECS service-linked role must be created. The role is created by omitting the `role` parameter in API requests, or the `Role` property in CloudFormation. For more information, see [Using service-linked roles for Amazon ECS](#).

## Example service definitions

Following are a few example use cases for specifying multiple target groups in a service definition. For the full syntax of a service definition, see [Service definition template](#).

### Having separate load balancers for internal and external traffic

In the following use case, a service uses two separate load balancers, one for internal traffic and a second for internet-facing traffic, for the same container and port.

```
"loadBalancers": [  
  //Internal ELB  
  {
```

```

    "targetGroupArn": "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/
    target_group_name_1/1234567890123456",
    "containerName": "nginx",
    "containerPort": 8080
  },
  //Internet-facing ELB
  {

    "targetGroupArn": "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/
    target_group_name_2/6543210987654321",
    "containerName": "nginx",
    "containerPort": 8080
  }
]

```

## Exposing multiple ports from the same container

In the following use case, a service uses one load balancer but exposes multiple ports from the same container. For example, a Jenkins container might expose port 8080 for the Jenkins web interface and port 50000 for the API.

```

"loadBalancers": [
  {

    "targetGroupArn": "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/
    target_group_name_1/1234567890123456",
    "containerName": "jenkins",
    "containerPort": 8080
  },
  {

    "targetGroupArn": "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/
    target_group_name_2/6543210987654321",
    "containerName": "jenkins",
    "containerPort": 50000
  }
]

```

## Exposing ports from multiple containers

In the following use case, a service uses one load balancer and two target groups to expose ports from separate containers.

```
"loadBalancers":[
  {
    "targetGroupArn":"arn:aws:elasticloadbalancing:region:123456789012:targetgroup/
target_group_name_1/1234567890123456",
    "containerName":"webserver",
    "containerPort":80
  },
  {
    "targetGroupArn":"arn:aws:elasticloadbalancing:region:123456789012:targetgroup/
target_group_name_2/6543210987654321",
    "containerName":"database",
    "containerPort":3306
  }
]
```

## Automatically scale your Amazon ECS service

*Automatic scaling* is the ability to increase or decrease the desired number of tasks in your Amazon ECS service automatically. Amazon ECS leverages the Application Auto Scaling service to provide this functionality. For more information, see the [Application Auto Scaling User Guide](#).

Amazon ECS publishes CloudWatch metrics with your service's average CPU and memory usage. For more information, see [Amazon ECS service utilization metrics](#). You can use these and other CloudWatch metrics to scale out your service (add more tasks) to deal with high demand at peak times, and to scale in your service (run fewer tasks) to reduce costs during periods of low utilization.

Amazon ECS Service Auto Scaling supports the following types of automatic scaling:

- [Use a target metric to scale Amazon ECS services](#)— Increase or decrease the number of tasks that your service runs based on a target value for a specific metric. This is similar to the way that your thermostat maintains the temperature of your home. You select temperature and the thermostat does the rest.
- [Use predefined increments based on CloudWatch alarms to scale Amazon ECS services](#)— Increase or decrease the number of tasks that your service runs based on a set of scaling adjustments, known as step adjustments, that vary based on the size of the alarm breach.
- [Use scheduled actions to scale Amazon ECS services](#)—Increase or decrease the number of tasks that your service runs based on the date and time.

- [Use historical patterns to scale Amazon ECS services with predictive scaling](#)—Increase or decrease the number of tasks that your service runs based on historical load data analytics to detect daily or weekly patterns in traffic flows.
- [Scale Amazon ECS services based on an Amazon SQS queue](#)—Increase or decrease the number of tasks that your service runs based on the backlog of messages in an Amazon SQS queue, using a backlog per task custom metric. This is useful for asynchronous applications where Amazon ECS tasks act as workers that consume messages from a queue.

## Considerations

When using scaling policies, consider the following:

- Amazon ECS sends metrics in 1-minute intervals to CloudWatch. Metrics are not available until the clusters and services send the metrics to CloudWatch, and you cannot create CloudWatch alarms for metrics that do not exist.
- The scaling policies support a cooldown period. This is the number of seconds to wait for a previous scaling activity to take effect.
  - For scale-out events, the intention is to continuously (but not excessively) scale out. After Service Auto Scaling successfully scales out using a scaling policy, it starts to calculate the cooldown time. The scaling policy won't increase the desired capacity again unless either a larger scale out is initiated or the cooldown period ends. While the scale-out cooldown period is in effect, the capacity added by the initiating scale-out activity is calculated as part of the desired capacity for the next scale-out activity.
  - For scale-in events, the intention is to scale in conservatively to protect your application's availability, so scale-in activities are blocked until the cooldown period has expired. However, if another alarm initiates a scale-out activity during the scale-in cooldown period, Service Auto Scaling scales out the target immediately. In this case, the scale-in cooldown period stops and doesn't complete.
- The service scheduler respects the desired count at all times, but as long as you have active scaling policies and alarms on a service, Service Auto Scaling could change a desired count that was manually set by you.
- If a service's desired count is set below its minimum capacity value, and an alarm initiates a scale-out activity, Service Auto Scaling scales the desired count up to the minimum capacity value and then continues to scale out as required, based on the scaling policy associated with the alarm.

However, a scale-in activity does not adjust the desired count, because it is already below the minimum capacity value.

- If a service's desired count is set above its maximum capacity value, and an alarm initiates a scale in activity, Service Auto Scaling scales the desired count out to the maximum capacity value and then continues to scale in as required, based on the scaling policy associated with the alarm. However, a scale-out activity does not adjust the desired count, because it is already above the maximum capacity value.
- During scaling activities, the actual running task count in a service is the value that Service Auto Scaling uses as its starting point, as opposed to the desired count. This is what processing capacity is supposed to be. This prevents excessive (runaway) scaling that might not be satisfied, for example, if there aren't enough container instance resources to place the additional tasks. If the container instance capacity is available later, the pending scaling activity may succeed, and then further scaling activities can continue after the cooldown period.
- If you want your task count to scale to zero when there's no work to be done, set a minimum capacity of 0. With target tracking scaling policies, when actual capacity is 0 and the metric indicates that there is workload demand, Service Auto Scaling waits for one data point to be sent before scaling out. In this case, it scales out by the minimum possible amount as a starting point and then resumes scaling based on the actual running task count.
- Application Auto Scaling turns off scale-in processes while Amazon ECS deployments are in progress. However, scale-out processes continue to occur, unless suspended, during a deployment. This behavior does not apply to Amazon ECS services using the external deployment controller. For more information, see [Service auto scaling and deployments](#).
- You have several Application Auto Scaling options for Amazon ECS tasks. Target tracking is the easiest mode to use. With it, all you need to do is set a target value for a metric, such as CPU average utilization. Then, the auto scaler automatically manages the number of tasks that are needed to attain that value. With step scaling you can more quickly react to changes in demand, because you define the specific thresholds for your scaling metrics, and how many tasks to add or remove when the thresholds are crossed. And, more importantly, you can react very quickly to changes in demand by minimizing the amount of time a threshold alarm is in breach.

For more information about best practices for service auto scaling, see [Optimizing Amazon ECS service auto scaling](#).

## Service auto scaling and deployments

Application Auto Scaling turns off scale-in processes while Amazon ECS deployments are in progress. However, scale-out processes continue to occur, unless suspended, during a deployment. This behavior does not apply to Amazon ECS services using the external deployment controller. If you want to suspend scale-out processes while deployments are in progress, take the following steps.

1. Call the [describe-scalable-targets](#) command, specifying the resource ID of the service associated with the scalable target in Application Auto Scaling (Example: `service/default/sample-webapp`). Record the output. You will need it when you call the next command.
2. Call the [register-scalable-target](#) command, specifying the resource ID, namespace, and scalable dimension. Specify `true` for both `DynamicScalingInSuspended` and `DynamicScalingOutSuspended`.
3. After deployment is complete, you can call the [register-scalable-target](#) command to resume scaling.

For more information, see [Suspending and resuming scaling for Application Auto Scaling](#).

## Use a target metric to scale Amazon ECS services

With target tracking scaling policies, you select a metric and set a target value. Amazon ECS Service Auto Scaling creates and manages the CloudWatch alarms that control the scaling policy and calculates the scaling adjustment based on the metric and the target value. The scaling policy adds or removes service tasks as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target tracking scaling policy also adjusts to the fluctuations in the metric due to a fluctuating load pattern and minimizes rapid fluctuations in the number of tasks running in your service.

Target tracking policies remove the need to manually define CloudWatch alarms and scaling adjustments. Amazon ECS handles this automatically based on the target you set.

Consider the following when using target tracking policies:

- A target tracking scaling policy assumes that it should perform scale out when the specified metric is above the target value. You cannot use a target tracking scaling policy to scale out when the specified metric is below the target value.

- A target tracking scaling policy does not perform scaling when the specified metric has insufficient data. It does not perform scale in because it does not interpret insufficient data as low utilization.
- You may see gaps between the target value and the actual metric data points. This is because Service Auto Scaling always acts conservatively by rounding up or down when it determines how much capacity to add or remove. This prevents it from adding insufficient capacity or removing too much capacity.
- To ensure application availability, the service scales out proportionally to the metric as fast as it can, but scales in more gradually.
- Application Auto Scaling turns off scale-in processes while Amazon ECS deployments are in progress. However, scale-out processes continue to occur, unless suspended, during a deployment. This behavior does not apply to Amazon ECS services using the external deployment controller. For more information, see [Service auto scaling and deployments](#).
- You can have multiple target tracking scaling policies for an Amazon ECS service, provided that each of them uses a different metric. The intention of Service Auto Scaling is to always prioritize availability, so its behavior differs depending on whether the target tracking policies are ready for scale out or scale in. It will scale out the service if any of the target tracking policies are ready for scale out, but will scale in only if all of the target tracking policies (with the scale-in portion turned on) are ready to scale in.
- Do not edit or delete the CloudWatch alarms that Service Auto Scaling manages for a target tracking scaling policy. Service Auto Scaling deletes the alarms automatically when you delete the scaling policy.
- The ALBRequestCountPerTarget metric for target tracking scaling policies is not supported for the blue/green deployment type.

For more information about target tracking scaling policies, see [Target tracking scaling policies](#) in the *Application Auto Scaling User Guide*.

## Create a target tracking scaling policy for Amazon ECS service auto scaling

Create a target tracking scaling policy to have Amazon ECS increase or decrease the desired task count in your service automatically. Target tracking works off of a target metric value.

## Console

1. In addition to the standard IAM permissions for creating and updating services, you need additional permissions. For more information, see [IAM permissions required for Amazon ECS service auto scaling](#).
2. Determine the metrics to use for the policy. The following metrics are available:
  - **ECSServiceAverageCPUUtilization** – The average CPU utilization the service should use.
  - **ECSServiceAverageMemoryUtilization** – Average memory utilization the service should use.
  - **ALBRequestCountPerTarget** – The average number of requests per minute that task should ideally receive.
3. Open the console at <https://console.aws.amazon.com/ecs/v2>.
4. On the **Clusters** page, choose the cluster.
5. On the cluster details page, in the **Services** section, and then choose the service.

The service details page appears.

6. Choose **Set the number of tasks**.
7. Under **Amazon ECS service task count**, choose **Use auto scaling**.

The **Task count** section appears.

- a. For **Minimum number of tasks**, enter the lower limit of the number of tasks for service auto scaling to use. The desired count will not go below this count.
- b. For **Maximum**, enter the upper limit of the number of tasks for service auto scaling to use. The desired count will not go above this count.
- c. Choose **Save**.

The policies page appears.

8. Choose **Create scaling policy**.

The **Create policy** page appears.

9. For **Scaling policy type**, choose **Target tracking**.
10. For **Policy name**, enter the name of the policy.
11. For **Metric type**, choose your metrics from the list of options.

12. For **Target utilization**, enter the target value for the percentage of tasks that Amazon ECS should maintain. Service auto scaling scales out your capacity until the average utilization is at the target utilization, or until it reaches the maximum number of tasks you specified.
13. Under **Additional Settings**, do the following
  - a. For **Scale-in cooldown period**, enter the amount of time in seconds after a scale-in activity completes before another scale-in activity can start.
  - b. For **Scale-out cooldown period**, enter the amount of time in seconds to wait for a previous scale-out activity to take effect.
  - c. To create only a scale-out policy, select **Disable scale-in**.
14. Choose **Create scaling policy**.

## AWS CLI

1. Register your Amazon ECS service as a scalable target using the [register-scalable-target](#) command.
2. Create a scaling policy using the [put-scaling-policy](#) command.

## Faster auto scaling with high-resolution metrics

By default, Amazon ECS publishes CPUUtilization and MemoryUtilization metrics at 60-second resolution. You can configure 20-second resolution to drive faster service auto scaling.

The following high-resolution predefined metrics are available for target tracking scaling policies:

| PredefinedMetricType                             | Description                                        |
|--------------------------------------------------|----------------------------------------------------|
| ECSServiceAverageCPUUtilizationHighResolution    | Average CPU utilization at 20-second resolution    |
| ECSServiceAverageMemoryUtilizationHighResolution | Average memory utilization at 20-second resolution |

## Create a new service with high-resolution metrics for faster auto scaling

### Console

1. On the **Clusters** page, choose the cluster you want to create the service in.
2. In the **Services** section, choose **Create**.
3. In the Create Service form, in the **Monitoring configuration** section, choose **Add metric configuration**.
4. For **Metric name**, select the metric you want to collect at high resolution. Choose `CPUUtilization` or `MemoryUtilization`.
5. For **Resolution (seconds)**, select **20**.
6. (Optional) To add both metrics at high resolution, choose **Add metric configuration** again and repeat the previous two steps for the other metric.
7. In the **Service auto scaling** section, choose **Use service auto scaling**.
8. For **Minimum number of tasks**, enter the lower limit of the number of tasks for service auto scaling to use. The desired count will not go below this count.
9. For **Maximum number of tasks**, enter the upper limit of the number of tasks for service auto scaling to use. The desired count will not go above this count.
10. For **Scaling policy type**, choose **Target tracking**.
11. For **Metric type**, select the corresponding high-resolution metric. For example, choose `ECSServiceAverageCPUUtilizationHighResolution` if you configured `CPUUtilization` at 20-second resolution, or `ECSServiceAverageMemoryUtilizationHighResolution` if you configured `MemoryUtilization` at 20-second resolution.
12. For **Target value**, enter the target utilization percentage. Service auto scaling scales out your capacity until the average utilization is at the target value, or until it reaches the maximum number of tasks you specified.
13. Under **Additional Settings**, configure the following:
  - a. For **Scale-out cooldown period**, enter the amount of time in seconds to wait for a previous scale-out activity to take effect.
  - b. For **Scale-in cooldown period**, enter the amount of time in seconds after a scale-in activity completes before another scale-in activity can start.
14. Choose **Create** to create the service.

## AWS CLI

1. Create the service with monitoring configuration using the [create-service](#) command.

```
aws ecs create-service --region us-east-1 \  
  --cluster my-cluster \  
  --service-name my-service \  
  --task-definition my-app:1 \  
  --desired-count 2 \  
  --monitoring  
  "metricConfigurations=[{metricNames=[CPUUtilization,MemoryUtilization],resolutionSeconds=2
```

2. Register the service as a scalable target using the [register-scalable-target](#) command.

```
aws application-autoscaling register-scalable-target \  
  --service-namespace ecs \  
  --resource-id service/my-cluster/my-service \  
  --scalable-dimension ecs:service:DesiredCount \  
  --min-capacity 1 \  
  --max-capacity 10 \  
  --region us-east-1
```

3. Create a target tracking scaling policy with a high-resolution predefined metric using the [put-scaling-policy](#) command.

```
aws application-autoscaling put-scaling-policy \  
  --service-namespace ecs \  
  --resource-id service/my-cluster/my-service \  
  --scalable-dimension ecs:service:DesiredCount \  
  --policy-name my-highres-cpu-policy \  
  --policy-type TargetTrackingScaling \  
  --target-tracking-scaling-policy-configuration '{  
    "TargetValue": 50.0,  
    "PredefinedMetricSpecification": {  
      "PredefinedMetricType": "ECSServiceAverageCPUUtilizationHighResolution"  
    }  
  }' \  
  --region us-east-1
```

4. Verify the policy was created using the [describe-scaling-policies](#) command.

```
aws application-autoscaling describe-scaling-policies \  
  --service-namespace ecs \  

```

```
--resource-id service/my-cluster/my-service \  
--scalable-dimension ecs:service:DesiredCount \  
--region us-east-1
```

## Update an existing service to use high-resolution metrics for faster auto scaling

Updating an existing service to use high-resolution metrics for faster service auto scaling is a two-step process. You must first update the monitoring resolution, which triggers a service deployment. After the deployment completes successfully and all tasks are emitting metrics at 20-second resolution, you can then configure a high-resolution scaling policy.

### Important

If your service was previously using 60-second metric resolution, high-resolution metrics for scaling policy will only be available on the Amazon ECS console after you have updated your service to use 20-second metric resolution and the service deployment completes.

## Console

### Step 1: Update monitoring resolution

1. On the **Clusters** page, choose the cluster that contains the service you want to update.
2. In the **Services** section, select the service and choose **Update**.
3. In the Update Service form, in the **Monitoring configuration** section, choose **Add metric configuration**.
4. For **Metric name**, select the metric you want to collect at high resolution. Choose `CPUUtilization` or `MemoryUtilization`.
5. For **Resolution (seconds)**, select **20**.
6. (Optional) To add both metrics at high resolution, choose **Add metric configuration** again and repeat the previous two steps for the other metric.
7. Choose **Update** to submit the change. This triggers a service deployment.
8. Wait for the deployment to complete. You can monitor progress on the service details page in the **Deployments** tab.

 **Note**

The high-resolution scaling metric options are greyed out in the service auto scaling section until the deployment succeeds and all tasks are emitting at 20-second resolution.

## Step 2: Configure high-resolution scaling policy

After the deployment completes, configure the scaling policy using one of the following methods:

### Option A: Service details page

1. On the service details page, choose the **Service auto scaling** tab.
2. Choose **Create scaling policy** (or edit an existing policy).
3. For **Scaling policy type**, choose **Target tracking**.
4. For **Metric type**, select the high-resolution metric. For example, `ECSServiceAverageCPUUtilizationHighResolution` or `ECSServiceAverageMemoryUtilizationHighResolution`.
5. For **Target value**, enter the target utilization percentage.
6. Under **Additional Settings**, configure the following:
  - a. For **Scale-out cooldown period**, enter the amount of time in seconds to wait for a previous scale-out activity to take effect.
  - b. For **Scale-in cooldown period**, enter the amount of time in seconds after a scale-in activity completes before another scale-in activity can start.
7. Choose **Create scaling policy**.

### Option B: Update Service form

1. On the service details page, choose **Update**.
2. In the **Service auto scaling** section, choose **Use service auto scaling** (if not already enabled).
3. For **Minimum number of tasks**, enter the lower limit.

4. For **Maximum number of tasks**, enter the upper limit.
5. For **Scaling policy type**, choose **Target tracking**.
6. For **Metric type**, select the high-resolution metric (now enabled after the deployment completed).
7. For **Target value**, enter the target utilization percentage.
8. Under **Additional Settings**, set the **Scale-out cooldown period** and **Scale-in cooldown period**.
9. Choose **Update** to submit the change.

## AWS CLI

### Step 1: Update monitoring resolution

1. Update the service with monitoring configuration using the [update-service](#) command.

```
aws ecs update-service --region us-east-1 \  
    --cluster my-cluster \  
    --service my-service \  
    --monitoring  
    "metricConfigurations=[{metricNames=[CPUUtilization,MemoryUtilization],resolutionSeconds=2
```

2. Wait for the deployment to complete. You can monitor progress using the [describe-services](#) command and checking the deployment status.

```
aws ecs describe-services --region us-east-1 \  
    --cluster my-cluster \  
    --services my-service
```

3. After the deployment completes, verify the monitoring configuration is active by describing the service revision. Get the active service revision ARN from the describe-services output, then run:

```
aws ecs describe-service-revisions --region us-east-1 \  
    --service-revision-arns arn:aws:ecs:us-east-1:012345678910:service-revision/my-cluster/my-service/1234567890123456789
```

Confirm the monitoring configuration appears in the response:

```
{
  "serviceRevisions": [
    {
      ...
      "monitoring": {
        "metricConfigurations": [
          {
            "metricNames": ["CPUUtilization", "MemoryUtilization"],
            "resolutionSeconds": 20
          }
        ]
      }
    }
  ]
}
```

## Step 2: Configure high-resolution scaling policy

1. Register the service as a scalable target if not already registered, using the [register-scalable-target](#) command.

```
aws application-autoscaling register-scalable-target \
  --service-namespace ecs \
  --resource-id service/my-cluster/my-service \
  --scalable-dimension ecs:service:DesiredCount \
  --min-capacity 1 \
  --max-capacity 10 \
  --region us-east-1
```

2. Create a target tracking scaling policy with a high-resolution predefined metric using the [put-scaling-policy](#) command. The following example targets 50% CPU utilization:

```
aws application-autoscaling put-scaling-policy \
  --service-namespace ecs \
  --resource-id service/my-cluster/my-service \
  --scalable-dimension ecs:service:DesiredCount \
  --policy-name my-highres-cpu-policy \
  --policy-type TargetTrackingScaling \
  --target-tracking-scaling-policy-configuration '{
    "TargetValue": 50.0,
```

```
"PredefinedMetricSpecification": {  
    "PredefinedMetricType": "ECSServiceAverageCPUUtilizationHighResolution"  
}  
' \  
--region us-east-1
```

### 3. Verify the policy was created:

```
aws application-autoscaling describe-scaling-policies \  
    --service-namespace ecs \  
    --resource-id service/my-cluster/my-service \  
    --scalable-dimension ecs:service:DesiredCount \  
    --region us-east-1
```

## Validate faster service auto scaling

### Part 1: Verify high-resolution metrics are publishing

1. Navigate to the CloudWatch console.
2. In the navigation pane, choose **Metrics**, then choose **All metrics**.
3. Choose the **AWS/ECS** namespace.
4. Choose **ClusterName, ServiceName**.
5. Locate the CPUUtilization and MemoryUtilization metrics for your service.
6. Set the period to **20 seconds**. You should see data points at 20-second intervals, confirming that high-resolution metrics are active.

### Part 2: Verify scaling policy is using the high-resolution metric

1. On the service details page, choose the **Service auto scaling** tab.
2. View your existing scaling policies and confirm the metric is set to a high-resolution variant (ECSServiceAverageCPUUtilizationHighResolution or ECSServiceAverageMemoryUtilizationHighResolution).
3. Alternatively, verify using the CLI:

```
aws application-autoscaling describe-scaling-policies \  
    --service-namespace ecs \  
    --resource-id service/my-cluster/my-service \  
    --scalable-dimension ecs:service:DesiredCount \  
    --region us-east-1
```

```
--resource-id service/my-cluster/my-service \  
--scalable-dimension ecs:service:DesiredCount \  
--region us-east-1
```

Confirm the `PredefinedMetricType` in the response is set to a high-resolution metric.

## Considerations

- Monitoring configuration changes create a new service revision and require a service deployment. The high-resolution scaling metric is not available until the deployment completes and all tasks are emitting at 20-second resolution.
- High-resolution metrics are supported for services using Application Load Balancers and Network Load Balancers. Services using Classic Load Balancers without target groups are not supported.
- High-resolution metrics are not supported for services using the `CODE_DEPLOY` or `EXTERNAL` deployment controller types.
- You can view the monitoring configuration for your service using `DescribeServiceRevisions`. The monitoring configuration is not returned in `CreateService` or `UpdateService` responses.

## Use predefined increments based on CloudWatch alarms to scale Amazon ECS services

With step scaling policies, you create and manage the CloudWatch alarms that invoke the scaling process. When an alarm is breached, Amazon ECS initiates the scaling policy associated with that alarm. The step scaling policy scales tasks using a set of adjustments, known as step adjustments. The size of the adjustment varies based on the magnitude of the alarm breach.

- If the breach exceeds the first threshold, Amazon ECS applies the first step adjustment.
- If the breach exceeds the second threshold, Amazon ECS applies the second step adjustment, and so on.

We strongly recommend that you use target tracking scaling policies to scale on metrics like average CPU utilization or average request count per target. Metrics that decrease when capacity increases and increase when capacity decreases can be used to proportionally scale out or in the number of tasks using target tracking. This helps ensure that Amazon ECS follows the demand curve for your applications closely.

## Create a step scaling policy for Amazon ECS service auto scaling

Create a step scaling policy to have Amazon ECS increase or decrease the desired number of tasks in your service automatically. Step scaling runs based on a set of scaling adjustments, known as step adjustments, that vary based on the size of the alarm breach.

### Console

1. In addition to the standard IAM permissions for creating and updating services, you need additional permissions. For more information, see [IAM permissions required for Amazon ECS service auto scaling](#).
2. Determine the metrics to use for the policy. The following metrics are available:
  - **ECSServiceAverageCPUUtilization** – The average CPU utilization the service should use.
  - **ECSServiceAverageMemoryUtilization** – Average memory utilization the service should use.
  - **ALBRequestCountPerTarget** – The average number of requests per minute that task should ideally receive.
3. Create the CloudWatch alarms for the metrics. For more information, see [Create a CloudWatch alarm based on a static threshold](#) in the *Amazon CloudWatch User Guide*.
4. Open the console at <https://console.aws.amazon.com/ecs/v2>.
5. On the **Clusters** page, choose the cluster.
6. On the cluster details page, in the **Services** section, and then choose the service.

The service details page appears.

7. Choose **Set the number of tasks**.
8. Under **Amazon ECS service task count**, choose **Use auto scaling**.

The **Task count section** appears.

- a. For **Minimum number of tasks**, enter the lower limit of the number of tasks for service auto scaling to use. The desired count will not go below this count.
- b. For **Maximum**, enter the upper limit of the number of tasks for service auto scaling to use. The desired count will not go above this count.
- c. Choose **Save**.

The policies page appears.

9. Choose **Create scaling policy**.

The **Create policy** page appears.

10. For **Scaling policy type**, choose **Step Scaling**.
11. Configure the scaling-out properties. Under **Steps to add tasks** do the following:
  - a. For **Policy name**, enter the name of the policy.
  - b. For **CloudWatch alarm name**, choose the CloudWatch alarm.
  - c. For **Metric aggregation type**, choose how to compare the selected metric to the defined threshold.
  - d. For **Adjustment types**, choose whether the adjustment is based on a change in the number of tasks, or a change in the percentage of tasks.
  - e. For **Actions to take**, enter the values for what action to take.

Choose **Add step** to add additional actions.

12. Configure the scaling-in properties. Under **Steps to remove tasks**, do the following:
  - a. For **Policy name**, enter the name of the policy.
  - b. For **CloudWatch alarm name**, choose the CloudWatch alarm.
  - c. For **Metric aggregation type**, choose how to compare the selected metric to the defined threshold.
  - d. For **Adjustment types**, choose whether the adjustment is based on a change in the number of tasks, or a change in the percentage of tasks.
  - e. For **Actions to take**, enter the values for what action to take.

Choose **Add step** to add additional actions.

13. For **Cooldown period**, enter the amount of time, in seconds, to wait for a previous scaling activity to take effect. For an add policy, this is the time after a scale-out activity that the scaling policy blocks scale-in activities and limits how many tasks can be scale out at a time. For a remove policy, this is the time after a scale-in activity that must pass before another scale-in activity can start.
14. Choose **Create scaling policy**.

## AWS CLI

1. Register your Amazon ECS service as a scalable target using the [register-scalable-target](#) command.

2. Create a scaling policy using the [put-scaling-policy](#) command.

## Use scheduled actions to scale Amazon ECS services

With scheduled scaling, you can set up automatic scaling for your application based on predictable load changes by creating scheduled actions that increase or decrease the number of tasks at specific times. This allows you to scale your application proactively to match predictable load changes.

These scheduled scaling actions allow you to optimize costs and performance. Your application has a sufficient number of tasks to handle the mid-week traffic peak, but does not over-provision the number of tasks at other times.

You can use scheduled scaling and scaling policies together to get the benefits of proactive and reactive approaches to scaling. After a scheduled scaling action runs, the scaling policy can continue to make decisions about whether to further scale the number of tasks. This helps you ensure that you have a sufficient number of tasks to handle the load for your application. While your application scales to match demand, current capacity must fall within the minimum and maximum number of tasks that was set by your scheduled action.

You can configure schedule scaling using the AWS CLI. For more information about scheduled scaling, see [Scheduled Scaling](#) in the *Application Auto Scaling User Guide*.

### Create a scheduled action for Amazon ECS service auto scaling

Create a scheduled action to have Amazon ECS increase or decrease the number of tasks that your service runs based on the date and time.

#### Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, choose the service.

The service details page appears.

4. Choose **Service auto scaling**.

The service auto scaling page appears.

5. If you haven't configured service auto scaling, choose **Set the number of tasks**.

The **Amazon ECS service task count** section appears.

Under **Amazon ECS service task count**, choose **Use service auto scaling to adjust your service's desired task count**.

The **Task count** section appears.

- a. For **Minimum number of tasks**, enter the lower limit of the number of tasks for service auto scaling to use. The desired count will not go below this count.
- b. For **Maximum**, enter the upper limit of the number of tasks for service auto scaling to use. The desired count will not go above this count.
- c. Choose **Choose Save**.

The policies page appears.

6. Choose **Scheduled actions**, and then choose **Create**.

The **Create Scheduled action** page appears.

7. For **Action name**, enter a unique name.
8. For **Time zone**, choose a time zone.

All of the time zones listed are from the IANA Time Zone database. For more information, see [List of tz database time zones](#).

9. For **Start time**, enter the **Date** and **Time** the action starts.

If you chose a recurring schedule, the start time defines when the first scheduled action in the recurring series runs.

10. For **Recurrence**, choose one of the available options.
  - To scale on a recurring schedule, choose how often Amazon ECS runs the scheduled action.
    - If you choose an option that begins with **Rate**, the cron expression is created for you.
    - If you choose **Cron**, enter a cron expression that specifies when to perform the action.
  - To scale only once, choose **Once**.
11. Under **Task adjustments**, do the following:
  - For **Minimum**, enter the minimum number of tasks the service should run.
  - For **Maximum**, enter the maximum number of tasks the service should run.

## 12. Choose **Create scheduled action**.

### CLI

Use the AWS CLI as follows to configure scheduled scaling policies for your service. Replace each *user input placeholder* with your own information.

#### Example: To scale one time only

Use the following [put-scheduled-action](#) command with the `--start-time "YYYY-MM-DDThh:mm:ssZ"` and either or both of the `--MinCapacity` and `--MaxCapacity` options.

```
aws application-autoscaling put-scheduled-action --service-namespace ecs \
  --resource-id service/my-cluster/my-service \
  --scheduled-action-name my-one-time-schedule \
  --start-time 2021-01-30T12:00:00 \
  --scalable-target-action MinCapacity=3,MaxCapacity=10
```

#### Example: To schedule scaling on a recurring schedule

Use the following [put-scheduled-action](#) command. Replace the *user input* with your values.

```
aws application-autoscaling put-scheduled-action --service-namespace ecs \
  --resource-id service/my-cluster/my-service \
  --scheduled-action-name my-recurring-action \
  --schedule "rate(5 hours)" \
  --start-time 2021-01-30T12:00:00 \
  --end-time 2021-01-31T22:00:00 \
  --scalable-target-action MinCapacity=3,MaxCapacity=10
```

The specified recurrence schedule runs based on the UTC time zone. To specify a different time zone, include the `--time-zone` option and the name of the IANA time zone, as in the following example.

```
--time-zone "America/New_York"
```

For more information, see [List of tz database time zones](#).

## Use historical patterns to scale Amazon ECS services with predictive scaling

Predictive scaling looks at past load data from traffic flows to analyze daily or weekly patterns. It then uses this analysis to anticipate future needs and proactively increase tasks in your service as needed.

Predictive auto scaling is most useful in the following situations.

- Cyclical traffic - Increased use of resources during regular business hours, and decreased use of resources during evenings and weekends.
- Recurring on-and-off workload patterns - Examples include batch processing, testing, or periodic data analysis.
- Applications with long initialization times - This can impact application performance during scale-out events causing of noticeable latency.

If your applications take a long time to initialize and traffic increases in a regular pattern, you should consider using predictive scaling. It helps you scale faster by proactively increasing the number of tasks for forecasted loads, instead of using dynamic scaling policies, such as Target Tracking or Step Scaling alone. By helping you avoid the possibility of over-provisioning the number of tasks, predictive scaling can also potentially save you money.

For example, consider an application that has high usage during business hours and low usage overnight. At the start of each business day, predictive scaling can scale-out tasks before the first influx of traffic. This helps your application maintain high availability and performance when going from a period of lower utilization to a period of higher utilization. You don't have to wait for dynamic scaling to react to changing traffic. You also don't have to spend time reviewing your application's load patterns and trying to schedule the right amount of tasks using scheduled scaling.

Predictive scaling is a service-level capability that scales the task of your service independently from the scaling of the underlying compute capacity (for example, EC2 or Fargate). For Fargate, AWS manages and automatically scales the underlying capacity based on task requirements. For EC2 capacity, you can use Auto Scaling group capacity providers to automatically scale underlying EC2 instances based on the scaling requirements of your tasks.

### Contents

- [How predictive scaling works in Amazon ECS](#)

- [Create a predictive scaling policy for Amazon ECS service auto scaling](#)
- [Evaluate your predictive scaling policies for Amazon ECS](#)
- [Use scheduled actions to override forecast values for Amazon ECS](#)

## How predictive scaling works in Amazon ECS

Here you can learn about considerations for using predictive scaling, how it works, and what the limits are.

### Considerations for using predictive scaling

- You want to make sure predictive scaling is suitable for your workload. You can check this by configuring scaling policies in **forecast only** mode and see what the console recommends. You should evaluate the forecast and recommendations before starting to use predictive scaling.
- Before predictive scaling can start forecasting, it needs at least 24 hours of historical data. The more historical data that is available, the more effective the forecast, with two weeks being ideal. You'll also need to wait 24 hours for before predictive scaling can generate new forecasts when you delete an Amazon ECS service and create a new one. One way to speed this up is to use custom metrics to aggregate metrics across old and new Amazon ECS service.
- Choose a load metric that accurately represents the full load on your application and is the aspect of your application that's most important to scale on.
- Dynamic scaling with predictive scaling helps you follow the demand for your application closely, so you can scale in during lulls and scale out during unexpected increases in traffic. When multiple scaling policies are active, each policy determines the desired number of tasks independently, and the desired number of tasks is set to the maximum of those.
- You can use predictive scaling alongside your dynamic scaling policies, such as target tracking or step scaling, so that your applications scale based on both real-time and historic patterns. By itself, predictive scaling doesn't scale-in your tasks.
- If you use a custom role when calling the `register-scalable-target` API, you may get an error saying predictive scaling policy can only work with SLR enabled. In this case you should call `register-scalable-target` again but without `role-arn`. Use SLR when registering the scalable target and call the `put-scaling-policy` API.

## How predictive scaling works

You use predictive scaling by creating a predictive scaling policy that specifies the CloudWatch metric to monitor and analyze. Predictive scaling must have at least 24 hours of data to start forecasting future values.

After you create the policy, predictive scaling starts analyzing metric data from up to the past 14 days to identify patterns. This analysis is used to generate the next 48 hours of requirements hourly forecasts. The latest CloudWatch data is used to update the forecast every six hours. As new data comes in, predictive scaling continuously improves the accuracy of future forecasts.

When you first enable predictive scaling, it runs in *forecast only* mode. It generates forecasts in this mode, but it doesn't scale your Amazon ECS service based on those forecasts. This means you can evaluate the accuracy and suitability of the forecast. You view forecast data by using the `GetPredictiveScalingForecast` API operation or the AWS Management Console.

When you decide to start using predictive scaling, switch the scaling policy to *forecast and scale* mode. The following occurs while in this mode.

Your Amazon ECS service is scaled at the start of each hour based on the forecast for that hour, by default. You can choose to start earlier by using the `SchedulingBufferTime` property in the `PutScalingPolicy` API operation. This makes new tasks launch ahead of forecasted demand and gives them time to boot and become ready to handle traffic.

### Maximum tasks limit

When you register Amazon ECS services for scaling, you define a maximum number of tasks that can be launched per service. By default, when scaling policies are set, they cannot increase the number of tasks higher than its maximum limit.

Alternatively, you can allow the service's maximum number of tasks to be automatically increased if the forecast approaches or exceeds the maximum number of tasks of the Amazon ECS service.

#### Warning

Use caution when allowing the maximum number of tasks to be automatically increased. This can lead to more tasks being launched than intended, if the increased maximum number of tasks isn't monitored and managed. The increased maximum number of tasks then becomes the new normal maximum number of tasks for the Amazon ECS service until

you manually update it. The maximum number of tasks doesn't automatically decrease back to the original maximum.

## Supported regions

- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Asia Pacific (Malaysia)
- Asia Pacific (Melbourne)
- Asia Pacific (Mumbai)
- Asia Pacific (New Zealand)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Taipei)
- Asia Pacific (Thailand)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)

- Europe (Ireland)
- Europe (London)
- Europe (Milan)
- Europe (Paris)
- Europe (Spain)
- Europe (Stockholm)
- Europe (Zurich)
- Israel (Tel Aviv)
- Mexico (Central)
- Middle East (Bahrain)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

## Create a predictive scaling policy for Amazon ECS service auto scaling

Create a predictive scaling policy to have Amazon ECS increase or decrease the number of tasks that your service runs based on historical data.

### Note

A new service needs to provide at least 24 hours of data before a forecast can be generated.

## Console

1. In addition to the standard IAM permissions for creating and updating services, you need additional permissions. For more information, see [IAM permissions required for Amazon ECS service auto scaling](#).
2. Determine the metrics to use for the policy. The following metrics are available:
  - **ECSServiceAverageCPUUtilization** – The average CPU utilization the service should use.
  - **ECSServiceAverageMemoryUtilization** – Average memory utilization the service should use.

- **ALBRequestCountPerTarget** – The average number of requests per minute that task should ideally receive.

You can alternatively use a custom metric. You need to define the following values:

- **Load** - a metric that accurately represents the full load on your application and is the aspect of your application that's most important to scale on.
- **Scaling metric** - the best predictor for how much utilization is ideal for your application.

3. Open the console at <https://console.aws.amazon.com/ecs/v2>.
4. On the **Clusters** page, choose the cluster.
5. On the cluster details page, in the **Services** section, choose the service.

The service details page appears.

6. Choose **Service auto scaling** and then choose **Set the number of tasks**.
7. Under **Amazon ECS service task count**, choose **Use auto scaling**.

The **Task count section** appears.

- a. For **Minimum number of tasks**, enter the lower limit of the number of tasks for service auto scaling to use. The desired count will not go below this count.
- b. For **Maximum**, enter the upper limit of the number of tasks for service auto scaling to use. The desired count will not go above this count.
- c. Choose **Save**.

The policies page appears.

8. Choose **Create scaling policy**.

The **Create policy** page appears.

9. For **Scaling policy type**, choose **Predictive Scaling**.
10. For **Policy name**, enter the name of the policy.
11. For **Metric pair**, choose your metrics from the list of options.

If you chose **Application Load Balancer request count per target**, then choose a target group in **Target group**. **Application Load Balancer request count per target** is only supported if you have attached an Application Load Balancer target group for your service.

If you chose **Custom metric pair**, choose individual metrics from the lists for **Load metric** and **Scaling metric**.

12. For **Target utilization**, enter the target value for the percentage of tasks that Amazon ECS should maintain. Service auto scaling scales out your capacity until the average utilization is at the target utilization, or until it reaches the maximum number of tasks you specified.
13. Choose **Create scaling policy**.

## AWS CLI

Use the AWS CLI as follows to configure predictive scaling policies for your Amazon ECS service. Replace each *user input placeholder* with your own information.

For more information about the CloudWatch metrics you can specify, see [PredictiveScalingMetricSpecification](#) in the *Amazon EC2 Auto Scaling API Reference*.

### Example 1: A predictive scaling policy with predefined memory.

The following is an example policy with a predefined memory configuration.

```
cat policy.json
{
  "MetricSpecifications": [
    {
      "TargetValue": 40,
      "PredefinedMetricPairSpecification": {
        "PredefinedMetricType": "ECSServiceMemoryUtilization"
      }
    }
  ],
  "SchedulingBufferTime": 3600,
  "MaxCapacityBreachBehavior": "HonorMaxCapacity",
  "Mode": "ForecastOnly"
}
```

The following example illustrates creating the policy by running the [put-scaling-policy](#) command with the configuration file specified.

```
aws application-autoscaling put-scaling-policy \
--service-namespace ecs \
```

```
--region us-east-1 \
--policy-name predictive-scaling-policy-example \
--resource-id service/MyCluster/test \
--policy-type PredictiveScaling \
--scalable-dimension ecs:service:DesiredCount \
--predictive-scaling-policy-configuration file://policy.json
```

If successful, this command returns the policy's ARN.

```
{
  "PolicyARN": "arn:aws:autoscaling:us-
east-1:012345678912:scalingPolicy:d1d72dfe-5fd3-464f-83cf-824f16cb88b7:resource/ecs/
service/MyCluster/test:policyName/predictive-scaling-policy-example",
  "Alarms": []
}
```

## Example 2: A predictive scaling policy with predefined CPU.

The following is an example policy with a predefined CPU configuration.

```
cat policy.json
{
  "MetricSpecifications": [
    {
      "TargetValue": 0.00000004,
      "PredefinedMetricPairSpecification": {
        "PredefinedMetricType": "ECSServiceCPUUtilization"
      }
    }
  ],
  "SchedulingBufferTime": 3600,
  "MaxCapacityBreachBehavior": "HonorMaxCapacity",
  "Mode": "ForecastOnly"
}
```

The following example illustrates creating the policy by running the [put-scaling-policy](#) command with the configuration file specified.

```
aws aas put-scaling-policy \
--service-namespace ecs \
--region us-east-1 \
--policy-name predictive-scaling-policy-example \
```

```
--resource-id service/MyCluster/test \  
--policy-type PredictiveScaling \  
--scalable-dimension ecs:service:DesiredCount \  
--predictive-scaling-policy-configuration file://policy.json
```

If successful, this command returns the policy's ARN.

```
{  
  "PolicyARN": "arn:aws:autoscaling:us-  
east-1:012345678912:scalingPolicy:d1d72dfe-5fd3-464f-83cf-824f16cb88b7:resource/ecs/  
service/MyCluster/test:policyName/predictive-scaling-policy-example",  
  "Alarms": []  
}
```

## Evaluate your predictive scaling policies for Amazon ECS

Before you use a predictive scaling policy to scale your services, review the recommendations and other data for your policy in the Amazon ECS console. This is important because you don't want a predictive scaling policy to scale your actual capacity until you know that its predictions are accurate.

If the service is new, allow 24 hours to create the first forecast.

When AWS creates a forecast, it uses historical data. If your service doesn't have much recent historical data yet, predictive scaling might temporarily backfill the forecast with aggregates created from the currently available historical aggregates. Forecasts are backfilled for up to two weeks before a policy's creation date.

## View your predictive scaling recommendations

For effective analysis, service auto scaling should have at least two predictive scaling policies to compare. (However, you can still review the findings for a single policy.) When you create multiple policies, you can evaluate a policy that uses one metric against a policy that uses a different metric. You can also evaluate the impact of different target value and metric combinations. After the predictive scaling policies are created, Amazon ECS immediately starts evaluating which policy would do a better job of scaling your group.

## To view your recommendations in the Amazon ECS console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.

2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, choose the service.

The service details page appears.

4. Choose **Service auto scaling**.
5. Choose the predictive scaling policy, and then choose **Actions, Predictive Scaling, View recommendation**.

You can view details about a policy along with our recommendation. The recommendation tells you whether the predictive scaling policy does a better job than not using it.

If you're unsure whether a predictive scaling policy is appropriate for your group, review the **Availability impact** and **Cost impact** columns to choose the right policy. The information for each column tells you what the impact of the policy is.

- **Availability impact:** Describes whether the policy would avoid negative impact to availability by provisioning enough tasks to handle the workload, compared to not using the policy.
- **Cost impact:** Describes whether the policy would avoid negative impact on your costs by not over-provisioning tasks, compared to not using the policy. By over-provisioning too much, your services are underutilized or idle, which only adds to the cost impact.

If you have multiple policies, then a **Best prediction** tag displays next to the name of the policy that gives the most availability benefits at lower cost. More weight is given to availability impact.

6. (Optional) To select the desired time period for recommendation results, choose your preferred value from the **Evaluation period** dropdown: **2 days**, **1 week**, or **2 weeks**. By default, the evaluation period is the last two weeks. A longer evaluation period provides more data points to the recommendation results. However, adding more data points might not improve the results if your load patterns have changed, such as after a period of exceptional demand. In this case, you can get a more focused recommendation by looking at more recent data.

#### **Note**

Recommendations are generated only for policies that are in **Forecast only** mode. The recommendations feature works better when a policy is in the **Forecast only** mode

throughout the evaluation period. If you start a policy in **Forecast and scale** mode and switch it to **Forecast only** mode later, the findings for that policy are likely to be biased. This is because the policy has already contributed toward the actual capacity.

## Review predictive scaling monitoring graphs

In the console, you can review the forecast of the previous days, weeks, or months to visualize how well the policy performs over time. You can also use this information to evaluate the accuracy of predictions when deciding whether to let a policy scale your actual number of tasks.

### To review predictive scaling monitoring graphs in the Amazon ECS console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, choose the service.

The service details page appears.

4. Choose **Service auto scaling**.
5. Choose the predictive scaling policy, and then choose **Actions, Predictive Scaling, View Graph**.
6. In the **Monitoring** section, you can view your policy's past and future forecasts for load and capacity against actual values. The **Load** graph shows load forecast and actual values for the load metric that you chose. The **Capacity** graph shows the number of tasks predicted by the policy. It also includes the actual number of tasks launched. The vertical line separates historical values from future forecasts. These graphs become available shortly after the policy is created.
7. (Optional) To change the amount of historical data shown in the chart, choose your preferred value from the **Evaluation period** dropdown. The evaluation period does not transform the data on this page in any way. It only changes the amount of historical data shown.

### Compare data in the Load graph

Each horizontal line represents a different set of data points reported in one-hour intervals:

1. **Actual observed load** uses the SUM statistic for your chosen load metric to show the total hourly load in the past.

2. **Load predicted by the policy** shows the hourly load prediction. This prediction is based on the previous two weeks of actual load observations.

## Compare data in the Capacity graph

Each horizontal line represents a different set of data points reported in one-hour intervals:

1. **Actual observed number of tasks** shows your Amazon ECS service actual capacity in the past, which depends on your other scaling policies and minimum group size in effect for the selected time period.
2. **Capacity predicted by the policy** shows the baseline capacity that you can expect to have at the beginning of each hour when the policy is in **Forecast and scale** mode.
3. **Inferred required number of tasks** shows the ideal number of tasks in your service to maintain the scaling metric at the target value you chose.
4. **Minimum number of tasks** shows the minimum number of tasks in your service.
5. **Maximum capacity** shows the maximum number of tasks in your service.

For the purpose of calculating the inferred required capacity, we begin by assuming that each task is equally utilized at a specified target value. In practice, the number of tasks are not equally utilized. By assuming that utilization is uniformly spread between tasks, however, we can make a likelihood estimate of the amount of capacity that is needed. The requirement for the number of tasks is then calculated to be inversely proportional to the scaling metric that you used for your predictive scaling policy. In other words, as the number of tasks increase, the scaling metric decreases at the same rate. For example, if the number of tasks doubles, the scaling metric must decrease by half.

The formula for the inferred required capacity:

$$\text{sum of } (\text{actualServiceUnits} * \text{scalingMetricValue}) / (\text{targetUtilization})$$

For example, we take the `actualServiceUnits` (10) and the `scalingMetricValue` (30) for a given hour. We then take the `targetUtilization` that you specified in your predictive scaling policy (60) and calculate the inferred required capacity for the same hour. This returns a value of 5. This means that five is the inferred amount of capacity required to maintain capacity in direct inverse proportion to the target value of the scaling metric.

**Note**

Various levers are available for you to adjust and improve the cost savings and availability of your application.

- You use predictive scaling for the baseline capacity and dynamic scaling to handle additional capacity. Dynamic scaling works independently from predictive scaling, scaling in and out based on current utilization. First, Amazon ECS calculates the recommended number of tasks for each non-scheduled scaling policy. Then, it scales based on the policy that provides the largest number of tasks.
- To allow scale in to occur when the load decreases, your service should always have at least one dynamic scaling policy with the scale-in portion enabled.
- You can improve scaling performance by making sure that your minimum and maximum capacity are not too restrictive. A policy with a recommended number of tasks that does not fall within the minimum and maximum capacity range will be prevented from scaling in and out.

**Monitor predictive scaling metrics for Amazon ECS with CloudWatch**

You can use Amazon CloudWatch to monitor your data for predictive scaling. A predictive scaling policy collects data that is used to forecast your future load. The data collected is automatically stored in CloudWatch at regular intervals and can be used to visualize how well the policy performs over time. You can also create CloudWatch alarms to notify you when performance indicators change beyond the limits that you defined.

**Visualize historical forecast data**

Load forecast data for a predictive scaling policy can be viewed in CloudWatch and can be useful when visualizing forecasts against other CloudWatch metrics in a single graph. You can also see trends over time by viewing a broader time range. You can access up to 15 months of historical metrics to get a better perspective on how your policy is performing.

**To view historical forecast data using the CloudWatch console**

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the navigation pane, choose **Metrics** and then **All metrics**.
3. Choose the **Application Auto Scaling** metric namespace.

4. Choose **Predictive Scaling Load Forecasts**.
5. In the search field, enter the name of the predictive scaling policy or the name of the Amazon ECS service group, and then press Enter to filter the results.
6. To graph a metric, select the check box next to the metric. To change the name of the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**. For more information, see [Graphing a metric](#) in the *Amazon CloudWatch User Guide*.
7. To change the statistic, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different statistic. Although you can choose any statistic for each metric, not all statistics are useful for **PredictiveScalingLoadForecast** metrics. For example, the **Average**, **Minimum**, and **Maximum** statistics are useful, but the **Sum** statistic is not.
8. To add another metric to the graph, under **Browse**, choose **All**, find the specific metric, and then select the check box next to it. You can add up to 10 metrics.
9. (Optional) To add the graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

## Create accuracy metrics using metric math

With metric math, you can query multiple CloudWatch metrics and use math expressions to create new time series based on these metrics. You can visualize the resulting time series on the CloudWatch console and add them to dashboards. For more information about metric math, see [Using metric math](#) in the *Amazon CloudWatch User Guide*.

Using metric math, you can graph the data that service auto scaling generates for predictive scaling in different ways. This helps you monitor policy performance over time, and helps you understand whether your combination of metrics can be improved.

For example, you can use a metric math expression to monitor the [mean absolute percentage error](#) (MAPE). The MAPE metric helps monitor the difference between the forecasted values and the actual values observed during a given forecast window. Changes in the value of MAPE can indicate whether the policy's performance is degrading over time as the nature of your application changes. An increase in MAPE signals a wider gap between the forecasted values and the actual values.

## Example: Metric math expression

To get started with this type of graph, you can create a metric math expression like the one shown in the following example.

Instead of a single metric, there is an array of metric data query structures for `MetricDataQueries`. Each item in `MetricDataQueries` gets a metric or performs a math expression. The first item, `e1`, is the math expression. The designated expression sets the `ReturnData` parameter to `true`, which ultimately produces a single time series. For all other metrics, the `ReturnData` value is `false`.

In the example, the designated expression uses the actual and forecasted values as input and returns the new metric (MAPE). `m1` is the CloudWatch metric that contains the actual load values (assuming CPU utilization is the load metric that was originally specified for the policy named `my-predictive-scaling-policy`). `m2` is the CloudWatch metric that contains the forecasted load values. The math syntax for the MAPE metric is as follows:

*Average of  $(\text{abs}((\text{Actual} - \text{Forecast})/(\text{Actual})))$*

### Visualize your accuracy metrics and set alarms

To visualize the accuracy metric data, select the **Metrics** tab in the CloudWatch console. You can graph the data from there. For more information, see [Adding a math expression to a CloudWatch graph](#) in the *Amazon CloudWatch User Guide*.

You can also set an alarm on a metric that you're monitoring from the **Metrics** section. While on the **Graphed metrics** tab, select the **Create alarm** icon under the **Actions** column. The **Create alarm** icon is represented as a small bell. For more information and notification options, see [Creating a CloudWatch alarm based on a metric math expression](#) and [Notifying users on alarm changes](#) in the *Amazon CloudWatch User Guide*.

Alternatively, you can use [GetMetricData](#) and [PutMetricAlarm](#) to perform calculations using metric math and create alarms based on the output.

### Use scheduled actions to override forecast values for Amazon ECS

Sometimes, you might have additional information about your future application requirements that the forecast calculation is unable to take into account. For example, forecast calculations might underestimate the tasks needed for an upcoming marketing event. You can use scheduled actions to temporarily override the forecast during future time periods. The scheduled actions can run on a recurring basis, or at a specific date and time when there are one-time demand fluctuations.

For example, you can create a scheduled action with a higher number of tasks than what is forecasted. At runtime, Amazon ECS updates the minimum number of tasks in your service. Because predictive scaling optimizes for the number of tasks, a scheduled action with a minimum

number of tasks that is higher than the forecast values is honored. This prevents the number of tasks from being less than expected. To stop overriding the forecast, use a second scheduled action to return the minimum number of tasks to its original setting.

The following procedure outlines the steps for overriding the forecast during future time periods.

## Topics

- [Step 1: \(Optional\) Analyze time series data](#)
- [Step 2: Create two scheduled actions](#)

### Important

This topic assumes that you are trying to override the forecast to scale to a higher capacity than what is forecasted. If you need to temporarily decrease the number of tasks without interference from a predictive scaling policy, use *forecast only* mode instead. While in forecast only mode, predictive scaling will continue to generate forecasts, but it will not automatically increase the number of tasks. You can then monitor resource utilization and manually decrease the number of tasks as needed.

## Step 1: (Optional) Analyze time series data

Start by analyzing the forecast time series data. This is an optional step, but it is helpful if you want to understand the details of the forecast.

### 1. Retrieve the forecast

After the forecast is created, you can query for a specific time period in the forecast. The goal of the query is to get a complete view of the time series data for a specific time period.

Your query can include up to two days of future forecast data. If you have been using predictive scaling for a while, you can also access your past forecast data. However, the maximum time duration between the start and end time is 30 days.

To get the forecast using the [get-predictive-scaling-forecast](#) AWS CLI command, provide the following parameters in the command:

- Enter the name of the cluster name in the `resource-id` parameter.
- Enter the name of the policy in the `--policy-name` parameter.

- Enter the start time in the `--start-time` parameter to return only forecast data for after or at the specified time.
- Enter the end time in the `--end-time` parameter to return only forecast data for before the specified time.

```
aws application-autoscaling get-predictive-scaling-forecast \  
  --service-namespace ecs \  
  --resource-id service/MyCluster/test \  
  --policy-name cpu40-predictive-scaling-policy \  
  --scalable-dimension ecs:service:DesiredCount \  
  --start-time "2021-05-19T17:00:00Z" \  
  --end-time "2021-05-19T23:00:00Z"
```

If successful, the command returns data similar to the following example.

```
{  
  "LoadForecast": [  
    {  
      "Timestamps": [  
        "2021-05-19T17:00:00+00:00",  
        "2021-05-19T18:00:00+00:00",  
        "2021-05-19T19:00:00+00:00",  
        "2021-05-19T20:00:00+00:00",  
        "2021-05-19T21:00:00+00:00",  
        "2021-05-19T22:00:00+00:00",  
        "2021-05-19T23:00:00+00:00"  
      ],  
      "Values": [  
        153.0655799339254,  
        128.8288551285919,  
        107.1179447150675,  
        197.3601844551528,  
        626.4039934516954,  
        596.9441277518481,  
        677.9675713779869  
      ],  
      "MetricSpecification": {  
        "TargetValue": 40.0,  
        "PredefinedMetricPairSpecification": {  
          "PredefinedMetricType": "ASGCPUUtilization"  
        }  
      }  
    }  
  ]  
}
```

```

    }
  }
],
"CapacityForecast": {
  "Timestamps": [
    "2021-05-19T17:00:00+00:00",
    "2021-05-19T18:00:00+00:00",
    "2021-05-19T19:00:00+00:00",
    "2021-05-19T20:00:00+00:00",
    "2021-05-19T21:00:00+00:00",
    "2021-05-19T22:00:00+00:00",
    "2021-05-19T23:00:00+00:00"
  ],
  "Values": [
    2.0,
    2.0,
    2.0,
    2.0,
    4.0,
    4.0,
    4.0
  ]
},
"UpdateTime": "2021-05-19T01:52:50.118000+00:00"
}

```

The response includes two forecasts: `LoadForecast` and `CapacityForecast`.

`LoadForecast` shows the hourly load forecast. `CapacityForecast` shows forecast values for the capacity that is needed on an hourly basis to handle the forecasted load while maintaining a `TargetValue` of 40.0 (40% average CPU utilization).

## 2. Identify the target time period

Identify the hour or hours when the one-time demand fluctuation should take place. Remember that dates and times shown in the forecast are in UTC.

### Step 2: Create two scheduled actions

Next, create two scheduled actions for a specific time period when your application will have a higher than forecasted load. For example, if you have a marketing event that will drive traffic to your site for a limited period of time, you can schedule a one-time action to update the minimum

capacity when it starts. Then, schedule another action to return the minimum capacity to the original setting when the event ends.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, and then choose the service.

The service details page appears.

4. Choose **Service Auto Scaling**.

The policies page appears.

5. Choose **Scheduled actions**, and then choose **Create**.

The **Create Schedule action** page appears.

6. For **Action name**, enter a unique name.
7. For **Time zone**, choose a time zone.

All of the time zones listed are from the IANA Time Zone database. For more information, see [List of tz database time zones](#).

8. For **Start time**, enter the **Date** and **Time** the action starts.
9. For **Recurrence**, choose **Once**.
10. Under **Task adjustments**, For Minimum, enter a value less than or equal to the maximum number of tasks..
11. Choose **Create scheduled action**.

The policies page appears.

12. Configure a second scheduled action to return the minimum number of tasks to the original setting at the end of the event. Predictive scaling can scale the number of tasks only when the value you set for **Minimum** is lower than the forecast values.

## To create two scheduled actions for one-time events (AWS CLI)

To use the AWS CLI to create the scheduled actions, use the [put-scheduled-update-group-action](#) command.

For example, let's define a schedule that maintains a minimum capacity of three instances on May 19 at 5:00 PM for eight hours. The following commands show how to implement this scenario.

The first [put-scheduled-update-group-action](#) command instructs Amazon EC2 Auto Scaling to update the minimum capacity of the specified Auto Scaling group at 5:00 PM UTC on May 19, 2021.

```
aws autoscaling put-scheduled-update-group-action --scheduled-action-name my-event-start \  
  --auto-scaling-group-name my-asg --start-time "2021-05-19T17:00:00Z" --minimum-  
  capacity 3
```

The second command instructs Amazon EC2 Auto Scaling to set the group's minimum capacity to one at 1:00 AM UTC on May 20, 2021.

```
aws autoscaling put-scheduled-update-group-action --scheduled-action-name my-event-end \  
  --auto-scaling-group-name my-asg --start-time "2021-05-20T01:00:00Z" --minimum-  
  capacity 1
```

After you add these scheduled actions to the Auto Scaling group, Amazon EC2 Auto Scaling does the following:

- At 5:00 PM UTC on May 19, 2021, the first scheduled action runs. If the group currently has fewer than three instances, the group scales out to three instances. During this time and for the next eight hours, Amazon EC2 Auto Scaling can continue to scale out if the predicted capacity is higher than the actual capacity or if there is a dynamic scaling policy in effect.
- At 1:00 AM UTC on May 20, 2021, the second scheduled action runs. This returns the minimum capacity to its original setting at the end of the event.

## Scaling based on recurring schedules

To override the forecast for the same time period every week, create two scheduled actions and provide the time and date logic using a cron expression.

The cron expression format consists of five fields separated by spaces: [Minute] [Hour] [Day\_of\_Month] [Month\_of\_Year] [Day\_of\_Week]. Fields can contain any allowed values, including special characters.

For example, the following cron expression runs the action every Tuesday at 6:30 AM. The asterisk is used as a wildcard to match all values for a field.

```
30 6 * * 2
```

## See also

For more information about how to manage scheduled actions, see [Use scheduled actions to scale Amazon ECS services](#).

## Advanced predictive scaling policy using custom metrics for Amazon ECS

You can use predefined or custom metrics in a predictive scaling policy. Custom metrics are useful when the predefined metrics, such as CPU, memory, etc) aren't enough to sufficiently describe your application load.

When creating a predictive scaling policy with custom metrics, you can specify other CloudWatch metrics provided by AWS. Alternatively, you can specify metrics that you define and publish yourself. You can also use metric math to aggregate and transform existing metrics into a new time series that AWS doesn't automatically track. An example is combining values in your data by calculating new sums or averages called *aggregating*. The resulting data is called an *aggregate*.

The following section contains best practices and examples of how to construct the JSON structure for the policy.

### Prerequisites

To add custom metrics to your predictive scaling policy, you must have `cloudwatch:GetMetricData` permissions.

To specify your own metrics instead of the metrics that AWS provides, you must first publish your metrics to CloudWatch. For more information, see [Publishing custom metrics](#) in the *Amazon CloudWatch User Guide*.

If you publish your own metrics, make sure to publish the data points at a minimum frequency of five minutes. Data points are retrieved from CloudWatch based on the length of the period that it needs. For example, the load metric specification uses hourly metrics to measure the load on your application. CloudWatch uses your published metric data to provide a single data value for any one-hour period by aggregating all data points with timestamps that fall within each one-hour period.

### Best practices

The following best practices can help you use custom metrics more effectively:

- The most useful metric for the load metric specification is a metric that represents the load on an Auto Scaling group as a whole.
- The most useful metric for the scaling metric specification to scale by is an average throughput or utilization per task metric.
- The target utilization must match the type of scaling metric. For a policy configuration that uses CPU utilization, this is a target percentage, for example.
- If these recommendations are not followed, the forecasted future values of the time series will probably be incorrect. To validate that the data is correct, you can view the forecasted values in the console. Alternatively, after you create your predictive scaling policy, inspect the `LoadForecast` objects returned by a call to the [GetPredictiveScalingForecast](#) API.
- We strongly recommend that you configure predictive scaling in forecast only mode so that you can evaluate the forecast before predictive scaling starts actively scaling.

## Limitations

- You can query data points of up to 10 metrics in one metric specification.
- For the purposes of this limit, one expression counts as one metric.

## Troubleshooting a predictive scaling policy with custom metrics

If an issue occurs while using custom metrics, we recommend that you do the following:

- If you encounter an issue in a blue/green deployment while using a search expression, make sure you created an search expression that's looking for a partial match and not an exact match. You should also check that the query is only finding Auto Scaling groups running in the specific application. For more information about the search expression syntax, see [CloudWatch search expression syntax](#) in the *Amazon CloudWatch User Guide*.
- The [put-scaling-policy](#) command validates an expression when you create your scaling policy. However, there's a possibility that this command might fail to identify the exact cause of the detected errors. To fix the issues, troubleshoot the errors that you receive in a response from a request to the [get-metric-data](#) command. You can also troubleshoot the expression from the CloudWatch console.
- You must specify `false` for `ReturnData` if `MetricDataQueries` specifies the `SEARCH()` function on its own without a math function like `SUM()`. This is because search expressions might return multiple time series, and a metric specification based on an expression can return only one time series.

- All metrics involved in a search expression should be of the same resolution.

## Constructing the JSON for predictive scaling custom metrics with Amazon ECS

The following section contains examples for how to configure predictive scaling to query data from CloudWatch. There are two different methods to configure this option, and the method that you choose affects which format you use to construct the JSON for your predictive scaling policy. When you use metric math, the format of the JSON varies further based on the metric math being performed.

1. To create a policy that gets data directly from other CloudWatch metrics provided by AWS or metrics that you publish to CloudWatch, see [Example predictive scaling policy with custom load and scaling metrics using the AWS CLI](#).

### Example predictive scaling policy with custom load and scaling metrics using the AWS CLI

To create a predictive scaling policy with custom load and scaling metrics with the AWS CLI, store the arguments for `--predictive-scaling-configuration` in a JSON file named `config.json`.

You start adding custom metrics by replacing the replaceable values in the following example with those of your metrics and your target utilization.

```
{
  "MetricSpecifications": [
    {
      "TargetValue": 50,
      "CustomizedScalingMetricSpecification": {
        "MetricDataQueries": [
          {
            "Id": "scaling_metric",
            "MetricStat": {
              "Metric": {
                "MetricName": "MyUtilizationMetric",
                "Namespace": "MyNameSpace",
                "Dimensions": [
                  {
                    "Name": "MyOptionalMetricDimensionName",
                    "Value": "MyOptionalMetricDimensionValue"
                  }
                ]
              }
            }
          }
        ]
      }
    }
  ]
}
```

```
    },  
    "Stat": "Average"  
  }  
}  
],  
{,  
  "CustomizedLoadMetricSpecification": {  
    "MetricDataQueries": [  
      {  
        "Id": "load_metric",  
        "MetricStat": {  
          "Metric": {  
            "MetricName": "MyLoadMetric",  
            "Namespace": "MyNameSpace",  
            "Dimensions": [  
              {  
                "Name": "MyOptionalMetricDimensionName",  
                "Value": "MyOptionalMetricDimensionValue"  
              }  
            ]  
          },  
          "Stat": "Sum"  
        }  
      }  
    ],  
  }  
},  
]  
}
```

For more information, see [MetricDataQuery](#) in the *Amazon EC2 Auto Scaling API Reference*.

**Note**

Following are some additional resources that can help you find metric names, namespaces, dimensions, and statistics for CloudWatch metrics:

- For information about the available metrics for AWS services, see [AWS services that publish CloudWatch metrics](#) in the *Amazon CloudWatch User Guide*.
- To get the exact metric name, namespace, and dimensions (if applicable) for a CloudWatch metric with the AWS CLI, see [list-metrics](#).

To create this policy, run the [put-scaling-policy](#) command using the JSON file as input, as demonstrated in the following example.

```
aws application-autoscaling put-scaling-policy --policy-name my-predictive-scaling-policy \  
  --auto-scaling-group-name my-asg --policy-type PredictiveScaling \  
  --predictive-scaling-configuration file://config.json
```

If successful, this command returns the policy's Amazon Resource Name (ARN).

```
{  
  "PolicyARN": "arn:aws:autoscaling:region:account-id:scalingPolicy:2f4f5048-d8a8-4d14-b13a-d1905620f345:autoScalingGroupName/my-asg:policyName/my-predictive-scaling-policy",  
  "Alarms": []  
}
```

## Use metric math expressions

The following section provides information about using metric math with predictive scaling policies in your policy.

### Understand metric math

If all you want to do is aggregate existing metric data, CloudWatch metric math saves you the effort and cost of publishing another metric to CloudWatch. You can use any metric that AWS provides, and you can also use metrics that you define as part of your applications.

For more information, see [Using metric math](#) in the *Amazon CloudWatch User Guide*.

If you choose to use a metric math expression in your predictive scaling policy, consider the following points:

- Metric math operations use the data points of the unique combination of metric name, namespace, and dimension keys/value pairs of metrics.
- You can use any arithmetic operator (+ - \* / ^), statistical function (such as AVG or SUM), or other function that CloudWatch supports.
- You can use both metrics and the results of other math expressions in the formulas of the math expression.

- Your metric math expressions can be made up of different aggregations. However, it's a best practice for the final aggregation result to use Average for the scaling metric and Sum for the load metric.
- Any expressions used in a metric specification must eventually return a single time series.

To use metric math, do the following:

- Choose one or more CloudWatch metrics. Then, create the expression. For more information, see [Using metric math](#) in the *Amazon CloudWatch User Guide*.
- Verify that the metric math expression is valid by using the CloudWatch console or the CloudWatch [GetMetricData](#) API.

### Example predictive scaling policy that combines metrics using metric math (AWS CLI)

Sometimes, instead of specifying the metric directly, you might need to first process its data in some way. For example, you might have an application that pulls work from an Amazon SQS queue, and you might want to use the number of items in the queue as criteria for predictive scaling. The number of messages in the queue does not solely define the number of instances that you need. Therefore, more work is needed to create a metric that can be used to calculate the backlog per instance.

The following is an example predictive scaling policy for this scenario. It specifies scaling and load metrics that are based on the Amazon SQS `ApproximateNumberOfMessagesVisible` metric, which is the number of messages available for retrieval from the queue. It also uses the Amazon EC2 Auto Scaling `GroupInServiceInstances` metric and a math expression to calculate the backlog per instance for the scaling metric.

```
aws application-autoscaling put-scaling-policy --policy-name my-sqs-custom-metrics-policy \  
  --policy-type PredictiveScaling \  
  --predictive-scaling-configuration file://config.json \  
  --service-namespace ecs \  
  --resource-id service/MyCluster/test \  
  "MetricSpecifications": [  
    {  
      "TargetValue": 100,  
      "CustomizedScalingMetricSpecification": {  
        "MetricDataQueries": [  
          {
```

```

        "Label": "Get the queue size (the number of messages waiting to be
processed)",
        "Id": "queue_size",
        "MetricStat": {
            "Metric": {
                "MetricName": "ApproximateNumberOfMessagesVisible",
                "Namespace": "AWS/SQS",
                "Dimensions": [
                    {
                        "Name": "QueueName",
                        "Value": "my-queue"
                    }
                ]
            },
            "Stat": "Sum"
        },
        "ReturnData": false
    },
    {
        "Label": "Get the group size (the number of running instances)",
        "Id": "running_capacity",
        "MetricStat": {
            "Metric": {
                "MetricName": "GroupInServiceInstances",
                "Namespace": "AWS/AutoScaling",
                "Dimensions": [
                    {
                        "Name": "AutoScalingGroupName",
                        "Value": "my-asg"
                    }
                ]
            },
            "Stat": "Sum"
        },
        "ReturnData": false
    },
    {
        "Label": "Calculate the backlog per instance",
        "Id": "scaling_metric",
        "Expression": "queue_size / running_capacity",
        "ReturnData": true
    }
]
},

```

```

    "CustomizedLoadMetricSpecification": {
      "MetricDataQueries": [
        {
          "Id": "load_metric",
          "MetricStat": {
            "Metric": {
              "MetricName": "ApproximateNumberOfMessagesVisible",
              "Namespace": "AWS/SQS",
              "Dimensions": [
                {
                  "Name": "QueueName",
                  "Value": "my-queue"
                }
              ],
            },
            "Stat": "Sum"
          },
          "ReturnData": true
        }
      ]
    }
  ]
}

```

The example returns the policy's ARN.

```

{
  "PolicyARN": "arn:aws:autoscaling:region:account-id:scalingPolicy:2f4f5048-d8a8-4d14-b13a-d1905620f345:autoScalingGroupName/my-asg:policyName/my-sqs-custom-metrics-policy",
  "Alarms": []
}

```

## Scale Amazon ECS services based on an Amazon SQS queue

You can scale your Amazon ECS service in response to the load in an Amazon Simple Queue Service (Amazon SQS) queue. This is useful for asynchronous applications in which the tasks in your service act as workers that consume and process messages from a queue. As the rate of incoming messages changes, Amazon ECS Service Auto Scaling adds tasks when the queue builds up and removes tasks when it drains. This keeps latency for messages waiting in the queue at an acceptable level without over-provisioning.

## Use the backlog per task metric

Amazon SQS publishes the depth of a queue to CloudWatch as the `ApproximateNumberOfMessagesVisible` metric, which reports the number of messages available for retrieval. Queue depth indicates that there is work to be done, but it is not a reliable metric to scale on directly. The number of messages in the queue does not change proportionally to the number of tasks that process it. The number of tasks that you need also depends on other factors, such as how long a task takes to process a message and the acceptable amount of latency (queue delay). A target tracking policy that tracks queue depth interprets a large queue as demand for proportionally more tasks. This can cause your service to scale out far beyond what the workload requires and increase cost.

Instead, scale on the *backlog per task*: the queue depth divided by the number of running tasks. You calculate this value with a CloudWatch metric math expression that divides the queue depth by the running task count. Backlog per task normalizes queue depth by the running task count. This makes it proportional to the load on each task, so it is suitable for scaling.

Set your target value to the *acceptable backlog per task*. To calculate it, divide the latency that your application can accept by the average time that a task takes to process a message.

For example, if the acceptable latency is 10 seconds and a task takes 0.1 seconds to process a message, the acceptable backlog per task is 10 divided by 0.1, which equals 100 messages per task. This is the target value for your policy. If the queue currently holds 1,500 messages and 10 tasks are running, the backlog per task is 150 (1,500 divided by 10), which exceeds the target. Your service scales out by five tasks to bring the backlog per task back in proportion to the target value.

## Use metric math to compute the metric

Application Auto Scaling target tracking policies support CloudWatch *metric math*. Metric math lets you query multiple CloudWatch metrics and use math expressions to create a new time series based on those metrics. You use a metric math expression to compute the backlog per task directly in the scaling policy. Application Auto Scaling evaluates the expression and manages the CloudWatch alarms that start scaling activities. For more information, see [Use metric math](#) in the *CloudWatch User Guide*.

To compute the backlog per task, you use the following two CloudWatch metrics:

- `ApproximateNumberOfMessagesVisible` (the Sum statistic) from the AWS/SQS namespace, for the number of messages waiting in the queue.

- `RunningTaskCount` (the Average statistic) from the `ECS/ContainerInsights` namespace, for the number of running tasks in your service. To use this metric, you must turn on CloudWatch Container Insights for your cluster. For more information, see [Monitor Amazon ECS containers using Container Insights with enhanced observability](#).

In the following example, `m1` is the queue depth and `m2` is the running task count. The metric math expression `m1 / m2` produces the backlog per task. Application Auto Scaling adjusts the number of tasks in your service to keep this value at your target value.

## Use step scaling for more control

We recommend target tracking for most queue-based workloads because it is the simplest approach. You set a single target value, and Amazon ECS Service Auto Scaling creates and manages the CloudWatch alarms and the scaling adjustments for you.

Use step scaling when you want full control over the scaling behavior. With step scaling, you create your own CloudWatch alarms and define separate scale-out and scale-in policies, each with its own step adjustments. You put the backlog per task metric math expression in the alarms, and set each alarm's action to the corresponding policy. This gives you control over the following:

- **The size of each scaling step** – You can define step adjustments that add more tasks as the backlog grows, so that a small breach adds a few tasks and a large breach adds many. You can scale by a percentage of the running task count or by a fixed number of tasks.
- **How quickly scaling responds** – You control responsiveness through the metric publishing frequency and the alarm evaluation settings. For example, you can publish a high-resolution queue metric every 10 seconds and configure a scale-out alarm to breach on a single data point, so that the service reacts to a growing backlog faster than the default one-minute resolution allows.
- **Different scale-out and scale-in behavior** – Because scale-out and scale-in are separate policies and alarms, you can react quickly to a rising backlog while scaling in conservatively. For example, you can require the backlog to stay low for several minutes before removing tasks.

For more information, see [Use predefined increments based on CloudWatch alarms to scale Amazon ECS services](#).

## Protect tasks that are processing messages

When your service scales in, Amazon ECS Service Auto Scaling can stop a task that is still processing a message. For long-running or non-idempotent work, this can cause the message to be reprocessed or its progress to be lost. To prevent this, use task scale-in protection to mark a task as protected while it is doing active work.

For queue workers, we recommend that the task protect itself through the Amazon ECS container agent endpoint. When the task starts processing a message, it sets the `ProtectionEnabled` attribute to `true` so that Amazon ECS does not stop it during a scale-in event. After the task finishes the message, it sets `ProtectionEnabled` to `false` so that the task is again eligible for termination. For more information, see [Protect your Amazon ECS tasks from being terminated by scale-in events](#).

## Considerations

Consider the following when you configure queue-based scaling for your Amazon ECS service:

- Because Application Auto Scaling evaluates the metric math expression for you, you do not need to publish a custom metric or run any additional code to compute backlog per task.
- The `RunningTaskCount` metric is available only when CloudWatch Container Insights is turned on for your cluster. If it is not, the metric math expression has no data for the divisor and scaling does not occur.
- Choose a target value based on the latency that your application's service level agreement (SLA) allows. A lower target value keeps queue delay shorter but runs more tasks. A higher target value reduces cost but increases the time that messages wait in the queue.
- Messages that have not finished processing when a task is stopped return to the Amazon SQS queue. Another running task can process them if you configure the visibility timeout appropriately. To keep a task from being stopped while it is processing a message, use task scale-in protection, as described in [Protect tasks that are processing messages](#).
- The general considerations for Amazon ECS Service Auto Scaling and target tracking also apply to queue-based scaling.

## Configure queue-based scaling

The following steps show how to create a target tracking scaling policy that uses a metric math expression to scale your Amazon ECS service on backlog per task. You use the AWS CLI for these tasks.

1. Confirm that you have the IAM permissions required to create and update services and to register scalable targets and scaling policies. For more information, see [IAM permissions required for Amazon ECS service auto scaling](#).
2. Turn on CloudWatch Container Insights for your cluster so that the RunningTaskCount metric is available. For more information, see [Monitor Amazon ECS containers using Container Insights with enhanced observability](#).
3. Register your Amazon ECS service as a scalable target by using the [register-scalable-target](#) command. The scalable dimension is `ecs:service:DesiredCount`.

```
aws application-autoscaling register-scalable-target \  
  --service-namespace ecs \  
  --scalable-dimension ecs:service:DesiredCount \  
  --resource-id service/my-cluster/my-service \  
  --min-capacity 1 \  
  --max-capacity 10
```

4. Store the metric math expression in a customized metric specification in a JSON file named `config.json`. Replace the queue name, cluster name, and service name with your own values, and set `TargetValue` to the acceptable backlog per task that you calculated.

```
{  
  "CustomizedMetricSpecification": {  
    "Metrics": [  
      {  
        "Label": "Get the queue depth",  
        "Id": "m1",  
        "MetricStat": {  
          "Metric": {  
            "MetricName": "ApproximateNumberOfMessagesVisible",  
            "Namespace": "AWS/SQS",  
            "Dimensions": [  
              { "Name": "QueueName", "Value": "my-queue" }  
            ]  
          },  
          "Stat": "Sum"  
        },  
        "ReturnData": false  
      },  
      {  
        "Label": "Get the running task count",  
        "Id": "m2",
```

```

        "MetricStat": {
            "Metric": {
                "MetricName": "RunningTaskCount",
                "Namespace": "ECS/ContainerInsights",
                "Dimensions": [
                    { "Name": "ClusterName", "Value": "my-cluster" },
                    { "Name": "ServiceName", "Value": "my-service" }
                ]
            },
            "Stat": "Average"
        },
        "ReturnData": false
    },
    {
        "Label": "Calculate the backlog per task",
        "Id": "e1",
        "Expression": "m1 / m2",
        "ReturnData": true
    }
]
},
"TargetValue": 100
}

```

5. Create the target tracking scaling policy by using the [put-scaling-policy](#) command with the JSON file as input. Application Auto Scaling creates and manages the two CloudWatch alarms (one for scale-out and one for scale-in) that invoke the policy.

```

aws application-autoscaling put-scaling-policy \
  --policy-name sqs-backlog-target-tracking-policy \
  --service-namespace ecs \
  --resource-id service/my-cluster/my-service \
  --scalable-dimension ecs:service:DesiredCount \
  --policy-type TargetTrackingScaling \
  --target-tracking-scaling-policy-configuration file://config.json

```

For more information about target tracking scaling policies, see [Target tracking scaling policies](#) in the *Application Auto Scaling User Guide*.

## Interconnect Amazon ECS services

Applications that run in Amazon ECS tasks often need to receive connections from the internet or to connect to other applications that run in Amazon ECS services. If you need external connections from the internet, we recommend using Elastic Load Balancing. For more information about integrated load balancing, see [the section called “Use load balancing to distribute service traffic”](#).

If you need an application to connect to other applications that run in Amazon ECS services, Amazon ECS provides the following ways to do this without a load balancer:

- *Amazon ECS Service Connect*

We recommend Service Connect, which provides Amazon ECS configuration for service discovery, connectivity, and traffic monitoring. With Service Connect, your applications can use short names and standard ports to connect to Amazon ECS services in the same cluster, other clusters, including across VPCs in the same AWS Region.

When you use Service Connect, Amazon ECS manages all of the parts of service discovery: creating the names that can be discovered, dynamically managing entries for each task as the tasks start and stop, running an agent in each task that is configured to discover the names. Your application can look up the names by using the standard functionality for DNS names and making connections. If your application does this already, you don't need to modify your application to use Service Connect.

You provide the complete configuration inside each service and task definition. Amazon ECS manages changes to this configuration in each service deployment, to ensure that all tasks in a deployment behave in the same way. For example, a common problem with DNS as service discovery is controlling a migration. If you change a DNS name to point to the new replacement IP addresses, it might take the maximum TTL time before all the clients begin using the new service. With Service Connect, the client deployment updates the configuration by replacing the client tasks. You can configure the deployment circuit breaker and other deployment configuration to affect Service Connect changes in the same way as any other deployment.

For more information, see [Use Service Connect to connect Amazon ECS services with short names](#).

- *Amazon ECS service discovery*

Another approach for service-to-service communication is direct communication using service discovery. In this approach, you can use the AWS Cloud Map service discovery integration with

Amazon ECS. Using service discovery, Amazon ECS syncs the list of launched tasks to AWS Cloud Map, which maintains a DNS hostname that resolves to the internal IP addresses of one or more tasks from that particular service. Other services in the Amazon VPC can use this DNS hostname to send traffic directly to another container using its internal IP address.

This approach to service-to-service communication provides low latency. There are no extra components between the containers. Traffic travels directly from one container to the other container.

This approach is suitable when using the `awsvpc` network mode, where each task has its own unique IP address. Most software only supports the use of DNS A records, which resolve directly to IP addresses. When using the `awsvpc` network mode, the IP address for each task are an A record. However, if you're using `bridge` network mode, multiple containers could be sharing the same IP address. Additionally, dynamic port mappings cause the containers to be randomly assigned port numbers on that single IP address. At this point, an A record is no longer enough for service discovery. You must also use an SRV record. This type of record can keep track of both IP addresses and port numbers but requires that you configure applications appropriately. Some prebuilt applications that you use might not support SRV records.

Another advantage of the `awsvpc` network mode is that you have a unique security group for each service. You can configure this security group to allow incoming connections from only the specific upstream services that need to talk to that service.

The main disadvantage of direct service-to-service communication using service discovery is that you must implement extra logic to have retries and deal with connection failures. DNS records have a time-to-live (TTL) period that controls how long they are cached for. It takes some time for the DNS record to be updated and for the cache to expire so that your applications can pick up the latest version of the DNS record. So, your application might end up resolving the DNS record to point at another container that's no longer there. Your application needs to handle retries and have logic to ignore bad backends.

For more information, see [Use service discovery to connect Amazon ECS services with DNS names](#)

- *Amazon VPC Lattice*

Amazon VPC Lattice is a managed application networking service that Amazon ECS customers use to observe, secure, and monitor applications built across AWS compute services, VPCs, and accounts without having to modify their code.

VPC Lattice uses target groups, which are a collection of compute resources. These targets run your application or service and can be Amazon EC2 instances, IP addresses, Lambda functions, and Application Load Balancers. By associating their Amazon ECS services with a VPC Lattice target group, customers can now enable Amazon ECS tasks as IP targets in VPC Lattice. Amazon ECS automatically registers tasks to the VPC Lattice target group when tasks for the registered service are launched.

For more information, see [Use Amazon VPC Lattice to connect, observe, and secure your Amazon ECS services](#).

## Network mode compatibility table

The following table covers the compatibility between these options and the task network modes. In the table, "client" refers to the application that's making the connections from inside an Amazon ECS task.

| Interconnection Options | Bridged                                                                    | awsvpc | Host                                                                       |
|-------------------------|----------------------------------------------------------------------------|--------|----------------------------------------------------------------------------|
| Service discovery       | yes, but requires clients be aware of SRV records in DNS without hostPort. | yes    | yes, but requires clients be aware of SRV records in DNS without hostPort. |
| Service Connect         | yes                                                                        | yes    | no                                                                         |
| VPC Lattice             | yes                                                                        | yes    | yes                                                                        |

## Use Service Connect to connect Amazon ECS services with short names

Amazon ECS Service Connect provides management of service-to-service communication as Amazon ECS configuration. It builds both service discovery and a service mesh in Amazon ECS. This provides the complete configuration inside each service that you manage by service deployments, a unified way to refer to your services within namespaces that doesn't depend on the VPC DNS configuration, and standardized metrics and logs to monitor all of your applications. Service Connect only interconnects services.

The following diagram shows an example Service Connect network with 2 subnets in the VPC and 2 services. A client service that runs WordPress with 1 task in each subnets. A server service that runs MySQL with 1 task in each subnet. Both services are highly available and resilient to task and Availability Zone issues because each service runs multiple tasks that are spread out over 2 subnets. The solid arrows show a connection from WordPress to MySQL. For example, a `mysql --host=mysql` CLI command that is run from inside the WordPress container in the task with the IP address `172.31.16.1`. The command uses the short name `mysql` on the default port for MySQL. This name and port connects to the Service Connect proxy in the same task. The proxy in the WordPress task uses round-robin load balancing and any previous failure information in outlier detection to pick which MySQL task to connect to. As shown by the solid arrows in the diagram, the proxy connects to the second proxy in the MySQL task with the IP Address `172.31.16.2`. The second proxy connects to the local MySQL server in the same task. Both proxies report connection performance that is visible in graphs in the Amazon ECS and Amazon CloudWatch consoles so that you can get performance metrics from all kinds of applications in the same way.

The following terms are used with Service Connect.

## port name

The Amazon ECS task definition configuration that assigns a name to a particular port mapping. This configuration is only used by Amazon ECS Service Connect.

## client alias

The Amazon ECS service configuration that assigns the port number that is used in the endpoint. Additionally, the client alias can assign the DNS name of the endpoint, overriding the discovery name. If a discovery name isn't provided in the Amazon ECS service, the client alias name overrides the port name as the endpoint name. For endpoint examples, see the definition of *endpoint*. Multiple client aliases can be assigned to an Amazon ECS service. This configuration is only used by Amazon ECS Service Connect.

## discovery name

The optional, intermediate name that you can create for a specified port from the task definition. This name is used to create a AWS Cloud Map service. If this name isn't provided, the port name from the task definition is used. Multiple discovery names can be assigned to a specific port an Amazon ECS service. This configuration is only used by Amazon ECS Service Connect.

AWS Cloud Map service names must be unique within a namespace. Because of this limitation, you can have only one Service Connect configuration without a discovery name for a particular task definition in each namespace.

## endpoint

The URL to connect to an API or website. The URL contains the protocol, a DNS name, and the port. For more information about endpoints in general, see [endpoint](#) in the *AWS glossary* in the Amazon Web Services General Reference.

Service Connect creates endpoints that connect to Amazon ECS services and configures the tasks in Amazon ECS services to connect to the endpoints. The URL contains the protocol, a DNS name, and the port. You select the protocol and port name in the task definition, as the port must match the application that is inside the container image. In the service, you select each port by name and can assign the DNS name. If you don't specify a DNS name in the Amazon ECS service configuration, the port name from the task definition is used by default. For example, a Service Connect endpoint could be `http://blog:80`, `grpc://checkout:8080`, or `http://_db.production.internal:99`.

## Service Connect service

The configuration of a single endpoint in an Amazon ECS service. This is a part of the Service Connect configuration, consisting of a single row in the **Service Connect and discovery name configuration** in the console, or one object in the `services` list in the JSON configuration of an Amazon ECS service. This configuration is only used by Amazon ECS Service Connect.

For more information, see [ServiceConnectService](#) in the Amazon Elastic Container Service API Reference.

## namespace

The short name or full Amazon Resource Name (ARN) of the AWS Cloud Map namespace for use with Service Connect. The namespace must be in the same AWS Region as the Amazon ECS service and cluster. The type of namespace in AWS Cloud Map doesn't affect Service Connect. The namespace can be one that is shared with your AWS account using AWS Resource Access Manager (AWS RAM) in AWS Regions that AWS RAM is available in. For more information about shared namespaces, see [Cross-account AWS Cloud Map namespace sharing](#) in the *AWS Cloud Map Developer Guide*.

Service Connect uses the AWS Cloud Map namespace as a logical grouping of Amazon ECS tasks that talk to one another. Each Amazon ECS service can belong to only one namespace. The services within a namespace can be spread across different Amazon ECS clusters within the same AWS Region. If the namespace is a shared namespace, the services can be spread across the namespace owner and namespace consumer AWS accounts. You can freely organize services by any criteria.

## client service

A service that runs a network client application. This service must have a namespace configured. Each task in the service can discover and connect to all of the endpoints in the namespace through a Service Connect proxy container.

If any of your containers in the task need to connect to an endpoint from a service in a namespace, choose a client service. If a frontend, reverse proxy, or load balancer application receives external traffic through other methods such as from Elastic Load Balancing, it could use this type of Service Connect configuration.

## client-server service

An Amazon ECS service that runs a network or web service application. This service must have a namespace and at least one endpoint configured. Each task in the service is reachable by using

the endpoints. The Service Connect proxy container listens on the endpoint name and port to direct traffic to the app containers in the task.

If any of the containers expose and listen on a port for network traffic, choose a client-server service. These applications don't need to connect to other client-server services in the same namespace, but the client configuration is needed. A backend, middleware, business tier, or most microservices can use this type of Service Connect configuration. If you want a frontend, reverse proxy, or load balancer application to receive traffic from other services configured with Service Connect in the same namespace, these services should use this type of Service Connect configuration.

The Service Connect feature creates a virtual network of related services. The same service configuration can be used across multiple different namespaces to run independent yet identical sets of applications. Service Connect defines the proxy container in the Amazon ECS service. This way, the same task definition can be used to run identical applications in different namespaces with different Service Connect configurations. Each task that the service makes runs a proxy container in the task.

Service Connect is suitable for connections between Amazon ECS services within the same namespace. For the following applications, you need to use an additional interconnection method to connect to an Amazon ECS service that is configured with Service Connect:

- Tasks that are configured in other namespaces
- Tasks that aren't configured for Service Connect
- Other applications outside of Amazon ECS

These applications can connect through the Service Connect proxy but can't resolve Service Connect endpoint names.

For these applications to resolve the IP addresses of Amazon ECS tasks, you need to use another interconnection method.

- [Configuring Amazon ECS Service Connect with the AWS CLI](#)

## Pricing

- Amazon ECS Service Connect pricing depends on whether you use AWS Fargate or Amazon EC2 infrastructure to host your containerized workloads. When using Amazon ECS on AWS Outposts, the pricing follows the same model that's used when you use Amazon EC2 directly. For more information, see [Amazon ECS Pricing](#).
- There is no additional charge for using Amazon ECS Service Connect.
- There is no additional charge for AWS Cloud Map usage when used by Service Connect.
- Customers pay for compute resources used by Amazon ECS Service Connect, including vCPU and Memory. As the Amazon ECS Service Connect agent runs inside a customer task, there is no additional charge for running it. The task resources are shared between the customer workload and the Amazon ECS Service Connect agent.
- When using Amazon ECS Service Connect traffic encryption functionality with AWS Private CA, customers pay for the private certificate authority they create and for each TLS certificate issued. For more details, see [AWS Private Certificate Authority pricing](#). To estimate the monthly cost of TLS certificates, customers need to know the number of Amazon ECS services that have TLS enabled, multiply it by the certificate cost, and then multiply it by six. As Amazon ECS Service Connect automatically rotates TLS certificates every five days, there are six certificates issued per Amazon ECS service, per month, on average.

## Amazon ECS Service Connect components

When you use Amazon ECS Service Connect, you configure each Amazon ECS service to run a server application that receives network requests (client-server service) or to run a client application that makes the requests (client service).

When you prepare to start using Service Connect, start with a client-server service. You can add a Service Connect configuration to a new service or an existing service. Amazon ECS creates a Service Connect endpoint in the namespace. Additionally, Amazon ECS creates a new deployment in the service to replace the tasks that are currently running.

Existing tasks and other applications can continue to connect to existing endpoints, and external applications. If a client-server service adds tasks by scaling out, new connections from clients will be balanced between all of the tasks. If a client-server service is updated, new connections from clients will be balanced between the tasks of the new version.

Existing tasks can't resolve and connect to the new endpoint. Only new tasks with a Service Connect configuration in the same namespace and that start running after this deployment can resolve and connect to this endpoint.

This means that the operator of the client application determines when the configuration of their app changes, even though the operator of the server application can change their configuration at any time. The list of endpoints in the namespace can change every time that any service in the namespace is deployed. Existing tasks and replacement tasks continue to behave the same as they did after the most recent deployment.

Consider the following examples.

First, assume that you are creating an application that is available to the public internet in a single AWS CloudFormation template and single CloudFormation stack. The public discovery and reachability should be created last by CloudFormation, including the frontend client service. The services need to be created in this order to prevent an time period when the frontend client service is running and available the public, but a backend isn't. This eliminates error messages from being sent to the public during that time period. In AWS CloudFormation, you must use the `dependsOn` to indicate to CloudFormation that multiple Amazon ECS services can't be made in parallel or simultaneously. You should add the `dependsOn` to the frontend client service for each backend client-server service that the client tasks connect to.

Second, assume that a frontend service exists without Service Connect configuration. The tasks are connecting to an existing backend service. Add a client-server Service Connect configuration to the backend service first, using the same name in the **DNS** or `clientAlias` that the frontend uses. This creates a new deployment, so all the deployment rollback detection or AWS Management Console, AWS CLI, AWS SDKs and other methods to roll back and revert the backend service to the previous deployment and configuration. If you are satisfied with the performance and behavior of the backend service, add a client or client-server Service Connect configuration to the frontend service. Only the tasks in the new deployment use the Service Connect proxy that is added to those new tasks. If you have issues with this configuration, you can roll back and revert to your previous configuration by using the deployment rollback detection or AWS Management Console, AWS CLI, AWS SDKs and other methods to roll back and revert the backend service to the previous

deployment and configuration. If you use another service discovery system that is based on DNS instead of Service Connect, any frontend or client applications begin using new endpoints and changed endpoint configuration after the local DNS cache expires, commonly taking multiple hours.

## Networking

By default, the Service Connect proxy listens on the `containerPort` from the task definition port mapping. Your security group rules must allow incoming (ingress) traffic to this port from the subnets where clients will run.

Even if you set a port number in the Service Connect service configuration, this doesn't change the port for the client-server service that the Service Connect proxy listens on. When you set this port number, Amazon ECS changes the port of the endpoint that the client services connect to, on the Service Connect proxy inside those tasks. The proxy in the client service connects to the proxy in the client-server service using the `containerPort`.

If you want to change the port that the Service Connect proxy listens on, change the `ingressPortOverride` in the Service Connect configuration of the client-server service. If you change this port number, you must allow inbound traffic on this port that is used by traffic to this service.

Traffic that your applications send to Amazon ECS services configured for Service Connect require that the Amazon VPC and subnets have route table rules and network ACL rules that allow the `containerPort` and `ingressPortOverride` port numbers that you are using.

You can use Service Connect to send traffic between VPCs. The same requirements for the route table rules, network ACLs, and security groups apply to both VPCs.

For example, two clusters create tasks in different VPCs. A service in each cluster is configured to use the same namespace. The applications in these two services can resolve every endpoint in the namespace without any VPC DNS configuration. However, the proxies can't connect unless the VPC peering, VPC, or subnet route tables, and VPC network ACLs allow the traffic on the `containerPort` and `ingressPortOverride` port numbers.

For tasks that use the bridge networking mode, you must create a security group with an inbound rule that allows traffic on the upper dynamic port range. Then, assign the security group to all the EC2 instances in the Service Connect cluster.

## Service Connect proxy

If you create or update a service with Service Connect configuration, Amazon ECS adds a new container to each new task as it is started. This pattern of using a separate container is called a **sidecar**. This container isn't present in the task definition and you can't configure it. Amazon ECS manages the Container configuration in the service. This allows you to reuse the same task definitions between multiple services, namespaces, and tasks without Service Connect.

### Proxy resources

- For task definitions, you must set the CPU and memory parameters.

We recommend adding an additional 256 CPU units and at least 64 MiB of memory to your task CPU and memory for the Service Connect proxy container. On AWS Fargate, the lowest amount of memory that you can set is 512 MiB of memory. On Amazon EC2, task definition memory is required.

- For the service, you set the log configuration in the Service Connect configuration.
- If you expect tasks in this service to receive more than 500 requests per second at their peak load, we recommend adding 512 CPU units to your task CPU in this task definition for the Service Connect proxy container.
- If you expect to create more than 100 Service Connect services in the namespace or 2000 tasks in total across all Amazon ECS services within the namespace, we recommend adding 128 MiB of memory to your task memory for the Service Connect proxy container. You should do this in every task definition that is used by all of the Amazon ECS services in the namespace.

### Proxy configuration

Your applications connect to the proxy in the sidecar container in the same task as the application is in. Amazon ECS configures the task and containers so that applications only connect to the proxy when the application is connected to the endpoint names in the same namespace. All other traffic doesn't use the proxy. The other traffic includes IP addresses in the same VPC, AWS service endpoints, and external traffic.

### Load balancing

Service Connect configures the proxy to use the round-robin strategy for load balancing between the tasks in a Service Connect endpoint. The local proxy that is in the task where the

connection comes from, picks one of the tasks in the client-server service that provides the endpoint.

For example, consider a task that runs WordPress in a service that is configured as a *client service* in a namespace called *local*. There is another service with 2 tasks that run the MySQL database. This service is configured to provide an endpoint called `mysql` through Service Connect in the same namespace. In the WordPress task, the WordPress application connects to the database using the endpoint name. Connections to this name go to the proxy that runs in a sidecar container in the same task. Then, the proxy can connect to either of the MySQL tasks using the round-robin strategy.

Load balancing strategies: round-robin

## Outlier detection

This feature uses data that the proxy has about prior failed connections to avoid sending new connections to the hosts that had the failed connections. Service Connect configures the outlier detection feature of the proxy to provide passive health checks.

Using the previous example, the proxy can connect to either of the MySQL tasks. If the proxy made multiple connections to a specific MySQL task, and 5 or more of the connections failed in the last 30 seconds, then the proxy avoids that MySQL task for 30 to 300 seconds.

## Retries

Service Connect configures the proxy to retry connection that pass through the proxy and fail, and the second attempt avoids using the host from the previous connection. This ensures that each connection through Service Connect doesn't fail for one-off reasons.

Number of retries: 2

## Timeout

Service Connect configures the proxy to wait a maximum time for your client-server applications to respond. The default timeout value is 15 seconds, but it can be updated.

Optional parameters:

**idleTimeout** - The amount of time in seconds a connection stays active while idle. A value of 0 disables `idleTimeout`.

The `idleTimeout` default for HTTP/HTTP2/GRPC is 5 minutes.

The `idleTimeout` default for TCP is 1 hour.

**perRequestTimeout** - The amount of time waiting for the upstream to respond with a complete response per request. A value of 0 turns off perRequestTimeout. This can only be set when the appProtocol for application container is HTTP/HTTP2/GRPC. The default is 15 seconds.

 **Note**

If idleTimeout is set to a time that is less than perRequestTimeout, the connection will close when the idleTimeout is reached and not the perRequestTimeout.

## Considerations

Consider the following when using Service Connect:

- Tasks that run in Fargate must use the Fargate Linux platform version 1.4.0 or higher to use Service Connect.
- The Amazon ECS agent version on the container instance must be 1.67.2 or higher.
- Container instances must run the Amazon ECS-optimized Amazon Linux 2023 AMI version 20230428 or later, or Amazon ECS-optimized Amazon Linux 2 AMI version 2.0.20221115 to use Service Connect. These versions have the Service Connect agent in addition to the Amazon ECS container agent. For more information about the Service Connect agent, see [Amazon ECS Service Connect Agent](#) on GitHub.
- Container instances must have the ecs:Poll permission for the resource `arn:aws:ecs:region:0123456789012:task-set/cluster/*`. If you are using the ecsInstanceRole, you don't need to add additional permissions. The AmazonEC2ContainerServiceforEC2Role managed policy has the necessary permissions. For more information, see [Amazon ECS container instance IAM role](#).
- Tasks that use the bridge network mode and use Service Connect don't support the hostname container definition parameter.
- Task definitions must set the task memory limit to use Service Connect. For more information, see [Service Connect proxy](#).
- Task definitions that set container memory limits aren't supported.

You can set container memory limits on your containers, but you must set the task memory limit to a number greater than the sum of the container memory limits. The additional CPU and memory in the task limits that aren't allocated in the container limits are used by the

Service Connect proxy container and other containers that don't set container limits. For more information, see [Service Connect proxy](#).

- You can configure Service Connect to use any AWS Cloud Map namespace in the same Region that are either in the same AWS account or are shared with your AWS account using AWS Resource Access Manager. For more information about using shared namespaces, see [Amazon ECS Service Connect with shared AWS Cloud Map namespaces](#).
- Each service can belong to only one namespace.
- Only the tasks that services create are supported.
- All endpoints must be unique within a namespace.
- All discovery names must be unique within a namespace.
- You must redeploy existing services before the applications can resolve new endpoints. New endpoints that are added to the namespace after the most recent deployment won't be added to the task configuration. For more information, see [the section called "Service Connect components"](#).
- Service Connect doesn't delete namespaces when clusters are deleted. You must delete namespaces in AWS Cloud Map.
- Application Load Balancer traffic defaults to routing through the Service Connect agent in awsvpc network mode. If you want non-service traffic to bypass the Service Connect agent, use the [ingressPortOverride](#) parameter in your Service Connect service configuration.
- Service Connect with TLS does not support bridge networking mode. Only awsvpc networking mode is supported.
- In awsvpc mode, the Service Connect proxy forwards traffic to the IPv4 localhost 127.0.0.1 for services in IPv4-only and dualstack configurations. For services in IPv6-only configuration, the proxy forwards traffic to the IPv6 localhost ::1. We recommend configuring your applications to listen to both localhosts for a seamless experience when a service is updated from IPv4-only or dualstack configuration to IPv6-only. For more information, see [Amazon ECS task networking options for EC2](#) and [Amazon ECS task networking options for Fargate](#).

### Service Connect doesn't support the following:

- Windows containers
- HTTP 1.0
- Standalone tasks
- Services that use the blue/green powered by CodeDeploy and external deployment types

- External container instance for Amazon ECS Anywhere aren't supported with Service Connect.
- PPv2
- FIPS mode

## Amazon ECS Service Connect configuration overview

When you use Service Connect, there are parameters you need to configure in your resources.

The following table describes the configuration parameters for the Amazon ECS resources.

| Parameter location | App type      | Description                                                                                                                                                                                                                                                                 | Required |
|--------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| Task definition    | Client        | There are no changes available for Service Connect in client task definitions.                                                                                                                                                                                              | N/A      |
| Task definition    | Client-server | Servers must add name fields to ports in the <code>portMappings</code> of containers. For more information, see <a href="#">portMappings</a> .                                                                                                                              | Yes      |
| Task definition    | Client-server | Servers can optionally provide an application protocol (for example, HTTP) to receive protocol-specific metrics for their server applications (for example, HTTP 5xx).                                                                                                      | No       |
| Service definition | Client        | Client services must add a <code>serviceConnectConfiguration</code> to configure the namespace to join. This namespace must contain all of the server services that this service needs to discover. For more information, see <a href="#">serviceConnectConfiguration</a> . | Yes      |
| Service definition | Client-server | Server services must add a <code>serviceConnectConfiguration</code> to                                                                                                                                                                                                      | Yes      |

## Overview of steps to configure Service Connect

The following steps provide an overview of how to configure Service Connect.

### Important

- Service Connect creates AWS Cloud Map services in your account. Modifying these AWS Cloud Map resources by manually registering/deregistering instances, changing instance attributes, or deleting a service may lead to unexpected behavior for your application traffic or subsequent deployments.
- Service Connect doesn't support links in the task definition.

1. Add port names to the port mappings in your task definitions. Additionally, you can identify the layer 7 protocol of the application, to get additional metrics.
2. Create a cluster with a AWS Cloud Map namespace, use a shared namespace, or create the namespace separately. For simple organization, create a cluster with the name that you want

for the namespace and specify the identical name for the namespace. In this case, Amazon ECS creates a new HTTP namespace with the necessary configuration. Service Connect doesn't use or create DNS hosted zones in Amazon Route 53.

3. Configure services to create Service Connect endpoints within the namespace.
4. Deploy services to create the endpoints. Amazon ECS adds a Service Connect proxy container to each task, and creates the Service Connect endpoints in AWS Cloud Map. This container isn't configured in the task definition, and the task definition can be reused without modification to create multiple services in the same namespace or in multiple namespaces.
5. Deploy client apps as services to connect to the endpoints. Amazon ECS connects them to the Service Connect endpoints through the Service Connect proxy in each task.

Applications only use the proxy to connect to Service Connect endpoints. There is no additional configuration to use the proxy. The proxy performs round-robin load balancing, outlier detection, and retries. For more information about the proxy, see [Service Connect proxy](#).

6. Monitor traffic through the Service Connect proxy in Amazon CloudWatch.

## Cluster configuration

You can set a default namespace for Service Connect when you create or update the cluster. The namespace name that you specify as a default can either be in the same AWS Region and account, or in the same AWS Region and shared by another AWS account using AWS Resource Access Manager.

If you create a cluster and specify a default Service Connect namespace, the cluster waits in the `PROVISIONING` status while Amazon ECS creates the namespace. You can see an attachment in the status of the cluster that shows the status of the namespace. Attachments aren't displayed by default in the AWS CLI, you must add `--include ATTACHMENTS` to see them.

If you want to use a namespace that is shared with your AWS account using AWS RAM, specify the Amazon Resource Name (ARN) of the namespace in the cluster configuration. For more information about shared AWS Cloud Map namespaces, see [Amazon ECS Service Connect with shared AWS Cloud Map namespaces](#).

## Service configuration

Service Connect is designed to require the minimum configuration. You need to set a name for each port mapping that you would like to use with Service Connect in the task definition. In

the service, you need to turn on Service Connect and select either a namespace in your AWS account or a shared namespace to make a client service. To make a client-server service, you need to add a single Service Connect service configuration that matches the name of one of the port mappings. Amazon ECS reuses the port number and port name from the task definition to define the Service Connect service and endpoint. To override those values, you can use the other parameters **Discovery**, **DNS**, and **Port** in the console, or `discoveryName` and `clientAliases`, respectively in the Amazon ECS API.

## Initial Health Check configuration

Service Connect ensures tasks are healthy before routing traffic to them. When a task launches (during deployments, scaling, or replacements), Service Connect monitors the health of your task to ensure it is ready to accept traffic. You must define health checks for the essential container in your task definition to enable this behavior.

The behavior of the initial health check accounts for potential delays with reaching the state when a task is ready to accept traffic:

- If a task is **HEALTHY**, it's immediately available for traffic.
- If a task's health is **UNKNOWN**, Service Connect follows the container health check configuration (see [the section called "Health check"](#)) of the task's essential containers to calculate a timeout, up to 8 minutes, before making it available to traffic, even if it remains **UNKNOWN**.
- If a task is **UNHEALTHY**, Amazon ECS may launch replacement tasks. If no healthy tasks are available, your deployment might be rolled back based on your service's configuration.

For all ongoing traffic, Service Connect uses passive health checks based on outlier detection to route traffic efficiently.

## Amazon ECS Service Connect with shared AWS Cloud Map namespaces

Amazon ECS Service Connect supports using shared AWS Cloud Map namespaces across multiple AWS accounts within the same AWS Region. This capability enables you to create distributed applications where services running in different AWS accounts can discover and communicate with each other through Service Connect. Shared namespaces are managed using AWS Resource Access Manager (AWS RAM), which allows secure cross-account resource sharing. For more information about shared namespaces, see [Cross-account AWS Cloud Map namespace sharing](#) in the *AWS Cloud Map Developer Guide*.

**⚠ Important**

You must use the `AWSRAMPermissionCloudMapECSFullPermission` managed permission to share the namespace for Service Connect to work properly with the namespace.

When you use shared AWS Cloud Map namespaces with Service Connect, services from multiple AWS accounts can participate in the same service namespace. This is particularly useful for organizations with multiple AWS accounts that need to maintain service-to-service communication across account boundaries while preserving security and isolation.

**ℹ Note**

To communicate with services that are in different VPCs, you will need to configure inter-VPC connectivity. This can be achieved using a VPC Peering connection. For more information, see [Create or delete a VPC Peering connection](#) in the *Amazon Virtual Private Cloud VPC Peering guide*.

## Using shared AWS Cloud Map namespaces with Amazon ECS Service Connect

Setting up shared AWS Cloud Map namespaces for Service Connect involves the following steps: Namespace owner creating the namespace, owner sharing it through AWS Resource Access Manager (AWS RAM), consumer accepting the resource share, and consumer configuring Service Connect to use the shared namespace.

### Step 1: Create the AWS Cloud Map namespace

The namespace owner creates a AWS Cloud Map namespace that will be shared with other accounts.

#### To create a namespace for sharing using the AWS Management Console

1. Open the AWS Cloud Map console at <https://console.aws.amazon.com/cloudmap/>.
2. Choose **Create namespace**.
3. Enter a **Namespace name**. This name will be used by services across all participating accounts.
4. For **Namespace type**, choose the appropriate type for your use case:

- **API calls** - HTTP namespaces for service discovery without DNS functionality.
- **API calls and DNS queries in VPCs** - Private DNS namespaces for service discovery with private DNS queries in a VPC.
- **API calls and public DNS queries** - Public DNS namespaces for service discovery with public DNS queries.

5. Choose **Create namespace**.

## Step 2: Share the namespace using AWS RAM

The namespace owner uses AWS RAM to share the namespace with other AWS accounts.

### To share a namespace using the AWS RAM console

1. Open the AWS RAM console at <https://console.aws.amazon.com/ram/>.
2. Choose **Create resource share**.
3. For **Name**, enter a descriptive name for the resource share.
4. In the **Resources** section:
  - a. For **Resource type**, choose **Cloud Map Namespaces**.
  - b. Select the namespace you created in the previous step.
5. In the **Managed permissions** section, specify **AWSRAMPermissionCloudMapECSFullPermission**.

#### Important

You must use the `AWSRAMPermissionCloudMapECSFullPermission` managed permission to share the namespace for Service Connect to work properly with the namespace.

6. In the **Principals** section, specify the AWS accounts you want to share the namespace with. You can enter account IDs or organizational unit IDs.
7. Choose **Create resource share**.

### Step 3: Accept the resource share

Namespace consumer accounts must accept the resource share invitation to use the shared namespace.

#### To accept a resource share invitation using the AWS RAM console

1. In the consumer account, open the AWS RAM console at <https://console.aws.amazon.com/ram/>.
2. In the navigation pane, choose **Shared with me**, then choose **Resource shares**.
3. Select the resource share invitation and choose **Accept resource share**.
4. After accepting, note the shared namespace ARN from the resource details. You'll use this ARN when configuring Service Connect services.

### Step 4: Configure an Amazon ECS service with the shared namespace

After accepting the shared namespace, the namespace consumer can configure Amazon ECS services to use the shared namespace. The configuration is similar to using a regular namespace, but you must specify the namespace ARN instead of the name. For a detailed service creation procedure, see [Creating an Amazon ECS rolling update deployment](#).

#### To create a service with a shared namespace using the AWS Management Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster that you want to create the service in.
3. Under **Services**, choose **Create**.
4. After filling in other details depending on your workload, in the **Service Connect** section, choose **Use Service Connect**.
5. For **Namespace**, enter the full ARN of the shared namespace.

The ARN format is: `arn:aws:servicediscovery:region:account-id:namespace/namespace-id`

6. Configure the remaining Service Connect settings as needed for your service type (client or client-server).
7. Complete the service creation process.

You can also configure services using the AWS CLI or AWS SDKs by specifying the shared namespace ARN in the namespace parameter of the `serviceConnectConfiguration`.

```
aws ecs create-service \
  --cluster my-cluster \
  --service-name my-service \
  --task-definition my-task-def \
  --service-connect-configuration '{
    "enabled": true,
    "namespace": "arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-
abcdef1234567890",
    "services": [{
      "portName": "web",
      "discoveryName": "my-service",
      "clientAliases": [{
        "port": 80,
        "dnsName": "my-service"
      }]
    }]
  }'
```

## Considerations

Consider the following when using shared AWS Cloud Map namespaces with Service Connect:

- AWS RAM must be available in the AWS Region where you want to use the shared namespace.
- The shared namespace must be in the same AWS Region as your Amazon ECS services and clusters.
- You must use the namespace ARN, not the ID, when configuring Service Connect with a shared namespace.
- All namespace types are supported: HTTP, Private DNS, and Public DNS namespaces.
- If access to a shared namespace is revoked, Amazon ECS operations that require interaction with the namespace (such as `CreateService`, `UpdateService`, and `ListServicesByNamespace`) will fail. For more information about troubleshooting permissions issues with shared namespaces, see [Troubleshooting Amazon ECS Service Connect with shared AWS Cloud Map namespaces](#).
- For service discovery using DNS queries in a shared private DNS namespace:
  - The namespace owner will need to call `create-vpc-association-authorization` with the ID of the private hosted zone associated with the namespace, and the consumer's VPC.

```
aws route53 create-vpc-association-authorization --hosted-zone-id Z1234567890ABC --  
vpc VPCRegion=us-east-1,VPCId=vpc-12345678
```

- The namespace consumer will need to call `associate-vpc-with-hosted-zone` with the ID of the private hosted zone.

```
aws route53 associate-vpc-with-hosted-zone --hosted-zone-id Z1234567890ABC --vpc  
VPCRegion=us-east-1,VPCId=vpc-12345678
```

- Only the namespace owner can manage the resource share.
- Namespace consumers can create and manage services within the shared namespace but cannot modify the namespace itself.
- Discovery names must be unique within the shared namespace, regardless of which account creates the service.
- Services in the shared namespace can discover and connect to services from other AWS accounts that have access to the namespace.
- When enabling TLS for Service Connect and using a shared namespace, the AWS Private CA Certificate Authority (CA) is scoped to the namespace. When access to the shared namespace is revoked, access to the CA is stopped.
- When working with a shared namespace, namespace owners and consumers don't have access to cross-account Amazon CloudWatch metrics by default. Target metrics are published only to accounts that own client services. An account that owns client services doesn't have access to metrics received by an account owning client-server services, and the other way around. To allow for cross-account access to metrics, set up CloudWatch cross-account observability. For more information about configuring cross-account observability, see [CloudWatch cross-account observability](#) in the *Amazon CloudWatch User Guide*. For more information about the CloudWatch metrics for Service Connect, see [Amazon ECS CloudWatch metrics](#).

## Troubleshooting Amazon ECS Service Connect with shared AWS Cloud Map namespaces

Use the following information to troubleshoot issues with shared AWS Cloud Map namespaces and Service Connect. For more information on locating error messages, see [Amazon ECS troubleshooting](#).

Error messages related to permissions issues appear due to missing permissions, or if access to the namespace is revoked.

**⚠ Important**

You must use the `AWSRAMPermissionCloudMapECSFullPermission` managed permission to share the namespace for Service Connect to work properly with the namespace.

Error message appears in one of the following formats:

An error occurred (ClientException) when calling the <OperationName> operation: User: `arn:aws:iam::<account-id>:user/<user-name>` is not authorized to perform: <ActionName> on resource: <ResourceArn> because no resource-based policy allows the <ActionName> action

The following scenarios can result in an error message in this format:

**Cluster creation or update failure**

These issues occur when Amazon ECS operations such as `CreateCluster` or `UpdateCluster` fail due to missing AWS Cloud Map permissions. The operations require permissions for the following AWS Cloud Map actions:

- `servicediscovery:GetNamespace`

Ensure that the resource share invitation has been accepted in the consumer account and that the correct namespace ARN is being used in the Service Connect configuration.

**Service creation or update failure**

These issues occur when Amazon ECS operations such as `CreateService` or `UpdateService` fail due to missing AWS Cloud Map permissions. The operations require permissions for the following AWS Cloud Map actions:

- `servicediscovery:CreateService`
- `servicediscovery:GetNamespace`
- `servicediscovery:GetOperation` (for creating a new AWS Cloud Map service)
- `servicediscovery:GetService` (for when a AWS Cloud Map service already exists)

Ensure that the resource share invitation has been accepted in the consumer account and that the correct namespace ARN is being used in the Service Connect configuration.

## ListServicesByNamespace operation fails

This issue occurs when the Amazon ECS ListServicesByNamespace operation fails. The operation requires permissions for the following AWS Cloud Map actions:

- `servicediscovery:GetNamespace`

To resolve this issue:

- Verify that the consumer account has the `servicediscovery:GetNamespace` permission.
- Use the namespace ARN when calling the API, not the name.
- Ensure the resource share is active and the invitation has been accepted.

User: <iam-user> is not authorized to perform: <ActionName> on resource: <ResourceArn> with an explicit deny in an identity-based policy.

The following scenarios can result in an error message in this format:

## Service deletion fails and gets stuck in DRAINING state

This issue occurs when Amazon ECS DeleteService operations fail due to the missing `servicediscovery:DeleteService` permission when access to the namespace is revoked. The service may appear to delete successfully initially but will get stuck in the DRAINING state. The error message appears as an Amazon ECS service event.

To resolve this issue, the namespace owner must share the namespace with the consumer account to allow service deletion to complete.

## Tasks in service fail to run

This issue occurs when tasks fail to start due to missing permissions. The error message is surfaced as a stopped task error. For more information, see [Resolve Amazon ECS stopped task errors](#).

The following AWS Cloud Map actions are required for running a task:

- `servicediscovery:GetOperation`
- `servicediscovery:RegisterInstance`

Ensure that the consumer account has the required permissions and that the shared namespace is accessible.

## Tasks fail to stop cleanly or get stuck in DEACTIVATING or DEPROVISIONING state

This issue occurs when tasks fail to deregister from the AWS Cloud Map service during shutdown due to missing permissions. The error is surfaced as a `statusReason` in the task attachment that can be retrieved using the `DescribeTasks` API. For more information, see [DescribeTasks](#) in the *Amazon Elastic Container Service API Reference*.

The following AWS Cloud Map actions are required to stop a task:

- `servicediscovery:DeregisterInstance`
- `servicediscovery:GetOperation`

If access to the shared namespace is revoked, tasks may remain in a DEACTIVATING or DEPROVISIONING state until namespace access is restored. Request the namespace owner to restore access to the namespace.

## Amazon ECS Service Connect access logs

Amazon ECS Service Connect supports access logs to provide detailed telemetry about individual requests processed by the Service Connect proxy. Access logs complement existing application logs by capturing per-request traffic metadata such as HTTP methods, paths, response codes, flags, and timing information. This enables deeper observability into request-level traffic patterns and service interactions for effective troubleshooting and monitoring.

To enable access logs, specify both the `logConfiguration` and `accessLogConfiguration` objects in the `serviceConnectConfiguration` object. You can configure the format of the logs and whether the logs should include query parameters in the `accessLogConfiguration`. The logs are delivered to the destination log group by the log driver specified in the `logConfiguration`.

```
{
  "serviceConnectConfiguration": {
    "enabled": true,
    "namespace": "myapp.namespace",
    "services": [
      ...
    ],
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
```

```

        "awslogs-group": "my-envoy-log-group",
        "awslogs-region": "us-west-2",
        "awslogs-stream-prefix": "myapp-envoy-logs"
    },
    "accessLogConfiguration": {
        "format": "TEXT",
        "includeQueryParameters": "ENABLED"
    }
}

```

## Considerations

Consider the following when you enable access to access logs

- Access logs and application logs are both written to `/dev/stdout`. To separate access logs from application logs, we recommend using the `awsfirelens` log driver with a custom Fluent Bit or Fluentd configuration.
- We recommend using the `awslogs` log driver to send application and access logs to the same CloudWatch destination.
- access logs are supported on Fargate services that use platform version `1.4.0` and higher.
- Query parameters such as request ids and tokens are excluded from access logs by default. To include query parameters in access logs, set `includeQueryParameters` to `"ENABLED"`.

## Access log formats

access logs can be formatted in either JSON format dictionaries or Text format strings, with differences in supported command operators for different types of access logs.

## HTTP access logs

The following command operators are included by default for HTTP logs:

### Text

```

[%START_TIME%] "%REQ(:METHOD)% %REQ(X-ENVOY-ORIGINAL-PATH?:PATH)% %PROTOCOL%"
%RESPONSE_CODE% %BYTES_RECEIVED% %BYTES_SENT% %DURATION%
%RESP(X-ENVOY-UPSTREAM-SERVICE-TIME)% "%REQ(X-FORWARDED-FOR)%" "%REQ(USER-AGENT)%"

```

```
"%REQ(X-REQUEST-ID)%" "%REQ(:AUTHORITY)%" "%UPSTREAM_HOST%" \n
```

## JSON

```
{
  "start_time": "%START_TIME%",
  "method": "%REQ(:METHOD)%",
  "path": "%REQ(X-ENVOY-ORIGINAL-PATH?:PATH)%",
  "protocol": "%PROTOCOL%",
  "response_code": "%RESPONSE_CODE%",
  "bytes_received": "%BYTES_RECEIVED%",
  "bytes_sent": "%BYTES_SENT%",
  "duration_ms": "%DURATION%",
  "upstream_service_time": "%RESP(X-ENVOY-UPSTREAM-SERVICE-TIME)%",
  "forwarded_for": "%REQ(X-FORWARDED-FOR)%",
  "user_agent": "%REQ(USER-AGENT)%",
  "request_id": "%REQ(X-REQUEST-ID)%",
  "authority": "%REQ(:AUTHORITY)%",
  "upstream_host": "%UPSTREAM_HOST%"
}
```

## HTTP2 access logs

In addition to the command operators included for HTTP logs, HTTP2 logs include the `%STREAM_ID%` operator by default.

### Text

```
[%START_TIME%] "%REQ(:METHOD)% %REQ(X-ENVOY-ORIGINAL-PATH?:PATH)% %PROTOCOL%"
%RESPONSE_CODE% %BYTES_RECEIVED% %BYTES_SENT% %DURATION%
%RESP(X-ENVOY-UPSTREAM-SERVICE-TIME)% "%REQ(X-FORWARDED-FOR)%" "%REQ(USER-AGENT)%"
"%REQ(X-REQUEST-ID)%" "%REQ(:AUTHORITY)%" "%UPSTREAM_HOST%" "%STREAM_ID%" \n
```

## JSON

```
{
  "start_time": "%START_TIME%",
  "method": "%REQ(:METHOD)%",
  "path": "%REQ(X-ENVOY-ORIGINAL-PATH?:PATH)%",
  "protocol": "%PROTOCOL%",
  "response_code": "%RESPONSE_CODE%",
```

```

"bytes_received": "%BYTES_RECEIVED%",
"bytes_sent": "%BYTES_SENT%",
"duration": "%DURATION%",
"upstream_service_time": "%RESP(X-ENVOY-UPSTREAM-SERVICE-TIME)%",
"forwarded_for": "%REQ(X-FORWARDED-FOR)%",
"user_agent": "%REQ(USER-AGENT)%",
"request_id": "%REQ(X-REQUEST-ID)%",
"authority": "%REQ(:AUTHORITY)%",
"upstream_host": "%UPSTREAM_HOST%",
"stream_id": "%STREAM_ID%"
}

```

## gRPC access logs

In addition to the command operators included for HTTP logs, gRPC access logs include the `%STREAM_ID%` and `%GRPC_STATUS( )%` operator by default.

### Text

```

[%START_TIME%] "%REQ(:METHOD)% %REQ(X-ENVOY-ORIGINAL-PATH?:PATH)% %PROTOCOL%"
%RESPONSE_CODE% %GRPC_STATUS( )% %BYTES_RECEIVED% %BYTES_SENT% %DURATION%
%RESP(X-ENVOY-UPSTREAM-SERVICE-TIME)% "%REQ(X-FORWARDED-FOR)%" "%REQ(USER-AGENT)%"
"%REQ(X-REQUEST-ID)%" "%REQ(:AUTHORITY)%" "%UPSTREAM_HOST%" "%STREAM_ID%"

```

### JSON

```

{
  "start_time": "%START_TIME%",
  "method": "%REQ(:METHOD)%",
  "path": "%REQ(X-ENVOY-ORIGINAL-PATH?:PATH)%",
  "protocol": "%PROTOCOL%",
  "response_code": "%RESPONSE_CODE%",
  "grpc_status": "%GRPC_STATUS( )%",
  "bytes_received": "%BYTES_RECEIVED%",
  "bytes_sent": "%BYTES_SENT%",
  "duration": "%DURATION%",
  "upstream_service_time": "%RESP(X-ENVOY-UPSTREAM-SERVICE-TIME)%",
  "forwarded_for": "%REQ(X-FORWARDED-FOR)%",
  "user_agent": "%REQ(USER-AGENT)%",
  "request_id": "%REQ(X-REQUEST-ID)%",
  "authority": "%REQ(:AUTHORITY)%",
  "upstream_host": "%UPSTREAM_HOST%",

```

```
"stream_id": "%STREAM_ID%"
}
```

## TCP access logs

The following command operators are included by default in TCP access logs:

### Text

```
[%START_TIME%] %DOWNSTREAM_REMOTE_ADDRESS% %DOWNSTREAM_REMOTE_PORT%
%BYTES_RECEIVED% %BYTES_SENT% %DURATION%
%CONNECTION_TERMINATION_DETAILS% %CONNECTION_ID%\n
```

### JSON

```
{
  "start_time": "%START_TIME%",
  "downstream_remote_address": "%DOWNSTREAM_REMOTE_ADDRESS%",
  "downstream_remote_port": "%DOWNSTREAM_REMOTE_PORT%",
  "bytes_received": "%BYTES_RECEIVED%",
  "bytes_sent": "%BYTES_SENT%",
  "duration": "%DURATION%",
  "connection_termination_details": "%CONNECTION_TERMINATION_DETAILS%",
  "connection_id": %CONNECTION_ID%
}
```

For more information about these command operators, see [Command Operators](#) in the Envoy documentation.

## Enabling access logs for Amazon ECS Service Connect

Access logs are not enabled by default for Amazon ECS services that use Service Connect. You can enable access logs in the following ways.

### Enable access logs using the AWS CLI

The following command shows how you can enable access logs for an Amazon ECS service using the AWS CLI by specifying a `accessLogConfiguration` when you create the service:

```
aws ecs create-service \
  --cluster my-cluster \
```

```

--service-name my-service \
--task-definition my-task-def \
--service-connect-configuration '{
    "enabled": true,
    "namespace": "arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-
abcdef1234567890",
    "services": [{
        "portName": "web",
        "discoveryName": "my-service",
        "clientAliases": [{
            "port": 80,
            "dnsName": "my-service"
        }]
    }],
    "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
            "awslogs-group": "my-envoy-log-group",
            "awslogs-region": "us-west-2",
            "awslogs-stream-prefix": "myapp-envoy-logs"
        }
    },
    "accessLogConfiguration": {
        "format": "TEXT",
        "includeQueryParameters": "ENABLED"
    }
}'

```

## Enable access logs using the console

For a detailed service creation procedure, see [Creating an Amazon ECS rolling update deployment](#).

## To create a service with a shared namespace using the AWS Management Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster that you want to create the service in.
3. Under **Services**, choose **Create**.
4. After filling in other details depending on your workload, in the **Service Connect** section, choose **Use Service Connect**.
5. Configure Service Connect settings as needed for your service type (client or client-server).
6. Expand **Access log configuration**. For **Format**, choose either **JSON** or **TEXT**.

7. To include query parameters in access logs, select **Include query parameters**.
8. Complete the service creation process.

## Amazon ECS Service Connect zone-aware routing

With Amazon ECS Service Connect zone-aware routing, traffic stays within the same Availability Zone (AZ) as the client. This reduces cross-AZ data transfer costs and latency without requiring additional infrastructure or application code changes. When endpoints are balanced across AZs, more than 80% of traffic stays local while traffic weights dynamically adjust as endpoints scale to maintain balanced load across target services. Zone-aware routing is on by default for all new and existing services that use Service Connect.

### How zone-aware routing works

The algorithm uses the Envoy zone-aware routing feature in the Service Connect proxy to route traffic based on endpoint locality:

1. **Endpoint discovery** - The proxy discovers all available endpoints for the destination service and their AZ placement.
2. **Same-AZ prioritization** - The proxy calculates what percentage of traffic stays in the same AZ based on the ratio of endpoint distribution between the source (client) and destination (server) AZs. When endpoints are evenly spread across zones, same-AZ traffic typically exceeds 80%.
3. **Residual capacity routing** - Traffic that cannot stay in the same AZ is distributed to other AZs based on their residual capacity. The proxy calculates the residual capacity of each zone and splits cross-AZ traffic proportionally among zones with positive residual capacity. As endpoints scale up or down, the proxy recalculates routing weights in real time.
4. **Overload protection and fallback** - To prevent overloading a single AZ, the proxy requires at least  $2 \times$  the number of AZs as available endpoints in the destination service. For a 3-AZ Region, this means at least 6 endpoints. Below this threshold, zone-aware routing deactivates and traffic is distributed evenly using round-robin load balancing. Routing reactivates automatically when the endpoint count exceeds the threshold. If endpoints in the same AZ become unavailable, traffic redistributes across other AZs to maintain availability.

### Verify zone-aware routing on Amazon EC2

On Amazon EC2 container instances that use the Docker runtime, you can inspect Envoy proxy statistics inside the Service Connect agent container to confirm that zone-aware routing is active.

Your container instances must use an ECS-optimized AMI version 20260323 or later. This procedure requires AWS Systems Manager Session Manager host access and `docker exec`. For AWS Fargate or container instances that use `containerd`, use Amazon Virtual Private Cloud Flow Logs to verify routing behavior as described in [the section called “Monitoring zone-aware routing”](#).

### To verify zone-aware routing on Amazon EC2 with Docker

1. Connect to the container instance with AWS Systems Manager Session Manager. Replace *instance-id* with your container instance ID.

```
aws ssm start-session --target instance-id
```

2. Open a shell in the Service Connect agent container.

```
sudo docker exec -it $(sudo docker ps --filter "name=ecs-service-connect" -q | head -1) /bin/sh
```

3. Query zone routing statistics from the Envoy admin interface.

```
curl --unix-socket /tmp/envoy_admin.sock http://unix/stats | grep "lb_zone"
```

4. Verify the output. A healthy deployment with zone-aware routing active shows zero cross-zone requests:

```
cluster.my-service.lb_zone_routing_cross_zone: 0  
cluster.my-service.lb_zone_cluster_too_small: 0
```

The following table describes the key zone routing metrics.

| Metric                     | Description                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lb_zone_routing_cross_zone | Number of requests routed to an endpoint in a different AZ. A sustained value of 0 confirms all traffic stays within the same AZ.                                  |
| lb_zone_cluster_too_small  | Number of times zone-aware routing was bypassed because the endpoint count was below the minimum threshold. Non-zero values during initial deployment are expected |

| Metric | Description                                                           |
|--------|-----------------------------------------------------------------------|
|        | and resolve as endpoints become healthy. A stable deployment shows 0. |

## Monitoring zone-aware routing

Use Amazon Virtual Private Cloud Flow Logs with the `az-id` field to observe traffic patterns at the network level. This shows which AZ each flow record originates from and terminates in, letting you measure same-AZ versus cross-AZ traffic ratios. You can also use AWS Cost Explorer to track cross-AZ data transfer charges before and after you redeploy your services to enable zone-aware routing.

For more information about configuring flow logs, see [VPC Flow Logs](#) in the *Amazon Virtual Private Cloud User Guide*.

## Considerations

Keep the following in mind when you use zone-aware routing:

- Zone-aware routing works with all launch types.
- Zone-aware routing is compatible with cross-account Service Connect namespaces shared through AWS Resource Access Manager.
- Existing services (both client and server) require a one-time redeployment to activate zone-aware routing. After the initial redeployment, routing adjusts dynamically as endpoints change without further redeployments.
- For the Amazon EC2 launch type, your container instances must use an Amazon ECS-optimized AMI version 20260323 or later.

## Encrypt Amazon ECS Service Connect traffic

Amazon ECS Service Connect supports automatic traffic encryption with Transport Layer Security (TLS) certificates for Amazon ECS services. When you point your Amazon ECS services toward an [AWS Private Certificate Authority \(AWS Private CA\)](#), Amazon ECS automatically provisions TLS certificates to encrypt traffic between your Amazon ECS Service Connect services. Amazon ECS generates, rotates, and distributes TLS certificates used for traffic encryption.

Automatic traffic encryption with Service Connect uses industry-leading encryption capabilities to secure your inter-service communication that helps you meet your security requirements. It

supports AWS Private Certificate Authority TLS certificates with 256-bit ECDSA and 2048-bit RSA encryption. You also have full control over private certificates and signing keys to help you meet compliance requirements. By default, TLS 1.3 is supported, but TLS 1.0 - 1.2 are not supported. Service Connect supports TLS 1.3 with the following ciphers:

- TLS\_AES\_128\_GCM\_SHA256
- TLS\_AES\_256\_GCM\_SHA384
- TLS\_CHACHA20\_POLY1305\_SHA256

#### **Note**

In order to use TLS 1.3, you must enable it on the listener on the target.  
Only inbound and outbound traffic passing through the Amazon ECS agent is encrypted.

## **Service Connect and Application Load Balancer health checks**

You can use Service Connect with Application Load Balancer health checks and TLS 1.3 encryption.

### **Application Load Balancer configuration**

Configure the Application Load Balancer with the following settings:

- Configure a TLS listener with a TLS 1.3 security policy (such as `ELBSecurityPolicy-TLS13-1-2-2021-06`). For more information, see [Security policies for your Application Load Balancer](#).
- Create a target group with the following settings:
  - Set the protocol to HTTPS
  - Attach the target group to the TLS listener
  - Configure the health check port to match your Service Connect service's container port

### **Service Connect configuration**

Configure a service with the following settings:

- Configure the service to use awsvpc network mode, as bridge network mode is not supported.
- Enable Service Connect for the service.

- Set up the load balancer configuration with the following settings:
  - Specify the target group you configured for your Application Load Balancer
  - Set the container port to match the Service Connect TLS service's container port
- Avoid setting `ingressPortOverride` for the service. For more information, see [ServiceConnectService](#) in the *Amazon Elastic Container Service API Reference*.

## Considerations

Consider the following when using Application Load Balancer, TLS and Service Connect:

- Use `awsvpc` network mode instead of `bridge` network mode for HTTPS health checks when using Service Connect with TLS encryption. HTTP health checks will continue to work with `bridge` mode.
- Configure the target group health check port to match the Service Connect service's container port, not the default HTTPS port (443).

## AWS Private Certificate Authority certificates and Service Connect

You need to have the infrastructure IAM role. For more information about this role, see [Amazon ECS infrastructure IAM role](#).

## AWS Private Certificate Authority modes for Service Connect

AWS Private Certificate Authority can run in two modes: general purpose and short-lived.

- General purpose - Certificates that can be configured with any expiration date.
- Short-lived - Certificates with a maximum validity of seven days.

While Amazon ECS supports both modes, we recommend using short-lived certificates. By default, certificates rotate every five days, and running in short-lived mode offers significant cost savings over general purpose.

Service Connect doesn't support certificate revocation and instead leverages short-lived certificates with frequent certificate rotation. You have the authority to modify the rotation frequency, disable, or delete the secrets using [managed rotation](#) in [Secrets Manager](#), but doing so can come with the following possible consequences.

- **Shorter Rotation Frequency** - A shorter rotation frequency incurs higher costs due to AWS Private CA, AWS KMS and Secrets Manager, and Auto Scaling experiencing an increased workload for rotation.
- **Longer Rotation Frequency** - Your applications' communications fail if the rotation frequency exceeds **seven** days.
- **Deletion of Secret** - Deleting the secret results in rotation failure and impacts customer application communications.

In the event of your secret rotation failing, a `RotationFailed` event is published in [AWS CloudTrail](#). You can also set up a [CloudWatch Alarm](#) for `RotationFailed`.

### Important

Don't add replica Regions to secrets. Doing so prevents Amazon ECS from deleting the secret, because Amazon ECS doesn't have permission to remove Regions from replication. If you already added the replication, run the following command.

```
aws secretsmanager remove-regions-from-replication \  
  --secret-id SecretId \  
  --remove-replica-regions region-name
```

## Subordinate Certificate Authorities

You can bring any AWS Private CA, root or subordinate, to Service Connect TLS to issue end-entity certificates for the services. The provided issuer is treated as the signer and root of trust everywhere. You can issue end-entity certificates for different parts of your application from different subordinate CAs. When using the AWS CLI, provide the Amazon Resource Name (ARN) of the CA to establish the trust chain.

## On-premises Certificate Authorities

To use your on-premises CA, you create and configure a subordinate CA in AWS Private Certificate Authority. This ensures all TLS certificates issued for your Amazon ECS workloads share the trust chain with the workloads you run on premises and are able to securely connect.

**⚠ Important**

Add the **required** tag `AmazonECSManaged : true` in your AWS Private CA.

**Infrastructure as code**

When using Service Connect TLS with Infrastructure as Code (IaC) tools, it's important to configure your dependencies correctly to avoid issues, such as services stuck in draining. Your AWS KMS key, if provided, IAM role, and AWS Private CA dependencies should be deleted after your Amazon ECS service.

If the namespace used for Service Connect is a shared namespace, you can choose to use a shared AWS Private CA resource. For more information, see [Attach a policy for cross-account access](#) in the *AWS Private Certificate Authority User Guide*.

**Service Connect and Secrets Manager**

**When using Amazon ECS Service Connect with TLS encryption, the service interacts with Secrets Manager in the following ways:**

Service Connect utilizes the infrastructure role provided to create secrets within Secrets Manager. These secrets are used to store the associated private keys for your TLS certificates for encrypting traffic between your Service Connect services.

**⚠ Warning**

The automatic creation and management of these secrets by Service Connect streamlines the process of implementing TLS encryption for your services. However, it's important to be aware of potential security implications. Other IAM roles that have read access to Secrets Manager may be able to access these automatically created secrets. This could expose sensitive cryptographic material to unauthorized parties, if access controls are not properly configured.

To mitigate this risk, follow these best practices:

- Carefully manage and restrict access to Secrets Manager, especially for secrets created by Service Connect.
- Regularly audit IAM roles and their permissions to ensure the principle of least privilege is maintained.

When granting read access to Secrets Manager, consider excluding the TLS private keys created by Service Connect. You can do this by using a condition in your IAM policies to exclude secrets with ARNs that match the pattern:

```
"arn:aws:secretsmanager:::secret:ecs-sc!"
```

An example IAM policy that denies the `GetSecretValue` action to all secrets with the `ecs-sc!` prefix:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "secretsmanager:GetSecretValue",
      "Resource": "arn:aws:secretsmanager:*:*:secret:ecs-sc!*"
    }
  ]
}
```

#### Note

This is a general example and may need to be adjusted based on your specific use case and AWS account configuration. Always test your IAM policies thoroughly to ensure they provide the intended access while maintaining security.

By understanding how Service Connect interacts with Secrets Manager, you can better manage the security of your Amazon ECS services while leveraging the benefits of automatic TLS encryption.

## Service Connect and AWS Key Management Service

You can use [AWS Key Management Service](#) to encrypt and decrypt your Service Connect resources. AWS KMS is a service managed by AWS where you can make and manage cryptographic keys that protect your data.

When using AWS KMS with Service Connect, you can either choose to use an AWS owned key that AWS manages for you, or you can choose an existing AWS KMS key. You can also [create a new AWS KMS key](#) to use.

### Providing your own encryption key

You can provide your own key materials, or you can use an external key store through AWS Key Management Service Import your own key into AWS KMS, and then specify the Amazon Resource Name (ARN) of that key in Amazon ECS Service Connect.

The following is an example AWS KMS policy. Replace the *user input* values with your own.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "id",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/role-name"
      },
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:GenerateDataKey",
        "kms:GenerateDataKeyPair"
      ],
      "Resource": "*"
    }
  ]
}
```

For more information about key policies, see [Creating a key policy](#) in the *AWS Key Management Service Developer Guide*.

#### Note

Service Connect supports only symmetric encryption AWS KMS keys. You can't use any other type of AWS KMS key to encrypt your Service Connect resources. For help

determining whether a AWS KMS key is a symmetric encryption key, see [Identify asymmetric KMS keys](#).

For more information on AWS Key Management Service symmetric encryption keys, see [Symmetric encryption AWS KMS keys](#) in the *AWS Key Management Service Developer Guide*.

## Enabling TLS for Amazon ECS Service Connect

You enable traffic encryption when you create or update a Service Connect service.

### To enable traffic encryption for a service in an existing namespace using the AWS Management Console

1. You need to have the infrastructure IAM role. For more information about this role, see [Amazon ECS infrastructure IAM role](#).
2. Open the console at <https://console.aws.amazon.com/ecs/v2>.
3. In the navigation pane, choose **Namespaces**.
4. Choose the **Namespace** with the **Service** you'd like to enable traffic encryption for.
5. Choose the **Service** you'd like to enable traffic encryption for.
6. Choose **Update Service** and scroll down to the Service Connect section.
7. Choose **Turn on traffic encryption** under your service information to enable TLS.
8. For **Service Connect TLS role**, choose an existing infrastructure IAM role or create a new one.
9. For **Signer certificate authority**, choose an existing certificate authority or create a new one.

For more information, see [AWS Private Certificate Authority certificates and Service Connect](#).

10. For **Choose an AWS KMS key**, choose an AWS owned and managed key or you can choose a different key. You can also choose to create a new one.

For an example of using the AWS CLI to configure TLS for your service, [Configuring Amazon ECS Service Connect with the AWS CLI](#).

## Verifying TLS is enabled for Amazon ECS Service Connect

Service Connect initiates TLS at the Service Connect agent and terminates it at the destination agent. As a result, the application code never sees TLS interactions. Use the following steps to verify that TLS is enabled.

1. Include the `openssl` CLI in your application image.
2. Enable [ECS Exec](#) on your services to connect to your tasks via SSM. Alternately, you can launch an Amazon EC2 instance in the same Amazon VPC as the service.
3. Retrieve the IP and port of a task from a service that you want to verify. You can retrieve the task IP address in the AWS Cloud Map console. The information is on the service details page for the namespace.
4. Log on to any of your tasks using `execute-command` like in the following example. Alternately, log on to the Amazon EC2 instance created in **Step 2**.

```
$ aws ecs execute-command --cluster cluster-name \  
  --task task-id \  
  --container container-name \  
  --interactive \  
  --command "/bin/sh"
```

### Note

Calling the DNS name directly does not reveal the certificate.

5. In the connected shell, use the `openssl` CLI to verify and view the certificate attached to the task.

Example:

```
openssl s_client -connect 10.0.147.43:6379 < /dev/null 2> /dev/null \  
| openssl x509 -noout -text
```

Example response:

```
Certificate:  
  Data:  
    Version: 3 (0x2)  
    Serial Number:
```

```

    <serial-number>
Signature Algorithm: ecdsa-with-SHA256
Issuer: <issuer>
Validity
    Not Before: Jan 23 21:38:12 2024 GMT
    Not After : Jan 30 22:38:12 2024 GMT
Subject: <subject>
Subject Public Key Info:
    Public Key Algorithm: id-ecPublicKey
    Public-Key: (256 bit)
    pub:
        <pub>
    ASN1 OID: prime256v1
    NIST CURVE: P-256
X509v3 extensions:
    X509v3 Subject Alternative Name:
        DNS:redis.yelb-cftc
    X509v3 Basic Constraints:
        CA:FALSE
    X509v3 Authority Key Identifier:
        keyid:<key-id>

    X509v3 Subject Key Identifier:
        1D:<id>
    X509v3 Key Usage: critical
        Digital Signature, Key Encipherment
    X509v3 Extended Key Usage:
        TLS Web Server Authentication, TLS Web Client Authentication
Signature Algorithm: ecdsa-with-SHA256
    <hash>

```

## Configuring Amazon ECS Service Connect with the AWS CLI

You can create an Amazon ECS service for a Fargate task that uses Service Connect with the AWS CLI.

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

## Prerequisites

The following are Service Connect prerequisites:

- Verify that the latest version of the AWS CLI is installed and configured. For more information, see [Installing or updating to the latest version of the AWS CLI](#).
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.
- You have a VPC, subnet, route table, and security group created to use. For more information, see [the section called “Create a virtual private cloud”](#).
- You have a task execution role with the name `ecsTaskExecutionRole` and the `AmazonECSTaskExecutionRolePolicy` managed policy is attached to the role. This role allows Fargate to write the NGINX application logs and Service Connect proxy logs to Amazon CloudWatch Logs. For more information, see [Creating the task execution role](#).

## Step 1: Create the cluster

Use the following steps to create your Amazon ECS cluster and namespace.

### To create the Amazon ECS cluster and AWS Cloud Map namespace

1. Create an Amazon ECS cluster named `tutorial` to use. The parameter `--service-connect-defaults` sets the default namespace of the cluster. In the example output, a AWS Cloud Map namespace of the name `service-connect` doesn't exist in this account and AWS Region, so the namespace is created by Amazon ECS. The namespace is made in AWS Cloud Map in the account, and is visible with all of the other namespaces, so use a name that indicates the purpose.

```
aws ecs create-cluster --cluster-name tutorial --service-connect-defaults  
namespace=service-connect
```

Output:

```
{  
  "cluster": {  
    "clusterArn": "arn:aws:ecs:us-west-2:123456789012:cluster/tutorial",  
    "clusterName": "tutorial",  
    "serviceConnectDefaults": {
```

```

        "namespace": "arn:aws:servicediscovery:us-
west-2:123456789012:namespace/ns-EXAMPLE"
    },
    "status": "PROVISIONING",
    "registeredContainerInstancesCount": 0,
    "runningTasksCount": 0,
    "pendingTasksCount": 0,
    "activeServicesCount": 0,
    "statistics": [],
    "tags": [],
    "settings": [
        {
            "name": "containerInsights",
            "value": "disabled"
        }
    ],
    "capacityProviders": [],
    "defaultCapacityProviderStrategy": [],
    "attachments": [
        {
            "id": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "type": "sc",
            "status": "ATTACHING",
            "details": []
        }
    ],
    "attachmentsStatus": "UPDATE_IN_PROGRESS"
}
}

```

## 2. Verify that the cluster is created:

```
aws ecs describe-clusters --clusters tutorial
```

Output:

```

{
    "clusters": [
        {
            "clusterArn": "arn:aws:ecs:us-west-2:123456789012:cluster/tutorial",
            "clusterName": "tutorial",
            "serviceConnectDefaults": {

```

```

        "namespace": "arn:aws:servicediscovery:us-
west-2:123456789012:namespace/ns-EXAMPLE"
      },
      "status": "ACTIVE",
      "registeredContainerInstancesCount": 0,
      "runningTasksCount": 0,
      "pendingTasksCount": 0,
      "activeServicesCount": 0,
      "statistics": [],
      "tags": [],
      "settings": [],
      "capacityProviders": [],
      "defaultCapacityProviderStrategy": []
    }
  ],
  "failures": []
}

```

3. (Optional) Verify that the namespace is created in AWS Cloud Map. You can use the AWS Management Console or the normal AWS CLI configuration as this is created in AWS Cloud Map.

For example, use the AWS CLI:

```
aws servicediscovery get-namespace --id ns-EXAMPLE
```

Output:

```

{
  "Namespace": {
    "Id": "ns-EXAMPLE",
    "Arn": "arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-
EXAMPLE",
    "Name": "service-connect",
    "Type": "HTTP",
    "Properties": {
      "DnsProperties": {
        "SOA": {}
      },
      "HttpProperties": {
        "HttpName": "service-connect"
      }
    }
  }
}

```

```
    }  
  },  
  "CreateDate": 1661749852.422,  
  "CreatorRequestId": "service-connect"  
}  
}
```

## Step 2: Create the service for the server

The Service Connect feature is intended for interconnecting multiple applications on Amazon ECS. At least one of those applications needs to provide a web service to connect to. In this step, you create:

- The task definition that uses the unmodified official NGINX container image and includes Service Connect configuration.
- The Amazon ECS service definition that configures Service Connect to provide service discovery and service mesh proxy for traffic to this service. The configuration reuses the default namespace from the cluster configuration to reduce the amount of service configuration that you make for each service.
- The Amazon ECS service. It runs one task using the task definition, and inserts an additional container for the Service Connect proxy. The proxy listens on the port from the container port mapping of the task definition. In a client application running in Amazon ECS, the proxy in the client task listens for outbound connections to the task definition port name, service discovery name or service client alias name, and the port number from the client alias.

## To create the web service with Service Connect

1. Register a task definition that's compatible with Fargate and uses the awsvpc network mode. Follow these steps:
  - a. Create a file that's named `service-connect-nginx.json` with the contents of the following task definition.

This task definition configures Service Connect by adding `name` and `appProtocol` parameters to the port mapping. The port name makes this port more identifiable in the service configuration when multiple ports are used. The port name is also used by default as the discoverable name for use by other applications in the namespace.

The task definition contains the task IAM role because the service has ECS Exec enabled.

**⚠ Important**

This task definition uses a `logConfiguration` to send the nginx output from `stdout` and `stderr` to Amazon CloudWatch Logs. This task execution role doesn't have the extra permissions required to make the CloudWatch Logs log group. Create the log group in CloudWatch Logs using the AWS Management Console or AWS CLI. If you don't want to send the nginx logs to CloudWatch Logs you can remove the `logConfiguration`.

Replace the AWS account id in the task execution role with your AWS account id.

```
{
  "family": "service-connect-nginx",
  "executionRoleArn": "arn:aws:iam::123456789012:role/ecsTaskExecutionRole",
  "taskRoleArn": "arn:aws:iam::123456789012:role/ecsTaskRole",
  "networkMode": "awsvpc",
  "containerDefinitions": [
    {
      "name": "webserver",
      "image": "public.ecr.aws/docker/library/nginx:latest",
      "cpu": 100,
      "portMappings": [
        {
          "name": "nginx",
          "containerPort": 80,
          "protocol": "tcp",
          "appProtocol": "http"
        }
      ],
      "essential": true,
      "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
          "awslogs-group": "/ecs/service-connect-nginx",
          "awslogs-region": "region",
          "awslogs-stream-prefix": "nginx"
        }
      }
    }
  ]
}
```

```
    }  
    }  
  ],  
  "cpu": "256",  
  "memory": "512"  
}
```

- b. Register the task definition using the `service-connect-nginx.json` file:

```
aws ecs register-task-definition --cli-input-json file://service-connect-  
nginx.json
```

## 2. Create a service:

- a. Create a file that's named `service-connect-nginx-service.json` with the contents of the Amazon ECS service that you're creating. This example uses the task definition that was created in the previous step. An `awsvpcConfiguration` is required because the example task definition uses the `awsvpc` network mode.

When you create the ECS service, specify Fargate, and the LATEST platform version that supports Service Connect. The `securityGroups` and `subnets` must belong to a VPC that has the requirements for using Amazon ECS. You can obtain the security group and subnet IDs from the Amazon VPC Console.

This service configures Service Connect by adding the `serviceConnectConfiguration` parameter. The namespace is not required because the cluster has a default namespace configured. Client applications running in ECS in the namespace connect to this service by using the `portName` and the port in the `clientAliases`. For example, this service is reachable using `http://nginx:80/`, as nginx provides a welcome page in the root location `/`. External applications that are not running in Amazon ECS or are not in the same namespace can reach this application through the Service Connect proxy by using the IP address of the task and the port number from the task definition. For your `tls` configuration, add the certificate `arn` for your `awsPcaAuthorityArn`, your `kmsKey`, and `roleArn` of your IAM role.

This service uses a `logConfiguration` to send the service connect proxy output from `stdout` and `stderr` to Amazon CloudWatch Logs. This task execution role doesn't have the extra permissions required to make the CloudWatch Logs log group. Create the log group in CloudWatch Logs using the AWS Management Console or AWS CLI.

We recommend that you create this log group and store the proxy logs in CloudWatch Logs. If you don't want to send the proxy logs to CloudWatch Logs you can remove the `logConfiguration`.

```

```

The `serviceConnectConfiguration` that you provided appears inside the first *deployment* of the output. As you make changes to the ECS service in ways that need to make changes to tasks, a new deployment is created by Amazon ECS.

### Step 3: Verify that you can connect

To verify that Service Connect is configured and working, follow these steps to connect to the web service from an external application. Then, see the additional metrics in CloudWatch the Service Connect proxy creates.

#### To connect to the web service from an external application

- Connect to the task IP address and container port using the task IP address

Use the AWS CLI to get the task ID, using the `aws ecs list-tasks --cluster tutorial`.

If your subnets and security group permit traffic from the public internet on the port from the task definition, you can connect to the public IP from your computer. The public IP isn't available from `describe-tasks`` however, so the steps involve going to the Amazon EC2 AWS Management Console or AWS CLI to get the details of the elastic network interface.

In this example, an Amazon EC2 instance in the same VPC uses the private IP of the task. The application is nginx, but the `server: envoy` header shows that the Service Connect proxy is used. The Service Connect proxy is listening on the container port from the task definition.

```
$ curl -v 10.0.19.50:80/
* Trying 10.0.19.50:80...
* Connected to 10.0.19.50 (10.0.19.50) port 80 (#0)
> GET / HTTP/1.1
> Host: 10.0.19.50
> User-Agent: curl/7.79.1
> Accept: */*
>
* Mark bundle as not supporting multiuse
< HTTP/1.1 200 OK
< server: envoy

<p><em>Thank you for using nginx.</em></p>
</body>
</html>
```

## To view Service Connect metrics

The Service Connect proxy creates application (HTTP, HTTP2, gRPC, or TCP connection) metrics in CloudWatch metrics. When you use the CloudWatch console, see the additional metric dimensions of **DiscoveryName**, (**DiscoveryName**, **ServiceName**, **ClusterName**), **TargetDiscoveryName**, and (**TargetDiscoveryName**, **ServiceName**, **ClusterName**) under the Amazon ECS namespace. For more information about these metrics and the dimensions, see [View Available Metrics](#) in the Amazon CloudWatch Logs User Guide.

## Use service discovery to connect Amazon ECS services with DNS names

Your Amazon ECS service can optionally be configured to use Amazon ECS service discovery. Service discovery uses AWS Cloud Map API actions to manage HTTP and DNS namespaces for your Amazon ECS services. For more information, see [What Is AWS Cloud Map](#) in the *AWS Cloud Map Developer Guide*.

Service discovery is available in the following AWS Regions:

| Region Name              | Region     |
|--------------------------|------------|
| US East (N. Virginia)    | us-east-1  |
| US East (Ohio)           | us-east-2  |
| US West (N. California)  | us-west-1  |
| US West (Oregon)         | us-west-2  |
| Africa (Cape Town)       | af-south-1 |
| Asia Pacific (Hong Kong) | ap-east-1  |

| Region Name                | Region         |
|----------------------------|----------------|
| Asia Pacific (Taipei)      | ap-east-2      |
| Asia Pacific (Mumbai)      | ap-south-1     |
| Asia Pacific (Hyderabad)   | ap-south-2     |
| Asia Pacific (Tokyo)       | ap-northeast-1 |
| Asia Pacific (Seoul)       | ap-northeast-2 |
| Asia Pacific (Osaka)       | ap-northeast-3 |
| Asia Pacific (Singapore)   | ap-southeast-1 |
| Asia Pacific (Sydney)      | ap-southeast-2 |
| Asia Pacific (Jakarta)     | ap-southeast-3 |
| Asia Pacific (Melbourne)   | ap-southeast-4 |
| Asia Pacific (Malaysia)    | ap-southeast-5 |
| Asia Pacific (New Zealand) | ap-southeast-6 |
| Asia Pacific (Thailand)    | ap-southeast-7 |
| Canada (Central)           | ca-central-1   |
| Canada West (Calgary)      | ca-west-1      |
| China (Beijing)            | cn-north-1     |
| China (Ningxia)            | cn-northwest-1 |
| Europe (Frankfurt)         | eu-central-1   |
| Europe (Zurich)            | eu-central-2   |
| Europe (Ireland)           | eu-west-1      |

| Region Name               | Region        |
|---------------------------|---------------|
| Europe (London)           | eu-west-2     |
| Europe (Paris)            | eu-west-3     |
| Europe (Milan)            | eu-south-1    |
| Europe (Stockholm)        | eu-north-1    |
| Israel (Tel Aviv)         | il-central-1  |
| Europe (Spain)            | eu-south-2    |
| Middle East (UAE)         | me-central-1  |
| Mexico (Central)          | mx-central-1  |
| Middle East (Bahrain)     | me-south-1    |
| South America (São Paulo) | sa-east-1     |
| AWS GovCloud (US-East)    | us-gov-east-1 |
| AWS GovCloud (US-West)    | us-gov-west-1 |

## Service Discovery concepts

Service discovery consists of the following components:

- **Service discovery namespace:** A logical group of service discovery services that share the same domain name, such as `example.com`, which is where you want to route traffic. You can create a namespace with a call to the `aws servicediscovery create-private-dns-namespace` command or in the Amazon ECS console. You can use the `aws servicediscovery list-namespaces` command to view the summary information about the namespaces that were created by the current account. For more information about the service discovery commands, see [create-private-dns-namespace](#) and [list-namespaces](#) in the *AWS Cloud Map (service discovery) AWS CLI Reference Guide*.

- **Service discovery service:** Exists within the service discovery namespace and consists of the service name and DNS configuration for the namespace. It provides the following core component:
  - **Service registry:** Allows you to look up a service via DNS or AWS Cloud Map API actions and get back one or more available endpoints that can be used to connect to the service.
- **Service discovery instance:** Exists within the service discovery service and consists of the attributes associated with each Amazon ECS service in the service directory.
- **Instance attributes:** The following metadata is added as custom attributes for each Amazon ECS service that is configured to use service discovery:
  - **AWS\_INSTANCE\_IPV4** – For an A record, the IPv4 address that Route 53 returns in response to DNS queries and AWS Cloud Map returns when discovering instance details, for example, 192.0.2.44.
  - **AWS\_INSTANCE\_IPV6** – For an AAAA record, the IPv6 address that Route 53 returns in response to DNS queries and AWS Cloud Map returns when discovering instance details, for example, 2001:0db8:85a3:0000:0000:abcd:0001:2345. Both **AWS\_INSTANCE\_IPv4** and **AWS\_INSTANCE\_IPv6** are added for Amazon ECS dualstack services. Only **AWS\_INSTANCE\_IPv6** is added for Amazon ECS IPv6-only services.
  - **AWS\_INSTANCE\_PORT** – The port value associated with the service discovery service.
  - **AVAILABILITY\_ZONE** – The Availability Zone into which the task was launched. For tasks using EC2, this is the Availability Zone in which the container instance exists. For tasks using Fargate, this is the Availability Zone in which the elastic network interface exists.
  - **REGION** – The Region in which the task exists.
  - **ECS\_SERVICE\_NAME** – The name of the Amazon ECS service to which the task belongs.
  - **ECS\_CLUSTER\_NAME** – The name of the Amazon ECS cluster to which the task belongs.
  - **EC2\_INSTANCE\_ID** – The ID of the container instance the task was placed on. This custom attribute is not added if the task is using Fargate.
  - **ECS\_TASK\_DEFINITION\_FAMILY** – The task definition family that the task is using.
  - **ECS\_TASK\_SET\_EXTERNAL\_ID** – If a task set is created for an external deployment and is associated with a service discovery registry, then the **ECS\_TASK\_SET\_EXTERNAL\_ID** attribute will contain the external ID of the task set.
- **Amazon ECS health checks:** Amazon ECS performs periodic container-level health checks. If an endpoint does not pass the health check, it is removed from DNS routing and marked as unhealthy.

## Service discovery considerations

The following should be considered when using service discovery:

- Service discovery is supported for tasks on Fargate that use platform version 1.1.0 or later. For more information, see [Fargate platform versions for Amazon ECS](#).
- Services configured to use service discovery have a limit of 1,000 tasks per service. This is due to a Route 53 service quota.
- The Create Service workflow in the Amazon ECS console only supports registering services into private DNS namespaces. When an AWS Cloud Map private DNS namespace is created, a Route 53 private hosted zone will be created automatically.
- The VPC DNS attributes must be configured for successful DNS resolution. For information about how to configure the attributes, see [DNS support in your VPC](#) in the *Amazon VPC User Guide*.
- Amazon ECS does not support registering services into shared AWS Cloud Map namespaces.
- The DNS records created for a service discovery service always register with the private IP address for the task, rather than the public IP address, even when public namespaces are used.
- Service discovery requires that tasks specify either the `awsvpc`, `bridge`, or `host` network mode (`none` is not supported).
- If the service task definition uses the `awsvpc` network mode, you can create any combination of A or SRV records for each service task. If you use SRV records, a port is required. You can additionally create AAAA records if the service uses dualstack subnets. If the service uses IPv6-only subnets, you can't create A records.
- If the service task definition uses the `bridge` or `host` network mode, the SRV record is the only supported DNS record type. Create a SRV record for each service task. The SRV record must specify a container name and container port combination from the task definition.
- DNS records for a service discovery service can be queried within your VPC. They use the following format: `<service-discovery-service-name>.<service-discovery-namespace>`.
- When doing a DNS query on the service name, A and AAAA records return a set of IP addresses that correspond to your tasks. SRV records return a set of IP addresses and ports for each task.
- If you have eight or fewer healthy records, Route 53 responds to all DNS queries with all of the healthy records.
- When all records are unhealthy, Route 53 responds to DNS queries with up to eight unhealthy records.

- You can configure service discovery for a service that's behind a load balancer, but service discovery traffic is always routed to the task and not the load balancer.
- Service discovery doesn't support the use of Classic Load Balancers.
- We recommend you use container-level health checks managed by Amazon ECS for your service discovery service.
  - **HealthCheckCustomConfig**—Amazon ECS manages health checks on your behalf. Amazon ECS uses information from container and health checks, and your task state, to update the health with AWS Cloud Map. This is specified using the `--health-check-custom-config` parameter when creating your service discovery service. For more information, see [HealthCheckCustomConfig](#) in the *AWS Cloud Map API Reference*.
- The AWS Cloud Map resources created when service discovery is used must be cleaned up manually.
- Tasks and instances are registered as UNHEALTHY until the container health checks return a value. If the health checks pass, the status is updated to HEALTHY. If the container health checks fail, the service discovery instance is deregistered.

## Service discovery pricing

Customers using Amazon ECS service discovery are charged for Route 53 resources and AWS Cloud Map discovery API operations. This involves costs for creating the Route 53 hosted zones and queries to the service registry. For more information, see [AWS Cloud Map Pricing](#) in the *AWS Cloud Map Developer Guide*.

Amazon ECS performs container level health checks and exposes them to AWS Cloud Map custom health check API operations. This is currently made available to customers at no extra cost. If you configure additional network health checks for publicly exposed tasks, you're charged for those health checks.

## Creating an Amazon ECS service that uses Service Discovery

Learn how to create a service containing a Fargate task that uses service discovery with the AWS CLI.

For a list of AWS Regions that support service discovery, see [Use service discovery to connect Amazon ECS services with DNS names](#).

For information about the Regions that support Fargate, see [the section called "AWS Fargate Regions"](#).

**Note**

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

## Prerequisites

Before you start this tutorial, make sure that the following prerequisites are met:

- The latest version of the AWS CLI is installed and configured. For more information, see [Installing or updating to the latest version of the AWS CLI](#).
- The steps described in [Set up to use Amazon ECS](#) are complete.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.
- You have created at least one VPC and one security group. For more information, see [the section called "Create a virtual private cloud"](#).

## Step 1: Create the Service Discovery resources in AWS Cloud Map

Follow these steps to create your service discovery namespace and service discovery service:

1. Create a private Cloud Map service discovery namespace. This example creates a namespace that's called `tutorial`. Replace `vpc-abcd1234` with the ID of one of your existing VPCs.

```
aws servicediscovery create-private-dns-namespace \  
  --name tutorial \  
  --vpc vpc-abcd1234
```

The output of this command is as follows.

```
{  
  "OperationId": "h2qe3s6dxftvvt7riu6lfy2f6c3jlf4-je6chs2e"  
}
```

2. Using the OperationId from the output of the previous step, verify that the private namespace was created successfully. Make note of the namespace ID because you use it in subsequent commands.

```
aws servicediscovery get-operation \
  --operation-id h2qe3s6dxftvvt7riu6lfy2f6c3jlfh4-je6chs2e
```

The output is as follows.

```
{
  "Operation": {
    "Id": "h2qe3s6dxftvvt7riu6lfy2f6c3jlfh4-je6chs2e",
    "Type": "CREATE_NAMESPACE",
    "Status": "SUCCESS",
    "CreateDate": 1519777852.502,
    "UpdateDate": 1519777856.086,
    "Targets": {
      "NAMESPACE": "ns-uejictsjen2i4eeg"
    }
  }
}
```

3. Using the NAMESPACE ID from the output of the previous step, create a service discovery service. This example creates a service named myapplication. Make note of the service ID and ARN because you use them in subsequent commands.

```
aws servicediscovery create-service \
  --name myapplication \
  --dns-config "NamespaceId=ns-uejictsjen2i4eeg",DnsRecords=[{Type=A,TTL=300}]" \
  --health-check-custom-config FailureThreshold=1
```

The output is as follows.

```
{
  "Service": {
    "Id": "srv-utcrh6wavdkggqtk",
    "Arn": "arn:aws:servicediscovery:region:aws_account_id:service/srv-utcrh6wavdkggqtk",
    "Name": "myapplication",
    "DnsConfig": {
```

```

        "NamespaceId": "ns-uejictsjen2i4eeg",
        "DnsRecords": [
            {
                "Type": "A",
                "TTL": 300
            }
        ],
    },
    "HealthCheckCustomConfig": {
        "FailureThreshold": 1
    },
    "CreatorRequestId": "e49a8797-b735-481b-a657-b74d1d6734eb"
}

```

## Step 2: Create the Amazon ECS resources

Follow these steps to create your Amazon ECS cluster, task definition, and service:

1. Create an Amazon ECS cluster. This example creates a cluster that's named `tutorial`.

```

aws ecs create-cluster \
    --cluster-name tutorial

```

2. Register a task definition that's compatible with Fargate and uses the `awsvpc` network mode. Follow these steps:
  - a. Create a file that's named `fargate-task.json` with the contents of the following task definition.

```

{
    "family": "tutorial-task-def",
    "networkMode": "awsvpc",
    "containerDefinitions": [
        {
            "name": "sample-app",
            "image": "public.ecr.aws/docker/library/httpd:2.4",
            "portMappings": [
                {
                    "containerPort": 80,
                    "hostPort": 80,
                    "protocol": "tcp"
                }
            ]
        }
    ]
}

```

```

        }
    ],
    "essential": true,
    "entryPoint": [
        "sh",
        "-c"
    ],
    "command": [
        "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample
App</title> <style>body {margin-top: 40px; background-color: #333;} </style>
</head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample
App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a
container in Amazon ECS.</p> </div></body></html>' > /usr/local/apache2/
htdocs/index.html && httpd-foreground\""
    ]
    }
],
"requiresCompatibilities": [
    "FARGATE"
],
"cpu": "256",
"memory": "512"
}

```

- b. Register the task definition using `fargate-task.json`.

```

aws ecs register-task-definition \
    --cli-input-json file://fargate-task.json

```

3. Create an ECS service by following these steps:

- a. Create a file that's named `ecs-service-discovery.json` with the contents of the ECS service that you're creating. This example uses the task definition that was created in the previous step. An `awsvpcConfiguration` is required because the example task definition uses the `awsvpc` network mode.

When you create the ECS service, specify Fargate and the LATEST platform version that supports service discovery. When the service discovery service is created in AWS Cloud Map, `registryArn` is the ARN returned. The `securityGroups` and `subnets` must belong to the VPC that's used to create the Cloud Map namespace. You can obtain the security group and subnet IDs from the Amazon VPC Console.

```
{
  "cluster": "tutorial",
  "serviceName": "ecs-service-discovery",
  "taskDefinition": "tutorial-task-def",
  "serviceRegistries": [
    {
      "registryArn":
"arn:aws:servicediscovery:region:aws_account_id:service/srv-utcrh6wavdkggqtk"
    }
  ],
  "launchType": "FARGATE",
  "platformVersion": "LATEST",
  "networkConfiguration": {
    "awsvpcConfiguration": {
      "assignPublicIp": "ENABLED",
      "securityGroups": [ "sg-abcd1234" ],
      "subnets": [ "subnet-abcd1234" ]
    }
  },
  "desiredCount": 1
}
```

- b. Create your ECS service using `ecs-service-discovery.json`.

```
aws ecs create-service \
  --cli-input-json file://ecs-service-discovery.json
```

### Step 3: Verify Service Discovery in AWS Cloud Map

You can verify that everything is created properly by querying your service discovery information. After service discovery is configured, you can either use AWS Cloud Map API operations, or call `dig` from an instance within your VPC. Follow these steps:

1. Using the service discovery service ID, list the service discovery instances. Make note of the instance ID (marked in bold) for resource cleanup.

```
aws servicediscovery list-instances \
  --service-id srv-utcrh6wavdkggqtk
```

The output is as follows.

```
{
  "Instances": [
    {
      "Id": "16becc26-8558-4af1-9fbd-f81be062a266",
      "Attributes": {
        "AWS_INSTANCE_IPV4": "172.31.87.2"
        "AWS_INSTANCE_PORT": "80",
        "AVAILABILITY_ZONE": "us-east-1a",
        "REGION": "us-east-1",
        "ECS_SERVICE_NAME": "ecs-service-discovery",
        "ECS_CLUSTER_NAME": "tutorial",
        "ECS_TASK_DEFINITION_FAMILY": "tutorial-task-def"
      }
    }
  ]
}
```

2. Use the service discovery namespace, service, and additional parameters such as ECS cluster name to query details about the service discovery instances.

```
aws servicediscovery discover-instances \
  --namespace-name tutorial \
  --service-name myapplication \
  --query-parameters ECS_CLUSTER_NAME=tutorial
```

3. The DNS records that are created in the Route 53 hosted zone for the service discovery service can be queried with the following AWS CLI commands:
  - a. Using the namespace ID, get information about the namespace, which includes the Route 53 hosted zone ID.

```
aws servicediscovery \
  get-namespace --id ns-uejictsjen2i4eeg
```

The output is as follows.

```
{
  "Namespace": {
    "Id": "ns-uejictsjen2i4eeg",
    "Arn": "arn:aws:servicediscovery:region:aws_account_id:namespace/ns-uejictsjen2i4eeg",
```

```

    "Name": "tutorial",
    "Type": "DNS_PRIVATE",
    "Properties": {
      "DnsProperties": {
        "HostedZoneId": "Z35JQ4ZFDRYPLV"
      }
    },
    "CreateDate": 1519777852.502,
    "CreatorRequestId": "9049a1d5-25e4-4115-8625-96dbda9a6093"
  }
}

```

- b. Using the Route 53 hosted zone ID from the previous step (see the text in bold), get the resource record set for the hosted zone.

```

aws route53 list-resource-record-sets \
  --hosted-zone-id Z35JQ4ZFDRYPLV

```

4. You can also query the DNS from an instance within your VPC using dig.

```

dig +short myapplication.tutorial

```

## Step 4: Clean up

When you're finished with this tutorial, clean up the associated resources to avoid incurring charges for unused resources. Follow these steps:

1. Deregister the service discovery service instances using the service ID and instance ID that you noted previously.

```

aws servicediscovery deregister-instance \
  --service-id srv-utcrh6wavdkggqtk \
  --instance-id 16becc26-8558-4af1-9fbd-f81be062a266

```

The output is as follows.

```

{
  "OperationId": "xhu73bsertlyffhm3faqi7kumsmx274n-jh0zimzv"
}

```

2. Using the OperationId from the output of the previous step, verify that the service discovery service instances were deregistered successfully.

```
aws servicediscovery get-operation \  
  --operation-id xhu73bsertlyffhm3faqi7kumsmx274n-jh0zimzv
```

```
{  
  "Operation": {  
    "Id": "xhu73bsertlyffhm3faqi7kumsmx274n-jh0zimzv",  
    "Type": "DEREGISTER_INSTANCE",  
    "Status": "SUCCESS",  
    "CreateDate": 1525984073.707,  
    "UpdateDate": 1525984076.426,  
    "Targets": {  
      "INSTANCE": "16becc26-8558-4af1-9fbd-f81be062a266",  
      "ROUTE_53_CHANGE_ID": "C5NSRG1J4I1FH",  
      "SERVICE": "srv-utcrh6wavdkggqtk"  
    }  
  }  
}
```

3. Delete the service discovery service using the service ID.

```
aws servicediscovery delete-service \  
  --id srv-utcrh6wavdkggqtk
```

4. Delete the service discovery namespace using the namespace ID.

```
aws servicediscovery delete-namespace \  
  --id ns-uejictsjen2i4eeg
```

The output is as follows.

```
{  
  "OperationId": "c3ncqglftesw4ibgj5baz6ktaoh6cg4t-jh0ztysj"  
}
```

5. Using the OperationId from the output of the previous step, verify that the service discovery namespace was deleted successfully.

```
aws servicediscovery get-operation \  
  --operation-id c3ncqglftesw4ibgj5baz6ktaoh6cg4t-jh0ztysj
```

```
--operation-id c3ncqglftesw4ibgj5baz6ktaoh6cg4t-jh0ztysj
```

The output is as follows.

```
{
  "Operation": {
    "Id": "c3ncqglftesw4ibgj5baz6ktaoh6cg4t-jh0ztysj",
    "Type": "DELETE_NAMESPACE",
    "Status": "SUCCESS",
    "CreateDate": 1525984602.211,
    "UpdateDate": 1525984602.558,
    "Targets": {
      "NAMESPACE": "ns-rymlehshst7hhukh",
      "ROUTE_53_CHANGE_ID": "CJP2A2M86XW30"
    }
  }
}
```

6. Update the desired count for the Amazon ECS service to 0. You must do this to delete the service in the next step.

```
aws ecs update-service \
  --cluster tutorial \
  --service ecs-service-discovery \
  --desired-count 0
```

7. Delete the Amazon ECS service.

```
aws ecs delete-service \
  --cluster tutorial \
  --service ecs-service-discovery
```

8. Delete the Amazon ECS cluster.

```
aws ecs delete-cluster \
  --cluster tutorial
```

## Use Amazon VPC Lattice to connect, observe, and secure your Amazon ECS services

Amazon VPC Lattice is a fully managed application networking service that enables Amazon ECS customers to observe, secure, and monitor applications built across AWS compute services, VPCs, and accounts—without requiring any code changes.

VPC Lattice uses target groups, which are a collection of compute resources. These targets run your application or service and can be Amazon EC2 instances, IP addresses, Lambda functions, and Application Load Balancers. By associating their Amazon ECS services with a VPC Lattice target group, customers can now enable Amazon ECS tasks as IP targets in VPC Lattice. Amazon ECS automatically registers tasks to the VPC Lattice target group when tasks for the registered service are launched.

### Note

When using five VPC Lattice configurations, your deployment time may be slightly longer than when using fewer configurations.

A listener rule is used to forward traffic to a specified target group when the conditions are met. A listener checks for connection requests using the protocol on the port you configured. A service routes requests to its registered targets based on the rules that you define when you configured your listener.

Amazon ECS also automatically replaces a task if it becomes unhealthy according to VPC Lattice health checks. Once associated with VPC Lattice, Amazon ECS customers can also take advantage of many other cross-compute connectivity, security, and observability features in VPC Lattice like connecting to services across clusters, VPCs, and accounts with AWS Resource Access Manager, IAM integration for authorization and authentication, and advanced traffic management features.

Amazon ECS customers can benefit from VPC Lattice in the following ways.

- **Increased developer productivity** - VPC Lattice boosts developer productivity by letting you focus on building features, while VPC Lattice handles networking, security and observability challenges in a uniform way across all compute platforms.
- **Better security posture** - VPC Lattice enables your developers to easily authenticate and secure communication across applications and compute platforms, enforce encryption in transit, and

apply granular access controls with VPC Lattice Auth policies. This allows you to adopt a stronger security posture that meets industry leading regulatory and compliance requirements.

- Improved application scalability and resilience - VPC Lattice lets you create a network of deployed applications with features like path, header, and method-based routing, authentication, authorization, and monitoring. These benefits are provided with no resource overhead on workloads and can support multi-cluster deployments that generate millions of requests per second without adding significant latency.
- Deployment flexibility with heterogeneous infrastructure - VPC Lattice provides consistent features across all compute services like Amazon ECS, Fargate, Amazon EC2, Amazon EKS, and Lambda and allows your organization the flexibility to choose suitable infrastructure for each application.

## How VPC Lattice works with other Amazon ECS services

Using VPC Lattice with Amazon ECS may change the way you use other Amazon ECS services, while others stay the same.

### Application Load Balancers

You no longer need to create a specific Application Load Balancer to use with the Application Load Balancer target group type in VPC Lattice that then links to the Amazon ECS service. You only need to configure your Amazon ECS service with a VPC Lattice target group instead. You can also still choose to use Application Load Balancer with Amazon ECS at the same time.

### Amazon ECS deployments

Amazon ECS rolling deployments and the Amazon ECS blue/green deployment strategy (including its linear and canary traffic-shifting configurations) work with VPC Lattice, and Amazon ECS safely brings tasks into and removes them from services during deployment. For the VPC Lattice resources required for blue/green, linear, and canary deployments, see [VPC Lattice resources for blue/green, linear, and canary deployments](#). The blue/green deployment powered by CodeDeploy (the CODE\_DEPLOY deployment controller) isn't supported.

To learn more about VPC Lattice, see the [Amazon VPC Lattice User Guide](#).

### Create a service that uses VPC Lattice

You can use either the AWS Management Console or the AWS CLI to create a service with VPC Lattice.

## Prerequisites

Before you start this tutorial, make sure that the following prerequisites are met:

- The latest version of the AWS CLI is installed and configured. For more information, see [Installing the AWS Command Line Interface](#).

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

- The steps described in [Set up to use Amazon ECS](#) are complete.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.

## Create a service that uses VPC Lattice with the AWS Management Console

Follow these steps to create a service with VPC Lattice using the AWS Management Console.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation page, choose **Clusters**.
3. On the **Clusters** page, choose the cluster to create the service in.
4. From the **Services** tab, choose **Create**.

If you've never created a service before, follow the steps found in [Creating an Amazon ECS service using the console](#), then continue with these steps when you reach the VPC Lattice section.

5. Choose to **Turn on VPC Lattice** by checking the button.
6. To use an existing role, for **ECS infrastructure role for Amazon ECS**, choose one that you've already created to use when creating the VPC Lattice target group. To create a new role, **Create ECS infrastructure role**.
7. Choose the **VPC**.

The **VPC** depends on the networking mode you selected when you registered your task definition. If you use the host or network mode with EC2, choose your VPC.

For the `awsvpc` mode, the VPC is automatically selected based on the VPC you chose under **Networking** and can't be changed.

- Under **Target Groups** choose the target group or groups. You need to choose at least one target group and can have a maximum of five. Choose **Add target group** to add additional target groups. Choose the **Port name**, **Protocol**, and **Port** for each target group you chose. To delete a target group, choose **Remove**.

 **Note**

- If you want to add existing target groups, you need use the AWS CLI. For instructions on how to add target groups using the AWS CLI, see [register-targets](#) in the *AWS Command Line Interface Reference*.
- While a VPC Lattice service can have multiple target groups, each target group can only be added to one service.
- To create a service in an IPv6-only configuration, choose target groups with an IP address type of IPv6.

- At this point, you navigate to the VPC Lattice console to continue setting up. This is where you include your new target groups in the listener default action or in the rules of an existing VPC Lattice service.

For more information, see [Listener rules for your VPC Lattice service](#).

 **Important**

You need to allow the inbound rule `vpc-lattice` prefix to your security group or tasks and health checks can fail.

## Create a service that uses VPC Lattice with the AWS CLI

Use the AWS CLI to create a service with VPC Lattice. Replace each *user input placeholder* with your own information.

- Create a target group configuration file. The following example is named `tg-config.json`

```
{
  "ipAddressType": "IPv4",
  "port": 443,
  "protocol": "HTTPS",
  "protocolVersion": "HTTP1",
  "vpcIdentifier": "vpc-f1663d9868EXAMPLE"
}
```

2. Use the following command to create a VPC Lattice target group.

```
aws vpc-lattice create-target-group \
  --name my-lattice-target-group-ip \
  --type IP \
  --config file://tg-config.json
```

 **Note**

To create a service in an IPv6-only configuration, create target groups with an IP address type of IPv6. For more information, see [create-target-group](#) in the *AWS CLI Command Reference*.

Example output:

```
{
  "arn": "arn:aws:vpc-lattice:us-east-2:123456789012:targetgroup/tg-0eaa4b9ab4EXAMPLE",
  "config": {
    "healthCheck": {
      "enabled": true,
      "healthCheckIntervalSeconds": 30,
      "healthCheckTimeoutSeconds": 5,
      "healthyThresholdCount": 5,
      "matcher": {
        "httpCode": "200"
      },
    },
    "path": "/",
    "protocol": "HTTPS",
    "protocolVersion": "HTTP1",
    "unhealthyThresholdCount": 2
  }
}
```

```

    },
    "ipAddressType": "IPv4",
    "port": 443,
    "protocol": "HTTPS",
    "protocolVersion": "HTTP1",
    "vpcIdentifier": "vpc-f1663d9868EXAMPLE"
  },
  "id": "tg-0eaa4b9ab4EXAMPLE",
  "name": "my-lattice-target-group-ip",
  "status": "CREATE_IN_PROGRESS",
  "type": "IP"
}

```

3. The following JSON file named *ecs-service-vpc-lattice.json* is an example used to attach an Amazon ECS service to a VPC Lattice target group. The portName in the following example is the same one you defined in your task definition's portMappings property's name field.

```

{
  "serviceName": "ecs-service-vpc-lattice",
  "taskDefinition": "ecs-task-def",
  "vpcLatticeConfigurations": [
    {
      "targetGroupArn": "arn:aws:vpc-lattice:us-
west-2:123456789012:targetgroup/tg-0eaa4b9ab4EXAMPLE",
      "portName": "testvpclattice",
      "roleArn": "arn:aws:iam::123456789012:role/
ecsInfrastructureRoleVpcLattice"
    }
  ],
  "desiredCount": 5,
  "role": "ecsServiceRole"
}

```

Use the following command to create an Amazon ECS service and attach it to the VPC Lattice target group using the preceding JSON example.

```

aws ecs create-service \
  --cluster clusterName \
  --serviceName ecs-service-vpc-lattice \
  --cli-input-json file://ecs-service-vpc-lattice.json

```

To use blue/green, linear, or canary deployments with VPC Lattice, add an `advancedConfiguration` block (the alternate target group and the production and test listener rules) to the `vpcLatticeConfigurations` entry and set the deployment strategy in `deploymentConfiguration`. For more information, see [VPC Lattice resources for blue/green, linear, and canary deployments](#).

 **Note**

VPC Lattice isn't supported on Amazon ECS Anywhere.

## Protect your Amazon ECS tasks from being terminated by scale-in events

You can use Amazon ECS task scale-in protection to protect your tasks from being terminated by scale-in events from either service auto scaling or deployments.

Certain applications require a mechanism to safeguard mission-critical tasks from termination by scale-in events during times of low utilization or during service deployments. For example:

- You have a queue-processing asynchronous application such as a video transcoding job where some tasks need to run for hours even when cumulative service utilization is low.
- You have a gaming application that runs game servers as Amazon ECS tasks that need to continue running even if all users have logged-out to reduce start-up latency of a server reboot.
- When you deploy a new code version, you need tasks to continue running because it would be expensive to reprocess.

To protect tasks that belong to your service from terminating in a scale-in event, set the `ProtectionEnabled` attribute to `true`. When you set `ProtectionEnabled` to `true`, tasks are protected for 2 hours by default. You can then customize the protection period by using the `ExpiresInMinutes` attribute. You can protect your tasks for a minimum of 1 minute and up to a maximum of 2880 minutes (48 hours). If you're using the AWS CLI, you can specify the `--protection-enabled` option.

After a task finishes its requisite work, you can set the `ProtectionEnabled` attribute to `false`, allowing the task to be terminated by subsequent scale-in events. If you're using the AWS CLI, you can specify the `--no-protection-enabled` option.

## Task scale-in protection mechanisms

You can set and get task scale-in protection using either the Amazon ECS container agent endpoint or the Amazon ECS API.

- **Amazon ECS container agent endpoint**

We recommend using the Amazon ECS container agent endpoint for tasks that can self-determine the need to be protected. Use this approach for queue-based or job-processing workloads.

When a container starts processing work, for example by consuming an SQS message, you can set the `ProtectionEnabled` attribute through the task scale-in protection endpoint path `$ECS_AGENT_URI/task-protection/v1/state` from within the container. Amazon ECS will not terminate this task during scale-in events. After your task finishes its work, you can clear the `ProtectionEnabled` attribute using the same endpoint, making the task eligible for termination during subsequent scale-in events.

For more information about the Amazon ECS container agent endpoint, see [Amazon ECS task scale-in protection endpoint](#).

- **Amazon ECS API**

You can use the Amazon ECS API to set and retrieve task scale-in protection if your application has a component that tracks the status of active tasks. Use `UpdateTaskProtection` to mark one or more tasks as protected. Use `GetTaskProtection` to retrieve the protection status.

An example of this approach would be if your application is hosting game server sessions as Amazon ECS tasks. When a user logs in to a session on the server (task), you can mark the task as protected. After the user logs out, you can either clear the protection specifically for this task or periodically clear protection for similar tasks that no longer have active sessions, depending on your requirement to keep idle servers.

For more information, see [UpdateTaskProtection](#) and [GetTaskProtection](#) in the *Amazon Elastic Container Service API Reference*.

You can combine both approaches. For example, use the Amazon ECS agent endpoint to set task protection from within a container and use the Amazon ECS API to remove task protection from your external controller service.

## Considerations

Consider the following points before using task scale-in protection:

- Task scale-in protection is only supported with tasks deployed from a service.
- Task scale-in protection is supported with tasks deployed from a service running on Amazon ECS Managed Instances.
- We recommend using the Amazon ECS container agent endpoint because the Amazon ECS agent has built-in retry mechanisms and a simpler interface.
- You can reset the task scale-in protection expiration period by calling `UpdateTaskProtection` for a task that already has protection turned on.
- Determine how long a task would need to complete its requisite work and set the `expiresInMinutes` property accordingly. If you set the protection expiration longer than necessary, then you will incur costs and face delays in the deployment of new tasks.
- With DEFERRED source service revision cleanup, Amazon ECS cleans up the tasks on the source service revision after the deployment completes, and tries for up to two weeks. Amazon ECS can't stop tasks that have scale-in protection. If tasks remain protected for more than two weeks after the deployment, Amazon ECS can't clean them up. For more information, see [Complete Amazon ECS rolling deployments early with early success criteria](#).
- Task scale-in protection is supported on Amazon ECS container agent 1.65.0 or later. You can add support for this feature on Amazon EC2 instances using older versions of the Amazon ECS container agent by updating the agent to the latest version. For more information, see [Updating the Amazon ECS container agent](#).
- Deployment considerations:
  - If the service uses a rolling update, new tasks will be created but tasks running older version will not be terminated until `protectionEnabled` is cleared or expires. You can adjust the `maximumPercentage` parameter in deployment configuration to a value that allows new tasks to be created when old tasks are protected.
  - If a blue/green update is applied, the blue deployment with protected tasks will not be removed if tasks have `protectionEnabled`. Traffic will be diverted to the new tasks that come up and older tasks will only be removed when `protectionEnabled` is cleared or

expires. Depending on the timeout of the CodeDeploy or CloudFormation updates, the deployment may timeout and the older Blue tasks may still be present.

- If you use CloudFormation, the update-stack has a 3 hour timeout. Therefore, if you set your task protection for longer than 3 hours, then your CloudFormation deployment may result in failure and rollback.

During the time your old tasks are protected, the CloudFormation stack shows `UPDATE_IN_PROGRESS`. If task scale-in protection is removed or expires within the 3 hour window, your deployment will succeed and move to the `UPDATE_COMPLETE` status. If the deployment is stuck in `UPDATE_IN_PROGRESS` for more than 3 hours, it will fail and show `UPDATE_FAILED` state, and will then be rolled back to old task set.

- Amazon ECS sends service events when protected tasks keep a deployment (rolling or blue/green) from reaching the steady state, so that you can take remedial actions. While trying to update the protection status of a task, if you receive a `DEPLOYMENT_BLOCKED` error message, it means the service has more protected tasks than the desired count of tasks for the service. To resolve this error, do one the following:
  - Wait for the current task protection to expire. Then set task protection.
  - Determine which tasks can be stopped. Then use `UpdateTaskProtection` with the `protectionEnabled` option set to `false` for these tasks.
  - Increase the desired task count of the service to more than the number of protected tasks.

## IAM permissions required for task scale-in protection

The task must have the Amazon ECS task role with the following permissions:

- `ecs:GetTaskProtection`: Allows the Amazon ECS container agent to call `GetTaskProtection`.
- `ecs:UpdateTaskProtection`: Allows the Amazon ECS container agent to call `UpdateTaskProtection`.

## Amazon ECS task scale-in protection endpoint

The Amazon ECS container agent automatically injects the `ECS_AGENT_URI` environment variable into the containers of Amazon ECS tasks to provide a method to interact with the container agent API endpoint.

We recommend using the Amazon ECS container agent endpoint for tasks that can self-determine the need to be protected.

When a container starts processing work, you can set the `protectionEnabled` attribute using the task scale-in protection endpoint path `$ECS_AGENT_URI/task-protection/v1/state` from within the container.

Use a PUT request to this URI from within a container to set task scale-in protection. A GET request to this URI returns the current protection status of a task.

### Task scale-in protection request parameters

You can set task scale-in protection using the `${ECS_AGENT_URI}/task-protection/v1/state` endpoint with the following request parameters.

#### `ProtectionEnabled`

Specify `true` to mark a task for protection. Specify `false` to remove protection and make the task eligible for termination.

Type: Boolean

Required: Yes

#### `ExpiresInMinutes`

The number of minutes the task is protected. You can specify a minimum of 1 minute to up to 2,880 minutes (48 hours). During this time period, your task will not be terminated by scale-in events from service Auto Scaling or deployments. After this time period lapses, the `protectionEnabled` parameter is set to `false`.

If you don't specify the time, then the task is automatically protected for 120 minutes (2 hours).

Type: Integer

Required: No

The following examples show how to set task protection with different durations.

### Example of how to protect a task with the default time period

This example shows how to protect a task with the default time period of 2 hours.

```
curl --request PUT --header 'Content-Type: application/json' ${ECS_AGENT_URI}/task-protection/v1/state --data '{"ProtectionEnabled":true}'
```

### Example of how to protect a task for 60 minutes

This example shows how to protect a task for 60 minutes using the `expiresInMinutes` parameter.

```
curl --request PUT --header 'Content-Type: application/json' ${ECS_AGENT_URI}/task-protection/v1/state --data '{"ProtectionEnabled":true,"ExpiresInMinutes":60}'
```

### Example of how to protect a task for 24 hours

This example shows how to protect a task for 24 hours using the `expiresInMinutes` parameter.

```
curl --request PUT --header 'Content-Type: application/json' ${ECS_AGENT_URI}/task-protection/v1/state --data '{"ProtectionEnabled":true,"ExpiresInMinutes":1440}'
```

## Examples for Windows containers

For Windows containers, you can use PowerShell's `Invoke-RestMethod` cmdlet instead of `curl`. The following examples show the PowerShell equivalents of the previous `curl` commands.

### Example of how to protect a Windows container task with the default time period

This example shows how to protect a task with the default time period of 2 hours using PowerShell.

```
Invoke-RestMethod -Uri $env:ECS_AGENT_URI/task-protection/v1/state -Method Put -Body '{"ProtectionEnabled":true}' -ContentType 'application/json'
```

### Example of how to protect a Windows container task for 60 minutes

This example shows how to protect a task for 60 minutes using the `expiresInMinutes` parameter with PowerShell.

```
Invoke-RestMethod -Uri $env:ECS_AGENT_URI/task-protection/v1/state -Method Put -Body '{"ProtectionEnabled":true,"ExpiresInMinutes":60}' -ContentType 'application/json'
```

## Example of how to protect a Windows container task for 24 hours

This example shows how to protect a task for 24 hours using the `expiresInMinutes` parameter with PowerShell.

```
Invoke-RestMethod -Uri $env:ECS_AGENT_URI/task-protection/v1/state -Method Put -Body
'{"ProtectionEnabled":true,"ExpiresInMinutes":1440}' -ContentType 'application/json'
```

The PUT request returns the following response.

```
{
  "protection": {
    "ExpirationDate": "2023-12-20T21:57:44.837Z",
    "ProtectionEnabled": true,
    "TaskArn": "arn:aws:ecs:us-west-2:111122223333:task/1234567890abcdef0"
  }
}
```

### Task scale-in protection response parameters

The following information is returned from the task scale-in protection endpoint `${ECS_AGENT_URI}/task-protection/v1/state` in the JSON response.

#### ExpirationDate

The epoch time when protection for the task will expire. If the task is not protected, this value is null.

#### ProtectionEnabled

The protection status of the task. If scale-in protection is enabled for a task, the value is `true`. Otherwise, it is `false`.

#### TaskArn

The full Amazon Resource Name (ARN) of the task that the container belongs to.

The following example shows the details returned for a protected task.

```
curl --request GET ${ECS_AGENT_URI}/task-protection/v1/state
```

For Windows containers, use the following PowerShell command to get the protection status:

```
Invoke-RestMethod -Uri $env:ECS_AGENT_URI/task-protection/v1/state -Method Get
```

```
{
  "protection":{
    "ExpirationDate":"2023-12-20T21:57:44Z",
    "ProtectionEnabled":true,
    "TaskArn":"arn:aws:ecs:us-west-2:111122223333:task/1234567890abcdef0"
  }
}
```

The following information is returned when a failure occurs.

**Arn**

The full Amazon Resource Name (ARN) of the task.

**Detail**

The details related to the failure.

**Reason**

The reason for the failure.

The following example shows the details returned for a task that is not protected.

```
{
  "failure":{
    "Arn":"arn:aws:ecs:us-west-2:111122223333:task/1234567890abcdef0",
    "Detail":null,
    "Reason":"TASK_NOT_VALID"
  }
}
```

The following information is returned when an exception occurs.

**requestID**

The AWS request ID for the Amazon ECS API call that results in an exception.

## Arn

The full Amazon Resource Name (ARN) of the task or service.

## Code

The error code.

## Message

The error message.

### Note

If a `RequestError` or `RequestTimeout` error appears, it is likely that it's a networking issue. Try using VPC endpoints for Amazon ECS.

The following example shows the details returned when an error occurs.

```
{
  "requestID": "12345-abc-6789-0123-abc",
  "error": {
    "Arn": "arn:aws:ecs:us-west-2:555555555555:task/my-cluster-name/1234567890abcdef0",
    "Code": "AccessDeniedException",
    "Message": "User: arn:aws:sts::444455556666:assumed-role/my-ecs-task-role/1234567890abcdef0 is not authorized to perform: ecs:GetTaskProtection on resource: arn:aws:ecs:us-west-2:555555555555:task/test/1234567890abcdef0 because no identity-based policy allows the ecs:GetTaskProtection action"
  }
}
```

The following error appears if the Amazon ECS agent is unable to get a response from the Amazon ECS endpoint for reasons such as network issues or the Amazon ECS control plane is down.

```
{
  "error": {
    "Arn": "arn:aws:ecs:us-west-2:555555555555:task/my-cluster-name/1234567890abcdef0",
    "Code": "RequestCanceled",
    "Message": "Timed out calling Amazon ECS Task Protection API"
  }
}
```

```
}
```

The following error appears when the Amazon ECS agent gets a throttling exception from Amazon ECS.

```
{
  "requestID": "12345-abc-6789-0123-abc",
  "error": {
    "Arn": "arn:aws:ecs:us-west-2:555555555555:task/my-cluster-name/1234567890abcdef0",
    "Code": "ThrottlingException",
    "Message": "Rate exceeded"
  }
}
```

## Use fault injection with your Amazon ECS and Fargate workloads

Customers can utilize fault injection with Amazon ECS on both Amazon EC2 and Fargate to test how their application responds to certain impairment scenarios. These tests provide information you can use to optimize your application's performance and resiliency.

When fault injection is enabled, the Amazon ECS container agent allows tasks access to new fault injection endpoints. You need to opt-in in order to use fault injection by setting the `enableFaultInjection` task definition parameter value to `true`. The default value is `false`.

```
{
  ...
  "enableFaultInjection": true
}
```

### Note

Fault injection only works with tasks using the `awsvpc` or `host` network modes. Fault injection isn't available on Windows.

For information on how to enable fault injection in the AWS Management Console, see [Creating an Amazon ECS task definition using the console](#).

You'll need to enable the feature for testing in the AWS Fault Injection Service. For more information, see [Use the AWS FIS `aws:ecs:task` actions](#).

**Note**

If you don't use the new Amazon ECS optimized AMIs, or have a custom AMI, install the following dependencies:

- `tc`
- `sch_netem` kernel module

## Amazon ECS fault injection endpoints

The Amazon ECS container agent automatically injects the `ECS_AGENT_URI` environment variable into the containers of Amazon ECS tasks to provide a method to interact with the container agent API endpoint. Each endpoint includes a `/start`, `/stop`, and `/status` endpoint. The endpoints only accept requests from tasks that have enabled fault injection, and each endpoint has a rate limit of **1** request per **5** seconds per container. Exceeding this limit results in an error.

**Note**

Amazon ECS Agent version `1.88.0+` is required to use the fault injection endpoints.

The three endpoints for use with fault injection are:

- [Network blackhole port endpoint](#)
- [Network packet loss endpoint](#)
- [Network latency endpoint](#)

A successful request results in a response code of `200` with a message of `running` when you call the `/start` endpoint, `stopped` for the `/stop` endpoint, and `running` or `not-running` for the `/status` endpoint.

```
{
  "Status": <string>
}
```

An unsuccessful request returns one of the follow error codes:

- 400 - Bad request
- 409 - Fault injection request conflicts with another running fault
- 429 - Request was throttled
- 500 - Server had an unexpected error

```
{  
  "Error": <string message>  
}
```

#### Note

Either one network latency fault or one network packet loss fault can be injected at a time. Trying to inject more than one results in the request being rejected.

## Network blackhole port endpoint

The `{ECS_AGENT_URI}/fault/v1/network-blackhole-port` endpoint drops inbound or outbound traffic for a specific port and protocol in a task's network namespace and is compatible with two modes:

- **awsvpc** - the changes are applied to the task network namespace
- **host** - the changes are applied to the default network namespace container instance

### `{ECS_AGENT_URI}/fault/v1/network-blackhole-port/start`

This endpoint starts the network blackhole port fault injections and has the following parameters:

#### Port

The specified port to use for the blackhole port fault injection.

Type: Integer

Required: Yes

#### Protocol

The protocol to use for the blackhole port fault injection.

Type: String

Valid values: tcp | udp

Required: Yes

### TrafficType

The traffic type used by the fault injection.

Type: String

Valid values: ingress | egress

Required: Yes

### SourcesToFilter

A JSON array of IPv4 or IPv6 addresses or CIDR blocks that are protected from the fault.

Type: Array of strings

Required: No

The following is an example request for using the start endpoint (replace the *red* values with your own):

```
Endpoint: ${ECS_AGENT_URI}/fault/v1/network-blackhole-port/start
```

```
Http method: POST
```

```
Request payload:
```

```
{
  "Port": 1234,
  "Protocol": "tcp|udp",
  "TrafficType": "ingress|egress"
  "SourcesToFilter": ["${IP1}", "${IP2}", ...],
}
```

### **{ECS\_AGENT\_URI}/fault/v1/network-blackhole-port/stop**

This endpoint stops the fault specified in the request. This endpoint has the following parameters:

## Port

The port impacted by the fault that should be stopped.

Type: Integer

Required: Yes

## Protocol

The protocol to use to stop the fault.

Type: String

Valid values: tcp | udp

Required: Yes

## TrafficType

The traffic type used by the fault injection.

Type: String

Valid values: ingress | egress

Required: Yes

The following is an example request for using the stop endpoint (replace the *red* values with your own):

```
Endpoint: ${ECS_AGENT_URI}/fault/v1/network-blackhole-port/stop
```

```
Http method: POST
```

```
Request payload:
```

```
{
  "Port": 1234,
  "Protocol": "tcp|udp",
  "TrafficType": "ingress|egress",
}
```

## `{ECS_AGENT_URI}/fault/v1/network-blackhole-port/status`

This endpoint is used to check the status of the fault injection. This endpoint has the following parameters:

### Port

The impacted port to check for the fault's status.

Type: Integer

Required: Yes

### Protocol

The protocol to use when checking for the fault's status.

Type: String

Valid values: tcp | udp

Required: Yes

### TrafficType

The traffic type used by the fault injection.

Type: String

Valid values: ingress | egress

Required: Yes

The following is an example request for using the status endpoint (replace the *red* values with your own):

```
Endpoint: ${ECS_AGENT_URI}/fault/v1/network-blackhole-port/status
```

```
Http method: POST
```

```
Request payload:
```

```
{  
  "Port": 1234,
```

```
"Protocol": "tcp|udp",
"TrafficType": "ingress|egress",
}
```

## Network latency endpoint

The `{ECS_AGENT_URI}/fault/v1/network-latency` endpoint adds delay and jitter to the task's network interface for traffic to a specific sources. The endpoint is compatible with two modes:

- **awsvpc** - the changes are applied to the task network interface
- **host** - the changes are applied to the default network interface

### `{ECS_AGENT_URI}/fault/v1/network-latency/start`

This `/start` endpoint begins the network latency fault injection and has the following parameters:

#### **DelayMilliseconds**

The number of milliseconds of delay to add to the network interface to use for the fault injection.

Type: Integer

Required: Yes

#### **JitterMilliseconds**

The number of milliseconds of jitter to add to the network interface to use for the fault injection.

Type: Integer

Required: Yes

#### **Sources**

A JSON array of IPv4 or IPv6 addresses or CIDR blocks that are destination for use with fault injection.

Type: Array of strings

Required: Yes

## SourcesToFilter

A JSON array of IPv4 or IPv6 addresses or CIDR blocks that are protected from the fault. `SourcesToFilter` takes priority over `Sources`.

Type: Array of strings

Required: No

The following is an example request for using the `/start` endpoint (replace the *red* values with your own):

```
Endpoint: ${ECS_AGENT_URI}/fault/v1/network-latency/start
```

```
Http method: POST
```

```
Request payload:
```

```
{
  "DelayMilliseconds": 123,
  "JitterMilliseconds": 123,
  "Sources": ["${IP1}", "${IP2}", ...],
  "SourcesToFilter": ["${IP1}", "${IP2}", ...],
}
```

## `{ECS_AGENT_URI}/fault/v1/network-latency/stop` and `/status`

The `{ECS_AGENT_URI}/fault/v1/network-latency/stop` endpoint stops the fault, and the `{ECS_AGENT_URI}/fault/v1/network-latency/status` checks the fault's status.

The following are two example requests for using the `/stop` and the `/status` endpoints. Both use the POST HTTP method.

```
Endpoint: ${ECS_AGENT_URI}/fault/v1/network-latency/stop
```

```
Endpoint: ${ECS_AGENT_URI}/fault/v1/network-latency/status
```

## Network packet loss endpoint

The `{ECS_AGENT_URI}/fault/v1/network-packet-loss` endpoint adds packet loss to the given network interface. This endpoint is compatible with two modes:

- **awsvpc** - the changes are applied to the task network interface
- **host** - the changes are applied to the default network interface

### **{ECS\_AGENT\_URI}/fault/v1/network-packet-loss/start**

This `/start` endpoint begins the network packet loss fault injection and has the following parameters:

#### **LossPercent**

The percentage of packet loss

Type: Integer

Required: Yes

#### **Sources**

A JSON array of IPv4 or IPv6 addresses or CIDR blocks to use for the fault injection tests.

Type: Array of strings

Required: Yes

#### **SourcesToFilter**

A JSON array of IPv4 or IPv6 addresses or CIDR blocks that are protected from the fault. `SourcesToFilter` takes priority over `Sources`.

Type: Array of strings

Required: No

The following is an example request for using the `start` endpoint (replace the *red* values with your own):

```
Endpoint: ${ECS_AGENT_URI}/fault/v1/network-packet-loss/start

Http method: POST

{
```

```
"LossPercent": 6,  
"Sources": ["${IP1}", "${IP2}", ...],  
"SourcesToFilter": ["${IP1}", "${IP2}", ...],  
}
```

## **{ECS\_AGENT\_URI}/fault/v1/network-packet-loss/stop and /status**

The {ECS\_AGENT\_URI}/fault/v1/network-packet-loss/stop endpoint stops the fault, and the {ECS\_AGENT\_URI}/fault/v1/network-packet-loss/status checks the fault's status. Only one of each type of fault is supported at a time.

The following are two example requests for using the /stop and the /status endpoints. Both use the POST HTTP method.

Endpoint: \${ECS\_AGENT\_URI}/fault/v1/network-packet-loss/stop

Endpoint: \${ECS\_AGENT\_URI}/fault/v1/network-packet-loss/status

## **Update Amazon ECS service parameters**

After you create a service, there are times when you might need to update the service parameters, for example, the number of tasks.

When the service scheduler launches new tasks, it determines task placement in your cluster with the following logic.

- Determine which of the container instances in your cluster can support your service's task definition. For example, they have the required CPU, memory, ports, and container instance attributes.
- By default, the service scheduler attempts to balance tasks across Availability Zones in this manner even though you can choose a different placement strategy.
  - Sort the valid container instances by the fewest number of running tasks for this service in the same Availability Zone as the instance. For example, if zone A has one running service task and zones B and C each have zero, valid container instances in either zone B or C are considered optimal for placement.
- Place the new service task on a valid container instance in an optimal Availability Zone (based on the previous steps), favoring container instances with the fewest number of running tasks for this service.

When the service scheduler stops running tasks, it attempts to maintain balance across the Availability Zones in your cluster using the following logic:

- Sort the container instances by the largest number of running tasks for this service in the same Availability Zone as the instance. For example, if zone A has one running service task and zones B and C each have two, container instances in either zone B or C are considered optimal for termination.
- Stop the task on a container instance in an optimal Availability Zone (based on the previous steps), favoring container instances with the largest number of running tasks for this service.

Use the list to determine if you can change the service parameter.

### **Availability Zone rebalancing**

Indicates whether to use Availability Zone rebalancing for the service.

You can change this parameter for rolling deployments.

### **Capacity provider strategy**

The details of a capacity provider strategy. You can set a capacity provider when you create a cluster, run a task, or update a service.

When you use Fargate, the capacity providers are FARGATE or FARGATE\_SPOT.

When you use Amazon EC2, the capacity providers are Auto Scaling groups.

You can change capacity providers for rolling deployments and blue/green deployments.

To refer to valid transitions, see [Service mutability](#).

### **Cluster**

You can't change the cluster name.

### **Deployment configuration**

The deployment configuration includes the CloudWatch alarms, and circuit breaker used to detect failures and the required configuration.

The deployment circuit breaker determines whether a service deployment will fail if the service can't reach a steady state. If you use the deployment circuit breaker, a service deployment will transition to a failed state and stop launching new tasks. If you use the rollback option, when

a service deployment fails, the service is rolled back to the last deployment that completed successfully.

When you update a service that uses Amazon ECS circuit breaker, Amazon ECS creates a service deployment and a service revision. These resources allow you to view detailed information about the service history. For more information, see [View service history using Amazon ECS service deployments](#).

The service scheduler uses the minimum healthy percent and maximum percent parameters (in the deployment configuration for the service) to determine the deployment strategy.

If a service uses the rolling update (ECS) deployment type, the **minimum healthy percent** represents a lower limit on the number of tasks in a service that must remain in the RUNNING state during a deployment, as a percentage of the desired number of tasks (rounded up to the nearest integer). The parameter also applies while any container instances are in the DRAINING state if the service contains tasks using EC2. Use this parameter to deploy without using additional cluster capacity. For example, if your service has a desired number of four tasks and a minimum healthy percent of 50 percent, the scheduler may stop two existing tasks to free up cluster capacity before starting two new tasks. The service considers tasks healthy for services that do not use a load balancer if they are in the RUNNING state. The service considers tasks healthy for services that do use a load balancer if they are in the RUNNING state and they are reported as healthy by the load balancer. The default value for minimum healthy percent is 100 percent.

If a service uses the rolling update (ECS) deployment type, the **maximum percent** parameter represents an upper limit on the number of tasks in a service that are allowed in the PENDING, RUNNING, or STOPPING state during a deployment, as a percentage of the desired number of tasks (rounded down to the nearest integer). The parameter also applies while any container instances are in the DRAINING state if the service contains tasks using EC2. Use this parameter to define the deployment batch size. For example, if your service has a desired number of four tasks and a maximum percent value of 200 percent, the scheduler may start four new tasks before stopping the four older tasks. This is provided that the cluster resources required to do this are available. The default value for the maximum percent is 200 percent.

When the service scheduler replaces a task during an update, the service first removes the task from the load balancer (if used) and waits for the connections to drain. Then, the equivalent of **docker stop** is issued to the containers running in the task. This results in a SIGTERM signal and a 30-second timeout, after which SIGKILL is sent and the containers are forcibly stopped. If the container handles the SIGTERM signal gracefully and exits within 30 seconds from receiving

it, no SIGKILL signal is sent. The service scheduler starts and stops tasks as defined by your minimum healthy percent and maximum percent settings.

The service scheduler also replaces tasks determined to be unhealthy after a container health check or a load balancer target group health check fails. This replacement depends on the `maximumPercent` and `desiredCount` service definition parameters. If a task is marked unhealthy, the service scheduler will first start a replacement task. Then, the following happens.

- If the replacement task has a health status of `HEALTHY`, the service scheduler stops the unhealthy task
- If the replacement task has a health status of `UNHEALTHY`, the scheduler will stop either the unhealthy replacement task or the existing unhealthy task to get the total task count to equal `desiredCount`.

If the `maximumPercent` parameter limits the scheduler from starting a replacement task first, the scheduler will stop an unhealthy task one at a time at random to free up capacity, and then start a replacement task. The start and stop process continues until all unhealthy tasks are replaced with healthy tasks. Once all unhealthy tasks have been replaced and only healthy tasks are running, if the total task count exceeds the `desiredCount`, healthy tasks are stopped at random until the total task count equals `desiredCount`. For more information about `maximumPercent` and `desiredCount`, see [Service definition parameters](#).

## Deployment controller

The deployment controller to use for the service. There are three deployment controller types available:

- `ECS`
- `EXTERNAL`
- `CODE_DEPLOY`

When you update a service, you can update the deployment controller it uses. The following list provides the valid transitions:

- Update from CodeDeploy blue/green deployments (`CODE_DEPLOY`) to ECS rolling or blue/green deployments (`ECS`).
- Update from CodeDeploy blue/green deployments (`CODE_DEPLOY`) to external deployments (`EXTERNAL`).
- Update from ECS rolling or blue/green deployments (`ECS`) to external deployments (`EXTERNAL`).

- Update from external deployments (EXTERNAL) to ECS rolling or blue/green deployments (ECS).

Consider the following when you update a service's deployment controller:

- You can't update the deployment controller of a service from the ECS deployment controller to any of the other controllers if it uses VPC Lattice or Amazon ECS Service Connect.
- You can't update the deployment controller of a service during an ongoing service deployment.
- You can't update the deployment controller of a service to CODE\_DEPLOY if there are no load balancers on the service.
- You can't update the deployment controller of a service from ECS to any of the other controllers if the deploymentConfiguration includes alarms, a deployment circuit breaker, or a BLUE\_GREEN deployment strategy. For more information, see [Amazon ECS service deployment controllers and strategies](#).
- The value you specify for versionConsistency in the container definition won't be used by Amazon ECS if you update the deployment controller of the service from ECS to any of the other controllers.
- If you update a service's deployment controller from ECS to any of the other controllers, the UpdateService and DescribeService API responses will still return deployments instead of taskSets. For more information about UpdateService and CreateService, see [UpdateService](#) and [CreateService](#) in the *Amazon ECS API Reference*.
- If a service uses a rolling update deployment strategy, updating the deployment controller from ECS to any of the other controllers will change how the maximumPercent value in the deploymentConfiguration is used. Instead of just being used as a cap on total tasks in a rolling update deployment, maximumPercent is used for replacing unhealthy tasks. For more information on how the scheduler replaces unhealthy tasks, see [Amazon ECS services](#).
- If you update a service's deployment controller from ECS to any of the other deployment controllers, any advancedConfiguration that you specify with your load balancer configuration will be ignored. For more information, see [LoadBalancer](#) and [AdvancedConfiguration](#) in the *Amazon ECS API reference*.

When updating the deployment controller for a service using CloudFormation, consider the following depending on the type of migration you're performing.

- If you have a CloudFormation template that contains the EXTERNAL deployment controller information as well as TaskSet and PrimaryTaskSet resources, and you

remove the task set resources from the template when updating from EXTERNAL to ECS, the `DescribeTaskSet` and `DeleteTaskSet` API calls will return a 400 error after the deployment controller is updated to ECS. This results in a CloudFormation delete failure on the task set resources, even though the CloudFormation stack transitions to `UPDATE_COMPLETE` status. For more information, see [Resource removed from stack but not deleted](#) in the AWS CloudFormation User Guide. To fix this issue, delete the task sets directly using the Amazon ECS `DeleteTaskSet` API. For more information about how to delete a task set, see [DeleteTaskSet](#) in the *Amazon Elastic Container Service API Reference*.

- If you're migrating from `CODE_DEPLOY` to ECS with a new task definition and CloudFormation performs a rollback operation, the Amazon ECS `UpdateService` request fails with the following error:

```
Resource handler returned message: "Invalid request provided: Unable to update task definition on services with a CODE_DEPLOY deployment controller. Use AWS CodeDeploy to trigger a new deployment. (Service: Ecs, Status Code: 400, Request ID: 0abda1e2-f7b3-4e96-b6e9-c8bc585181ac) (SDK Attempt Count: 1)" (RequestToken: ba8767eb-c99e-efed-6ec8-25011d9473f0, HandlerErrorCode: InvalidRequest)
```

- After a successful migration from ECS to EXTERNAL deployment controller, you need to manually remove the ACTIVE task set, because Amazon ECS no longer manages the deployment. For information about how to delete a task set, see [DeleteTaskSet](#) in the *Amazon Elastic Container Service API Reference*.

## Desired task count

The number of instantiations of the task to place and keep running in your service.

If you want to temporarily stop your service, set this value to 0. Then, when you are ready to start the service, update the service with the original value.

You can change this parameter for rolling deployments, and blue/green deployments.

## Enable managed tags

Determines whether to turn on Amazon ECS managed tags for the tasks in the service.

Only tasks launched after the update will reflect the update. To update the tags on all tasks, use the force deployment option.

You can change this parameter for rolling deployments, and blue/green deployments.

## Enable ECS Exec

Determines whether Amazon ECS Exec is used.

If you do not want to override the value that was set when the service was created, you can set this to null when performing this action.

You can change this parameter for rolling deployments.

## Health check grace period

The period of time, in seconds, that the Amazon ECS service scheduler ignores unhealthy Elastic Load Balancing, VPC Lattice, and container health checks after a task has first started. If you don't specify a health check grace period value, the default value of 0 is used. If you don't use any of the health checks, then `healthCheckGracePeriodSeconds` is unused.

If your service's tasks take a while to start and respond to health checks, you can specify a health check grace period of up to 2,147,483,647 seconds (about 69 years). During that time, the Amazon ECS service scheduler ignores health check status. This grace period can prevent the service scheduler from marking tasks as unhealthy and stopping them before they have time to come up.

You can change this parameter for rolling deployments and blue/green deployments.

## Load balancers

You must use a service-linked role when you update a load balancer.

A list of Elastic Load Balancing load balancer objects. It contains the load balancer name, the container name, and the container port to access from the load balancer. The container name is as it appears in a container definition.

Amazon ECS does not automatically update the security groups associated with Elastic Load Balancing load balancers or Amazon ECS container instances.

When you add, update, or remove a load balancer configuration, Amazon ECS starts new tasks with the updated Elastic Load Balancing configuration, and then stops the old tasks when the new tasks are running.

For services that use rolling updates, you can add, update, or remove Elastic Load Balancing target groups. You can update from a single target group to multiple target groups and from multiple target groups to a single target group.

For services that use blue/green deployments, you can update Elastic Load Balancing target groups by using [CreateDeployment](#) through CodeDeploy. Note that multiple target groups are not supported for blue/green deployments. For more information see [Register multiple target groups with a service](#).

For services that use the external deployment controller, you can add, update, or remove load balancers by using [CreateTaskSet](#). Note that multiple target groups are not supported for external deployments. For more information see [Register multiple target groups with a service](#).

Pass an empty list to remove load balancers.

You can change this parameter for rolling deployments.

### Network configuration

The service network configuration.

You can change this parameter for rolling deployments.

### Placement constraints

An array of task placement constraint objects to update the service to use. If no value is specified, the existing placement constraints for the service will remain unchanged. If this value is specified, it will override any existing placement constraints defined for the service. To remove all existing placement constraints, specify an empty array.

You can specify a maximum of 10 constraints for each task. This limit includes constraints in the task definition and those specified at runtime.

You can change this parameter for rolling deployments, and blue/green deployments.

### Placement strategy

The task placement strategy objects to update the service to use. If no value is specified, the existing placement strategy for the service will remain unchanged. If this value is specified, it will override the existing placement strategy defined for the service. To remove an existing placement strategy, specify an empty object.

You can change this parameter for rolling deployments, and blue/green deployments.

### Platform version

The Fargate platform version your service runs on.

A service using a Linux platform version cannot be updated to use a Windows platform version and vice versa.

You can change this parameter for rolling deployments.

### **Propagate tags**

Determines whether to propagate the tags from the task definition or the service to the task. If no value is specified, the tags aren't propagated.

Only tasks launched after the update will reflect the update. To update the tags on all tasks, set `forceNewDeployment` to `true`, so that Amazon ECS starts new tasks with the updated tags.

You can change this parameter for rolling deployments, and blue/green deployments.

### **Service Connect configuration**

The configuration for Amazon ECS Service Connect. This parameter determines how the service connects to other services within your application.

You can change this parameter for rolling deployments.

### **Service registries**

You must use a service-linked role when you update the service registries.

The details for the service discovery registries to assign to this service. For more information, see [Service Discovery](#).

When you add, update, or remove the service registries configuration, Amazon ECS starts new tasks with the updated service registries configuration, and then stops the old tasks when the new tasks are running.

Pass an empty list to remove the service registries.

You can change this parameter for rolling deployments.

### **Task definition**

The task definition and revision to use for the service.

If you change the ports used by containers in a task definition, you might need to update the security groups for the container instances to work with the updated ports.

If you update the task definition for the service, the container name and container port that are specified in the load balancer configuration must remain in the task definition.

The container image pull behavior differs for the compute options. For more information, see one of the following:

- [Architect for AWS Fargate for Amazon ECS](#)
- [Architect for EC2 capacity for Amazon ECS](#)
- [External \(Amazon ECS Anywhere\) for Amazon ECS](#)

You can change this parameter for rolling deployments.

## Volume configuration

The details of the volume that was configuredAtLaunch. When configuredAtLaunch is set to true in the task definition, this service parameter configures one Amazon EBS volume for each task in the service to be created and attached during deployment.

You can configure the size, volumeType, IOPS, throughput, snapshot and encryption in [ServiceManagedEBSVolumeConfiguration](#). The name of the volume must match the name from the task definition. If set to null, no new deployment is triggered. Otherwise, if this configuration differs from the existing one, it triggers a new deployment.

You can change this parameter for rolling deployments.

## VPC Lattice configuration

The VPC Lattice configuration for your service. This defines how your service integrates with VPC Lattice for service-to-service communication.

You can change this parameter for rolling deployments.

## AWS CDK considerations

The AWS CDK doesn't track resource states. It doesn't know whether you are creating or updating a service. Customers should use the escape hatch to access the ecs Service L1 construct directly.

For information about escape hatches, see [Customize constructs from the AWS Construct Library](#) in the *AWS Cloud Development Kit (AWS CDK) v2 Developer Guide*.

To migrate your existing service to the ecs.Service construct, do the following:

1. Use the escape hatch to access the Service L1 construct.
2. Manually set the following properties in the Service L1 construct.

If your service uses Amazon EC2 capacity:

- `daemon?`
- `placementConstraints?`
- `placementStrategies?`
- If you use the `awsvpc` network mode, you need to set the `vpcSubnets?` and the `securityGroups?` constructs.

If your service uses Fargate:

- `FargatePlatformVersion`
- The `vpcSubnets?` and the `securityGroups?` constructs.

3. Set the `launchType` as follows:

```
const cfnEcsService = service.node.findChild('Service') as ecs.CfnService;
cfnEcsService.launchType = "FARGATE";
```

To migrate from a launch type to a capacity provider, do the following:

1. Use the escape hatch to access the `Service` L1 construct.
2. Add the `capacityProviderStrategies?` construct.
3. Deploy the service.

## Updating an Amazon ECS service

After you create a service, there are times when you might need to update the service parameters, for example the number of tasks.

When you update a service that uses Amazon ECS circuit breaker, Amazon ECS creates a service deployment and a service revision. These resources allow you to view detailed information about the service history. For more information, see [View service history using Amazon ECS service deployments](#).

### Prerequisites

Before updating a service, verify which service parameters can be changed for your deployment type. For a complete list of changeable parameters, see [Update Amazon ECS service parameters](#).

## Procedure

### Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, select the check box next to the service, and then choose **Update**.
4. To have your service start a new deployment, select **Force new deployment**.
5. For **Task definition**, choose the task definition family and revision.

#### Important

The console validates that the selected task definition family and revision are compatible with the defined compute configuration. If you receive a warning, verify both your task definition compatibility and the compute configuration that you selected.

6. If you chose **Replica**, for **Desired tasks**, enter the number of tasks to launch and maintain in the service.
7. If you chose **Replica**, to have Amazon ECS monitor the distribution of tasks across Availability Zones, and redistribute them when there is an imbalance, under **Availability Zone service rebalancing**, select **Availability Zone service rebalancing**.
8. For **Min running tasks**, enter the lower limit on the number of tasks in the service that must remain in the RUNNING state during a deployment, as a percentage of the desired number of tasks (rounded up to the nearest integer). For more information, see [Deployment configuration](#).
9. For **Max running tasks**, enter the upper limit on the number of tasks in the service that are allowed in the RUNNING or PENDING state during a deployment, as a percentage of the desired number of tasks (rounded down to the nearest integer).
10. To configure how tasks are deployed for your service, expand **Deployment options** and then configure your options.
  - a. For **Deployment controller type**, specify the service deployment controller. The Amazon ECS console supports the following controller types: ECS.

- b. For **Deployment strategy**, choose the strategy used by Amazon ECS to deploy new versions of the service.
- c. Depending on the choice of **Deployment strategy**, do the following:

| Deployment strategy   | Steps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <b>Rolling update</b> | <ol style="list-style-type: none"><li>a. For <b>Min running tasks</b> %, specify a minimum percentage value of tasks that must run during a service deployment. For more information, see <a href="#">Deploy Amazon ECS services by replacing tasks</a>.</li><li>b. For <b>Max running tasks</b> %, specify a maximum percentage value of tasks that can run during a service deployment. For more information, see <a href="#">Deploy Amazon ECS services by replacing tasks</a>.</li></ol> |  |
| <b>Blue/green</b>     | For <b>Bake time</b> , specify a time duration, in minutes, that blue and green service revisions should run simultaneously. For more information, see <a href="#">Amazon ECS blue/green deployments</a> .                                                                                                                                                                                                                                                                                   |  |

- d. To run Lambda functions for a lifecycle stage, under **Deployment lifecycle hooks** do the following for each unique Lambda function:

- i. Choose **Add**.

Repeat for every unique function you want to run.

- ii. For **Lambda function**, enter the function name.
- iii. For **Role**, choose the role that you created in the prerequisites with the blue/green permissions.

For more information, see [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#).

- iv. For **Lifecycle stages**, select the stages the Lambda function runs.
- v. (Optional) For **Hook details**, enter a key value pair that provides information about the hook.

11. Under **Deployment configuration**, to complete the deployment before the target service revision reaches the full desired count, configure early success criteria. You can also choose when Amazon ECS cleans up the tasks on the source service revision.

- a. Turn on **Early success criteria**.
- b. For **Healthy percent**, enter the percentage of tasks that must be running and healthy on the target service revision before Amazon ECS completes the deployment.
- c. For **Source service revision cleanup**, choose **Blocking** or **Deferred**.

12. To configure how Amazon ECS detects and handles deployment failures, expand **Deployment failure detection**, and then choose your options.

- a. To stop a deployment when the tasks cannot start, select **Use the Amazon ECS deployment circuit breaker**.

To have the software automatically roll back the deployment to the last completed deployment state when the deployment circuit breaker sets the deployment to a failed state, select **Rollback on failures**.

- b. To stop a deployment based on application metrics, select **Use CloudWatch alarm(s)**. Then, from **CloudWatch alarm name**, choose the alarms. To create a new alarm, go to the CloudWatch console.

To have the software automatically roll back the deployment to the last completed deployment state when a CloudWatch alarm sets the deployment to a failed state, select **Rollback on failures**.

13. To change the compute options, expand **Compute configuration**, and then do the following:
- a. For services on AWS Fargate, for **Platform version**, choose the new version.

b. For services that use a capacity provider strategy, for **Capacity provider strategy**, do the following:
  - To add an additional capacity provider, choose **Add more**. Then, for **Capacity provider**, choose the capacity provider.
  - To remove a capacity provider, to the right of the capacity provider, choose **Remove**.

A service that's using an Auto Scaling group capacity provider can't be updated to use a Fargate capacity provider. A service that's using a Fargate capacity provider can't be updated to use an Auto Scaling group capacity provider.

14. (Optional) To configure service Auto Scaling, expand **Service auto scaling**, and then specify the following parameters. To use predictive auto scaling, which looks at past load data from traffic flows, configure it after you create the service. For more information, see [Use historical patterns to scale Amazon ECS services with predictive scaling](#).
- a. To use service auto scaling, select **Service auto scaling**.

b. For **Minimum number of tasks**, enter the lower limit of the number of tasks for service auto scaling to use. The desired count will not go below this count.

c. For **Maximum number of tasks**, enter the upper limit of the number of tasks for service auto scaling to use. The desired count will not go above this count.

d. Choose the policy type. Under **Scaling policy type**, choose one of the following options.

| To use this policy type | Do this                                                             |  |
|-------------------------|---------------------------------------------------------------------|--|
| Target tracking         | a. For <b>Scaling policy type</b> , choose <b>Target tracking</b> . |  |

| To use this policy type | Do this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|

For an add policy, this is the time after a scale-out activity that the scaling policy blocks scale-in activities and limits how many tasks can be scale out at a time. For a remove policy, this is the time after a scale-in activity that must pass before</li></ul> |  |

| To use this policy type | Do this                              |  |
|-------------------------|--------------------------------------|--|
|                         | another scale-in activity can start. |  |

15. (Optional) To use Service Connect, select **Turn on Service Connect**, and then specify the following:
  - a. Under **Service Connect configuration**, specify the client mode.
    - If your service runs a network client application that only needs to connect to other services in the namespace, choose **Client side only**.
    - If your service runs a network or web service application and needs to provide endpoints for this service, and connects to other services in the namespace, choose **Client and server**.
  - b. To use a namespace that is not the default cluster namespace, for **Namespace**, choose the service namespace. This can be a namespace created separately in the same AWS Region in your AWS account or a namespace in the same Region that is shared with your account using AWS Resource Access Manager (AWS RAM). For more information about shared AWS Cloud Map namespaces, see [Cross-account AWS Cloud Map namespace sharing](#) in the *AWS Cloud Map Developer Guide*.
  - c. (Optional) Specify a log configuration. Select **Use log collection**. The default option sends container logs to CloudWatch Logs. The other log driver options are configured using AWS FireLens. For more information, see [Send Amazon ECS logs to an AWS service or AWS Partner](#).

The following describes each container log destination in more detail.

- **Amazon CloudWatch** – Configure the task to send container logs to CloudWatch Logs. The default log driver options are provided, which create a CloudWatch log group on your behalf. To specify a different log group name, change the driver option values.
- **Amazon Data Firehose** – Configure the task to send container logs to Firehose. The default log driver options are provided, which send logs to a Firehose delivery stream. To specify a different delivery stream name, change the driver option values.
- **Amazon Kinesis Data Streams** – Configure the task to send container logs to Kinesis Data Streams. The default log driver options are provided, which send logs to an

Kinesis Data Streams stream. To specify a different stream name, change the driver option values.

- **Amazon OpenSearch Service** – Configure the task to send container logs to an OpenSearch Service domain. The log driver options must be provided.
  - **Amazon S3** – Configure the task to send container logs to an Amazon S3 bucket. The default log driver options are set by default, but you must specify a valid Amazon S3 bucket name.
- d. To enable access logs, follow these steps:
- i. Expand **Access log configuration**. For **Format**, choose either **JSON** or **TEXT**.
  - ii. To include query parameters in access logs, select **Include query parameters**.

 **Note**

To disable access logs, for **Format**, choose **None**.

16. If your task uses a data volume that's compatible with configuration at deployment, you can configure the volume by expanding **Volume**.

The volume name and volume type are configured when you create a task definition revision and can't be changed when you update a service. To update the volume name and type, you must create a new task definition revision and update the service by using the new revision.

| To configure this volume type | Do this                                                                                                                                                                                                                                                           |  |

| To configure this volume type | Do this                                     |  |
|-------------------------------|---------------------------------------------|--|
|                               | <a href="#">Tagging Amazon EBS volumes.</a> |  |

17. (Optional) To help identify your service, expand the **Tags** section, and then configure your tags.

- [Add a tag] Choose **Add tag**, and do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
- [Remove a tag] Next to the tag, choose **Remove tag**.

18. Choose **Update**.

## AWS CLI

- Run `update-service`. For information about running the command, see [update-service](#) in the AWS Command Line Interface Reference.

The following `update-service` example updates the desired task count of the service `my-http-service` to 2.

Replace the *user-input* with your values.

```
aws ecs update-service \
  --cluster MyCluster \
  --service my-http-service \
  --desired-count 2
```

## Next steps

Track your deployment and view your service history for services that Amazon ECS circuit breaker. For more information, see [View service history using Amazon ECS service deployments](#).

## Updating an Amazon ECS service to use a capacity provider

If you have an existing service that uses the Amazon EC2 or Fargate launchtype and you want to use Amazon ECS Managed Instances, you need to update the service to use your Amazon ECS Managed Instances capacity provider.

### Prerequisites

Create a capacity provider for your Amazon ECS Managed Instances. For more information, see [Creating a capacity provider for Amazon ECS Managed Instances](#).

### Procedure

#### Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, select the check box next to the service, and then choose **Update**.
4. Select **Force new deployment**.
5. Under **Compute configuration**, choose the Capacity provider strategy. Then, choose one of the following:
  - When your Amazon ECS Managed Instances capacity provider is the default capacity provider, choose **Use cluster default**.
  - When your Amazon ECS Managed Instances capacity provider isn't the default capacity provider, choose **Use custom (Advanced)**. Choose your Amazon ECS Managed Instances capacity provider, and then for **Weight** choose 1.
6. Choose **Update**.

#### AWS CLI

- Run `update-service`. For information about running the command, see [update-service](#) in the AWS Command Line Interface Reference.

Replace the *user-input* with your values.

```
aws ecs update-service \
```

```
--cluster my-cluster \  
--service my-service \  
--capacity-provider-strategy capacityProvider=my-managed-instance-capacity-provider,weight=1 \  
--force-new-deployment
```

## Deleting an Amazon ECS service using the console

The following are some of the reasons you would delete a service:

- The application is no longer needed
- You are migrating the service to a new environment
- The application is not actively being used
- The application is using more resources than needed and you are trying to optimize your costs

The service is automatically scaled down to zero before it is deleted. Load balancer resources or service discovery resources associated with the service are not affected by the service deletion. To delete your Elastic Load Balancing resources, see one of the following topics, depending on your load balancer type: [Delete an Application Load Balancer](#) or [Delete a Network Load Balancer](#).

When you delete a service, Amazon ECS deletes all service deployments and service revisions for the service.

When you delete a service, if there are still running tasks that require cleanup, the service status moves from ACTIVE to DRAINING, and the service is no longer visible in the console or in the `ListServices` API operation. After all tasks have transitioned to either STOPPING or STOPPED status, the service status moves from DRAINING to INACTIVE. Services in the DRAINING or INACTIVE status can still be viewed with the `DescribeServices` API operation.

### Important

If you attempt to create a new service with the same name as an existing service in either ACTIVE or DRAINING status, you'll receive an error.

## Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.

2. On the **Clusters** page, select the cluster for the service.
3. On the **Clusters** page, choose the cluster.
4. On the **Cluster : *name*** page, choose the **Services** tab.
5. Select the services, and then choose **Delete**.
6. To delete a service even if it wasn't scaled down to zero tasks, select **Force delete service**.
7. At the confirmation prompt, enter **delete**, and then choose **Delete**.

## Migrate an Amazon ECS short service ARN to a long ARN

Amazon ECS assigns a unique Amazon Resource Name (ARN) to each service. Services that were created before 2021 have a short ARN format:

```
arn:aws:ecs:region:aws_account_id:service/service-name
```

Amazon ECS changed the ARN format to include the cluster name. This is a long ARN format:

```
arn:aws:ecs:region:aws_account_id:service/cluster-name/service-name
```

Your service must have the long ARN format in order to tag your service.

You can migrate a service with a short ARN format to the long ARN format without having to recreate the service. You can use the API, CLI, or the console. You can't undo the migration operation.

The migration process is seamless and ensures zero downtime for your service. During migration:

- **Service availability:** Your service continues to run normally with no interruption to traffic or functionality.
- **Running tasks:** Existing tasks continue to run without disruption. New tasks launched after migration will use the long ARN format if the `taskLongArnFormat` account setting is enabled.
- **Container instances:** Container instances are not affected by the service ARN migration and continue to operate normally.
- **Service configuration:** All service settings, including task definition, networking, and load balancer configurations, remain unchanged.

If you want to use CloudFormation to tag a service with short ARN format, you must migrate the service using the API, CLI, or console. After the migration completes you can use CloudFormation to tag the service.

If you want to use Terraform to tag a service with short ARN format, you must migrate the service using the API, CLI, or console. After the migration completes you can use Terraform to tag the service.

After the migration is complete, the service has the following changes:

- The long ARN format

```
arn:aws:ecs:region:aws_account_id:service/cluster-name/service-name
```

- When you migrate using the console, Amazon ECS adds a tag to the service with the key set to "ecs:serviceArnMigratedAt" and the value set to the migration timestamp (UTC format).

This tag counts toward your tag quota.

- When the `PhysicalResourceId` in a CloudFormation stack represents a service ARN, the value does not change and will continue to be the short service ARN.

## Prerequisites

Perform the following operations before you migrate the service ARN.

1. To see if you have a short service ARN, view the service details in the Amazon ECS console (you see a warning when the service has the short ARN format), or the `serviceARN` return parameter from `describe-services`. When the ARN does not include the cluster name, you have a short ARN. The following is the format of a short ARN:

```
arn:aws:ecs:region:aws_account_id:service/service-name
```

2. Note the created at date.
3. If you have IAM policies that use the short ARN format, update it to the long ARN format.

Replace each *user input placeholder* with your own information.

```
arn:aws:ecs:region:aws_account_id:service/cluster-name/service-name
```

For more information, see [Editing IAM policies](#) in the *AWS Identity and Access Management User Guide*.

4. If you have tools that use the short ARN format, update it to the long ARN format.

Replace each *user input placeholder* with your own information.

```
arn:aws:ecs:region:aws_account_id:service/cluster-name/service-name
```

5. Enable the service long ARN format. Run `put-account-setting` with the `serviceLongArnFormat` option set to `enabled`. For more information, see, [put-account-setting](#) in the *Amazon Elastic Container Service API Reference*.

Run the command as the root user when your service has an unknown `createdAt` date.

```
aws ecs put-account-setting --name serviceLongArnFormat --value enabled
```

#### Example output

```
{
  "setting": {
    "name": "serviceLongArnFormat",
    "value": "enabled",
    "principalArn": "arn:aws:iam::123456789012:role/your-role",
    "type": user
  }
}
```

6. Enable the task long ARN format. This account setting controls the ARN format for new tasks that are launched after the service migration is complete. Run `put-account-setting` with the `taskLongArnFormat` option set to `enabled`. For more information, see, [put-account-setting](#) in the *Amazon Elastic Container Service API Reference*.

Run the command as the root user when your service has an unknown `createdAt` date.

```
aws ecs put-account-setting --name taskLongArnFormat --value enabled
```

#### Example output

```
{
  "setting": {
    "name": "taskLongArnFormat",
    "value": "enabled",
    "principalArn": "arn:aws:iam::123456789012:role/your-role",
  }
}
```

```
    "type": user
  }
}
```

### Note

The `taskLongArnFormat` setting does not directly migrate existing tasks. It only affects the ARN format of new tasks that are created after the setting is enabled. Existing running tasks retain their current ARN format until they are replaced through normal service operations (such as deployments or scaling activities).

## Procedure

Use the following to migrate your service ARN.

### Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. In the **Services** section, choose a service that has a warning in the ARN column.

The service details page appears.

4. Choose **Migrate to long ARN**.

The Migrate service dialog box appears.

5. Choose **Migrate**.

### CLI

After you complete the prerequisites, you can tag your service. Run the following command:

Amazon ECS considers passing the long ARN format in a `tag-resource` API request for a service with a short ARN as a signal to migrate the service to use the long ARN format.

```
aws ecs tag-resource \  
  --resource-arn arn:aws:ecs:region:aws_account_id:service/cluster-name/service-name \  
  --tags key=key1,value=value1
```

The following example tags MyService with a tag that has a key set to "TestService" and a value set to "WebServers":

```
aws ecs tag-resource \  
  --resource-arn arn:aws:ecs:us-east-1:123456789012:service/MyCluster/MyService \  
  --tags key=TestService1,value=WebServers
```

## Terraform

After you complete the prerequisites, you can tag your service. Create an `aws_ecs_service` resource and set the tags reference. For more information, see [Resource: aws\\_ecs\\_service](#) in the Terraform documentation.

```
resource "aws_ecs_service" "MyService" {  
  name      = "example"  
  cluster = aws_ecs_cluster.MyService.id  
  
  tags = {  
    "Name"      = "MyService"  
    "Environment" = "Production"  
    "Department" = "QualityAssurance"  
  }  
}
```

## Next steps

You can add tags to the service. For more information, see [Adding tags to Amazon ECS resources](#).

If you want Amazon ECS to propagate the tags from the task definition or the service to the task, run `update-service` with the `propagateTags` parameter. For more information, see [update-service](#) in the *AWS Command Line Interface Reference*.

## Troubleshooting

Some users might encounter the following error when they migrate from the short ARN format to the long ARN format.

There was an error while migrating the ARN of service *service-name*. The specified account does not have `serviceLongArnFormat` or `taskLongArnFormat` account settings enabled. Add account settings in order to enable tagging.

If you have already enabled the `serviceLongArnFormat` account setting but still encounter this error, it might be because the account settings for the long ARN format hasn't been enabled for the specific IAM principal that originally created the service.

1. Identify the principal that created the service.

1. In the console, the information is available in the **Created by** field in the **Configuration and networking** tab on the Service details page in the Amazon ECS console.
2. For the AWS CLI, run the following command:

Replace the *user-input* with your values.

```
aws ecs describe-services --cluster cluster-name --services service-name --query 'services[0].{createdBy: createdBy}'
```

2. Enable the required account settings for that specific principal. You can do this in one of the following ways:
  - a. Assume the IAM user or role for that principal. Then run `put-account-setting`.
  - b. Use the root user to run the command while specifying the creating principal with the `principal-arn`.

Example.

Replace the *principal-arn* with the value from Step 1.

```
aws ecs put-account-setting --name serviceLongArnFormat --value enabled --principal-arn arn:aws:iam::123456789012:role/jdoe
```

Both methods enable the required `serviceLongArnFormat` account setting on the principal that created the service, which allows the ARN migration to proceed.

## Amazon ECS service throttle logic

The Amazon ECS service scheduler includes protective logic that throttles task launches when tasks repeatedly fail to start. This helps prevent unnecessary resource consumption and reduces costs.

When tasks in a service fail to transition from `PENDING` to `RUNNING` state and instead move directly to `STOPPED`, the scheduler:

- Incrementally increases the time between restart attempts
- Continues increasing delays up to a maximum of 27 minutes between attempts
- Generates a service event message to notify you of the issue

 **Note**

The maximum delay period of 27 minutes may change in future updates.

When throttling is activated, you receive this service event message:

```
(service service-name) is unable to consistently start tasks successfully.
```

Important characteristics of the throttle logic:

- Services continue retry attempts indefinitely
- The only modification is the increased time between restarts
- There are no user-configurable parameters

## Resolving throttling issues

To resolve throttling, you can:

- Update the service to use a new task definition, which immediately returns the service to normal, non-throttled operation. For more information, see [Updating an Amazon ECS service](#).
- Address the underlying cause of the task failures.

Common causes of task failures that trigger throttling include:

- Insufficient cluster resources (ports, memory, or CPU)
  - Indicated by an [insufficient resource service event message](#)
- Container image pull failures
  - Can be caused by invalid image names, tags, or insufficient permissions
  - Results in `CannotPullContainerError` in [Viewing Amazon ECS stopped task errors](#)
- Insufficient disk space

- Results in `CannotCreateContainerError` in [stopped task errors](#)
- For resolution steps, see [Troubleshoot the Docker API error \(500\): devmapper in Amazon ECS](#)

### Important

The following scenarios do NOT trigger throttle logic:

- Tasks that stop after reaching `RUNNING` state
- Tasks stopped due to failed Elastic Load Balancing health checks
- Tasks where the container command exits with a non-zero code after reaching `RUNNING` state

## Amazon ECS service definition parameters

A service definition defines how to run your Amazon ECS service. The following parameters can be specified in a service definition.

### Launch type

`launchType`

Type: String

Valid values: `EC2` | `FARGATE` | `EXTERNAL`

Required: No

The launch type on which to run your service. If a launch type is not specified, the default `capacityProviderStrategy` is used by default.

When you update a service, this parameter triggers a new service deployment.

If a `launchType` is specified, the `capacityProviderStrategy` parameter must be omitted.

## Capacity provider strategy

### `capacityProviderStrategy`

Type: Array of objects

Required: No

The capacity provider strategy to use for the service.

When you update a service, this parameter doesn't trigger a new service deployment.

A capacity provider strategy consists of one or more capacity providers along with the `base` and `weight` to assign to them. A capacity provider must be associated with the cluster to be used in a capacity provider strategy. The `PutClusterCapacityProviders` API is used to associate a capacity provider with a cluster. Only capacity providers with an `ACTIVE` or `UPDATING` status can be used.

If a `capacityProviderStrategy` is specified, the `launchType` parameter must be omitted. If no `capacityProviderStrategy` or `launchType` is specified, the `defaultCapacityProviderStrategy` for the cluster is used.

If you want to specify a capacity provider that uses an Auto Scaling group, the capacity provider must already be created. New capacity providers can be created with the `CreateCapacityProvider` API operation.

To use an AWS Fargate capacity provider, specify either the `FARGATE` or `FARGATE_SPOT` capacity providers. The AWS Fargate capacity providers are available to all accounts and only need to be associated with a cluster to be used.

The `PutClusterCapacityProviders` API operation is used to update the list of available capacity providers for a cluster after the cluster is created.

### `capacityProvider`

Type: String

Required: Yes

The short name or full Amazon Resource Name (ARN) of the capacity provider.

### `weight`

Type: Integer

Valid range: Integers between 0 and 1,000.

Required: No

The weight value designates the relative percentage of the total number of tasks launched that use the specified capacity provider.

For example, assume that you have a strategy that contains two capacity providers and both have a weight of one. When the base is satisfied, the tasks split evenly across the two capacity providers. Using that same logic, assume that you specify a weight of 1 for *capacityProviderA* and a weight of 4 for *capacityProviderB*. Then, for every one task that is run using *capacityProviderA*, four tasks use *capacityProviderB*.

base

Type: Integer

Valid range: Integers between 0 and 100,000.

Required: No

The base value designates how many tasks, at a minimum, to run on the specified capacity provider. Only one capacity provider in a capacity provider strategy can have a base defined.

## Task definition

taskDefinition

Type: String

Required: No

The family and revision (*family:revision*) or full Amazon Resource Name (ARN) of the task definition to run in your service. If a revision isn't specified, the latest ACTIVE revision of the specified family is used.

When you update a service, this parameter triggers a new service deployment.

A task definition must be specified when using the rolling update (ECS) deployment controller.

## Platform operating system

platformFamily

Type: string

Required: Conditional

Default: Linux

This parameter is required for Amazon ECS services hosted on Fargate.

This parameter is ignored for Amazon ECS services hosted on Amazon EC2.

The operating system on the containers that runs the service. The valid values are LINUX, WINDOWS\_SERVER\_2019\_FULL, WINDOWS\_SERVER\_2019\_CORE, WINDOWS\_SERVER\_2022\_FULL, and WINDOWS\_SERVER\_2022\_CORE.

The platformFamily value for every task that you specify for the service must match the service platformFamily value. For example, if you set the platformFamily to WINDOWS\_SERVER\_2019\_FULL, the platformFamily value for all the tasks must be WINDOWS\_SERVER\_2019\_FULL.

## Platform version

platformVersion

Type: String

Required: No

The platform version on which your tasks in the service are running. A platform version is only specified for tasks using the Fargate launch type. If one is not specified, the latest version (LATEST) is used by default.

When you update a service, this parameter triggers a new service deployment.

AWS Fargate platform versions are used to refer to a specific runtime environment for the Fargate task infrastructure. When specifying the LATEST platform version when running a task or creating a service, you get the most current platform version available for your tasks. When

you scale up your service, those tasks receive the platform version that was specified on the service's current deployment. For more information, see [Fargate platform versions for Amazon ECS](#).

 **Note**

Platform versions are not specified for tasks using the EC2 launch type.

## Cluster

`cluster`

Type: String

Required: No

The short name or full Amazon Resource Name (ARN) of the cluster on which to run your service. If you do not specify a cluster, the default cluster is assumed.

## Service name

`serviceName`

Type: String

Required: Yes

The name of your service. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed. Service names must be unique within a cluster, but you can have similarly named services in multiple clusters within a Region or across multiple Regions.

## Scheduling strategy

`schedulingStrategy`

Type: String

Valid values: REPLICA | DAEMON

Required: No

The scheduling strategy to use. If no scheduling strategy is specified, the REPLICA strategy is used. For more information, see [Amazon ECS services](#).

There are two service scheduler strategies available:

- **REPLICA**—The replica scheduling strategy places and maintains the desired number of tasks across your cluster. By default, the service scheduler spreads tasks across Availability Zones. You can use task placement strategies and constraints to customize task placement decisions. For more information, see [Replica scheduling strategy](#).
- **DAEMON**—The daemon scheduling strategy deploys exactly one task on each active container instance that meets all of the task placement constraints that you specify in your cluster. When using this strategy, there is no need to specify a desired number of tasks, a task placement strategy, or use Service Auto Scaling policies. For more information, see [Daemon scheduling strategy](#).

 **Note**

Fargate tasks do not support the DAEMON scheduling strategy.

## Desired count

`desiredCount`

Type: Integer

Required: No

The number of instantiations of the specified task definition to place and keep running in your service.

When you update a service, this parameter doesn't trigger a new service deployment.

This parameter is required if the REPLICA scheduling strategy is used. If the service uses the DAEMON scheduling strategy, this parameter is optional.

When you use service auto scaling, when you update a currently running service with a `desiredCount` less than the number of tasks currently running, the service scales down to the specified `desiredCount`.

## Deployment configuration

### deploymentConfiguration

Type: Object

Required: No

Optional deployment parameters that control how many tasks run during the deployment and the ordering of stopping and starting tasks.

When you update a service, this parameter doesn't trigger a new service deployment.

#### maximumPercent

Type: Integer

Required: No

If a service is using the rolling update (ECS) deployment type, the `maximumPercent` parameter represents an upper limit on the number of your service's tasks that are allowed in the `RUNNING`, `STOPPING`, or `PENDING` state during a deployment. It is expressed as a percentage of the `desiredCount` that is rounded down to the nearest integer. You can use this parameter to define the deployment batch size. For example, if your service is using the `REPLICA` service scheduler and has a `desiredCount` of four tasks and a `maximumPercent` value of 200%, the scheduler starts four new tasks before stopping the four older tasks. This is provided that the cluster resources required to do this are available. The default `maximumPercent` value for a service using the `REPLICA` service scheduler is 200%.

The Amazon ECS scheduler uses this parameter to replace unhealthy tasks by starting replacement tasks first and then stopping the unhealthy tasks, as long as cluster resources for starting replacement tasks are available. For more information about how the scheduler replaces unhealthy tasks, see [Amazon ECS services](#).

If your service is using the `DAEMON` service scheduler type, the `maximumPercent` should remain at 100%. This is the default value.

The maximum number of tasks during a deployment is the `desiredCount` multiplied by the `maximumPercent`/100, rounded down to the nearest integer value.

If a service is using either the blue/green (`CODE_DEPLOY`) or `EXTERNAL` deployment types and tasks that use the `EC2` launch type, the **maximum percent** value is set to the default

value. The value is used to define the upper limit on the number of the tasks in the service that remain in the RUNNING state while the container instances are in the DRAINING state.

 **Note**

You can't specify a custom `maximumPercent` value for a service that uses either the blue/green (`CODE_DEPLOY`) or `EXTERNAL` deployment types and has tasks that use the EC2.

If the service uses either the blue/green (`CODE_DEPLOY`) or `EXTERNAL` deployment types, and the tasks in the service use the Fargate, the maximum percent value is not used. The value is still returned when describing your service.

`minimumHealthyPercent`

Type: Integer

Required: No

If a service is using the rolling update (ECS) deployment type, the `minimumHealthyPercent` represents a lower limit on the number of your service's tasks that must remain in the RUNNING state during a deployment. This is expressed as a percentage of the `desiredCount` that is rounded up to the nearest integer. You can use this parameter to deploy without using additional cluster capacity.

For example, if your service has a `desiredCount` of four tasks, a `minimumHealthyPercent` of 50%, and a `maximumPercent` of 100%, the service scheduler stops two existing tasks to free up cluster capacity before starting two new tasks.

If any tasks are unhealthy and if `maximumPercent` doesn't allow the Amazon ECS scheduler to start replacement tasks, the scheduler stops the unhealthy tasks one-by-one — using the `minimumHealthyPercent` as a constraint — to clear up capacity to launch replacement tasks. For more information about how the scheduler replaces unhealthy tasks, see [Amazon ECS services](#).

For services that *do not* use a load balancer, consider the following:

- A service is considered healthy if all essential containers within the tasks in the service pass their health checks.

- If a task has no essential containers with a health check defined, the service scheduler waits for 40 seconds after a task reaches a `RUNNING` state before the task is counted towards the minimum healthy percent total.
- If a task has one or more essential containers with a health check defined, the service scheduler waits for the task to reach a healthy status before counting it towards the minimum healthy percent total. A task is considered healthy when all essential containers within the task have passed their health checks. The amount of time the service scheduler can wait for is determined by the container health check settings. For more information, see [Health check](#).

For services that *do* use a load balancer, consider the following:

- If a task has no essential containers with a health check defined, the service scheduler waits for the load balancer target group health check to return a healthy status before counting the task towards the minimum healthy percent total.
- If a task has an essential container with a health check defined, the service scheduler waits for both the task to reach a healthy status and the load balancer target group health check to return a healthy status before counting the task towards the minimum healthy percent total.

The default value for a replica service for `minimumHealthyPercent` is 100%. The default `minimumHealthyPercent` value for a service using the `DAEMON` service schedule is 0% for the AWS CLI, the AWS SDKs, and the APIs and 50% for the AWS Management Console.

The minimum number of healthy tasks during a deployment is the `desiredCount` multiplied by the `minimumHealthyPercent/100`, rounded up to the nearest integer value.

If a service is using either the blue/green (`CODE_DEPLOY`) or `EXTERNAL` deployment types and is running tasks that use the EC2, the **minimum healthy percent** value is set to the default value. The value is used to define the lower limit on the number of the tasks in the service that remain in the `RUNNING` state while the container instances are in the `DRAINING` state.

 **Note**

You can't specify a custom `maximumPercent` value for a service that uses either the blue/green (`CODE_DEPLOY`) or `EXTERNAL` deployment types and has tasks that use the EC2.

If a service is using either the blue/green (CODE\_DEPLOY) or EXTERNAL deployment types and is running tasks that use Fargate, the minimum healthy percent value is not used, although it is returned when describing your service.

#### earlySuccessCriteria

Type: Object

Required: No

The early success criteria that determine when Amazon ECS completes a rolling deployment. With early success criteria, Amazon ECS completes the deployment when a percentage of tasks that you define are running and healthy on the target service revision. You can also configure whether Amazon ECS cleans up the tasks on the source service revision before or after it completes the deployment. For more information, see [Complete Amazon ECS rolling deployments early with early success criteria](#).

#### enable

Type: Boolean

Required: No

Specifies whether early success criteria is turned on for the service. The default value is `false`.

#### healthyPercent

Type: Integer

Required: No

Specifies the percentage of the desired count that must be running and healthy on the target service revision before Amazon ECS completes the deployment, rounded up. The value must be between the service `minimumHealthyPercent` and 100, inclusive. The default value is 100.

#### sourceServiceRevisionCleanup

Type: String

Valid values: BLOCKING | DEFERRED

Required: No

Determines when Amazon ECS cleans up the tasks on the source service revision. With BLOCKING, Amazon ECS cleans up the tasks on the source service revision before it completes the deployment. With DEFERRED, Amazon ECS completes the deployment first, and then cleans up the tasks on the source service revision outside of the deployment. The default value is BLOCKING.

## Deployment controller

deploymentController

Type: Object

Required: No

The deployment controller to use for the service. If no deployment controller is specified, the ECS controller is used. For more information, see [Amazon ECS services](#).

When you update a service, this parameter doesn't trigger a new service deployment.

type

Type: String

Valid values: ECS | CODE\_DEPLOY | EXTERNAL

Required: yes

The deployment controller type to use. There are three deployment controller types available:

ECS

The Amazon ECS deployment controller supports multiple deployment strategies: rolling update, blue/green, linear, and canary. The rolling update deployment type involves replacing the current running version of the container with the latest version. Blue/green deployments create a new environment and shift traffic all at once. Linear deployments gradually shift traffic in equal percentage increments. Canary deployments shift a small percentage of traffic first, then shift the remaining traffic. The number of containers Amazon ECS adds or removes from the service during a rolling update is controlled by

adjusting the minimum and maximum number of healthy tasks allowed during a service deployment, as specified in the [deploymentConfiguration](#).

#### CODE\_DEPLOY

The blue/green (CODE\_DEPLOY) deployment type uses the blue/green deployment model powered by CodeDeploy, which allows you to verify a new deployment of a service before sending production traffic to it.

#### EXTERNAL

Use the external deployment type when you want to use any third-party deployment controller for full control over the deployment process for an Amazon ECS service.

## Task placement

### placementConstraints

Type: Array of objects

Required: No

An array of placement constraint objects to use for tasks in your service. You can specify a maximum of 10 constraints per task. This limit includes constraints in the task definition and those specified at run time. If you use Fargate, task placement constraints aren't supported.

When you update a service, this parameter doesn't trigger a new service deployment.

### type

Type: String

Required: No

The type of constraint. Use `distinctInstance` to ensure that each task in a particular group is running on a different container instance. Use `memberOf` to restrict the selection to a group of valid candidates. The value `distinctInstance` is not supported in task definitions.

### expression

Type: String

Required: No

A cluster query language expression to apply to the constraint. You can't specify an expression if the constraint type is `distinctInstance`. For more information, see [Create expressions to define container instances for Amazon ECS tasks](#).

## placementStrategy

Type: Array of objects

Required: No

The placement strategy objects to use for tasks in your service. You can specify a maximum of four strategy rules per service.

When you update a service, this parameter doesn't trigger a new service deployment.

### type

Type: String

Valid values: `random` | `spread` | `binpack`

Required: No

The type of placement strategy. The `random` placement strategy randomly places tasks on available candidates. The `spread` placement strategy spreads placement across available candidates evenly based on the `field` parameter. The `binpack` strategy places tasks on available candidates that have the least available amount of the resource that's specified with the `field` parameter. For example, if you binpack on memory, a task is placed on the instance with the least amount of remaining memory but still enough to run the task.

### field

Type: String

Required: No

The field to apply the placement strategy against. For the `spread` placement strategy, valid values are `instanceId` (or `host`, which has the same effect), or any platform or custom attribute that's applied to a container instance, such as `attribute:ecs.availability-zone`. For the `binpack` placement strategy, valid values are `cpu` and `memory`. For the `random` placement strategy, this field is not used.

## Tags

### tags

Type: Array of objects

Required: No

The metadata that you apply to the service to help you categorize and organize them. Each tag consists of a key and an optional value, both of which you define. When a service is deleted, the tags are deleted as well. A maximum of 50 tags can be applied to the service. For more information, see [Tagging Amazon ECS resources](#).

When you update a service, this parameter doesn't trigger a new service deployment.

### key

Type: String

Length Constraints: Minimum length of 1. Maximum length of 128.

Required: No

One part of a key-value pair that make up a tag. A key is a general label that acts like a category for more specific tag values.

### value

Type: String

Length Constraints: Minimum length of 0. Maximum length of 256.

Required: No

The optional part of a key-value pair that make up a tag. A value acts as a descriptor within a tag category (key).

### enableECSTags

Type: Boolean

Valid values: true | false

Required: No

Specifies whether to use Amazon ECS managed tags for the tasks in the service. If no value is specified, the default value is `false`. For more information, see [Use tags for billing](#).

When you update a service, this parameter doesn't trigger a new service deployment.

`propagateTags`

Type: String

Valid values: `TASK_DEFINITION` | `SERVICE`

Required: No

Specifies whether to copy the tags from the task definition or the service to the tasks in the service. If no value is specified, the tags are not copied. Tags can only be copied to the tasks within the service during service creation. To add tags to a task after service creation or task creation, use the `TagResource` API action.

When you update a service, this parameter doesn't trigger a new service deployment.

## Network configuration

`networkConfiguration`

Type: Object

Required: No

The network configuration for the service. This parameter is required for task definitions that use the `awsvpc` network mode to receive their own Elastic Network Interface, and it isn't supported for other network modes. If using Fargate, the `awsvpc` network mode is required. For more information about networking for EC2, see [Amazon ECS task networking options for EC2](#). For more information about networking for Fargate, see [Amazon ECS task networking options for Fargate](#).

When you update a service, this parameter triggers a new service deployment.

`awsvpcConfiguration`

Type: Object

Required: No

An object representing the subnets and security groups for a task or service.

#### subnets

Type: Array of strings

Required: Yes

The subnets that are associated with the task or service. There is a limit of 16 subnets that can be specified according to `awsVpcConfiguration`.

#### securityGroups

Type: Array of strings

Required: No

The security groups associated with the task or service. If you don't specify a security group, the default security group for the VPC is used. There's a limit of five security groups that can be specified based on `awsVpcConfiguration`.

#### assignPublicIP

Type: String

Valid values: ENABLED | DISABLED

Required: No

Whether the task's elastic network interface receives a public IP address. If no value is specified, the default value of DISABLED is used.

#### healthCheckGracePeriodSeconds

Type: Integer

Required: No

The period of time, in seconds, that the Amazon ECS service scheduler ignores unhealthy Elastic Load Balancing, VPC Lattice, and container health checks after a task has first started. If you do not specify a health check grace period value, the default value of 0 is used. If you do not use any of the health checks, then `healthCheckGracePeriodSeconds` is unused.

If your service's tasks take a while to start and respond, you can specify a health check grace period of up to 2,147,483,647 seconds (about 69 years). During that time, the Amazon ECS

service scheduler ignores the health check status. This grace period can prevent the service scheduler from marking tasks as unhealthy and stopping them before they have time to come up.

When you update a service, this parameter doesn't trigger a new service deployment.

## loadBalancers

Type: Array of objects

Required: No

A load balancer object representing the load balancers to use with your service. For services that use an Application Load Balancer or Network Load Balancer, there's a limit of five target groups that you can attach to a service.

When you update a service, this parameter triggers a new service deployment.

After you create a service, the load balancer configuration can't be changed from the AWS Management Console. You can use the AWS Copilot, AWS CloudFormation, AWS CLI or SDK to modify the load balancer configuration for the ECS rolling deployment controller only, not AWS CodeDeploy blue/green or external. When you add, update, or remove a load balancer configuration, Amazon ECS starts a new deployment with the updated Elastic Load Balancing configuration. This causes tasks to register to and deregister from load balancers. We recommend that you verify this on a test environment before you update the Elastic Load Balancing configuration. For information about how to modify the configuration, see [UpdateService](#) in the *Amazon Elastic Container Service API Reference*.

For Application Load Balancers and Network Load Balancers, this object must contain the load balancer target group ARN, the container name (as it appears in a container definition), and the container port to access from the load balancer. When a task from this service is placed on a container instance, the container instance and port combination is registered as a target in the target group specified.

### targetGroupArn

Type: String

Required: No

The full Amazon Resource Name (ARN) of the Elastic Load Balancing target group that's associated with a service.

A target group ARN is only specified when using an Application Load Balancer or Network Load Balancer.

`loadBalancerName`

Type: String

Required: No

The name of the load balancer to associate with the service.

If you're using an Application Load Balancer or a Network Load Balancer, omit the load balancer name parameter.

`containerName`

Type: String

Required: No

The name of the container (as it appears in a container definition) to associate with the load balancer.

`containerPort`

Type: Integer

Required: No

The port on the container to associate with the load balancer. This port must correspond to a `containerPort` in the task definition used by tasks in the service. For tasks that use EC2, the container instance must allow inbound traffic on the `hostPort` of the port mapping.

`role`

Type: String

Required: No

The short name or full ARN of the IAM role that allows Amazon ECS to make calls to your load balancer on your behalf. This parameter is only permitted if you are using a load balancer with a single target group for your service, and your task definition does not use the `awsvpc` network mode. If you specify the `role` parameter, you must also specify a load balancer object with the `loadBalancers` parameter.

When you update a service, this parameter doesn't trigger a new service deployment.

If your specified role has a path other than `/`, then you must either specify the full role ARN (this is recommended) or prefix the role name with the path. For example, if a role with the name `bar` has a path of `/foo/` then you would specify `/foo/bar` as the role name. For more information, see [Friendly Names and Paths](#) in the *IAM User Guide*.

 **Important**

If your account has already created the Amazon ECS service-linked role, that role is used by default for your service unless you specify a role here. The service-linked role is required if your task definition uses the `awsvpc` network mode, in which case you should not specify a role here. For more information, see [Using service-linked roles for Amazon ECS](#).

## serviceConnectConfiguration

Type: Object

Required: No

The configuration for this service to discover and connect to services, and be discovered by, and connected from, other services within a namespace.

When you update a service, this parameter triggers a new service deployment.

For more information, see [Use Service Connect to connect Amazon ECS services with short names](#).

enabled

Type: Boolean

Required: Yes

Specifies whether to use Service Connect with this service.

namespace

Type: String

Required: No

The short name or full Amazon Resource Name (ARN) of the AWS Cloud Map namespace for use with Service Connect. The namespace must be in the same AWS Region as the Amazon ECS service and cluster. The type of namespace doesn't affect Service Connect. For more information about AWS Cloud Map, see [Working with Services](#) in the *AWS Cloud Map Developer Guide*.

## services

Type: Array of objects

Required: No

An array of Service Connect service objects. These are names and aliases (also known as endpoints) that are used by other Amazon ECS services to connect to this service.

This field isn't required for a "client" Amazon ECS service that's a member of a namespace only to connect to other services within the namespace. An example is frontend application that accepts incoming requests from either a load balancer that's attached to the service or by other means.

An object selects a port from the task definition, assigns a name for the AWS Cloud Map service, and an array of aliases (also known as endpoints) and ports for client applications to refer to this service.

## portName

Type: String

Required: Yes

The `portName` must match the name of one of the `portMappings` from all of the containers in the task definition of this Amazon ECS service.

## discoveryName

Type: String

Required: No

The `discoveryName` is the name of the new AWS Cloud Map service that Amazon ECS creates for this Amazon ECS service. This must be unique within the AWS Cloud Map namespace.

If this field isn't specified, `portName` is used.

## `clientAliases`

Type: Array of objects

Required: No

The list of client aliases for this service connect service. You use these to assign names that can be used by client applications. The maximum number of client aliases that you can have in this list is 1.

Each alias ("endpoint") is a DNS name and port number that other Amazon ECS services ("clients") can use to connect to this service.

Each name and port combination must be unique within the namespace.

These names are configured within each task of the client service, not in AWS Cloud Map. DNS requests to resolve these names don't leave the task, and don't count toward the quota of DNS requests per second per elastic network interface.

## `port`

Type: Integer

Required: Yes

The listening port number for the service connect proxy. This port is available inside of all of the tasks within the same namespace.

To avoid changing your applications in client Amazon ECS services, set this to the same port that the client application uses by default.

## `dnsName`

Type: String

Required: No

The `dnsName` is the name that you use in the applications of client tasks to connect to this service. The name must be a valid DNS label.

The default value is the `discoveryName.namespace` if this field is not specified. If the `discoveryName` isn't specified, the `portName` from the task definition is used.

To avoid changing your applications in client Amazon ECS services, set this to the same name that the client application uses by default. For example, a few common

names are database, db, or the lowercase name of a database, such as `mysql` or `redis`.

### `ingressPortOverride`

Type: Integer

Required: No

(Optional) The port number for the Service Connect proxy to listen on.

Use the value of this field to bypass the proxy for traffic on the port number that's specified in the named `portMapping` in the task definition of this application, and then use it in your Amazon VPC security groups to allow traffic into the proxy for this Amazon ECS service.

In `awsvpc` mode, the default value is the container port number that's specified in the named `portMapping` in the task definition of this application. In `bridge` mode, the default value is the dynamic ephemeral port of the Service Connect proxy.

### `logConfiguration`

Type: [LogConfiguration](#) Object

Required: No

This defines where the Service Connect proxy logs are published. Use the logs for debugging during unexpected events. This configuration sets the `logConfiguration` parameter in the Service Connect proxy container in each task in this Amazon ECS service. The proxy container isn't specified in the task definition.

We recommend that you use the same log configuration as the application containers of the task definition for this Amazon ECS service. For FireLens, this is the log configuration of the application container. It's not the FireLens log router container that uses the `fluent-bit` or `fluentd` container image.

### `accessLogConfiguration`

Type: [ServiceConnectAccessLogConfiguration](#) Object

Required: No

The configuration for Service Connect access logging including log format and whether the logs should include query strings. Access logs capture detailed information about

requests made to your service, including request patterns, response code, and timing data. To enable access logs, you must also specify a `logConfiguration` in the `serviceConnectConfiguration`.

## `serviceRegistries`

Type: Array of objects

Required: No

The details of the service discovery configuration for your service. For more information, see [Use service discovery to connect Amazon ECS services with DNS names](#).

When you update a service, this parameter triggers a new service deployment.

### `registryArn`

Type: String

Required: No

The Amazon Resource Name (ARN) of the service registry. The currently supported service registry is AWS Cloud Map. For more information, see [Working with Services](#) in the *AWS Cloud Map Developer Guide*.

### `port`

Type: Integer

Required: No

The port value that's used if your service discovery service specified an SRV record. This field is required if both the `awsvpc` network mode and SRV records are used.

### `containerName`

Type: String

Required: No

The container name value to be used for your service discovery service. This value is specified in the task definition. If the task definition that your service task specifies uses the `bridge` or `host` network mode, you must specify a `containerName` and `containerPort` combination from the task definition. If the task definition that your service task specifies uses the `awsvpc` network mode and a type `SRV` DNS record is used, you must specify either a `containerName` and `containerPort` combination or a `port` value, but not both.

## containerPort

Type: Integer

Required: No

The port value to be used for your service discovery service. This value is specified in the task definition. If the task definition your service task specifies uses the bridge or host network mode, you must specify a `containerName` and `containerPort` combination from the task definition. If the task definition your service task specifies uses the `awsvpc` network mode and a type SRV DNS record is used, you must specify either a `containerName` and `containerPort` combination or a `port` value, but not both.

## Client token

### clientToken

Type: String

Required: No

The unique, case-sensitive identifier that you provide to ensure the idempotency of the request. It can be up to 32 ASCII characters long.

## Availability Zone rebalancing

### availabilityZoneRebalancing

Type: String

Required: No

Indicates whether the service uses Availability Zone rebalancing. The valid values are `ENABLED` and `DISABLED`.

When you update a service, this parameter doesn't trigger a new service deployment.

Default behavior:

- For new services : If no value is specified, the default is `DISABLED`.
- For existing services : If no value is specified, Amazon ECS defaults the value to to the existing value. If no value was previously set, Amazon ECS sets the value to `DISABLED`.

For more information about Availability Zone rebalancing, see [Balancing an Amazon ECS service across Availability Zones](#).

## Volume configurations

### volumeConfigurations

Type: Object

Required: No

The configuration that will be used to create volumes for tasks that are managed by the service. Only volumes that are marked as `configuredAtLaunch` in the task definition can be configured by using this object.

When you update a service, this parameter triggers a new service deployment.

This object is required for attaching Amazon EBS volumes to tasks that are managed by a service. For more information, see [Use Amazon EBS volumes with Amazon ECS](#).

#### name

Type: String

Required: Yes

The name of a volume that's configured when creating or updating a service. Up to 255 letters (uppercase and lowercase), numbers, underscores (`_`), and hyphens (`-`) are allowed. This value must match the volume name that's specified in the task definition.

#### managedEBSVolume

Type: Object

Required: No

The volume configuration used for creating Amazon EBS volumes that are attached to tasks that are maintained by a service when the service is created or updated. One volume is attached per task.

#### encrypted

Type: Boolean

Required: No

Valid values: `true|false`

Specifies whether to encrypt each created Amazon EBS volume. If you've turned on Amazon EBS encryption by default for a particular AWS Region for your AWS account but set this parameter to `false`, this parameter will be overridden, and the volumes will be encrypted with the KMS key specified for encryption by default. For more information about Amazon EBS encryption by default, see [Enable Amazon EBS encryption by default](#) in the *Amazon EBS User Guide*. For more information about encrypting Amazon EBS volumes attached to Amazon ECS tasks, see [Encrypt data stored in Amazon EBS volumes attached to Amazon ECS tasks](#).

`kmsKeyId`

Type: String

Required: No

The identifier of the AWS Key Management Service (AWS KMS) key to use for Amazon EBS encryption. If `kmsKeyId` is specified, the encrypted state must be `true`.

The key specified using this parameter overrides the Amazon EBS default or any cluster-level KMS key for Amazon ECS managed storage encryption that you may have specified. For more information, see [Encrypt data stored in Amazon EBS volumes attached to Amazon ECS tasks](#).

You can specify the KMS key by using any of the following:

- **Key ID** – For example, `1234abcd-12ab-34cd-56ef-1234567890ab`.
- **Key alias** – For example, `alias/ExampleAlias`.
- **Key ARN** – For example, `arn:aws:kms:us-east-1:012345678910:key/1234abcd-12ab-34cd-56ef-1234567890ab`.
- **Alias ARN** – For example, `arn:aws:kms:us-east-1:012345678910:alias/ExampleAlias`.

 **Important**

AWS authenticates the KMS key asynchronously. Therefore, if you specify an ID, alias, or ARN that isn't valid, the action can appear to succeed, but it eventually

fails. For more information, see [Troubleshooting Amazon EBS volume attachment issues](#).

## volumeType

Type: String

Required: No

Valid values: gp2|gp3|io1|io2|sc1|st1|standard

The Amazon EBS volume type. For more information about volume types, see [Amazon EBS volume types](#) in the *Amazon EBS User Guide*. The default volume type is gp3.

### Note

The standard volume type is not supported for Fargate tasks.

## sizeInGiB

Type: Integer

Required: No

Valid range: Integers between 1 and 16,384

The size of the EBS volume in gibibytes (GiB). If you do not provide a snapshot ID to configure a volume for attachment, you must provide a size value. If you configure a volume for attachment by using a snapshot, the default value is the snapshot size. You can then specify a size greater than or equal to the snapshot size.

For gp2 and gp3 volume types, the valid range is 1-16,384.

For io1 and io2 volume types, the valid range is 4-16,384.

For st1 and sc1 volume types, the valid range is 125-16,384.

For the standard volume type, the valid range is 1-1,024.

## snapshotId

Type: String

Required: No

The ID of the snapshot of an existing Amazon EBS volume that Amazon ECS uses to create new volumes for attachment. You must specify either a `snapshotId` or a `sizeInGiB`.

`volumeInitializationRate`

Type: Integer

Required: No

The rate, in MiB/s, at which data is fetched from a snapshot of an existing Amazon EBS volume to create new volumes for attachment. This property can be specified only if you specify a `snapshotId`. For more information about this volume initialization rate, including the range of supported rates for initialization, see [Initialize Amazon EBS volumes](#) in the *Amazon EBS User Guide*.

`iops`

Type: Integer

Required: No

The number of I/O operations per second (IOPS). For `gp3`, `io1`, and `io2` volumes, this represents the number of IOPS that are provisioned for the volume. For `gp2` volumes, this value represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. This parameter is required for `io1` and `io2` volumes. This parameter is not supported for `gp2`, `st1`, `sc1`, or standard volumes.

For `gp3` volumes, the valid range of values is 3,000 to 16,000.

For `io1` volumes, the valid range of values is 100 to 64,000.

For `io2` volumes, the valid range of values is 100 to 64,000.

`throughput`

Type: Integer

Required: No

The throughput to provision for the volumes that are attached to tasks that are maintained by a service.

** Important**

This parameter is supported only for gp3 volumes.

**roleArn**

Type: String

Required: Yes

The Amazon Resource ARN (ARN) of the infrastructure AWS Identity and Access Management (IAM) role that provides Amazon ECS permissions to manage Amazon EBS resources for your tasks. For more information, see [Amazon ECS infrastructure IAM role](#).

**tagSpecifications**

Type: Object

Required: No

The specification for tags to be applied to each Amazon EBS volume.

**resourceType**

Type: String

Required: Yes

Valid values: volume

The type of resource to tag on creation.

**tags**

Type: Array of objects

Required: No

The metadata that you apply to volumes to help you categorize and organize them. Each tag consists of a key and an optional value, both of which you define. AmazonECSCreated and AmazonECSManaged are reserved tags that are added by Amazon ECS on your behalf, so you can specify a maximum of 48 tags of your own. When a volume is deleted, the tags are deleted as well. For more information, see [Tagging Amazon ECS resources](#).

## key

Type: String

Length Constraints: Minimum length of 1. Maximum length of 128.

Required: No

One part of a key-value pair that makes up a tag. A key is a general label that acts like a category for more specific tag values.

## value

Type: String

Length Constraints: Minimum length of 0. Maximum length of 256.

Required: No

The optional part of a key-value pair that makes up a tag. A value acts as a descriptor within a tag category (key).

## propagateTags

Type: String

Valid values: TASK\_DEFINITION | SERVICE | NONE

Required: No

Specifies whether to copy the tags from the task definition or the service to a volume. If NONE is specified or no value is specified, the tags aren't copied.

## fileSystemType

Type: String

Required: No

Valid values: xfs|ext3|ext4|NTFS

The type of file system on a volume. The volume's file system type determines how data is stored and retrieved in the volume. For volumes created from a snapshot, you must specify the same filesystem type that the volume was using when the snapshot was created. If there is a filesystem type mismatch, the task will fail to start.

The valid values for Linux are `xfs`, `ext3`, and `ext4`. The default for volumes that are attached to Linux tasks is `XFS`.

The valid values for Windows are `NTFS`. The default for volumes that are attached to Windows tasks is `NTFS`.

## Service definition template

The following shows the JSON representation of an Amazon ECS service definition.

EC2

```

                        }
                    ]
                },
                {
                    "propagateTags": "NONE"
                }
            ],
            "roleArn": "",
            "filesystemType": ""
        }
    }
]
}

```

You can create this service definition template using the following AWS CLI command.

```
aws ecs create-service --generate-cli-skeleton
```

# Tagging Amazon ECS resources

To help you manage your Amazon ECS resources, you can optionally assign your own metadata to each resource using *tags*. Each *tag* consists of a *key* and an optional *value*.

You can use tags to categorize your Amazon ECS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type. You can quickly identify a specific resource based on the tags that you assigned to it. For example, you can define a set of tags for your account's Amazon ECS container instances. This helps you track each instance's owner and stack level.

You can use tags for your Cost and Usage reports. You can use these reports to analyze the cost and usage of your Amazon ECS resources. For more information, see [the section called “Usage Reports”](#).

## Warning

There are many APIs that return tag keys and their values. Denying access to `DescribeTags` doesn't automatically deny access to tags returned by other APIs. As a best practice, we recommend that you do not include sensitive data in your tags.

We recommend that you devise a set of tag keys that meets your needs for each resource type. You can use a consistent set of tag keys for easier management of your resources. You can search and filter the resources based on the tags you add.

Tags don't have any semantic meaning to Amazon ECS and are interpreted strictly as a string of characters. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the earlier value. When you delete a resource, any tags for the resource are also deleted.

If you use AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to manage tags.

## How resources are tagged

There are multiple ways that Amazon ECS tasks, services, task definitions, and clusters are tagged:

- A user manually tags a resource by using the AWS Management Console, Amazon ECS API, the AWS CLI, or an AWS SDK.
- A user creates a service or runs a standalone task and selects the Amazon ECS-managed tags option.

Amazon ECS automatically tags all newly launched tasks. For more information, see [the section called “Amazon ECS-managed tags”](#).

- A user creates a resource using the console. The console automatically tags the resources.

These tags are returned in the AWS CLI, and AWS SDK responses and are displayed in the console. You cannot modify or delete these tags.

For information about the added tags, see the **Tags automatically added by the console** column in the **Tagging support for Amazon ECS resources** table.

If you specify tags when you create a resource and the tags can't be applied, Amazon ECS rolls back the creation process. This ensures that resources are either created with tags or not created at all, and that no resources are left untagged at any time. By tagging resources while they're being created, you can eliminate the need to run custom tagging scripts after resource creation.

The following table describes the Amazon ECS resources that support tagging.

| Resource            | Supports tags | Supports tag propagation                                                         | Tags automatically added by the console                                                                                 |
|---------------------|---------------|----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Amazon ECS tasks    | Yes           | Yes, from the task definition.                                                   | <p><i>Key:</i> <code>aws:ecs:clusterName</code></p> <p><i>Value:</i> <code>cluster-name</code></p>                      |
| Amazon ECS services | Yes           | Yes, from either the task definition or the service to the tasks in the service. | <p><i>Key:</i> <code>ecs:service:stackId</code></p> <p><i>Value</i> <code>arn:aws:cloudformation: <i>arn</i></code></p> |

| Resource                    | Supports tags | Supports tag propagation | Tags automatically added by the console                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|---------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Amazon ECS task sets        | Yes           | No                       | N/A                                                                                                                                                                                                                                                                                                                                                                                |
| Amazon ECS task definitions | Yes           | No                       | <p><i>Key:</i> <code>ecs:taskDefinition:createdFrom</code></p> <p><i>Value:</i> <code>ecs-console-v2</code></p>                                                                                                                                                                                                                                                                    |
| Amazon ECS clusters         | Yes           | No                       | <p><i>Key:</i> <code>aws:cloudformation:logical-id</code></p> <p><i>Value:</i> <code>ECSCluster</code></p> <p><i>Key:</i> <code>aws:cloudformation:stack-id</code></p> <p><i>Value:</i> <code>arn:aws:cloudformation: <i>arn</i></code></p> <p><i>Key:</i> <code>aws:cloudformation:stack-name</code></p> <p><i>Value:</i> <code>ECS-Console-V2-Cluster- <i>EXAMPLE</i></code></p> |

| Resource                       | Supports tags                                                                          | Supports tag propagation                                                                                                                                                                                                                                                                | Tags automatically added by the console |
|--------------------------------|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| Amazon ECS container instances | Yes                                                                                    | Yes, from the Amazon EC2 instance. For more information, see <a href="#">Adding tags to an Amazon EC2 container instance for Amazon ECS</a> .                                                                                                                                           | N/A                                     |
| Amazon ECS External instances  | Yes                                                                                    | No                                                                                                                                                                                                                                                                                      | N/A                                     |
| Amazon ECS capacity provider   | Yes.<br><br>You cannot tag the predefined FARGATE and FARGATE_SPOT capacity providers. | Yes, only from capacity providers for Amazon ECS Managed Instances. You can propagate tags from the capacity provider for Amazon ECS Managed Instances to all resources managed by the provider such as Amazon EC2 instances, launch template, Elastic Network Interfaces, and volumes. | N/A                                     |

## Tagging resources on creation

The following resources support tagging on creation using the Amazon ECS API, AWS CLI, or AWS SDK:

- Amazon ECS tasks
- Amazon ECS services
- Amazon ECS task definition
- Amazon ECS task sets
- Amazon ECS clusters
- Amazon ECS container instances
- Amazon ECS capacity providers

Amazon ECS has the option to use tagging authorization for resource creation. When the AWS account is configured for tagging authorization, users must have permissions for actions that create the resource, such as `ecsCreateCluster`. If you specify tags in the resource-creating action, AWS performs additional authorization to verify if users or roles have permissions to create tags. Therefore, you must grant explicit permissions to use the `ecs:TagResource` action. For more information, see [the section called "Tag resources during creation"](#). For information about how to configure the option, see [the section called "Tagging authorization"](#).

## Restrictions

The following restrictions apply to tags:

- A maximum of 50 tags can be associated with a resource.
- Tag keys can't be repeated for one resource. Each tag key must be unique, and can only have one value.
- Keys can be up to 128 characters long in UTF-8.
- Values can be up to 256 characters long in UTF-8.
- If multiple AWS services and resources use your tagging schema, limit the types of characters you use. Some services might have restrictions on allowed characters. Generally, allowed characters are letters, numbers, spaces, and the following characters: `+ - = . _ : / @`.
- Tag keys and values are case sensitive.

- You can't use `aws:`, `AWS:`, or any upper or lowercase combination of such as a prefix for either keys or values. These are reserved only for AWS use. You can't edit or delete tag keys or values with this prefix. Tags with this prefix don't count against your tags-per-resource limit.

## Amazon ECS-managed tags

When you use Amazon ECS-managed tags, Amazon ECS automatically tags all newly launched tasks and any Amazon EBS volumes attached to the tasks with the cluster information and either the user-added task definition tags or the service tags. The following describes the added tags:

- Standalone tasks – a tag with a *Key* as `aws:ecs:clusterName` and a *Value* set to the cluster name. All task definition tags that were added by users. An Amazon EBS volume attached to a standalone task will receive the tag with a *Key* as `aws:ecs:clusterName` and a *Value* set to the cluster name. For more information about Amazon EBS volume tagging, see [Tagging Amazon EBS volumes](#).
- Tasks that are part of a service – a tag with a *Key* as `aws:ecs:clusterName` and a *Value* set to the cluster name. A tag with a *Key* as `aws:ecs:serviceName` and a *Value* set to the service name. Tags from one of the following resources:
  - Task definitions – All task definition tags that were added by users.
  - Services – All service tags that were added by users.

An Amazon EBS volume attached to a task that is part of a service will receive a tag with a *Key* as `aws:ecs:clusterName` and a *Value* set to the cluster name, and a tag with a *Key* as `aws:ecs:serviceName` and a *Value* set to the service name. For more information about Amazon EBS volume tagging, see [Tagging Amazon EBS volumes](#).

The following options are required for this feature:

- You must opt in to the new Amazon Resource Name (ARN) and resource identifier (ID) formats. For more information, see [Amazon Resource Names \(ARNs\) and IDs](#).
- When you use the APIs to create a service or run a task, you must set `enableECSTags` to `true` for `run-task` and `create-service`. For more information, see [create-service](#) and [run-task](#) in the *AWS Command Line Interface API Reference*.
- Amazon ECS uses managed tags to determine when some features are enabled, for example cluster Auto Scaling. We recommend that you do not manually modify tags so that the Amazon ECS can effectively manage the features.

## Use tags for billing

AWS provides a reporting tool called Cost Explorer that you can use to analyze the cost and usage of your Amazon ECS resources.

You can use Cost Explorer to view charts of your usage and costs. You can view data from the last 13 months, and forecast how much you're likely to spend for the next three months. You can use Cost Explorer to see patterns in how much you spend on AWS resources over time. For example, you can use it to identify areas that need further inquiry and see trends that you can use to understand your costs. You also can specify time ranges for the data, and view time data by day or by month.

You can use Amazon ECS-managed tags or user-added tags for your Cost and Usage Report. For more information, see [Amazon ECS usage reports](#).

To see the cost of your combined resources, you can organize your billing information based on resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information about setting up a cost allocation report with tags, see [The Monthly Cost Allocation Report](#) in the *AWS Billing User Guide*.

Additionally, you can turn on *Split Cost Allocation Data* to get task-level CPU and memory usage data in your Cost and Usage Reports. For more information, see [Task-level Cost and Usage Reports](#).

### Note

If you've turned on reporting, it can take up to 24 hours before the data for the current month is available for viewing.

## Adding tags to Amazon ECS resources

You can tag new or existing tasks, services, task definitions, or clusters. For information about tagging your container instances, see [Adding tags to an Amazon EC2 container instance for Amazon ECS](#).

**⚠ Warning**

Do not add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including billing. Tags are not intended to be used for private or sensitive data.

You can use the following resources to specify tags when you create the resource.

| Task                        | Console                                                                           | AWS CLI                                  | API Action                             |
|-----------------------------|-----------------------------------------------------------------------------------|------------------------------------------|----------------------------------------|
| Run one or more tasks.      | <a href="#">Running an application as an Amazon ECS task</a>                      | <a href="#">run-task</a>                 | <a href="#">RunTask</a>                |
| Create a service.           | <a href="#">Creating an Amazon ECS rolling update deployment</a>                  | <a href="#">create-service</a>           | <a href="#">CreateService</a>          |
| Create a task set.          | <a href="#">Deploy Amazon ECS services using a third-party controller</a>         | <a href="#">create-task-set</a>          | <a href="#">CreateTaskSet</a>          |
| Register a task definition. | <a href="#">the section called “Creating a task definition using the console”</a> | <a href="#">register-task-definition</a> | <a href="#">RegisterTaskDefinition</a> |
| Create a cluster.           | <a href="#">Creating an Amazon ECS cluster for Fargate workloads</a>              | <a href="#">create-cluster</a>           | <a href="#">CreateCluster</a>          |

| Task                                                         | Console                                                                       | AWS CLI                                  | API Action                             |
|--------------------------------------------------------------|-------------------------------------------------------------------------------|------------------------------------------|----------------------------------------|
| Run one or more container instances.                         | <a href="#">Launching an Amazon ECS Linux container instance</a>              | <a href="#">run-instances</a>            | <a href="#">RunInstances</a>           |
| Create a capacity provider for Amazon ECS Managed Instances. | <a href="#">Creating a capacity provider for Amazon ECS Managed Instances</a> | <a href="#">create-capacity-provider</a> | <a href="#">CreateCapacityProvider</a> |

## Adding tags to existing resources (Amazon ECS console)

You can add or delete tags that are associated with your clusters, services, tasks, and task definitions directly from the resource's page.

### To modify a tag for an individual resource

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. From the navigation bar, select the AWS Region to use.
3. In the navigation pane, select a resource type (for example, **Clusters**).
4. Select the resource from the resource list, choose the **Tags** tab, and then choose **Manage tags**.
5. Configure your tags.

[Add a tag] Choose **Add tag**, and then do the following:

- For **Key**, enter the key name.
  - For **Value**, enter the key value.
6. Choose **Save**.

## Adding tags to existing resources (AWS CLI)

You can add or overwrite one or more tags by using the AWS CLI or an API.

**Note**

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

- AWS CLI - [tag-resource](#)
- API action - [TagResource](#)

## Tags for Amazon ECS Managed Instances

Amazon ECS Managed Instances support a combination of custom tags and tags added by AWS that can be used for cost optimization. For more information about using tags for billing, see [Use tags for billing](#).

### Tags added by AWS

AWS adds the following tags to each Amazon ECS Managed Instance created by the capacity provider:

- Amazon ECS automatically adds the reserved tags `AmazonECSCreated` and `AmazonECSManaged` to Amazon ECS Managed Instances.
- Amazon ECS adds the following system tags to each instance:
  - A tag with a *Key* as `aws:ecs:clusterName` and a *Value* set to the name of the cluster.
  - A tag with a *Key* as `aws:ecs:capacityProviderName` and a *Value* set to the name of the capacity provider.
  - A tag with a *Key* as `aws:ecs:containerInstanceId` and a *Value* as the container instance ID for the Amazon ECS Managed Instance.
- Amazon EC2 adds the system tag `aws:ec2:managed-launch` with the value `ecs-managed-instances`. In addition, Amazon EC2 adds system tags denoting the launch template that was used to create the managed instance, and the Amazon EC2 fleet that the managed instance is part of.

## Custom tags

You can add additional custom tags to Amazon ECS Managed Instances by adding tags to the capacity provider and enabling tag propagation using the `propagateTags` property. Tags on the capacity provider propagate to the managed instances that the capacity provider launches

The following example capacity provider definition shows how tags can be specified and propagated from the capacity provider when creating the capacity provider using the `CAPACITY_PROVIDER` value for `propagateTags`.

```
{
  "name": "my-cluster-managed-instances-cp",
  "cluster": "my-cluster",
  "tags": [
    {
      "key": "tag_key",
      "value": "tag_value"
    }
  ],
  "managedInstancesProvider": {
    "infrastructureRoleArn": "arn:aws:iam::123456789012:role/ecsInfrastructureRole",
    "propagateTags": "CAPACITY_PROVIDER",
    "instanceLaunchTemplate": {
      "ec2InstanceProfileArn": "arn:aws:iam::123456789012:instance-profile/ecsInstanceProfile",
      "networkConfiguration": {
        "subnets": [
          "subnet-abcdef01234567",
          "subnet-bcdefa98765432"
        ],
        "securityGroups": [
          "sg-0123456789abcdef"
        ]
      }
    }
  }
}
```

**Note**

- When you add new tags to a capacity provider, the newly added tags will not be propagated to existing instances but will be propagated to any newly created instances.
- Customers are allowed to add tags directly to the EC2 instances, but those tags don't propagate back to the capacity provider
- You can also tag or untag the capacity provider using [Adding tags to existing resources \(AWS CLI\)](#) or [Adding tags to existing resources \(Amazon ECS console\)](#)

For more information about Amazon ECS Managed Instances capacity providers, see [Amazon ECS Managed Instances capacity providers](#).

## Adding tags to an Amazon EC2 container instance for Amazon ECS

You can associate tags with your Amazon EC2 container instances for Amazon ECS using one of the following methods:

- Method 1 – When creating the container instance using the Amazon EC2 API, CLI, or console, specify tags by passing user data to the instance using the container agent configuration parameter `ECS_CONTAINER_INSTANCE_TAGS`. This creates tags that are associated with the container instance in Amazon ECS only, they cannot be listed using the Amazon EC2 API. For more information, see [Bootstrapping Amazon ECS Linux container instances to pass data](#).

**Important**

If you launch your container instances using an Amazon EC2 Auto Scaling group, then you should use the `ECS_CONTAINER_INSTANCE_TAGS` agent configuration parameter to add tags. This is due to the way in which tags are added to Amazon EC2 instances that are launched using Auto Scaling groups.

The following is an example of a user data script that associates tags with your container instance:

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_CONTAINER_INSTANCE_TAGS={"tag_key": "tag_value"}
EOF
```

- Method 2 – When you create your container instance using the Amazon EC2 API, CLI, or console, first specify tags using the `TagSpecification.N` parameter. Then, pass user data to the instance by using the container agent configuration parameter `ECS_CONTAINER_INSTANCE_PROPAGATE_TAGS_FROM`. Doing so propagates them from Amazon EC2 to Amazon ECS.

The following is an example of a user data script that propagates the tags that are associated with an Amazon EC2 instance, and registers the instance with a cluster that's named `MyCluster`.

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_CONTAINER_INSTANCE_PROPAGATE_TAGS_FROM=ec2_instance
EOF
```

To provide access to allow container instance tags to propagate from Amazon EC2 to Amazon ECS, manually add the following permissions as an inline policy to the Amazon ECS container instance IAM role. For more information, see [Adding and Removing IAM Policies](#).

- `ec2:DescribeTags`

The following is an example policy that's used to add these permissions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeTags"
      ],
      "Resource": "*"
    }
  ]
}
```

```
]
}
```

## Adding tags to External container instances for Amazon ECS

You can associate tags with your external container instances for Amazon ECS by using one of the following methods.

- Method 1 – Before running the installation script to register your external instance with your cluster, create or edit the Amazon ECS container agent configuration file at `/etc/ecs/ecs.config` and add the `ECS_CONTAINER_INSTANCE_TAGS` container agent configuration parameter. This creates tags that are associated with the external instance.

The following is example syntax.

```
ECS_CONTAINER_INSTANCE_TAGS={"tag_key": "tag_value"}
```

- Method 2 – After your external instance is registered to your cluster, you can use the AWS Management Console to add tags. For more information, see [Adding tags to existing resources \(Amazon ECS console\)](#).

## Amazon ECS usage reports

AWS provides a reporting tool called Cost Explorer that you can use to analyze the cost and usage of your Amazon ECS resources.

You can use Cost Explorer to view charts of your usage and costs. You can view data from the last 13 months, and forecast how much you're likely to spend for the next three months. You can use Cost Explorer to see patterns in how much you spend on AWS resources over time. For example, you can use it to identify areas that need further inquiry and see trends that you can use to understand your costs. You also can specify time ranges for the data, and view time data by day or by month.

The metering data in your Cost and Usage Report shows usage across all of your Amazon ECS tasks. The metering data includes CPU usage as vCPU-Hours and memory usage as GB-Hours for each task that was run. How that data is presented depends on the compute option of the task.

For tasks using Fargate, the `lineItem/Operation` column shows `FargateTask` and you will see the cost associated with each task.

For tasks that use EC2, the `lineItem/Operation` column shows `ECSTask-EC2` and the tasks don't have a direct cost associated with them. The metering data that's shown in the report, such as memory usage, represents the total resources that the task reserved over the billing period that you specify. You can use this data to determine the cost of your underlying cluster of Amazon EC2 instances. The cost and usage data for your Amazon EC2 instances are listed separately under the Amazon EC2 service.

You can also use the Amazon ECS managed tags to identify the service or cluster that each task belongs to. For more information, see [Use tags for billing](#).

### Important

The metering data is only viewable for tasks that are launched on or after November 16, 2018. Tasks that are launched before this date don't show metering data.

The following is an example of some of the fields that you can use to sort cost allocation data in Cost Explorer.

- Cluster name
- Service name
- Resource tags
- Launch type
- AWS Region
- Usage type

For more information about creating an AWS Cost and Usage Report, see [AWS Cost and Usage Report](#) in the *AWS Billing User Guide*.

## Task-level Cost and Usage Reports

AWS Cost Management can provide CPU and memory usage data in the AWS Cost and Usage Report for the each task on Amazon ECS, including tasks on Fargate and tasks on EC2. This data is called *Split Cost Allocation Data*. You can use this data to analyze costs and usage for applications.

Additionally, you can split and allocate the costs to individual business units and teams with cost allocation tags and cost categories. For more information about *Split Cost Allocation Data*, see [Understanding split cost allocation data](#) in the AWS Cost and Usage Report User Guide.

You can opt in to task-level *Split Cost Allocation Data* for the account in the AWS Cost Management Console. If you have a management (payer) account, you can opt in from the payer account to apply this configuration to every linked account.

After you set up *Split Cost Allocation Data*, there will be additional columns under the **splitLineItem** header in the report. For more information see [Split line item details](#) in the AWS Cost and Usage Report User Guide

For tasks on EC2, this data splits the cost of the EC2 instance based on the resource usage or reservations and the remaining resources on the instance.

The following are prerequisites:

- Set the ECS\_DISABLE\_METRICS Amazon ECS agent configuration parameter to `false`.

When this setting is `false`, the Amazon ECS agent sends metrics to Amazon CloudWatch. On Linux, this setting is `false` by default and metrics are sent to CloudWatch. On Windows, this setting is `true` by default, so you must change the setting to `false` to send the metrics to CloudWatch for AWS Cost Management to use. For more information about ECS agent configuration, see [Amazon ECS container agent configuration](#).

- The minimum Docker version for reliable metrics is Docker version v20.10.13 and newer, which is included in Amazon ECS-optimized AMI 20220607 and newer.

To use *Split Cost Allocation Data*, you must create a report, and select **Split cost allocation data**. For more information, see [Creating Cost and Usage Reports](#) in the AWS Cost and Usage Report User Guide.

AWS Cost Management calculates the *Split Cost Allocation Data* with the task CPU and memory usage. AWS Cost Management can use the task CPU and memory reservation instead of the usage, if the usage is unavailable. If you see the CUR is using the reservations, check that your container instances meet the prerequisites and the task resource usage metrics appear in CloudWatch.

# Monitoring Amazon ECS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon ECS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. Before you start monitoring Amazon ECS, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

The metrics made available depend on the compute option of the tasks and services in your clusters. If you are using Fargate for your services, then CPU and memory utilization metrics are provided to assist in the monitoring of your services. For EC2, you own and need to monitor the EC2 instances that make up your underlying infrastructure. Additional CPU and memory reservation and utilization metrics are made available at the cluster, service, and task.

The next step is to establish a baseline for normal Amazon ECS performance in your environment, by measuring performance at various times and under different load conditions. As you monitor Amazon ECS, store historical monitoring data so that you can compare it with current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

To establish a baseline you should, at a minimum, monitor the following items:

- The CPU and memory reservation and utilization metrics for your Amazon ECS clusters
- The CPU and memory utilization metrics for your Amazon ECS services

For more information, see [Viewing Amazon ECS metrics](#).

# Best practices for monitoring Amazon ECS

Use the following best practices for monitoring Amazon ECS.

- Make monitoring a priority to head off small problems before they become big ones
- Create a monitoring plan that includes answers to the following question
  - What are your monitoring goals?
  - What resources will you monitor?
  - How often will you monitor these resources?
  - What monitoring tools will you use?
  - Who will perform the monitoring tasks?
  - Who should be notified when something goes wrong?
- Automate monitoring as much as possible.
- Check the Amazon ECS log files. For more information, see [Viewing Amazon ECS container agent logs](#).
- Use Runtime Monitoring to help protect your accounts, containers, workloads, and the data within your AWS environment. For more information, see [Identify unauthorized behavior using Runtime Monitoring](#).

## Monitoring tools for Amazon ECS

AWS provides various tools that you can use to monitor Amazon ECS. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

### Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon ECS and report when something is wrong:

- Amazon CloudWatch alarms – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and

been maintained for a specified number of periods. For more information, see [Monitor Amazon ECS using CloudWatch](#).

For services with tasks that use Fargate, you can use CloudWatch alarms to scale in and scale out the tasks in your service based on CloudWatch metrics, such as CPU and memory utilization. For more information, see [Automatically scale your Amazon ECS service](#).

For clusters with tasks or services using EC2, you can use CloudWatch alarms to scale in and scale out the container instances based on CloudWatch metrics, such as cluster memory reservation.

For your container instances that were launched with the Amazon ECS-optimized Amazon Linux AMI, you can use CloudWatch Logs to view different logs from your container instances in one convenient location. You must install the CloudWatch agent on your container instances. For more information, see [Download and configure the CloudWatch agent using the command line](#) in the *Amazon CloudWatch User Guide*. You must also add the ECS-CloudWatchLogs policy to the `ecsInstanceRole` role. For more information, see [Monitoring container instances permissions](#).

- Amazon CloudWatch Logs – Monitor, store, and access the log files from the containers in your Amazon ECS tasks by specifying the `awslogs` log driver in your task definitions. For more information, see [Send Amazon ECS logs to CloudWatch](#).

You can also monitor, store, and access the operating system and Amazon ECS container agent log files from your Amazon ECS container instances. This method for accessing logs can be used for containers using EC2.

- Amazon CloudWatch Events – Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see [Automate responses to Amazon ECS errors using EventBridge](#) in this guide and [EventBridge is the evolution of Amazon CloudWatch Events](#) in the *Amazon EventBridge User Guide*.
- Container Insights – Collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. Container Insights collects data as performance log events using embedded metric format. These performance log events are entries that use a structured JSON schema that allow high-cardinality data to be ingested and stored at scale. From this data, CloudWatch creates aggregated metrics at the cluster, task, and service level as CloudWatch metrics. The metrics that Container Insights collects are available in CloudWatch automatic dashboards, and are also viewable in the Metrics section of the CloudWatch console.

- **AWS CloudTrail log monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see [Log Amazon ECS API calls using AWS CloudTrail](#) in this guide, and [Working with CloudTrail Log Files](#) in the *AWS CloudTrail User Guide*.
- **Runtime Monitoring** – Detect threats for clusters and containers within your AWS environment. Runtime Monitoring uses a GuardDuty security agent that adds runtime visibility into individual Amazon ECS workloads, for example, file access, process execution, and network connections.

## Manual monitoring tools

Another important part of monitoring Amazon ECS involves manually monitoring those items that the CloudWatch alarms don't cover. The CloudWatch, Trusted Advisor, and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your container instances and the containers in your tasks.

- Amazon ECS console:
  - Cluster metrics for EC2
  - Service metrics
  - Service health status
  - Service deployment events
- CloudWatch home page:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services you care about.
- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all your AWS resource metrics.
- Create and edit alarms to be notified of problems.
- **Container health check** - These are commands that run locally on a container and validate application health and availability. You configure these per container in your task definition.

- AWS Trusted Advisor can help you monitor your AWS resources to improve performance, reliability, security, and cost effectiveness. Four Trusted Advisor checks are available to all users; more than 50 checks are available to users with a Business or Enterprise support plan. For more information, see [AWS Trusted Advisor](#).

Trusted Advisor has these checks that relate to Amazon ECS:

- A fault tolerance which indicates that you have a service running in a single Availability Zone.
- A fault tolerance which indicates that you have not used the spread placement strategy for multiple Availability Zones.
- AWS Compute Optimizer is a service that analyzes the configuration and utilization metrics of your AWS resources. It reports whether your resources are optimal, and generates optimization recommendations to reduce the cost and improve the performance of your workloads.

For more information, see [AWS Compute Optimizer recommendations for Amazon ECS](#).

- Amazon ECS MCP server – Use AI assistants to monitor deployments, troubleshoot container issues, and inspect configurations using natural language. The MCP server provides real-time visibility into service health, analyzes task failures, and accelerates issue resolution. For more information, see [Amazon ECS MCP server](#).

## Monitor Amazon ECS using CloudWatch

You can monitor your Amazon ECS resources using Amazon CloudWatch, which collects and processes raw data from Amazon ECS into readable, near real-time metrics. These statistics are recorded for a period of two weeks so that you can access historical information and gain a better perspective on how your clusters or services are performing. Amazon ECS metric data is automatically sent to CloudWatch in 1-minute periods. For more information about CloudWatch, see the [Amazon CloudWatch User Guide](#).

Amazon ECS provides free metrics for clusters and services. For an additional cost, you can turn on Amazon ECS CloudWatch Container Insights for your cluster for per-task metrics, including CPU, memory, and EBS filesystem utilization. For more information about Container Insights, see [Monitor Amazon ECS containers using Container Insights with enhanced observability](#).

## Considerations

The following should be considered when using Amazon ECS CloudWatch metrics.

- Any Amazon ECS service hosted on Fargate has CloudWatch CPU and memory utilization metrics automatically, so you don't need to take any manual steps.
- For any Amazon ECS task or service hosted on Amazon EC2 instances, the Amazon EC2 instance requires version 1.4.0 or later (Linux) or 1.0.0 or later (Windows) of the container agent for CloudWatch metrics to be generated. However, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see [Updating the Amazon ECS container agent](#).
- The minimum Docker version for reliable CloudWatch metrics is Docker version 20.10.13 and newer.
- Your Amazon EC2 instances also require the `ecs:StartTelemetrySession` permission on the IAM role that you launch your Amazon EC2 instances with. If you created your Amazon ECS container instance IAM role before CloudWatch metrics were available for Amazon ECS, you might need to add this permission. For information about the container instance IAM role and attaching the managed IAM policy for container instances, see [Amazon ECS container instance IAM role](#).
- You can disable CloudWatch metrics collection on your Amazon EC2 instances by setting `ECS_DISABLE_METRICS=true` in your Amazon ECS container agent configuration. For more information, see [Amazon ECS container agent configuration](#).

## Recommended metrics

Amazon ECS provides free CloudWatch metrics you can use to monitor your resources. The CPU and memory reservation and the CPU, memory, and EBS filesystem utilization across your cluster as a whole, and the CPU, memory, and EBS filesystem utilization on the services in your clusters can be measured using these metrics. For your GPU workloads, you can measure your GPU reservation across your cluster.

The infrastructure your Amazon ECS tasks are hosted on in your clusters determines which metrics are available. For tasks hosted on Fargate infrastructure, Amazon ECS provides CPU, memory, and EBS filesystem utilization metrics to assist in the monitoring of your services. For tasks hosted on EC2 instances, Amazon ECS provides CPU, memory, and GPU reservation metrics and CPU and memory utilization metrics at the cluster and service level. You need to monitor the Amazon EC2 instances that make your underlying infrastructure separately. For more information about monitoring your Amazon EC2 instances, see [Monitoring Amazon EC2](#) in the *Amazon EC2 User Guide*.

For information about the recommended alarms to use with Amazon ECS, see one of the following in the *Amazon CloudWatch Logs User Guide*:

- [Amazon ECS](#)
- [Amazon ECS with Container Insights](#)

## Viewing Amazon ECS metrics

After you have resources running in your cluster, you can view the metrics on the Amazon ECS and CloudWatch consoles. The Amazon ECS console provides a 24-hour maximum, minimum, and average view of your cluster and service metrics. The CloudWatch console provides a fine-grained and customizable display of your resources, as well as the number of running tasks in a service.

### Amazon ECS console

Amazon ECS service CPU and memory utilization metrics are available on the Amazon ECS console. The view provided for service metrics shows the average, minimum, and maximum values for the previous 24-hour period, with data points available in 5-minute intervals. For more information, see [Amazon ECS service utilization metrics](#).

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. Select the cluster that you want to view metrics for.
3. Determine the metrics to view.

| To view metrics from | Steps                                                                                                                                                                                                  |  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Clusters             | On the cluster details page, choose the <b>Metrics</b> tab.<br>There is also a link provided to the CloudWatch console to view your CloudWatch Container Insights metrics if you have those turned on. |  |
| Services             | On the cluster details page, on the <b>Services</b> tab, select the service. The metrics are                                                                                                           |  |

| To view metrics from | Steps                                                |  |
|----------------------|------------------------------------------------------|--|
|                      | then available on the <b>Health and metrics</b> tab. |  |

## CloudWatch console

For Fargate, Amazon ECS service metrics can also be viewed on the CloudWatch console. The console provides the most detailed view of Amazon ECS metrics, and you can tailor the views to suit your needs. You can view the service utilization and service RUNNING task count.

For EC2 capacity providers, Amazon ECS cluster and service metrics can also be viewed on the CloudWatch console. The console provides the most detailed view of Amazon ECS metrics, and you can tailor the views to suit your needs.

For information about how to view the metrics, see [View available metrics](#) the *Amazon CloudWatch User Guide*.

## Amazon ECS CloudWatch metrics

You can use CloudWatch usage metrics to provide visibility into your accounts usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

Amazon ECS sends metrics to CloudWatch at one-minute intervals. These metrics are collected for resources that have tasks in the RUNNING state. If a cluster, service, or other resource has no running tasks, no metrics will be reported for that resource during that period. For example, if you have a cluster with one service but that service has no tasks in a RUNNING state, there will be no metrics sent to CloudWatch. Similarly, if you have two services and one of them has running tasks while the other doesn't, only the metrics for the service with running tasks would be sent.

| Metric         | Description                                                              | Valid Dimension | Useful Statistics         | Unit    |
|----------------|--------------------------------------------------------------------------|-----------------|---------------------------|---------|
| CPUReservation | The percentage of CPU units that are reserved in the cluster or service. | ClusterName     | Average, Minimum, Maximum | Percent |

| Metric | Description                                                                                                                                                                                                                                                                                                                                                                                                                     | Valid Dimension | Useful Statistics | Unit |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-------------------|------|
|        | <p>The CPU reservation ( filtered by <code>ClusterName</code> ) is measured as the total CPU units that are reserved by Amazon ECS tasks on the cluster, divided by the total CPU units for all of the Amazon EC2 instances registered in the cluster. Only Amazon EC2 instances in ACTIVE or DRAINING status will affect CPU reservation metrics. The metric is only supported for tasks hosted on an Amazon EC2 instance.</p> |                 |                   |      |

| Metric         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Valid Dimension                                        | Useful Statistics               | Unit    |

| Metric            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Valid Dimension            | Useful Statistics         | Unit    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|---------------------------|---------|
| MemoryReservation | <p>The percentage of memory that is reserved by running tasks in the cluster.</p> <p>Cluster memory reservation is measured as the total memory that is reserved by Amazon ECS tasks on the cluster, divided by the total amount of memory for all of the Amazon EC2 instances registered in the cluster. This metric can only be filtered by <code>ClusterName</code> . Only Amazon EC2 instances in ACTIVE or DRAINING status will affect memory reservation metrics. The cluster level memory reservation</p> | <code>ClusterName</code> . | Average, Minimum, Maximum | Percent |

**Note**

When calculating memory utilization, if `MemoryReservation` is specified, it's used in the calculation instead of total memory.

| Metric            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Valid Dimension                                        | Useful Statistics               | Unit    |

## Dimensions for Amazon ECS metrics

Amazon ECS metrics use the AWS/ECS namespace and provide metrics for the following dimensions. Amazon ECS only sends metrics for resources that have tasks in the `RUNNING` state. For example, if you have a cluster with one service in it but that service has no tasks in a `RUNNING` state, there will be no metrics sent to CloudWatch. If you have two services and one of them has running tasks and the other doesn't, only the metrics for the service with running tasks would be sent.

| Dimension                  | Definition                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ClusterName</code>   | This dimension filters the data that you request for all resources in a specified cluster. All Amazon ECS metrics are filtered by <code>ClusterName</code> .                                                                                                                                                                                                                                                  |
| <code>ServiceName</code>   | This dimension filters the data that you request for all resources in a specified service or daemon within a specified cluster. For daemon metrics, the <code>ServiceName</code> dimension value has the prefix <code>daemon:</code> followed by the daemon name. For example, a daemon named <code>my-daemon</code> would have a <code>ServiceName</code> dimension value of <code>daemon:my-daemon</code> . |
| <code>DiscoveryName</code> | This dimension filters the data that you request for traffic metrics to a specified Service Connect discovery name across all Amazon ECS clusters.                                                                                                                                                                                                                                                            |

| Dimension                                                                        | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                  | <p>Note that a specific port in a running container can have multiple discovery names.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>DiscoveryName</code> , <code>ServiceName</code> , <code>ClusterName</code> | <p>This dimension filters the data that you request for traffic metrics to a specified Service Connect discovery name across tasks that have this discovery name and that are created by this service in this cluster.</p> <p>Use this dimension to see the inbound traffic metrics for a specific service, if you have reused the same discovery name in multiple services in different namespaces.</p> <p>Note that a specific port in a running container can have multiple discovery names.</p>                                                                                                            |
| <code>TargetDiscoveryName</code>                                                 | <p>This dimension filters the data that you request for traffic metrics to a specified Service Connect discovery name across all Amazon ECS clusters.</p> <p>Different from <code>DiscoveryName</code>, these traffic metrics only measure inbound traffic to this <code>DiscoveryName</code> that come from other Amazon ECS tasks that have a Service Connect configuration in this namespace. This includes tasks made by services with either a client-only or client-server Service Connect configuration.</p> <p>Note that a specific port in a running container can have multiple discovery names.</p> |

| Dimension                                                                              | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <code>TargetDiscoveryName</code> , <code>ServiceName</code> , <code>ClusterName</code> | <p>This dimension filters the data that you request for traffic metrics to a specified Service Connect discovery name but only counts traffic from tasks created by this service in this cluster.</p> <p>Use this dimension to see the inbound traffic metrics that come from a specific client in another service.</p> <p>Different from <code>DiscoveryName</code>, <code>ServiceName</code>, <code>ClusterName</code>, these traffic metrics only measure inbound traffic to this <code>DiscoveryName</code> that come from other Amazon ECS tasks that have a Service Connect configuration in this namespace. This includes tasks made by services with either a client-only or client-server Service Connect configuration.</p> <p>Note that a specific port in a running container can have multiple discovery names.</p> |

## AWS Fargate usage metrics

You can use CloudWatch usage metrics to provide visibility into your accounts usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

AWS Fargate usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about Fargate service quotas, [Amazon ECS endpoints and quotas](#) in the *Amazon Web Services General Reference*.

AWS Fargate publishes the following metrics in the `AWS/Usage` namespace.

| Metric        | Description                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| ResourceCount | The total number of the specified resource running on your account. The resource is defined by the dimensions associated with the metric. |

The following dimensions are used to refine the usage metrics that are published by AWS Fargate.

| Dimension | Description                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service   | The name of the AWS service containing the resource. For AWS Fargate usage metrics, the value for this dimension is Fargate.                                                                                         |
| Type      | The type of entity that is being reported. Currently, the only valid value for AWS Fargate usage metrics is Resource.                                                                                                |
| Resource  | The type of resource that is running. The type of resource that is running. Currently, the only valid value for AWS Fargate usage metrics is vCPU which returns information about the running instances.             |
| Class     | The class of resource being tracked. The class of resource being tracked. For AWS Fargate usage metrics with vCPU as the value of the Resource dimension, the valid values are Standard/OnDemand and Standard/Spot . |

You can use the Service Quotas console to visualize your usage on a graph and configure alarms that alert you when your AWS Fargate usage approaches a service quota. For information about how to create a CloudWatch alarm to notify you when you're close to a quota value threshold, see [Service Quotas and Amazon CloudWatch](#) alarms in the *Service Quotas User Guide*.

## Amazon ECS cluster reservation metrics

Cluster reservation metrics are measured as the percentage of CPU, memory, and GPUs that are reserved by all Amazon ECS tasks on a cluster when compared to the aggregate CPU, memory, and GPUs that were registered for each active container instance in the cluster. Only container instances in ACTIVE or DRAINING status will affect cluster reservation metrics. This metric is used only on clusters with tasks or services hosted on EC2 instances. It's not supported on clusters with tasks hosted on AWS Fargate.

$$\text{Cluster CPU reservation} = \frac{(\text{Total CPU units reserved by tasks in cluster}) \times 100}{(\text{Total CPU units registered by container instances in cluster})}$$

$$\text{Cluster memory reservation} = \frac{(\text{Total MiB of memory reserved by tasks in cluster} \times 100)}{(\text{Total MiB of memory registered by container instances in cluster})}$$

$$\text{Cluster GPU reservation} = \frac{(\text{Total GPUs reserved by tasks in cluster} \times 100)}{(\text{Total GPUs registered by container instances in cluster})}$$

When you run a task in a cluster, Amazon ECS parses its task definition and reserves the aggregate CPU units, MiB of memory, and GPUs that are specified in its container definitions. Each minute, Amazon ECS calculates the number of CPU units, MiB of memory, and GPUs that are currently reserved for each task that is running in the cluster. The total amount of CPU, memory, and GPUs reserved for all tasks running on the cluster is calculated, and those numbers are reported to CloudWatch as a percentage of the total registered resources for the cluster. If you specify a soft limit (`memoryReservation`) in the task definition, it's used to calculate the amount of reserved memory. Otherwise, the hard limit (`memory`) is used. The total MiB of memory reserved by tasks in a cluster also includes temporary file system (`tmpfs`) volume size and `sharedMemorySize` if defined in the task definition. For more information about hard and soft limits, shared memory size, and `tmpfs` volume size, see [Task Definition Parameters](#).

For example, a cluster has two active container instances registered: a `c4.4xlarge` instance and a `c4.large` instance. The `c4.4xlarge` instance registers into the cluster with 16,384 CPU units and 30,158 MiB of memory. The `c4.large` instance registers with 2,048 CPU units and 3,768 MiB of memory. The aggregate resources of this cluster are 18,432 CPU units and 33,926 MiB of memory.

If a task definition reserves 1,024 CPU units and 2,048 MiB of memory, and ten tasks are started with this task definition on this cluster (and no other tasks are currently running), a total of 10,240 CPU units and 20,480 MiB of memory are reserved. This is reported to CloudWatch as 55% CPU reservation and 60% memory reservation for the cluster.

The following illustration shows the total registered CPU units in a cluster and what their reservation and utilization means to existing tasks and new task placement. The lower (Reserved, used) and center (Reserved, not used) blocks represent the total CPU units that are reserved for the existing tasks that are running on the cluster, or the `CPUReservation` CloudWatch metric. The lower block represents the reserved CPU units that the running tasks are actually using on the cluster, or the `CPUUtilization` CloudWatch metric. The upper block represents CPU units that are not reserved by existing tasks; these CPU units are available for new task placement. Existing tasks can use these unreserved CPU units as well, if their need for CPU resources increases. For more information, see the [cpu](#) task definition parameter documentation.

## Amazon ECS cluster utilization metrics

The cluster utilization metrics are available for CPU, memory, and, when there is an EBS volume attached to your tasks, EBS filesystem utilization. These metrics are only available for clusters with tasks or services hosted on Amazon EC2 instances. They're not supported on clusters with tasks hosted on AWS Fargate.

### Amazon ECS cluster level CPU and memory utilization metrics

The CPU and memory utilization is measured as the percentage of CPU and memory that is used by all tasks on a cluster when compared to the aggregate CPU and memory that was registered for each active Amazon EC2 instances registered to the cluster. Only Amazon EC2 instances in ACTIVE or DRAINING status will affect cluster utilization metrics.

$$\text{Cluster CPU utilization} = \frac{(\text{Total CPU units used by tasks in cluster}) \times 100}{(\text{Total CPU units registered by container instances in cluster})}$$

$$\text{Cluster memory utilization} = \frac{(\text{Total MiB of memory used by tasks in cluster} \times 100)}{(\text{Total MiB of memory registered by container instances in cluster})}$$

Each minute, the Amazon ECS container agent on each Amazon EC2 instance calculates the number of CPU units and MiB of memory that is currently being used for each task that is running on that Amazon EC2 instance, and this information is reported back to Amazon ECS. The total amount of CPU and memory used for all tasks running on the cluster is calculated, and those numbers are reported to CloudWatch as a percentage of the total registered resources for the cluster.

For example, a cluster has two active Amazon EC2 instances registered, a `c4.4xlarge` instance and a `c4.large` instance. The `c4.4xlarge` instance registers into the cluster with 16,384 CPU units and 30,158 MiB of memory. The `c4.large` instance registers with 2,048 CPU units and 3,768 MiB of memory. The aggregate resources of this cluster are 18,432 CPU units and 33,926 MiB of memory.

If ten tasks are running on this cluster and each task consumes 1,024 CPU units and 2,048 MiB of memory, a total of 10,240 CPU units and 20,480 MiB of memory are used on the cluster. This is reported to CloudWatch as 55% CPU utilization and 60% memory utilization for the cluster.

## Amazon ECS cluster-level Amazon EBS filesystem utilization

The cluster level EBS filesystem utilization metric is measured as the total amount of the EBS filesystem in use by the tasks running on the cluster, divided by the total amount of EBS filesystem storage that was allocated for all of the tasks in the cluster.

$$\text{Cluster EBS filesystem utilization} = \frac{\text{(Total GB of EBS filesystem used by tasks in cluster)} \times 100}{\text{(Total GB of EBS filesystem allocated to tasks in cluster)}}$$

## Amazon ECS service utilization metrics

The service utilization metrics are available for CPU, memory, and, when there is an EBS volume attached to your tasks, EBS filesystem utilization. The service level metrics are supported for services with tasks hosted on both Amazon EC2 instances and Fargate.

### Service level CPU and memory utilization

The CPU and memory utilization is measured as the percentage of CPU and memory that is used by the Amazon ECS tasks that belong to a service on a cluster when compared to the CPU and memory that is specified in the service's task definition.

When viewing these metrics in CloudWatch, you can choose different statistics:

- **Average:** The average utilization across all tasks in the service. This is calculated using the following formula.
- **Minimum:** The utilization of the task with the lowest resource usage in the service. This represents the percentage of CPU or memory used by the least resource-intensive task compared to what was specified in the task definition.
- **Maximum:** The utilization of the task with the highest resource usage in the service. This represents the percentage of CPU or memory used by the most resource-intensive task compared to what was specified in the task definition.

The following formulas show how the Average statistic is calculated:

$$\text{Service CPU utilization} = \frac{(\text{Total CPU units used by tasks in service}) \times 100}{(\text{Total CPU units specified in the task definition}) \times (\text{Number of tasks in the service})}$$

$$\text{Service memory utilization} = \frac{(\text{Total MiB of memory used by tasks in service} \times 100)}{(\text{Total MiB of memory specified in the task definition}) \times (\text{Number of tasks in the service})}$$

### Note

The preceding formulas apply only to the Average statistic. The Minimum and Maximum statistics represent the individual task with the lowest and highest resource utilization, respectively, rather than an aggregate calculation across all tasks.

Amazon ECS collects metrics every 20 seconds. Each minute, the Amazon ECS container agent calculates the number of CPU units and MiB of memory that are currently being used for each running task owned by the service. This information is reported back to Amazon ECS. The total amount of CPU and memory used for all tasks owned by the service that are running on the cluster is calculated, and those numbers are reported to CloudWatch as a percentage of the total resources that are specified for the service in the service's task definition. The minimum and maximum values are the smallest and largest of the 20 second metrics. The average is the aggregate of the 3 values.

If you specify a soft limit (`memoryReservation`), it's used to calculate the amount of reserved memory. Otherwise, the hard limit (`memory`) is used. For more information about hard and soft limits, see [Task size](#).

For example, the task definition for a service specifies a total of 512 CPU units and 1,024 MiB of memory (with the hard limit `memory` parameter) for all of its containers. The service has a desired count of 1 running task, the service is running on a cluster with 1 `c4.large` container instance (with 2,048 CPU units and 3,768 MiB of total memory), and there are no other tasks running on the cluster. Although the task specifies 512 CPU units, because it is the only running task on a

container instance with 2,048 CPU units, it can use up to four times the specified amount (2,048 / 512). However, the specified memory of 1,024 MiB is a hard limit and it can't be exceeded, so in this case, service memory utilization can't exceed 100%.

If the previous example used the `soft limit memoryReservation` instead of the `hard limit memory` parameter, the service's tasks could use more than the specified 1,024 MiB of memory as needed. In this case, the service's memory utilization could exceed 100%.

If your application has a sudden spike in memory utilization for a short amount of time, you will not see the service memory utilization increasing because Amazon ECS collects multiple data points every minute, and then aggregates them to one data point that is sent to CloudWatch.

If this task is performing CPU-intensive work during a period and using all 2,048 of the available CPU units and 512 MiB of memory, the service reports 400% CPU utilization and 50% memory utilization. If the task is idle and using 128 CPU units and 128 MiB of memory, the service reports 25% CPU utilization and 12.5% memory utilization.

#### **Note**

In this example, the CPU utilization will only go above 100% when the CPU units are defined at the container level. If you define CPU units at the task level, the utilization will not go above the defined task-level limit.

## Service level EBS filesystem utilization

The service level EBS filesystem utilization is measured as the total amount of the EBS filesystem in use by the tasks that belong to the service, divided by the total amount of EBS filesystem storage that is allocated for all tasks that belong to the service.

## Service LIVE task count

With the `LiveTaskCount` metric, you get a complete view of the tasks in your service that are actively running and generating metrics. It counts the tasks in the `ACTIVATING`, `RUNNING`, and `DEACTIVATING` states, including tasks that are running but transitioning to a stopped state, such as tasks that are draining connections during a scale-in event.

This behavior makes the metric well suited for auto scaling alarms and capacity monitoring, because a task that is still serving traffic while it drains is still counted.

LiveTaskCount is available at no cost. For more information, see [Amazon ECS CloudWatch metrics](#).

## Service RUNNING task count

You can use CloudWatch metrics to view the number of tasks in your services that are in the RUNNING state. For example, you can set a CloudWatch alarm for this metric to alert you if the number of running tasks in your service falls below a specified value.

The RunningTaskCount metric counts the tasks whose current state and desired state are both RUNNING. This makes it a health and stability signal for your service. It doesn't count tasks that are still running while they transition to a stopped state. To count those tasks as well, use LiveTaskCount. For more information, see [Service LIVE task count](#).

### Service RUNNING task count in Amazon ECS CloudWatch Container Insights

A "Number of Running Tasks" (RunningTaskCount) metric is available per cluster and per service when you use Amazon ECS CloudWatch Container Insights. You can use Container Insights for all new clusters created by opting in to the containerInsights account setting, on individual clusters by turning on the cluster settings during cluster creation, or on existing clusters by using the UpdateClusterSettings API.

#### Note

Beginning October 1, 2026, you aren't billed for the RunningTaskCount metric in CloudWatch Container Insights, regardless of the number of Amazon ECS services or clusters in your account.

Other metrics collected by CloudWatch Container Insights are charged as custom metrics. For more information about CloudWatch pricing, see [CloudWatch Pricing](#).

To view this metric, see [Amazon ECS Container Insights Metrics](#) in the *Amazon CloudWatch User Guide*.

## High-resolution service metrics

By default, Amazon ECS publishes CPUUtilization and MemoryUtilization service metrics to CloudWatch at 60-second resolution. You can configure 20-second resolution by setting a

monitoring configuration on your service. This enables faster detection of resource utilization changes and can be used to drive faster service auto scaling.

To enable high-resolution metrics, specify a monitoring configuration with `resolutionSeconds` set to 20 when creating or updating your service. For the full setup instructions including how to configure a high-resolution scaling policy, see [Faster auto scaling with high-resolution metrics](#).

## Amazon ECS service utilization metrics use cases

The following list provides information about when to use the Amazon ECS metrics.

- **Resource utilization monitoring:** Use average statistics to monitor CPU and memory consumption patterns, establish performance baselines, and detect gradual performance degradation trends.
- **Cost optimization:** Use average statistics to monitor resource usage, right-size containers, adjust reservations based on usage patterns, and implement scheduled scaling.
- **Performance benchmarking:** Use average statistics to compare metrics between service revisions, establish performance KPIs, and validate optimization improvements.
- **Resource floor detection:** Use average statistics to identify minimum resource needs during idle periods, set appropriate reservations, and detect abnormal drops.
- **Anomaly detection:** Use minimum statistics to spot unusual resource utilization drops that indicate potential problems, such as initialization failures or unexpected idle periods.
- **Scaling policy refinement:** Use minimum statistics to establish optimal scale-in thresholds based on minimum viable utilization to prevent aggressive scaling.
- **Capacity planning:** Use maximum statistics to set appropriate task sizes and plan infrastructure with sufficient headroom for traffic spikes.
- **Performance bottleneck identification:** Use maximum statistics to detect resource saturation points, identify bottlenecks, and determine when to increase task size.
- **Scaling policy configuration:** Use maximum statistics to set optimal scale-out thresholds based on peak patterns and configure burst capacity.
- **SLA compliance monitoring:** Use maximum statistics to track peak response times and error rates to ensure service performance meets defined SLAs.

## Related metrics information

For information about Container Insights, see [Container Insights use cases](#) in the *CloudWatch User Guide*.

# Automate responses to Amazon ECS errors using EventBridge

Using Amazon EventBridge, you can automate your AWS services and respond automatically to system events such as application availability issues or resource changes. Events from AWS services are delivered to EventBridge in near real time. You can write simple rules to indicate which events are of interest to you and what automated actions to take when an event matches a rule. The actions that can be automatically configured to include the following:

- Adding events to log groups in CloudWatch Logs
- Invoking an AWS Lambda function
- Invoking Amazon EC2 Run Command
- Relaying the event to Amazon Kinesis Data Streams
- Activating an AWS Step Functions state machine
- Notifying an Amazon SNS topic or an Amazon Simple Queue Service (Amazon SQS) queue

For more information, see [Getting started with Amazon EventBridge](#) in the *Amazon EventBridge User Guide*.

You can use Amazon ECS events for EventBridge to receive near real-time notifications regarding the current state of your Amazon ECS clusters. If your tasks are using EC2, you can see the state of both the container instances and the current state of all tasks running on those container instances. If your tasks are using Fargate, you can see the state of the container instances.

Using EventBridge, you can build custom schedulers on top of Amazon ECS that are responsible for orchestrating tasks across clusters and monitoring the state of clusters in near real time. You can eliminate scheduling and monitoring code that continuously polls the Amazon ECS service for status changes and instead handle Amazon ECS state changes asynchronously using any EventBridge target. Targets might include AWS Lambda, Amazon Simple Queue Service, Amazon Simple Notification Service, or Amazon Kinesis Data Streams.

An Amazon ECS event stream ensures that every event is delivered at least one time. If duplicate events are sent, the event provides enough information to identify duplicates. For more information, see [Handling Amazon ECS events](#).

Events are relatively ordered, so that you can easily tell when an event occurred in relation to other events.

## Topics

- [Amazon ECS events](#)
- [Handling Amazon ECS events](#)

## Amazon ECS events

Amazon ECS tracks the state of each of your tasks and services. If the state of a task or service changes, an event is generated and is sent to Amazon EventBridge. These events are classified as task state change events and service action events. These events and their possible causes are described in greater detail in the following sections.

Amazon ECS generates and sends the following types of events to EventBridge:

- Container instance state change
- Task state change
- Deployment state change
- Hook state change
- Service action
- Container instance health change
- Daemon deployment state change
- Daemon service action

### Note

Amazon ECS might add other event types, sources, and details in the future. If you are deserializing event JSON data in code, make sure that your application is prepared to handle unknown properties to avoid issues if and when these additional properties are added.

In some cases, multiple events are generated for the same activity. For example, when a task is started on a container instance, a task state change event is generated for the new task.

A container instance state change event is generated to account for the change in available resources, such as CPU, memory, and available ports, on the container instance. Likewise, if a container instance is terminated, events are generated for the container instance, the container agent connection status, and every task that was running on the container instance.

Container state change and task state change events contain two `version` fields: one in the main body of the event, and one in the `detail` object of the event. The following describes the differences between these two fields:

- The `version` field in the main body of the event is set to 0 on all events. For more information about EventBridge parameters, see [AWS service event metadata](#) in the *Amazon EventBridge User Guide*.
- The `version` field in the `detail` object of the event describes the version of the associated resource. Each time a resource changes state, this version is incremented. Because events can be sent multiple times, this field allows you to identify duplicate events. Duplicate events have the same version in the `detail` object. If you are replicating your Amazon ECS container instance and task state with EventBridge, you can compare the version of a resource reported by the Amazon ECS APIs with the version reported in EventBridge for the resource (inside the `detail` object) to verify that the version in your event stream is current.

Service action events only contain the `version` field in the main body.

Service action events specify the service in 2 different fields:

- For events generated by `create-service`, the service is in the `serviceName` field.
- For events generated by `update-service`, the service is in the `service` field.

If you use automated tooling for service events, you need to code for both fields.

For information about how to create a rule for service action events, see [Amazon ECS service action events](#).

For additional information about how to integrate Amazon ECS and EventBridge, see [Integrating Amazon EventBridge and Amazon ECS](#).

## Amazon ECS container instance state change events

The following scenarios cause container instance state change events:

You call the `StartTask`, `RunTask`, or `StopTask` API operations, either directly or with the AWS Management Console or SDKs.

Placing or stopping tasks on a container instance modifies the available resources on the container instance, such as CPU, memory, and available ports.

The Amazon ECS service scheduler starts or stops a task.

Placing or stopping tasks on a container instance modifies the available resources on the container instance, such as CPU, memory, and available ports.

The Amazon ECS container agent calls the `SubmitTaskStateChange` API operation with a `STOPPED` status for a task with a desired status of `RUNNING`.

The Amazon ECS container agent monitors the state of tasks on your container instances, and it reports any state changes. If a task that is supposed to be `RUNNING` is transitioned to `STOPPED`, the agent releases the resources that were allocated to the stopped task, such as CPU, memory, and available ports.

You deregister the container instance with the `DeregisterContainerInstance` API operation, either directly or with the AWS Management Console or SDKs.

Deregistering a container instance changes the status of the container instance and the connection status of the Amazon ECS container agent.

A task was stopped when an EC2 instance was stopped.

When you stop a container instance, the tasks that are running on it are transitioned to the `STOPPED` status.

The Amazon ECS container agent registers a container instance for the first time.

The first time the Amazon ECS container agent registers a container instance (at launch or when first run manually), this creates a state change event for the instance.

The Amazon ECS container agent connects or disconnects from Amazon ECS.

When the Amazon ECS container agent connects or disconnects from the Amazon ECS backend, it changes the `agentConnected` status of the container instance.

 **Note**

The Amazon ECS container agent disconnects and reconnects several times per hour as a part of its normal operation, so agent connection events should be expected. These

events are not an indication that there is an issue with the container agent or your container instance.

You upgrade the Amazon ECS container agent on an instance.

The container instance detail contains an object for the container agent version. If you upgrade the agent, this version information changes and generates an event.

### Example Container instance state change event

Container instance state change events are delivered in the following format. The detail section resembles the [ContainerInstance](#) object that is returned from a [DescribeContainerInstances](#) API operation in the *Amazon Elastic Container Service API Reference*. For more information about EventBridge parameters, see [AWS service event metadata](#) in the *Amazon EventBridge User Guide*.

## Amazon ECS task state change events

The following scenarios cause task state change events:

You call the `StartTask`, `RunTask`, or `StopTask` API operations, either directly or with the AWS Management Console, AWS CLI, or SDKs.

Starting or stopping tasks creates new task resources or modifies the state of existing task resources.

The Amazon ECS service scheduler starts or stops a task.

Starting or stopping tasks creates new task resources or modifies the state of existing task resources.

The Amazon ECS container agent calls the `SubmitTaskStateChange` API operation.

For EC2, the Amazon ECS container agent monitors the state of your tasks on your container instances. The Amazon ECS container agent reports any state changes. State changes might include changes from `PENDING` to `RUNNING` or from `RUNNING` to `STOPPED`.

You force deregistration of the underlying container instance with the `DeregisterContainerInstance` API operation and the `force` flag, either directly or with the AWS Management Console or SDKs.

Deregistering a container instance changes the status of the container instance and the connection status of the Amazon ECS container agent. If tasks are running on the container

instance, the `force` flag must be set to allow deregistration. This stops all tasks on the instance.

The underlying container instance is stopped or terminated.

When you stop or terminate a container instance, the tasks that are running on it are transitioned to the STOPPED status.

A container in the task changes state.

The Amazon ECS container agent monitors the state of containers within tasks. For example, if a container that is running within a task stops, this container state change generates an event.

A task using the Fargate Spot capacity provider receives a termination notice.

When a task is using the FARGATE\_SPOT capacity provider and is stopped due to a Spot interruption, a task state change event is generated.

### Example Task state change event

Task state change events are delivered in the following format. Note the following about the fields:

- The health status of the event is not available in the task state change event. If you need the task health status, you can run [describe-tasks](#).
- When your containers use an image hosted with Amazon ECR, the `imageDigest` field is returned.
- The values for the `createdAt`, `connectivityAt`, `pullStartedAt`, `startedAt`, `pullStoppedAt`, and `updatedAt` fields are ISO string timestamps.
- The `detail-type` value is "ECS Task State Change".
- When the event is generated for a stopped task, the `stoppedReason` and `stopCode` fields provide additional information about why the task stopped (for example, "User initiated").

For more information about EventBridge parameters, see [AWS service event metadata](#) in the *Amazon EventBridge Events Reference*.

For information about how to configure an Amazon EventBridge event rule that only captures task events where the task has stopped running because one of its essential containers has terminated, see [Sending Amazon Simple Notification Service alerts for Amazon ECS task stopped events](#)

## Amazon ECS service action events

Amazon ECS sends service action events with the detail type **ECS Service Action**. Unlike the container instance and task state change events, the service action events do not include a version

number in the `details` response field. The following is an event pattern that is used to create an EventBridge rule for Amazon ECS service action events. For more information, see [Getting started with EventBridge](#) in the *Amazon EventBridge User Guide*.

```
{
  "source": [
    "aws.ecs"
  ],
  "detail-type": [
    "ECS Service Action"
  ]
}
```

Amazon ECS sends events with INFO, WARN, and ERROR event types. The following are the service action events.

### Service action events with INFO event type

#### SERVICE\_STEADY\_STATE

The service is healthy and at the desired number of tasks, thus reaching a steady state. The service scheduler reports the status periodically, so you might receive this message multiple times.

#### TASKSET\_STEADY\_STATE

The task set is healthy and at the desired number of tasks, thus reaching a steady state.

#### CAPACITY\_PROVIDER\_STEADY\_STATE

A capacity provider associated with a service reaches a steady state.

#### SERVICE\_DESIRED\_COUNT\_UPDATED

When the service scheduler updates the computed desired count for a service or task set. This event is not sent when the desired count is manually updated by a user.

#### TASKS\_STOPPED

The service has stopped the running task.

#### SERVICE\_DEPLOYMENT\_IN\_PROGRESS

A service deployment is in progress. The service deployment can be either a rollback, or a new service revision.

## SERVICE\_DEPLOYMENT\_COMPLETED

A service deployment is in the steady state and is complete. The service deployment can be either a rollback, or to deploy an updated service revision.

### Service action events with **WARN** event type

#### SERVICE\_TASK\_START\_IMPAIRED

The service is unable to consistently start tasks successfully.

#### SERVICE\_DISCOVERY\_INSTANCE\_UNHEALTHY

A service using service discovery contains an unhealthy task. The service scheduler detects that a task within a service registry is unhealthy.

#### VPC\_LATTICE\_TARGET\_UNHEALTHY

The service using VPC Lattice has detected one of the targets for the VPC Lattice is unhealthy.

### Service action events with **ERROR** event type

#### SERVICE\_DAEMON\_PLACEMENT\_CONSTRAINT\_VIOLATED

A task in a service using the DAEMON service scheduler strategy no longer meets the placement constraint strategy for the service.

#### ECS\_OPERATION\_THROTTLED

The service scheduler has been throttled due to the Amazon ECS API throttle limits.

#### SERVICE\_DISCOVERY\_OPERATION\_THROTTLED

The service scheduler has been throttled due to the AWS Cloud Map API throttle limits. This can occur on services configured to use service discovery.

#### SERVICE\_TASK\_PLACEMENT\_FAILURE

The service scheduler is unable to place a task. The cause will be described in the reason field.

A common cause for this service event being generated is because of a lack of resources in the cluster to place the task. For example, not enough CPU or memory capacity on the available

container instances or no container instances being available. Another common cause is when the Amazon ECS container agent is disconnected on the container instance, causing the scheduler to be unable to place the task.

#### SERVICE\_TASK\_CONFIGURATION\_FAILURE

The service scheduler is unable to place a task due to a configuration error. The cause will be described in the reason field.

A common cause of this service event being generated is because tags were being applied to the service but the user or role had not opted in to the new Amazon Resource Name (ARN) format in the Region. For more information, see [Amazon Resource Names \(ARNs\) and IDs](#). Another common cause is that Amazon ECS was unable to assume the task IAM role provided.

#### SERVICE\_HEALTH\_UNKNOWN

The service was unable to describe the health data for tasks.

#### SERVICE\_DEPLOYMENT\_FAILED

A service deployment did not reach the steady. This happens when a CloudWatch is triggered or the circuit breaker detects a service deployment failure.

### Example Service steady state event

Service steady state events are delivered in the following format. For more information about EventBridge parameters, see [Events in EventBridge](#) in the *Amazon EventBridge User Guide*.

```

    "clusterArn": "arn:aws:ecs:us-west-2:111122223333:cluster/default",
    "createdAt": "2019-11-19T19:27:22.695Z"
  }
}
```

## Example Capacity provider steady state event

Capacity provider steady state events are delivered in the following format.

```
{
  "version": "0",
  "id": "b9baa007-2f33-0eb1-5760-0d02a572d81f",
  "detail-type": "ECS Service Action",
  "source": "aws.ecs",
  "account": "111122223333",
  "time": "2019-11-19T19:37:00Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:ecs:us-west-2:111122223333:service/default/servicetest"
  ],
  "detail": {
    "eventType": "INFO",
    "eventName": "CAPACITY_PROVIDER_STEADY_STATE",
    "clusterArn": "arn:aws:ecs:us-west-2:111122223333:cluster/default",
    "capacityProviderArns": [
      "arn:aws:ecs:us-west-2:111122223333:capacity-provider/ASG-tutorial-
capacity-provider"
    ],
    "createdAt": "2019-11-19T19:37:00.807Z"
  }
}
```

## Example Service task start impaired event

Service task start impaired events are delivered in the following format.

```
{
  "version": "0",
  "id": "57c9506e-9d21-294c-d2fe-e8738da7e67d",
  "detail-type": "ECS Service Action",
  "source": "aws.ecs",
  "account": "111122223333",
```

```

    "time": "2019-11-19T19:55:38Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:ecs:us-west-2:111122223333:service/default/servicetest"
    ],
    "detail": {
        "eventType": "WARN",
        "eventName": "SERVICE_TASK_START_IMPAIRED",
        "clusterArn": "arn:aws:ecs:us-west-2:111122223333:cluster/default",
        "createdAt": "2019-11-19T19:55:38.725Z"
    }
}

```

### Example Service task placement failure event

Service task placement failure events are delivered in the following format. For more information, see [Events in EventBridge](#) in the *Amazon EventBridge User Guide*.

In the following example, the task was attempting to use the FARGATE\_SPOT capacity provider but the service scheduler was unable to acquire any Fargate Spot capacity.

```

{
    "version": "0",
    "id": "ddca6449-b258-46c0-8653-e0e3a6d0468b",
    "detail-type": "ECS Service Action",
    "source": "aws.ecs",
    "account": "111122223333",
    "time": "2019-11-19T19:55:38Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:ecs:us-west-2:111122223333:service/default/servicetest"
    ],
    "detail": {
        "eventType": "ERROR",
        "eventName": "SERVICE_TASK_PLACEMENT_FAILURE",
        "clusterArn": "arn:aws:ecs:us-west-2:111122223333:cluster/default",
        "capacityProviderArns": [
            "arn:aws:ecs:us-west-2:111122223333:capacity-provider/FARGATE_SPOT"
        ],
        "reason": "RESOURCE:FARGATE",
        "createdAt": "2019-11-06T19:09:33.087Z"
    }
}

```

In the following example for EC2, the task was attempted to launch on the Container Instance 2dd1b186f39845a584488d2ef155c131 but the service scheduler was unable to place the task because of insufficient CPU.

```
{
  "version": "0",
  "id": "ddca6449-b258-46c0-8653-e0e3a6d0468b",
  "detail-type": "ECS Service Action",
  "source": "aws.ecs",
  "account": "111122223333",
  "time": "2019-11-19T19:55:38Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:ecs:us-west-2:111122223333:service/default/servicetest"
  ],
  "detail": {
    "eventType": "ERROR",
    "eventName": "SERVICE_TASK_PLACEMENT_FAILURE",
    "clusterArn": "arn:aws:ecs:us-west-2:111122223333:cluster/default",
    "containerInstanceArns": [
      "arn:aws:ecs:us-west-2:111122223333:container-instance/default/2dd1b186f39845a584488d2ef155c131"
    ],
    "reason": "RESOURCE:CPU",
    "createdAt": "2019-11-06T19:09:33.087Z"
  }
}
```

## Amazon ECS service deployment state change events

Amazon ECS sends service deployment change state events with the detail type **ECS Deployment State Change**. The following is an event pattern that is used to create an EventBridge rule for Amazon ECS service deployment state change events. For more information about creating an EventBridge rule, see [Getting started with Amazon EventBridge](#) in the *Amazon EventBridge User Guide*.

```
{
  "source": [
    "aws.ecs"
  ],
  "detail-type": [
    "ECS Deployment State Change"
  ]
}
```

```
]
}
```

Amazon ECS sends events with INFO and ERROR event types. For more information, see [Amazon ECS service action events](#)

The following are the service deployment state change events.

#### SERVICE\_DEPLOYMENT\_IN\_PROGRESS

The service deployment is in progress. This event is sent for both initial deployments and rollback deployments.

#### SERVICE\_DEPLOYMENT\_COMPLETED

The service deployment has completed. This event is sent once a service reaches a steady state after a deployment.

#### SERVICE\_DEPLOYMENT\_FAILED

The service deployment has failed. This event is sent for services with deployment circuit breaker logic turned on.

### Example service deployment in progress event

Service deployment in progress events are delivered when both an initial and a rollback deployment is started. The difference between the two is in the `reason` field. For more information about EventBridge parameters, see [AWS service event metadata](#) in the *Amazon EventBridge User Guide*.

The following shows an example output for an initial deployment starting.

```
{
  "version": "0",
  "id": "ddca6449-b258-46c0-8653-e0e3a6EXAMPLE",
  "detail-type": "ECS Deployment State Change",
  "source": "aws.ecs",
  "account": "111122223333",
  "time": "2020-05-23T12:31:14Z",
  "region": "us-west-2",
  "resources": [
```

```

        "arn:aws:ecs:us-west-2:111122223333:service/default/servicetest"
    ],
    "detail": {
        "eventType": "INFO",
        "eventName": "SERVICE_DEPLOYMENT_IN_PROGRESS",
        "deploymentId": "ecs-svc/123",
        "updatedAt": "2020-05-23T11:11:11Z",
        "reason": "ECS deployment deploymentId in progress."
    }
}

```

The following shows an example output for a rollback deployment starting. The reason field provides the ID of the deployment the service is rolling back to.

```

{
    "version": "0",
    "id": "ddca6449-b258-46c0-8653-e0e3aEXAMPLE",
    "detail-type": "ECS Deployment State Change",
    "source": "aws.ecs",
    "account": "111122223333",
    "time": "2020-05-23T12:31:14Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:ecs:us-west-2:111122223333:service/default/servicetest"
    ],
    "detail": {
        "eventType": "INFO",
        "eventName": "SERVICE_DEPLOYMENT_IN_PROGRESS",
        "deploymentId": "ecs-svc/123",
        "updatedAt": "2020-05-23T11:11:11Z",
        "reason": "ECS deployment circuit breaker: rolling back to
deploymentId deploymentID."
    }
}

```

## Example service deployment completed event

Service deployment completed state events are delivered in the following format. For more information, see [Deploy Amazon ECS services by replacing tasks](#).

```

{
    "version": "0",

```

```

    "id": "ddca6449-b258-46c0-8653-e0e3aEXAMPLE",
    "detail-type": "ECS Deployment State Change",
    "source": "aws.ecs",
    "account": "111122223333",
    "time": "2020-05-23T12:31:14Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:ecs:us-west-2:111122223333:service/default/servicetest"
    ],
    "detail": {
        "eventType": "INFO",
        "eventName": "SERVICE_DEPLOYMENT_COMPLETED",
        "deploymentId": "ecs-svc/123",
        "updatedAt": "2020-05-23T11:11:11Z",
        "reason": "ECS deployment deploymentID completed."
    }
}

```

### Example service deployment failed event

Service deployment failed state events are delivered in the following format. A service deployment failed state event will only be sent for services that have deployment circuit breaker logic turned on. For more information, see [Deploy Amazon ECS services by replacing tasks](#).

```

{
    "version": "0",
    "id": "ddca6449-b258-46c0-8653-e0e3aEXAMPLE",
    "detail-type": "ECS Deployment State Change",
    "source": "aws.ecs",
    "account": "111122223333",
    "time": "2020-05-23T12:31:14Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:ecs:us-west-2:111122223333:service/default/servicetest"
    ],
    "detail": {
        "eventType": "ERROR",
        "eventName": "SERVICE_DEPLOYMENT_FAILED",
        "deploymentId": "ecs-svc/123",
        "updatedAt": "2020-05-23T11:11:11Z",
        "reason": "ECS deployment circuit breaker: task failed to start."
    }
}

```

## Amazon ECS service deployment hook state change events

Amazon ECS sends hook state change events with the detail type **ECS Hook State Change**. These events are emitted when a deployment lifecycle hook changes status. The following is an event pattern that is used to create an EventBridge rule for Amazon ECS hook state change events.

```
{
  "source": [
    "aws.ecs"
  ],
  "detail-type": [
    "ECS Hook State Change"
  ]
}
```

The following are the hook state change events.

### HOOK\_IN\_PROGRESS

A hook is in progress.

### HOOK\_AWAITING\_ACTION

A pause hook has started and requires action to complete. Call `ContinueServiceDeployment` to continue or roll back the deployment.

### HOOK\_SUCCEEDED

The hook completed successfully. For pause hooks, this means `ContinueServiceDeployment` was called with the `CONTINUE` action.

### HOOK\_FAILED

The hook failed. For pause hooks, this means `ContinueServiceDeployment` was called with the `ROLLBACK` action.

### HOOK\_TIMED\_OUT

A hook timed out without completing.

## Example hook awaiting action event

The following shows an example event when a pause hook starts and is awaiting action.

```
{
  "version": "0",
  "id": "3329f79b-3dca-07f8-b1c2-5fe99f0b5e87",
  "detail-type": "ECS Hook State Change",
  "source": "aws.ecs",
  "account": "123456789012",
  "time": "2026-03-05T15:54:41Z",
  "region": "us-west-2",
  "resources": ["arn:aws:ecs:us-west-2:123456789012:service-deployment/my-cluster/my-
service/0EYSiB0qap8xf0N76FsbE"],
  "detail": {
    "eventType": "INFO",
    "eventName": "HOOK_AWAITING_ACTION",
    "hookId": "ecs-pause-e7tK9G_WRJqNF_EOMjztDXfKenlJuEUVjsNSTf4WLKw",
    "hookType": "PAUSE",
    "expiresAt": "2026-03-05T16:04:41Z",
    "lifecycleStage": "POST_TEST_TRAFFIC_SHIFT",
    "clusterArn": "arn:aws:ecs:us-west-2:123456789012:cluster/my-cluster",
    "serviceArn": "arn:aws:ecs:us-west-2:123456789012:service/my-cluster/my-
service",
    "serviceDeploymentArn": "arn:aws:ecs:us-west-2:123456789012:service-deployment/
my-cluster/my-service/0EYSiB0qap8xf0N76FsbE",
    "updatedAt": "2026-03-05T15:54:41.618059641Z"
  }
}
```

## Amazon ECS container instance health change events

The following scenarios cause container instance health change events.

### The Amazon ECS container agent detects a change in container runtime health.

The container agent periodically evaluates the health of the container runtime (for example, the Docker daemon) on the container instance. If the runtime becomes unresponsive or recovers, the agent reports the change and an event is generated.

Availability: EC2 launch type.

### The Amazon ECS container agent detects a change in accelerated compute device health.

On instances with accelerated compute devices such as GPUs, the container agent monitors device health. If a device becomes impaired or recovers, an event is generated.

Availability: Amazon ECS Managed Instances launch type.

### **The Amazon ECS container agent detects a change in daemon health.**

The container agent monitors required daemon tasks on the container instance. If a daemon task fails, an event is generated.

Availability: Amazon ECS Managed Instances launch type.

### **The Amazon ECS container agent loses connectivity to the Amazon ECS control plane.**

Amazon ECS continuously monitors the connectivity between the container agent and the Amazon ECS control plane. When a container instance remains disconnected beyond a threshold, Amazon ECS marks the instance as impaired.

Availability: Amazon ECS Managed Instances, AWS Fargate, and Amazon EC2 launch types.

### **The overall health status of the container instance changes.**

Amazon ECS computes an overall health status from the individual health check results. When the overall status transitions, an event is generated.

Availability: Amazon ECS Managed Instances and EC2 launch type.

### **Example container instance health change event**

Container instance health change events are delivered in the following format. For more information about parameters, see [AWS service event metadata](#) in the *User Guide*.

### **Sample container runtime health event**

```
{
  "version": "0",
  "id": "EXAMPLE-48f8-c0ff-0dab-EXAMPLE2ac34",
  "detail-type": "ECS Container Instance Health Change",

        "statusReason": "Agent disconnected since 2026-07-29T22:34:13Z"
      }
    ]
  }
}
```

## Handling Amazon ECS events

Amazon ECS sends events on an *at least once* basis. This means you might receive multiple copies of a given event. Additionally, events may not be delivered to your event listeners in the order in which the events occurred.

To order of events properly, the `detail` section of each event contains a `version` property. Each time a resource changes state, this `version` is incremented. Duplicate events have the same `version` in the `detail` object. If you are replicating your Amazon ECS container instance and

task state with EventBridge, you can compare the version of a resource reported by the Amazon ECS APIs with the version reported in EventBridge for the resource to verify that the version in your event stream is current. Events with a higher version property number should be treated as occurring later than events with lower version numbers.

## Example: Handling events in an AWS Lambda function

The following example shows a Lambda function written in Python 3.9 that captures both task and container instance state change events and saves them to one of two Amazon DynamoDB tables:

- *ECSCtrInstanceState* – Stores the latest state for a container instance. The table ID is the `containerInstanceArn` value of the container instance.
- *ECSTaskState* – Stores the latest state for a task. The table ID is the `taskArn` value of the task.

```
import json
import boto3

def lambda_handler(event, context):
    id_name = ""
    new_record = {}

    # For debugging so you can see raw event format.
    print('Here is the event:')
    print((json.dumps(event)))

    if event["source"] != "aws.ecs":
        raise ValueError("Function only supports input from events with a source type of: aws.ecs")

    # Switch on task/container events.
    table_name = ""
    if event["detail-type"] == "ECS Task State Change":
        table_name = "ECSTaskState"
        id_name = "taskArn"
        event_id = event["detail"]["taskArn"]
    elif event["detail-type"] == "ECS Container Instance State Change":
        table_name = "ECSCtrInstanceState"
        id_name = "containerInstanceArn"
        event_id = event["detail"]["containerInstanceArn"]
    else:
```

```

        raise ValueError("detail-type for event is not a supported type. Exiting
without saving event.")

    new_record["cw_version"] = event["version"]
    new_record.update(event["detail"])

    # "status" is a reserved word in DDB, but it appears in containerPort
    # state change messages.
    if "status" in event:
        new_record["current_status"] = event["status"]
        new_record.pop("status")

    # Look first to see if you have received a newer version of an event ID.
    # If the version is OLDER than what you have on file, do not process it.
    # Otherwise, update the associated record with this latest information.
    print("Looking for recent event with same ID...")
    dynamodb = boto3.resource("dynamodb", region_name="us-east-1")
    table = dynamodb.Table(table_name)
    saved_event = table.get_item(
        Key={
            id_name : event_id
        }
    )
    if "Item" in saved_event:
        # Compare events and reconcile.
        print(("EXISTING EVENT DETECTED: Id " + event_id + " - reconciling"))
        if saved_event["Item"]["version"] < event["detail"]["version"]:
            print("Received event is a more recent version than the stored event -
updating")
            table.put_item(
                Item=new_record
            )
        else:
            print("Received event is an older version than the stored event -
ignoring")
        else:
            print(("Saving new event - ID " + event_id))

            table.put_item(
                Item=new_record
            )

```

The following Fargate example shows a Lambda function written in Python 3.9 that captures task state change events and saves them to the following Amazon DynamoDB table:

```
import json
import boto3

def lambda_handler(event, context):
    id_name = ""
    new_record = {}

    # For debugging so you can see raw event format.
    print('Here is the event:')
    print((json.dumps(event)))

    if event["source"] != "aws.ecs":
        raise ValueError("Function only supports input from events with a source type of: aws.ecs")

    # Switch on task/container events.
    table_name = ""
    if event["detail-type"] == "ECS Task State Change":
        table_name = "ECSTaskState"
        id_name = "taskArn"
        event_id = event["detail"]["taskArn"]
    else:
        raise ValueError("detail-type for event is not a supported type. Exiting without saving event.")

    new_record["cw_version"] = event["version"]
    new_record.update(event["detail"])

    # "status" is a reserved word in DDB, but it appears in containerPort
    # state change messages.
    if "status" in event:
        new_record["current_status"] = event["status"]
        new_record.pop("status")

    # Look first to see if you have received a newer version of an event ID.
    # If the version is OLDER than what you have on file, do not process it.
    # Otherwise, update the associated record with this latest information.
    print("Looking for recent event with same ID...")
    dynamodb = boto3.resource("dynamodb", region_name="us-east-1")
```

```
table = dynamodb.Table(table_name)
saved_event = table.get_item(
    Key={
        id_name : event_id
    }
)
if "Item" in saved_event:
    # Compare events and reconcile.
    print(("EXISTING EVENT DETECTED: Id " + event_id + " - reconciling"))
    if saved_event["Item"]["version"] < event["detail"]["version"]:
        print("Received event is a more recent version than the stored event -
updating")
        table.put_item(
            Item=new_record
        )
    else:
        print("Received event is an older version than the stored event -
ignoring")
else:
    print(("Saving new event - ID " + event_id))

    table.put_item(
        Item=new_record
    )
```

## Monitor Amazon ECS containers using Container Insights with enhanced observability

Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. Container Insights with enhanced observability provides all the Container Insights metrics, plus additional task and container metrics.

Container Insights discovers all the running containers in a cluster and collects performance data at every layer of the performance stack. Operational data is collected as performance log events. These are entries that use a structured JSON schema for high-cardinality data to be ingested and stored at scale. From this data, CloudWatch creates higher-level aggregated metrics at the cluster, service, and task level as CloudWatch metrics. The metrics include utilization for resources such as CPU, memory, disk, and network. The metrics are available in CloudWatch automatic dashboards.

The metrics only reflect the resources with running tasks during the specified time range. For example, if you have a cluster with one service in it but that service has no tasks in a RUNNING

state, there will be no metrics sent to CloudWatch. If you have two services and one of them has running tasks and the other doesn't, only the metrics for the service with running tasks will be sent.

On December 2, 2024, AWS released Container Insights with enhanced observability for Amazon ECS. This version supports enhanced observability for Amazon ECS clusters using the Amazon EC2 and Fargates. After you configure Container Insights with enhanced observability on Amazon ECS, Container Insights auto-collects detailed infrastructure telemetry from the cluster level down to the container level in your environment and displays these critical performance data in curated dashboards removing the heavy lifting in observability set-up. For information about how to set up Container Insights with enhanced observability, see [Container Insights with enhanced observability](#).

We recommend that you use Container Insights with enhanced observability instead of Container Insights because it provides detailed visibility in your container environment, reducing the mean time to resolution. For more information, see [Amazon ECS Container Insights with enhanced observability metrics](#) in the *Amazon CloudWatch User Guide*.

The events that you can view are the ones that Amazon ECS sends to Amazon EventBridge. For more information, see [Amazon ECS events](#).

 **Important**

Beginning October 1, 2026, you aren't billed for the RunningTaskCount metric in CloudWatch Container Insights, regardless of the number of Amazon ECS services or clusters in your account.  
Other metrics collected by CloudWatch Container Insights are charged as custom metrics. For more information about CloudWatch pricing, see [CloudWatch Pricing](#).

## Additional metrics for Amazon ECS Managed Instances

The following table lists the additional metrics available for Amazon ECS Managed Instances when using Container Insights.

| Metric             | Description                                                  | Dimensions                                      | Unit    |
|--------------------|--------------------------------------------------------------|-------------------------------------------------|---------|
| Instance0SFilesyst | The percentage of total disk space that is used (os volume). | ClusterName - when ContainerInsights is enabled | Percent |

| Metric                            | Description                                                    | Dimensions                                                                                                                                                                                                                                                       | Unit    |
|-----------------------------------|----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| emUtilization                     |                                                                | <p>ClusterName , CapacityProviderName - when ContainerInsights is enabled</p> <p>ClusterName , CapacityProviderName , ContainerInstanceId , EC2InstanceId - when EnhancedContainerInsights is enabled</p>                                                        |         |
| InstanceDataFilesystemUtilization | The percentage of total disk space that is used (data volume). | <p>ClusterName - when ContainerInsights is enabled</p> <p>ClusterName , CapacityProviderName - when ContainerInsights is enabled</p> <p>ClusterName , CapacityProviderName , ContainerInstanceId , EC2InstanceId - when EnhancedContainerInsights is enabled</p> | Percent |

| Metric                | Description                                                                                                                                                                    | Dimensions                                                                                                                                                                                                                                                                       | Unit  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| InstanceGPULimit      | The total number of GPUs available on the instance. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types.                      | <p>ClusterName - when EnhancedContainerInsights is enabled</p> <p>ClusterName , CapacityProviderName - when EnhancedContainerInsights is enabled</p> <p>ClusterName , CapacityProviderName , ContainerInstanceId , EC2InstanceId - when EnhancedContainerInsights is enabled</p> | Count |
| InstanceGPUUsageTotal | The number of GPUs currently allocated to running tasks on the instance. Available only for Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types. | <p>ClusterName - when EnhancedContainerInsights is enabled</p> <p>ClusterName , CapacityProviderName - when EnhancedContainerInsights is enabled</p> <p>ClusterName , CapacityProviderName , ContainerInstanceId , EC2InstanceId - when EnhancedContainerInsights is enabled</p> | Count |

## GPU application restart metrics

For Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types, the TaskGPURestartAppXidCount and ContainerGPURestartAppXidCount metrics count

NVIDIA Xid errors whose immediate-action resolution bucket is `RESTART_APP`. These Xids indicate application-level faults where NVIDIA recommends restarting the affected application rather than the instance. Use these metrics to detect transient GPU faults affecting a specific task or container without implying underlying hardware failure.

The following Xid codes are included. For the complete list and descriptions, see the [NVIDIA Xid Errors](#) documentation.

| Xid | Error type                              |
|-----|-----------------------------------------|
| 8   | GPU stopped processing                  |
| 11  | Invalid or corrupted push buffer stream |
| 13  | Graphics Engine Exception               |
| 25  | ECC page retirement in progress         |
| 31  | GPU memory page fault                   |
| 32  | Invalid or corrupted push buffer stream |
| 39  | Bus error                               |
| 40  | Video processor exception               |
| 41  | Unexpected fault                        |
| 60  | Video processor exception               |
| 68  | Video processor exception               |
| 69  | Graphics Engine class error             |
| 70  | CE user channel error                   |
| 71  | GPU semaphore timeout                   |
| 72  | GPU semaphore access error              |
| 75  | Inforom page blacklist event            |

| <b>Xid</b> | <b>Error type</b>          |
|------------|----------------------------|
| 76         | Display engine error       |
| 77         | Display engine error       |
| 80         | Corrupted data sent to GPU |
| 82         | NVJPG error                |
| 83         | NVDEC error                |
| 84         | Mismatched SLI link        |
| 85         | Resource constraint        |
| 86         | Operating system error     |
| 88         | NVDEC error                |
| 89         | NVENC error                |
| 94         | Contained ECC error        |
| 96         | NVDEC error                |
| 97         | NVDEC error                |
| 98         | NVDEC error                |
| 99         | NVJPG error                |
| 100        | NVJPG error                |
| 101        | NVJPG error                |
| 102        | NVJPG error                |
| 103        | GSP RPC timeout            |
| 104        | GSP halt                   |

| Xid | Error type                                 |
|-----|--------------------------------------------|
| 105 | GSP error                                  |
| 126 | C2C NVLink replay error                    |
| 127 | C2C NVLink error                           |
| 128 | NVLink error                               |
| 129 | NVLink recovery error                      |
| 130 | NVLink fatal error                         |
| 131 | NVLink non-fatal error                     |
| 132 | NVLink error                               |
| 133 | NVLink error                               |
| 134 | NVLink error                               |
| 135 | NVLink error                               |
| 139 | GPU memory page retirement recording event |

## Monitoring Amazon ECS Managed Instances

Monitoring is an important part of maintaining the reliability, availability, and performance of your Amazon ECS Managed Instances workloads. AWS provides several tools and services to help you monitor your containerized applications and infrastructure.

### Container Insights monitoring

CloudWatch Container Insights provides comprehensive monitoring for your containerized applications and microservices. Container Insights automatically collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices running on Amazon ECS Managed Instances.

Container Insights collects metrics at the cluster, service, and task level, providing visibility into:

- CPU and memory utilization
- Network performance metrics
- Storage utilization
- Task and service performance

The metrics are available in CloudWatch dashboards and can be used to create alarms and automated responses to performance issues. Container Insights also provides enhanced monitoring capabilities that help you identify and troubleshoot issues quickly.

 **Note**

Container Insights comes at an additional cost. For more information about pricing, see [CloudWatch pricing](#).

## GPU monitoring

For Amazon ECS Managed Instances running NVIDIA GPU-enabled Amazon EC2 instance types, Container Insights with enhanced observability collects GPU metrics from NVIDIA Data Center GPU Manager (DCGM) at the container, task, and instance levels. GPU metrics are not collected with basic Container Insights; enable enhanced observability to access GPU telemetry.

No additional agent installation is required. GPU metrics are collected automatically on supported instance types when Container Insights with enhanced observability is enabled on the cluster.

For the list of GPU metrics and dimensions, see [Amazon ECS Container Insights with enhanced observability metrics](#).

## Instance monitoring

For monitoring the underlying infrastructure that supports your Amazon ECS Managed Instances workloads, you can use Amazon EC2 metrics available through CloudWatch.

Amazon ECS Managed Instances come with two Amazon EBS volumes:

- Root volume used for the OS filesystem
- Data volume used by the applications

When Container Insights is enabled, Amazon ECS automatically publishes instance-level OS and data filesystem utilization metrics.

Available metrics for Amazon ECS Managed Instances include:

- Amazon EC2 metrics: CPU utilization, network performance, disk operations, and status checks. For more information, see [Monitor your instances using CloudWatch](#)
- Amazon ECS metrics (when Container Insights is enabled): OS and data volume file system utilization. For more information, see [Amazon ECS Container Insights metrics](#)
- Amazon EBS metrics: IOPS, throughput, read and write latency. For more information, see [Amazon EBS CloudWatch metrics](#)

These metrics are automatically available without manual agent installation.

### Detailed monitoring for Amazon ECS Managed Instances

CloudWatch provides two categories of monitoring: *basic monitoring* and *detailed monitoring*. By default, your managed instance is configured for basic monitoring. You can optionally enable detailed monitoring to help you more quickly identify and act on operational issues. You can turn on or off detailed monitoring when you create or update a Amazon ECS Managed Instances capacity provider.

Enabling detailed monitoring on a managed instance does not affect the monitoring of its attached Amazon EBS volumes.

The following table highlights the differences between basic monitoring and detailed monitoring for your managed instances.

| Monitoring type     | Description                                                                                                                                                                                    | Charges                                                               |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| Basic monitoring    | Status check metrics are available in 1-minute periods. All other metrics are available in 5-minute periods.                                                                                   | No charge.                                                            |
| Detailed monitoring | All metrics, including status check metrics, are available in 1-minute periods. To get this level of data, you must specifically enable it for the managed instance. For the managed instances | You are charged per metric that Amazon ECS Managed Instances sends to |

| Monitoring type | Description                                                                                                            | Charges                                                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | where you've enabled detailed monitoring, you can also get aggregated data across groups of similar managed instances. | CloudWatch. You are not charged for data storage. For more information, see <b>Paid tier</b> and <b>Example 1 - EC2 Detailed Monitoring</b> on the <a href="#">CloudWatch pricing page</a> . |

### Required permissions

To enable detailed monitoring for a managed instance, your user must have permission to use the `MonitorInstances` API action. To turn off detailed monitoring for a managed instance, your user must have permission to use the `UnmonitorInstances` API action.

## Determine Amazon ECS task health using container health checks

When you create a task definition, you can configure a health check for your containers. Health checks are commands that run locally on a container and validate application health and availability.

The Amazon ECS container agent only monitors and reports on the health checks that are specified in the task definition. Amazon ECS doesn't monitor Docker health checks that are embedded in a container image but aren't specified in the container definition. Health check parameters that are specified in a container definition override any Docker health checks that exist in the container image.

When a health check is defined in a task definition, the container runs the health check process inside the container, and then evaluate the exit code to determine the application health.

The health check consists the following parameters:

- **Command** – The command that the container runs to determine if it's healthy. The string array can start with `CMD` to run the command arguments directly, or `CMD-SHELL` to run the command

with the container's default shell. Use `CMD-SHELL` when you need shell features like pipes, redirects, command chaining, or environment variable expansion. For example, `CMD-SHELL` allows you to use commands like `curl -f http://localhost/ || exit 1` where the shell interprets the `||` operator. Use `CMD` for simple commands that don't require shell interpretation.

- **Interval** – The period of time (in seconds) between each health check.
- **Timeout** – The period of time (in seconds) to wait for a health check to succeed before it's considered a failure.
- **Retries** – The number of times to retry a failed health check before the container is considered unhealthy.
- **Start period** – The optional grace period to provide containers time to bootstrap in before failed health checks count towards the maximum number of retries.

If a health check succeeds within the `startPeriod`, then the container is considered healthy and any subsequent failures count toward the maximum number of retries.

For information about how to specify a health check in a task definition, see [Health check](#).

The following describes the possible health status values for a container:

- **HEALTHY**–The container health check has passed successfully.
- **UNHEALTHY**–The container health check has failed.
- **UNKNOWN**–The container health check is being evaluated, there's no container health check defined, or Amazon ECS doesn't have the health status of the container.

The health check commands run on the container. Therefore you must include the commands in the container image.

The health check connects to the application through the container's loopback interface at `localhost` or `127.0.0.1`. An exit code of `0` indicates success, and non-zero exit code indicates failure.

Consider the following when using container health checks:

- Container health checks require version 1.17.0 or greater of the Amazon ECS container agent.
- Container health checks are supported for Fargate tasks if you're using Linux platform version 1.1.0 or greater or Windows platform version 1.1.0 or greater

## How Amazon ECS determines task health

Containers that are essential and have health check command in the task definition are the only ones considered to determine the task health.

The following rules are evaluated in order:

1. If the status of one essential container is `UNHEALTHY`, then the task status is `UNHEALTHY`.
2. If the status of one essential container is `UNKNOWN`, then the task status is `UNKNOWN`.
3. If the status of all essential containers are `HEALTHY`, then the task status is `HEALTHY`.

Consider the following task health example with 2 essential containers.

| Container 1 health | Container 2 health | Task health |
|--------------------|--------------------|-------------|
| UNHEALTHY          | UNKNOWN            | UNHEALTHY   |
| UNHEALTHY          | HEALTHY            | UNHEALTHY   |
| HEALTHY            | UNKNOWN            | UNKNOWN     |
| HEALTHY            | HEALTHY            | HEALTHY     |

Consider the following task health example with 3 containers.

| Container 1 health | Container 2 health | Container 3 health | Task health |
|--------------------|--------------------|--------------------|-------------|
| UNHEALTHY          | UNKNOWN            | UNKNOWN            | UNHEALTHY   |
| UNHEALTHY          | UNKNOWN            | HEALTHY            | UNHEALTHY   |
| UNHEALTHY          | HEALTHY            | HEALTHY            | UNHEALTHY   |
| HEALTHY            | UNKNOWN            | HEALTHY            | UNKNOWN     |
| HEALTHY            | UNKNOWN            | UNKNOWN            | UNKNOWN     |
| HEALTHY            | HEALTHY            | HEALTHY            | HEALTHY     |

## How health checks are affected by agent disconnects

If the Amazon ECS container agent becomes disconnected from the Amazon ECS service, this won't cause a container to transition to an UNHEALTHY status. This is by design, to ensure that containers remain running during agent restarts or temporary unavailability. The health check status is the "last heard from" response from the Amazon ECS agent, so if the container was considered HEALTHY prior to the disconnect, that status will remain until the agent reconnects and another health check occurs. There are no assumptions made about the status of the container health checks.

## Viewing Amazon ECS container health

You can view the container health in the console, and using the API in the `DescribeTasks` response. For more information, see [DescribeTasks](#) in the *Amazon Elastic Container Service API Reference*.

If you use logging for your container, for example Amazon CloudWatch Logs, you can configure the health check command to forward the container health output to your logs. Make sure to use `2&1` to catch both the `stdout` and `stderr` information. The following example uses `CMD-SHELL` because it requires shell features like the pipe (`>>`) and logical OR (`|`) operators:

```
"command": [  
    "CMD-SHELL",  
    "curl -f http://localhost/ >> /proc/1/fd/1 2>&1 || exit 1"  
],
```

## Monitor Amazon ECS container instance health

Amazon ECS provides container instance health monitoring. You can quickly determine whether Amazon ECS has detected any problems that might prevent your container instances from running containers. Amazon ECS performs automated checks on every running container instance with agent version `1.57.0` or later to identify issues. For more information on verifying the agent version on a container instance, see [Updating the Amazon ECS container agent](#).

You must be using AWS CLI version `1.22.3` or later or AWS CLI version `2.3.6` or later. For information about how to update the AWS CLI, see [Installing or updating the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide Version 2*.

To view the container instance health, run `describe-container-instances` with the `CONTAINER_INSTANCE_HEALTH` option.

The `overallStatus` is determined by the individual health check statuses in the `details` array. The most severe status takes precedence in the following order: `IMPAIRED`, `INSUFFICIENT_DATA`, `INITIALIZING`, and `OK`.

The following are the valid values for `overallStatus`:

- `OK` – All health checks are passing.
- `IMPAIRED` – One or more health checks have failed.
- `INSUFFICIENT_DATA` – Data for one or more health checks is unavailable.
- `INITIALIZING` – One or more health checks are being initialized.

The health check type values include:

- `CONTAINER_RUNTIME` – Monitors the health of the container runtime (for example, the Docker daemon). Available on EC2 launch type.
- `ACCELERATED_COMPUTE` – Monitors the health of accelerated compute devices such as GPUs. When a GPU is impaired, the `statusReason` contains the NVIDIA Xid error code in the format `XID_<number>`. Available on Amazon ECS Managed Instances launch type.
- `DAEMON` – Monitors the health of required daemon tasks on the container instance. Available on Amazon ECS Managed Instances launch type.
- `AGENT_CONNECTIVITY` – Monitors the connectivity between the Amazon ECS container agent and the Amazon ECS control plane. Available on Amazon ECS Managed Instances, AWS Fargate, and Amazon EC2 launch types.

You can also monitor health status changes through events. For more information, see [Amazon ECS container instance health change events](#).

The following is an example of how to run `describe-container-instances`.

```
aws ecs describe-container-instances \
  --cluster cluster_name \
  --container-instances 47279cd2cadb41cbaef2dcEXAMPLE \
  --include CONTAINER_INSTANCE_HEALTH
```

The following is an example of the health status object in the output.

```
"healthStatus": {  
  "overallStatus": "OK",  
  "details": [{  
    "type": "CONTAINER_RUNTIME",  
    "status": "OK",  
    "lastUpdated": "2021-11-10T03:30:26+00:00",  
    "lastStatusChange": "2021-11-10T03:26:41+00:00"  
  }]  
}
```

## Container instance-health issues

When the overallStatus any status other than OK, try the following:

- Wait, and then run `describe-container-instances`
- View your container instance health in the EC2 console or by using the CLI.
- Review the CloudWatch metrics. For more information, see [Monitor Amazon ECS using CloudWatch](#)
- Check the AWS Health Dashboard to see if there are any issues with the service.

## Identify Amazon ECS optimization opportunities using application trace data

Amazon ECS integrates with AWS Distro for OpenTelemetry to collect trace data from your application. Amazon ECS uses an AWS Distro for OpenTelemetry sidecar container to collect and route trace data to AWS X-Ray. For more information, see [Setting up AWS Distro for OpenTelemetry Collector in Amazon ECS](#). You can then use AWS X-Ray to identify errors and exceptions, analyze performance bottlenecks and response times.

For the AWS Distro for OpenTelemetry Collector to send trace data to AWS X-Ray, your application must be configured to create the trace data. For more information, see [Instrumenting your application for AWS X-Ray](#) in the *AWS X-Ray Developer Guide*.

## Required IAM permissions for AWS Distro for OpenTelemetry integration with AWS X-Ray

The Amazon ECS integration with AWS Distro for OpenTelemetry requires that you create a task role and specify the role in your task definition. We recommend that you configure the AWS Distro for OpenTelemetry sidecar to route container logs to CloudWatch Logs.

### Important

If you also collect application metrics using the AWS Distro for OpenTelemetry integration, ensure your task IAM role also contains the permissions necessary for that integration. For more information, see [Correlate Amazon ECS application performance using application metrics](#).

After you create the role, create a policy with the following permissions, and then attach it to the role.

- `logs:PutLogEvents`
- `logs:CreateLogGroup`
- `logs:CreateLogStream`
- `logs:DescribeLogStreams`
- `logs:DescribeLogGroups`
- `logs:PutRetentionPolicy`
- `xray:PutTraceSegments`
- `xray:PutTelemetryRecords`
- `xray:GetSamplingRules`
- `xray:GetSamplingTargets`
- `xray:GetSamplingStatisticSummaries`
- `ssm:GetParameters`

## Specifying the AWS Distro for OpenTelemetry sidecar for AWS X-Ray integration in your task definition

The Amazon ECS console simplifies creating the AWS Distro for OpenTelemetry sidecar container by using the **Use trace collection** option. For more information, see [Creating an Amazon ECS task definition using the console](#).

If you're not using the Amazon ECS console, you can add the AWS Distro for OpenTelemetry sidecar container to your task definition. The following task definition snippet shows the container definition for adding the AWS Distro for OpenTelemetry sidecar for AWS X-Ray integration.

```
{
  "family": "otel-using-xray",
  "taskRoleArn": "arn:aws:iam::111122223333:role/AmazonECS_OpenTelemetryXrayRole",
  "executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole",
  "containerDefinitions": [{
    "name": "aws-otel-emitter",
    "image": "application-image",
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
        "awslogs-create-group": "true",
        "awslogs-group": "/ecs/aws-otel-emitter",
        "awslogs-region": "us-east-1",
        "awslogs-stream-prefix": "ecs"
      }
    },
    "dependsOn": [{
      "containerName": "aws-otel-collector",
      "condition": "START"
    }]
  },
  {
    "name": "aws-otel-collector",
    "image": "public.ecr.aws/aws-observability/aws-otel-collector:v0.30.0",
    "essential": true,
    "command": [
      "--config=/etc/ecs/otel-instance-metrics-config.yaml"
    ],
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
```

```
    "awslogs-create-group": "True",
    "awslogs-group": "/ecs/ecs-aws-otel-sidecar-collector",
    "awslogs-region": "us-east-1",
    "awslogs-stream-prefix": "ecs"
  }
}
],
"networkMode": "awsvpc",
"requiresCompatibilities": [
  "FARGATE"
],
"cpu": "1024",
"memory": "3072"
}
```

## Correlate Amazon ECS application performance using application metrics

Amazon ECS on Fargate supports collecting metrics from your applications running on Fargate and exporting them to either Amazon CloudWatch or Amazon Managed Service for Prometheus.

You can use the collected metadata to correlate application performance data with underlying infrastructure data, reducing the mean time to resolve the problem.

Amazon ECS uses an AWS Distro for OpenTelemetry sidecar container to collect and route your application metrics to the destination. The Amazon ECS console experience simplifies the process of adding this integration when creating your task definitions.

### Topics

- [Exporting application metrics to Amazon CloudWatch](#)
- [Exporting application metrics to Amazon Managed Service for Prometheus](#)

## Exporting application metrics to Amazon CloudWatch

Amazon ECS on Fargate supports exporting your custom application metrics to Amazon CloudWatch as custom metrics. This is done by adding the AWS Distro for OpenTelemetry sidecar container to your task definition. The Amazon ECS console simplifies this process by adding the **Use**

**metric collection** option when creating a new task definition. For more information, see [Creating an Amazon ECS task definition using the console](#).

The application metrics are exported to CloudWatch Logs with log group name `/aws/ecs/application/metrics` and the metrics can be viewed in the `ECS/AWSOTel/Application` namespace. Your application must be instrumented with the OpenTelemetry SDK. For more information, see [Introduction to AWS Distro for OpenTelemetry](#) in the AWS Distro for OpenTelemetry documentation.

## Considerations

The following should be considered when using the Amazon ECS on Fargate integration with AWS Distro for OpenTelemetry to send application metrics to Amazon CloudWatch.

- This integration only sends your custom application metrics to CloudWatch. If you want task-level metrics, you can turn on Container Insights in the Amazon ECS cluster configuration. For more information, see [Monitor Amazon ECS containers using Container Insights with enhanced observability](#).
- The AWS Distro for OpenTelemetry integration is supported for Amazon ECS workloads hosted on Fargate and Amazon ECS workloads hosted on Amazon EC2 instances. External instances aren't currently supported.
- CloudWatch supports a maximum of 30 dimensions per metric. By default, Amazon ECS defaults to including the `TaskARN`, `ClusterARN`, `LaunchType`, `TaskDefinitionFamily`, and `TaskDefinitionRevision` dimensions to the metrics. The remaining 25 dimensions can be defined by your application. If more than 30 dimensions are configured, CloudWatch can't display them. When this occurs, the application metrics will appear in the `ECS/AWSOTel/Application` CloudWatch metric namespace but without any dimensions. You can instrument your application to add additional dimensions. For more information, see [Using CloudWatch metrics with AWS Distro for OpenTelemetry](#) in the AWS Distro for OpenTelemetry documentation.

## Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon CloudWatch

The Amazon ECS integration with AWS Distro for OpenTelemetry requires that you create a task IAM role and specify the role in your task definition. We recommend that the AWS Distro for OpenTelemetry sidecar also be configured to route container logs to CloudWatch Logs which

requires a task execution IAM role be created and specified in your task definition as well. The Amazon ECS console takes care of the task execution IAM role on your behalf, but the task IAM role must be created manually and added to your task definition. For more information about the task execution IAM role, see [Amazon ECS task execution IAM role](#).

### Important

If you're also collecting application trace data using the AWS Distro for OpenTelemetry integration, ensure your task IAM role also contains the permissions necessary for that integration. For more information, see [Identify Amazon ECS optimization opportunities using application trace data](#).

If your application requires any additional permissions, you should add them to this policy. Each task definition may only specify one task IAM role. For example, if you are using a custom configuration file stored in Systems Manager, you should add the `ssm:GetParameters` permission to this IAM policy.

## To create the service role for Elastic Container Service (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Service or use case**, choose **Elastic Container Service**, and then choose the **Elastic Container Service Task** use case.
5. Choose **Next**.
6. In the **Add permissions** section, search for **AWSDistroOpenTelemetryPolicyForXray**, then select the policy.
7. (Optional) Set a [permissions boundary](#). This is an advanced feature that is available for service roles, but not service-linked roles.
  - a. Open the **Set permissions boundary** section, and then choose **Use a permissions boundary to control the maximum role permissions**.

IAM includes a list of the AWS managed and customer-managed policies in your account.

- b. Select the policy to use for the permissions boundary.

8. Choose **Next**.
9. Enter a role name or a role name suffix to help you identify the purpose of the role.

 **Important**

When you name a role, note the following:

- Role names must be unique within your AWS account, and can't be made unique by case.

For example, don't create roles named both **PRODRROLE** and **prodrole**. When a role name is used in a policy or as part of an ARN, the role name is case sensitive, however when a role name appears to customers in the console, such as during the sign-in process, the role name is case insensitive.

- You can't edit the name of the role after it's created because other entities might reference the role.

10. (Optional) For **Description**, enter a description for the role.
11. (Optional) To edit the use cases and permissions for the role, in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections, choose **Edit**.
12. (Optional) To help identify, organize, or search for the role, add tags as key-value pairs. For more information about using tags in IAM, see [Tags for AWS Identity and Access Management resources](#) in the *IAM User Guide*.
13. Review the role, and then choose **Create role**.

## Specifying the AWS Distro for OpenTelemetry sidecar in your task definition

The Amazon ECS console simplifies the experience of creating the AWS Distro for OpenTelemetry sidecar container by using the **Use metric collection** option. For more information, see [Creating an Amazon ECS task definition using the console](#).

If you're not using the Amazon ECS console, you can add the AWS Distro for OpenTelemetry sidecar container to your task definition manually. The following task definition example shows the container definition for adding the AWS Distro for OpenTelemetry sidecar for Amazon CloudWatch integration.

```
{
```

```

"family": "otel-using-cloudwatch",
"taskRoleArn": "arn:aws:iam::111122223333:role/AmazonECS_OpenTelemetryCloudWatchRole",
"executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole",
"containerDefinitions": [
  {
    "name": "aws-otel-emitter",
    "image": "application-image",
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
        "awslogs-create-group": "true",
        "awslogs-group": "/ecs/aws-otel-emitter",
        "awslogs-region": "us-east-1",
        "awslogs-stream-prefix": "ecs"
      }
    },
    "dependsOn": [{
      "containerName": "aws-otel-collector",
      "condition": "START"
    }]
  },
  {
    "name": "aws-otel-collector",
    "image": "public.ecr.aws/aws-observability/aws-otel-collector:v0.30.0",
    "essential": true,
    "command": [
      "--config=/etc/ecs/ecs-cloudwatch.yaml"
    ],
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
        "awslogs-create-group": "True",
        "awslogs-group": "/ecs/ecs-aws-otel-sidecar-collector",
        "awslogs-region": "us-east-1",
        "awslogs-stream-prefix": "ecs"
      }
    }
  }
],
"networkMode": "awsvpc",
"requiresCompatibilities": [
  "FARGATE"
],
"cpu": "1024",

```

```
"memory": "3072"  
}
```

## Exporting application metrics to Amazon Managed Service for Prometheus

Amazon ECS supports exporting your task-level CPU, memory, network, and storage metrics and your custom application metrics to Amazon Managed Service for Prometheus. This is done by adding the AWS Distro for OpenTelemetry sidecar container to your task definition. The Amazon ECS console simplifies this process by adding the **Use metric collection** option when creating a new task definition. For more information, see [Creating an Amazon ECS task definition using the console](#).

The metrics are exported to Amazon Managed Service for Prometheus and can be viewed using the Amazon Managed Grafana dashboard. Your application must be instrumented with either Prometheus libraries or with the OpenTelemetry SDK. For more information about instrumenting your application with the OpenTelemetry SDK, see [Introduction to AWS Distro for OpenTelemetry](#) in the AWS Distro for OpenTelemetry documentation.

When using the Prometheus libraries, your application must expose a `/metrics` endpoint which is used to scrape the metrics data. For more information about instrumenting your application with Prometheus libraries, see [Prometheus client libraries](#) in the Prometheus documentation.

### Considerations

The following should be considered when using the Amazon ECS on Fargate integration with AWS Distro for OpenTelemetry to send application metrics to Amazon Managed Service for Prometheus.

- The AWS Distro for OpenTelemetry integration is supported for Amazon ECS workloads hosted on Fargate and Amazon ECS workloads hosted on Amazon EC2 instances. External instances aren't supported currently.
- By default, AWS Distro for OpenTelemetry includes all available task-level dimensions for your application metrics when exporting to Amazon Managed Service for Prometheus. You can also instrument your application to add additional dimensions. For more information, see [Getting Started with Prometheus Remote Write Exporter for Amazon Managed Service for Prometheus](#) in the AWS Distro for OpenTelemetry documentation.

## Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon Managed Service for Prometheus

The Amazon ECS integration with Amazon Managed Service for Prometheus using the AWS Distro for OpenTelemetry sidecar requires that you create a task IAM role and specify the role in your task definition. This task IAM role must be created manually prior to registering your task definition. For more information about creating a task role, see [Amazon ECS task IAM role](#).

We recommend that the AWS Distro for OpenTelemetry sidecar also be configured to route container logs to CloudWatch Logs which requires a task execution IAM role be created and specified in your task definition as well. The Amazon ECS console takes care of the task execution IAM role on your behalf, but the task IAM role must be created manually. For more information about creating a task execution IAM role, see [Amazon ECS task execution IAM role](#).

### Important

If you're also collecting application trace data using the AWS Distro for OpenTelemetry integration, ensure your task IAM role also contains the permissions necessary for that integration. For more information, see [Identify Amazon ECS optimization opportunities using application trace data](#).

The following permissions are required for AWS Distro for OpenTelemetry integration with Amazon Managed Service for Prometheus:

- logs:PutLogEvents
- logs:CreateLogGroup
- logs:CreateLogStream
- logs:DescribeLogStreams
- logs:DescribeLogGroups
- cloudwatch:PutMetricData

## Specifying the AWS Distro for OpenTelemetry sidecar in your task definition

The Amazon ECS console simplifies the experience of creating the AWS Distro for OpenTelemetry sidecar container by using the **Use metric collection** option. For more information, see [Creating an Amazon ECS task definition using the console](#).

If you're not using the Amazon ECS console, you can add the AWS Distro for OpenTelemetry sidecar container to your task definition manually. The following task definition example shows the container definition for adding the AWS Distro for OpenTelemetry sidecar for Amazon Managed Service for Prometheus integration.

```
{
  "family": "otel-using-cloudwatch",
  "taskRoleArn": "arn:aws:iam::111122223333:role/AmazonECS_OpenTelemetryCloudWatchRole",
  "executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole",
  "containerDefinitions": [{
    "name": "aws-otel-emitter",
    "image": "application-image",
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
        "awslogs-create-group": "true",
        "awslogs-group": "/ecs/aws-otel-emitter",
        "awslogs-region": "aws-region",
        "awslogs-stream-prefix": "ecs"
      }
    },
    "dependsOn": [{
      "containerName": "aws-otel-collector",
      "condition": "START"
    }]
  },
  {
    "name": "aws-otel-collector",
    "image": "public.ecr.aws/aws-observability/aws-otel-collector:v0.30.0",
    "essential": true,
    "command": [
      "--config=/etc/ecs/ecs-amp.yaml"
    ],
    "environment": [{
      "name": "AWS_PROMETHEUS_ENDPOINT",
      "value": "https://aps-workspaces.aws-region.amazonaws.com/workspaces/  
ws-a1b2c3d4-5678-90ab-cdef-EXAMPLE11111/api/v1/remote_write"
    }],
    "logConfiguration": {
      "logDriver": "awslogs",
      "options": {
        "awslogs-create-group": "True",
        "awslogs-group": "/ecs/ecs-aws-otel-sidecar-collector",
```

```
    "awslogs-region": "aws-region",
    "awslogs-stream-prefix": "ecs"
  }
}
],
"networkMode": "awsvpc",
"requiresCompatibilities": [
  "FARGATE"
],
"cpu": "1024",
"memory": "3072"
}
```

## Log Amazon ECS API calls using AWS CloudTrail

Amazon Elastic Container Service is integrated with [AWS CloudTrail](#), a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon ECS as events. The calls captured include calls from the Amazon ECS console and code calls to the Amazon ECS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon ECS, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see [Working with CloudTrail Event history](#) in the *AWS CloudTrail User Guide*. There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a [CloudTrail Lake](#) event data store.

## CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see [Creating a trail for your AWS account](#) and [Creating a trail for an organization](#) in the *AWS CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#). For information about Amazon S3 pricing, see [Amazon S3 Pricing](#).

## CloudTrail Lake event data stores

*CloudTrail Lake* lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to [Apache ORC](#) format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying [advanced event selectors](#). The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see [Working with AWS CloudTrail Lake](#) in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the [pricing option](#) you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#).

## Amazon ECS management events in CloudTrail

[Management events](#) provide information about management operations that are performed on resources in your AWS account. These are also known as control plane operations. By default, CloudTrail logs management events.

Amazon Elastic Container Service logs all Amazon ECS control plane operations as management events. For example, calls to the `CreateService`, `RunTask` and `DeleteCluster` sections

generate entries in the CloudTrail log files. For a list of the Amazon Elastic Container Service control plane operations that Amazon ECS logs to CloudTrail, see the [Amazon Elastic Container Service API Reference](#).

## Amazon ECS data events in CloudTrail

[Data events](#) provide information about the resource operations performed on or in a resource. By default, CloudTrail doesn't log data events. The CloudTrail **Event history** doesn't record data events.

Additional charges apply for data events. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#).

You can log data events for the Amazon ECS resource types by using the CloudTrail console, AWS CLI, or CloudTrail API operations. For more information about how to log data events, see [Logging data events with the AWS Management Console](#) and [Logging data events with the AWS Command Line Interface](#) in the *AWS CloudTrail User Guide*.

The following table lists the Amazon ECS resource types for which you can log data events. The **Data event type (console)** column shows the value to choose from the **Data event type** list on the CloudTrail console. The **resources.type value** column shows the `resources.type` value, which you would specify when configuring advanced event selectors using the AWS CLI or CloudTrail APIs. The **Data APIs logged to CloudTrail** column shows the API calls logged to CloudTrail for the resource type.

| Data event type (console) | resources.type value                     | Data APIs logged to CloudTrail                                                                                                                                                                                                                                                            |
|---------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AwsApiCall</b>         | <code>AWS::ECS::ContainerInstance</code> | <ul style="list-style-type: none"><li><code>ecs:Poll</code> (for EC2 and Amazon ECS Managed Instances)</li><li><code>ecs:StartTelemetrySession</code> (for EC2 and Amazon ECS Managed Instances)</li><li><code>ecs:PutSystemLogEvents</code> (for Amazon ECS Managed Instances)</li></ul> |

You can configure advanced event selectors to filter on the `eventName`, `readOnly`, and `resources.ARN` fields to log only those events that are important to you. For more information about these fields, see [AdvancedFieldSelector](#) in the *AWS CloudTrail API Reference*.

## Amazon ECS event examples

An event represents a single request from any source and includes information about the requested API operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so events don't appear in any specific order.

The following example shows a CloudTrail event that demonstrates the `CreateService` action.

### Note

This example has been formatted for improved readability. In a CloudTrail log file, all entries and events are concatenated into a single line. In addition, this example has been limited to a single Amazon ECS entry. In a real CloudTrail log file, you see entries and events from multiple AWS services.

```
{
  "eventVersion": "1.04",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AIDACKCEVSQ6C2EXAMPLE:account_name",
    "arn": "arn:aws:sts::123456789012:user/Mary_Major",
    "accountId": "123456789012",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "attributes": {
        "mfaAuthenticated": "false",
        "creationDate": "2018-06-20T18:32:25Z"
      },
      "sessionIssuer": {
        "type": "Role",

For information about CloudTrail record contents, see [CloudTrail record contents](#) in the *AWS CloudTrail User Guide*.

## Viewing CloudWatch Logs Live Tail for Amazon ECS services and tasks

CloudWatch Logs Live Tail helps you quickly troubleshoot incidents by viewing a streaming list of new log events as they are ingested. You can view task and service events in the Amazon ECS console. This view provides a cohesive view of your task and service health.

Each task in an Amazon ECS service has dedicated log streams for each container. If a service scales up, each task instance has its own set of log streams. The naming convention for log streams follows the pattern:

```
log-group-prefix/container-name/task-id
```

A single task writes to the same log streams during its lifetime. The log stream contains messages from that task's containers and also any output from your application code. Every message is timestamped, including your custom logs.

 **Note**

Live Tail sessions incur costs by session usage time, per minute. For more information about pricing, see [Amazon CloudWatch Pricing](#).

## Required permissions

The following permissions are required for the console IAM user to start and stop CloudWatch Logs Live Tail sessions:

- logs:DescribeLogGroups
- logs:StartLiveTail
- logs:StopLiveTail

## Procedure

- Open the console at <https://console.aws.amazon.com/ecs/v2>.
- Determine the resource you want to view

| Resource | Steps                                                                                                        |  |
|----------|--------------------------------------------------------------------------------------------------------------|--|
| Tasks    | <div>a. On the <b>Clusters</b> page, choose the cluster.</div> <div>The cluster details page displays.</div> |  |

| Resource | Steps                                                                                                                                                                                                       |  |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|          | b. Choose the <b>Tasks</b> tab.<br><br>The task details page displays.<br><br>c. Choose the <b>Logs</b> tab.                                                                                                |  |
| Services | a. On the <b>Clusters</b> page, choose the cluster.<br><br>The cluster details page displays.<br><br>b. Choose the service.<br><br>The service details page displays.<br><br>c. Choose the <b>Logs</b> tab. |  |

3. Choose **CloudWatch Logs Live Tail**, and then choose **Start**.
4. (Optional) To filter the streams, under **Filter**, for **Select log groups**, choose the log group.

## AWS CLI references

You can also use the AWS CLI to start Live Tail sessions for CloudWatch Logs. The following resources provide detailed information about using the AWS CLI with Live Tail:

- [start-live-tail command reference](#) - Complete command syntax, parameters, and examples for the `aws logs start-live-tail` command.
- [CloudWatch Logs Live Tail user guide](#) - Comprehensive guide including AWS CLI usage with both print-only and interactive modes.
- [StartLiveTail SDK examples](#) - Programmatic examples for using the StartLiveTail API with various AWS SDKs.

# Monitor Amazon ECS operations with Action Logs

## Amazon ECS Action Logs overview

With Amazon ECS Action Logs, you can monitor all actions that Amazon ECS performs on your behalf during container lifecycle operations. Action Logs capture timestamped records of every resource operation, state transition, and service-initiated API call within your clusters.

Action Logs record previously invisible operations such as container image downloads, load balancer registrations, and security group configurations. Without Action Logs, you can only observe the start and end states of your resources. With Action Logs, you can see every intermediate step that Amazon ECS takes between those states.

When you enable Action Logs, Amazon Q in the AWS Management Console can access these logs to help you debug deployment failures and daemon issues directly from the console.

## Benefits of Action Logs

Action Logs provide the following benefits for managing your Amazon ECS workloads:

- **Visibility into service actions** – View previously invisible actions that Amazon ECS performs between state transitions, including infrastructure provisioning, network configuration, and resource registration.
- **Improved troubleshooting** – Diagnose deployment failures and infrastructure problems without contacting AWS Support. Action Logs support a growing set of failure reasons.
- **Extended failure metadata** – Retain metadata about failed tasks beyond the standard 1-hour retention period. You can review detailed failure information at your own pace.
- **Self-service debugging** – Investigate and resolve issues independently by reviewing the complete sequence of actions that led to a failure.

## What gets logged

Action Logs capture actions for the following Amazon ECS operations:

- **Service deployments** – State transitions, rollbacks, and lifecycle hook execution.
- **Managed Daemon lifecycle** – Create, update, delete, and instance drain operations for Managed Daemons.

## How Action Logs work

You opt in to Action Logs at the cluster level. You can enable Action Logs through the Amazon ECS console or by using the Amazon CloudWatch APIs (`PutDeliverySource`, `PutDeliveryDestination`, and `CreateDelivery`).

After you enable Action Logs, Amazon ECS emits structured JSON logs through the CloudWatch Ingestion Hub. Amazon ECS delivers logs to your chosen destination: CloudWatch Logs, Amazon S3, or Amazon Data Firehose.

Action Logs use fire-and-forget publishing. Log publishing never blocks or degrades Amazon ECS resource operations. If a transient delivery failure occurs, Amazon ECS continues processing your workloads without interruption.

## Log schema overview

Each Action Log entry contains the following fields:

- `timestamp` – Unix milliseconds when the event occurred.
- `logLevel` – The severity level: `INFO`, `WARN`, or `ERROR`.
- `account` – The AWS account ID.
- `region` – The AWS Region where the event occurred.
- `resourceArn` – The cluster ARN that represents the opt-in scope.
- `actionSourceId` – The sub-resource identifier, such as a service ARN or daemon ARN.
- `eventName` – The action identifier, for example `DAEMON_DEPLOYMENT_IN_PROGRESS`.
- `detail` – An event-specific JSON payload with additional context about the action.

## Log destinations and organization

You can deliver Action Logs to the following destinations:

- **CloudWatch Logs** – CloudWatch Logs stores logs in a log group named `/aws/vendedlogs/ecs/action-logs/{resourceId}`. Amazon ECS creates a separate log stream for each sub-resource, using the `{actionSourceId}` as the log stream name.
- **Amazon S3** – Amazon S3 partitions logs by account, Region, and 5-minute time windows. Amazon S3 compresses the files using gzip for efficient storage.

- **Amazon Data Firehose** – Amazon Data Firehose delivers logs as newline-delimited JSON records in near real-time.

## Pricing

Action Logs is a paid feature that uses standard CloudWatch vended logs pricing. You pay for log ingestion and storage based on the volume of logs that your clusters generate. You can configure retention through your destination settings. When you enable Action Logs through the Amazon ECS console, CloudWatch Logs uses a default retention of 7 days.

### Topics

- [Getting started with Amazon ECS Action Logs](#)
- [Troubleshooting with Amazon ECS Action Logs](#)

## Getting started with Amazon ECS Action Logs

Amazon ECS Action Logs use the Amazon CloudWatch Logs vended log delivery mechanism to publish detailed records of service actions to your preferred destination. When you enable Action Logs, you can see every step that Amazon ECS takes during deployments and daemon operations, including infrastructure provisioning, resource registration, and failure details. This visibility helps you troubleshoot issues without contacting AWS Support and reduces the time to identify root causes. You can enable Action Logs for your clusters using the Amazon ECS console or CloudWatch Logs APIs.

### Prerequisites

Before you enable Action Logs, verify that your IAM identity has the required permissions.

#### Required IAM permissions

Your IAM identity must have the following permissions to enable and manage Action Logs:

```
{
  "Effect": "Allow",
  "Action": [
    "logs:PutDeliverySource",
    "logs:PutDeliveryDestination",
    "logs:CreateDelivery",
```

```
        "logs:GetDelivery",
        "ecs:AllowVendedLogDeliveryForResource"
    ],
    "Resource": "*"
}
```

## Destination resource policy

The destination CloudWatch Logs log group must have a resource policy that allows the `delivery.logs.amazonaws.com` service to write logs. Add the following statement to the log group resource policy:

```
{
  "Effect": "Allow",
  "Principal": {
    "Service": "delivery.logs.amazonaws.com"
  },
  "Action": [
    "logs:CreateLogStream",
    "logs:PutLogEvents"
  ],
  "Resource": "arn:aws:logs:region:account-id:log-group:log-group-name:log-stream:*"
}
```

## Enable Action Logs using the Amazon ECS console

You can enable Action Logs directly from the cluster details page in the Amazon ECS console.

### To enable Action Logs using the console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**, and then select the cluster.
3. Choose the **Configuration** tab.
4. In the **Action logs** section, choose **Add**.
5. For **Destination**, choose one of the following:
  - **CloudWatch Logs** (default)
  - **Amazon S3**
  - **Amazon Data Firehose**

For CloudWatch Logs, Amazon ECS creates a default log group named `/aws/vendedlogs/ecs/action-logs/cluster-name` with a 7-day retention period.

6. Choose **Save**.

## Enable Action Logs using CloudWatch Logs APIs

You can enable Action Logs programmatically by using the CloudWatch Logs vended log delivery APIs. This approach requires three steps: register the delivery source, configure the destination, and create the delivery.

### To enable Action Logs using the AWS CLI

1. Register the delivery source by running the following command:

```
aws logs put-delivery-source \  
  --name my-ecs-action-logs \  
  --resource-arn arn:aws:ecs:region:account-id:cluster/cluster-name \  
  --log-type ACTION_LOGS
```

2. Configure the delivery destination by running the following command:

```
aws logs put-delivery-destination \  
  --name my-ecs-logs-destination \  
  --output-format json \  
  --delivery-destination-configuration '{"destinationResourceArn":  
  "arn:aws:logs:region:account-id:log-group:/aws/vendedlogs/ecs/action-logs/cluster-  
name"}'
```

3. Create the delivery to link the source to the destination by running the following command:

```
aws logs create-delivery \  
  --delivery-source-name my-ecs-action-logs \  
  --delivery-destination-arn arn:aws:logs:region:account-id:delivery-  
destination:my-ecs-logs-destination
```

## Verify log delivery

After you enable Action Logs, verify that logs are delivered to your destination.

## To verify log delivery

1. Trigger an action in your cluster. For example, create or update a daemon service.
2. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
3. In the navigation pane, choose **Log groups**.
4. Select your Action Logs log group and verify that new log streams appear.

## Delete Action Logs

You can delete Action Logs by using the AWS CLI or the Amazon ECS console.

To delete Action Logs, your IAM identity must have the following additional permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "logs:DeleteDelivery",
    "logs:DeleteDeliverySource",
    "logs:DeleteDeliveryDestination"
  ],
  "Resource": "*"
}
```

## To delete Action Logs using the AWS CLI

1. Delete the delivery by running the following command:

```
aws logs delete-delivery \
  --delivery-id delivery-id
```

2. Delete the delivery source by running the following command:

```
aws logs delete-delivery-source \
  --name my-ecs-action-logs
```

3. Delete the delivery destination by running the following command:

```
aws logs delete-delivery-destination \
  --name my-ecs-logs-destination
```

To delete Action Logs using the console, navigate to the cluster details page, choose the **Configuration** tab, and then choose **Delete** in the **Action logs** section.

## Next steps

After you enable Action Logs, use the following resources to monitor and troubleshoot your Amazon ECS clusters:

- [Troubleshooting with Amazon ECS Action Logs](#)

## Troubleshooting with Amazon ECS Action Logs

Action Logs help you diagnose issues by providing detailed records of Amazon ECS service-initiated operations. Each log entry contains a timestamp, log level, event name, and a detail payload with context about what happened and why. This topic covers common troubleshooting scenarios and provides ready-to-use CloudWatch Logs Insights queries.

### Understanding log levels

Action Logs use three log levels to indicate the severity of each event:

#### INFO

Normal operations such as deployment started, task launched, or resource provisioned. These events indicate that Amazon ECS is performing actions as expected.

#### WARN

Non-fatal issues that might need attention, such as retry attempts or capacity constraints. Amazon ECS continues to make progress, but the operation might take longer than expected.

#### ERROR

Failures that require action, such as deployment failed, provisioning error, or task start impaired. Review these events to identify the root cause and take corrective action.

#### Tip

Start by filtering for ERROR or WARN log levels to identify issues quickly. You can then expand your search to INFO events for additional context.

## Debugging a failed service deployment

### Symptoms

Deployment stuck in progress or automatically rolled back.

### What to look for

Filter for ERROR logs where eventName contains DEPLOYMENT. Check the detail payload for the deployment ARN, status reason, and failed task count.

The following example shows a deployment failure where no rollback candidate was available:

```
{
  "resourceArn": "arn:aws:ecs:us-east-1:111122223333:cluster/my-cluster",
  "actionSourceId": "service/my-cluster/my-service",
  "logLevel": "ERROR",
  "eventTimestamp": 1784573730986,
  "detail": {
    "statusReason": "No rollback candidate was found to run the rollback.",
    "serviceDeploymentArn": "arn:aws:ecs:us-east-1:111122223333:service-deployment/my-cluster/my-service/abc123def456",
    "status": "FAILED",
    "eventName": "SERVICE_DEPLOYMENT_ROLLBACK_FAILED"
  }
}
```

### Resolution

Check the detail.statusReason field to identify why tasks failed. Use the following CloudWatch Logs Insights query to find all deployment errors:

```
fields @timestamp, detail.statusReason
| filter logLevel = "ERROR" and detail.deploymentArn like /my-cluster\my-service/
| sort @timestamp desc
| limit 20
```

## Diagnosing managed daemon issues

### Symptoms

Daemon not starting on instances or daemon deployment stuck.

## What to look for

Filter logs by the daemon ARN to find events related to your daemon. You can also filter by `logLevel` to narrow results to warnings or errors.

The following example shows a daemon task that failed to start due to insufficient memory on the target instance:

```
{
  "timestamp": 1719500050000,
  "logLevel": "WARN",
  "account": "123456789012",
  "region": "us-east-1",
  "resourceArn": "arn:aws:ecs:us-east-1:123456789012:cluster/my-cluster",
  "actionSourceId": "arn:aws:ecs:us-east-1:123456789012:daemon/my-cluster/my-logging-
daemon",
  "eventName": "DAEMON_TASK_START_IMPAIRED",
  "detail": {
    "statusReason": "RESOURCE:MEMORY - Unable to place daemon task on container
instance: insufficient memory",
    "containerInstanceArn": "arn:aws:ecs:us-east-1:123456789012:container-instance/my-
cluster/a1b2c3d4"
  }
}
```

## Resolution

Verify that target instances have sufficient resources to run the daemon task. If instances are draining, the daemon might not start until new instances become available. Use the following query to filter events for a specific daemon:

```
fields @timestamp, logLevel, detail.statusReason
| filter actionSourceId like /my-logging-daemon/
| filter logLevel in ["ERROR", "WARN"]
| sort @timestamp desc
| limit 20
```

## Understanding daemon task stop reasons

### Symptoms

Daemon tasks stopping unexpectedly.

## What to look for

Filter for WARN and ERROR logs that contain daemon task failure details. The following fields in the detail payload provide information about why a daemon task stopped:

`detail.stopCode`

A machine-readable code that categorizes the reason for the task stop.

`detail.statusReason`

A human-readable description of why the task stopped. This field is not present in all log entries.

`detail.containerStoppedReason`

Additional context about the specific container that caused the task to stop.

For a full list of task stop codes and their descriptions, see [Amazon ECS stopped tasks error messages](#).

### Note

Expected daemon task stops, such as `UserInitiated`, are filtered out from Action Logs. You only see unexpected or error-related daemon task stops.

## Useful CloudWatch Logs Insights queries

Use the following CloudWatch Logs Insights queries to investigate common issues with your Amazon ECS services.

### All errors in the last hour

```
fields @timestamp, logLevel, eventName, detail.statusReason
| filter logLevel = "ERROR"
| sort @timestamp desc
| limit 50
```

**Note**

The `detail.statusReason` field is not present in all log entries. If the field is empty in your results, use the `eventName` and other fields in the `detail` payload for context.

## Events for a specific service

```
fields @timestamp, logLevel, detail.statusReason
| filter @message like /my-service/
| sort @timestamp desc
| limit 50
```

## Deployment timeline for a specific deployment

```
fields @timestamp, logLevel, detail.statusReason
| filter detail.deploymentArn like /my-cluster\my-service\abc123/
| sort @timestamp asc
```

## Daemon task failures grouped by reason

```
filter logLevel = "ERROR" and detail.stopCode != ""
| stats count(*) as failureCount by detail.stopCode, detail.statusReason
| sort failureCount desc
| limit 20
```

# Monitor workloads using Amazon ECS metadata

You can use the task and container metadata to troubleshoot your workloads and to make configuration changes based on the runtime environment.

Metadata includes the following categories:

- Task-level attributes that provide information about where the task is running.
- Container-level attributes that provide the Docker ID, name, and image details.

This provides visibility into the container.

- Network settings such as IP addresses, subnets, and network mode.

This helps with network configuration and troubleshooting.

- Task status and health

This lets you know if the tasks are running.

You can view metadata by any of the following methods:

- Container metadata file

Beginning with version 1.15.0 of the Amazon ECS container agent, various container metadata is available within your containers or the host container instance. By enabling this feature, you can query the information about a task, container, and container instance from within the container or the host container instance. The metadata file is created on the host instance and mounted in the container as a Docker volume and therefore is not available when a task is hosted on AWS Fargate.

- Task metadata endpoint

The Amazon ECS container agent injects an environment variable into each container, referred to as the *task metadata endpoint* which provides various task metadata and [Docker stats](#) to the container.

- Container introspection

The Amazon ECS container agent provides an API operation for gathering details about the container instance on which the agent is running and the associated tasks running on that instance.

## Amazon ECS environment variables

Environment variables control a task's behavior such as the capacity used to run the task. Amazon ECS sets the following environment variables for your tasks:

- `AWS_CONTAINER_CREDENTIALS_RELATIVE_URI` - The full HTTP URL endpoint for the SDK to use when making a request for credentials. This includes both the scheme and the host. For more information, see [Container credential provider](#) in the *AWS SDKs Reference Guide*.
- `ECS_CONTAINER_METADATA_URI_V4` - The address of the task metadata version 4. For more information, see [Amazon ECS task metadata endpoint version 4](#).

- `ECS_CONTAINER_METADATA_URI` - The address of the task metadata version 3. For more information, see [Amazon ECS task metadata endpoint version 3](#).
- `ECS_AGENT_URI` - The base address for different endpoints supported by Fargate. For more information, see:
  - [Amazon ECS task scale-in protection endpoint](#)
  - [Amazon ECS fault injection endpoints](#)
- `AWS_EXECUTION_ENV` - The information about the compute option the task runs on.
  - For Fargate, Amazon ECS sets this to `AWS_ECS_FARGATE`.
  - For EC2, Amazon ECS sets this to `AWS_ECS_EC2`.
- `AWS_DEFAULT_REGION` - The default AWS Region for your AWS account. This is the default Region where your task runs.
- `AWS_REGION` - The Region where the task runs. If defined, this value overrides the `AWS_DEFAULT_REGION`.

You can view the environment variables in the task metadata. For more information, see one of the following topics:

- Fargate - [Amazon ECS task metadata available for tasks on Fargate](#)
- EC2 - [Task metadata available for Amazon ECS tasks on EC2](#)

## Amazon ECS container metadata file

Beginning with version 1.15.0 of the Amazon ECS container agent, various container metadata is available within your containers or the host container instance. By enabling this feature, you can query the information about a task, container, and container instance from within the container or the host container instance. The metadata file is created on the host instance and mounted in the container as a Docker volume and therefore is not available when a task is hosted on AWS Fargate.

The container metadata file is cleaned up on the host instance when the container is cleaned up. You can adjust when this happens with the `ECS_ENGINE_TASK_CLEANUP_WAIT_DURATION` container agent variable. For more information, see [Automatic Amazon ECS task and image cleanup](#).

### Topics

- [Container metadata file locations](#)

- [Turning on Amazon ECS container metadata](#)
- [Amazon ECS container metadata file format](#)

## Container metadata file locations

By default, the container metadata file is written to the following host and container paths.

- **For Linux instances:**

- Host path: `/var/lib/ecs/data/metadata/cluster_name/task_id/container_name/ecs-container-metadata.json`

 **Note**

The Linux host path assumes that the default data directory mount path (`/var/lib/ecs/data`) is used when the agent is started. If you are not using an Amazon ECS-optimized AMI (or the `ecs-init` package to start and maintain the container agent), be sure to set the `ECS_HOST_DATA_DIR` agent configuration variable to the host path where the container agent's state file is located. For more information, see [Amazon ECS container agent configuration](#).

- Container path: `/opt/ecs/metadata/random_ID/ecs-container-metadata.json`

- **For Windows instances:**

- Host path: `C:\ProgramData\Amazon\ECS\data\metadata\itask_id\icontainer_name\ecs-container-metadata.json`
- Container path: `C:\ProgramData\Amazon\ECS\metadata\irandom_ID\ecs-container-metadata.json`

However, for easy access, the container metadata file location is set to the `ECS_CONTAINER_METADATA_FILE` environment variable inside the container. You can read the file contents from inside the container with the following command:

- **For Linux instances:**

```
cat $ECS_CONTAINER_METADATA_FILE
```

- **For Windows instances (PowerShell):**

```
Get-Content -path $env:ECS_CONTAINER_METADATA_FILE
```

## Turning on Amazon ECS container metadata

You can turn on container metadata at the container instance level by setting the `ECS_ENABLE_CONTAINER_METADATA` container agent variable to `true`. You can set this variable in the `/etc/ecs/ecs.config` configuration file and restart the agent. You can also set it as a Docker environment variable at runtime when the agent container is started. For more information, see [Amazon ECS container agent configuration](#).

If the `ECS_ENABLE_CONTAINER_METADATA` is set to `true` when the agent starts, metadata files are created for any containers created from that point forward. The Amazon ECS container agent cannot create metadata files for containers that were created before the `ECS_ENABLE_CONTAINER_METADATA` container agent variable was set to `true`. To ensure that all containers receive metadata files, you should set this agent variable at container instance launch. The following is an example user data script that will set this variable as well as register your container instance with your cluster.

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=your_cluster_name
ECS_ENABLE_CONTAINER_METADATA=true
EOF
```

## Amazon ECS container metadata file format

The following information is stored in the container metadata JSON file.

### Cluster

The name of the cluster that the container's task is running on.

### ContainerInstanceARN

The full Amazon Resource Name (ARN) of the host container instance.

### TaskARN

The full Amazon Resource Name (ARN) of the task that the container belongs to.

## TaskDefinitionFamily

The name of the task definition family the container is using.

## TaskDefinitionRevision

The task definition revision the container is using.

## ContainerID

The Docker container ID (and not the Amazon ECS container ID) for the container.

## ContainerName

The container name from the Amazon ECS task definition for the container.

## DockerContainerName

The container name that the Docker daemon uses for the container (for example, the name that shows up in **docker ps** command output).

## ImageID

The SHA digest for the Docker image used to start the container.

## ImageName

The image name and tag for the Docker image used to start the container.

## PortMappings

Any port mappings associated with the container.

## ContainerPort

The port on the container that is exposed.

## HostPort

The port on the host container instance that is exposed.

## BindIp

The bind IP address that is assigned to the container by Docker. This IP address is only applied with the bridge network mode, and it is only accessible from the container instance.

## Protocol

The network protocol used for the port mapping.

## Networks

The network mode and IP address for the container.

## NetworkMode

The network mode for the task to which the container belongs.

## IPv4Addresses

The IP addresses associated with the container.

### Important

If your task is using the `awsvpc` network mode, the IP address of the container will not be returned. In this case, you can retrieve the IP address by reading the `/etc/hosts` file with the following command:

```
tail -1 /etc/hosts | awk '{print $1}'
```

## MetadataFileStatus

The status of the metadata file. When the status is `READY`, the metadata file is current and complete. If the file is not ready yet (for example, the moment the task is started), a truncated version of the file format is available. To avoid a likely race condition where the container has started, but the metadata has not yet been written, you can parse the metadata file and wait for this parameter to be set to `READY` before depending on the metadata. This is usually available in less than 1 second from when the container starts.

## AvailabilityZone

The Availability Zone the host container instance resides in.

## HostPrivateIPv4Address

The private IP address for the task the container belongs to.

## HostPublicIPv4Address

The public IP address for the task the container belongs to.

## Example Amazon ECS container metadata file (READY)

The following example shows a container metadata file in the READY status.

```
{
  "Cluster": "arn:aws:ecs:us-east-1:123456789012:cluster/MyCluster",
  "TaskARN": "arn:aws:ecs:us-east-1:123456789012:task/MyCluster/
b593651c4d6b44a6b2b583f45c957e15",
  "Family": "curltest-container",
  "Revision": "2",
  "DesiredStatus": "RUNNING",
  "KnownStatus": "RUNNING",
  "Limits":
    {
      "CPU": 0.25,
      "Memory": 512
    },

### Example Incomplete Amazon ECS container metadata file (not yet READY)

The following example shows a container metadata file that has not yet reached the READY status. The information in the file is limited to a few parameters that are known from the task definition. The container metadata file should be ready within 1 second after the container starts.

```

{
  "Cluster": "default",
  "ContainerInstanceARN": "arn:aws:ecs:us-west-2:012345678910:container-instance/
default/1f73d099-b914-411c-a9ff-81633b7741dd",
  "TaskARN": "arn:aws:ecs:us-west-2:012345678910:task/default/
d90675f8-1a98-444b-805b-3d9cabb6fcd4",
  "ContainerName": "metadata"
}

```

```
}
```

## Amazon ECS task metadata available for tasks on Amazon ECS Managed Instances

Amazon ECS on Amazon ECS Managed Instances provides a method to retrieve various metadata, network metrics, and [Docker stats](#) about your containers and the tasks they are a part of. This is referred to as the *task metadata endpoint*. The task metadata endpoint version 4 is available for Amazon ECS tasks on Amazon ECS Managed Instances.

All containers belonging to tasks that are launched with the `awsvpc` network mode receive a local IPv4 address within a predefined link-local address range. When a container queries the metadata endpoint, the container agent can determine which task the container belongs to based on its unique IP address, and metadata and stats for that task are returned.

### Topics

- [Amazon ECS task metadata endpoint version 4 for tasks on Amazon ECS Managed Instances](#)

## Amazon ECS task metadata endpoint version 4 for tasks on Amazon ECS Managed Instances

### Important

If you are using Amazon ECS tasks hosted on Amazon EC2 instances, see [Amazon ECS task metadata endpoint](#).

Beginning with Amazon ECS Managed Instances, an environment variable named `ECS_CONTAINER_METADATA_URI_V4` is injected into each container in a task. When you query the task metadata endpoint version 4, various task metadata and [Docker stats](#) are available to tasks.

The task metadata endpoint is on by default for all Amazon ECS tasks run on Amazon ECS Managed Instances.

**Note**

To avoid the need to create new task metadata endpoint versions in the future, additional metadata may be added to the version 4 output. We will not remove any existing metadata or change the metadata field names.

**Amazon ECS Managed Instances task metadata endpoint version 4 paths**

The following task metadata endpoints are available to containers:

`${ECS_CONTAINER_METADATA_URI_V4}`

This path returns metadata for the container.

`${ECS_CONTAINER_METADATA_URI_V4}/task`

This path returns metadata for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see [Amazon ECS task metadata v4 JSON response for tasks on Amazon ECS Managed Instances](#).

`${ECS_CONTAINER_METADATA_URI_V4}/stats`

This path returns Docker stats for the Docker container. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

**Note**

Amazon ECS tasks on Amazon ECS Managed Instances require that the container run for ~1 second prior to returning the container stats.

`${ECS_CONTAINER_METADATA_URI_V4}/task/stats`

This path returns Docker stats for all of the containers associated with the task. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

**Note**

Amazon ECS tasks on Amazon ECS Managed Instances require that the container run for ~1 second prior to returning the container stats.

`${ECS_CONTAINER_METADATA_URI_V4}/tasks`

This path returns metadata for all tasks running on the container instance. The response is a JSON array of task metadata objects, where each element has the same structure as the response from the `/task` endpoint. For more information about the response for each task, see [Amazon ECS task metadata v4 JSON response for tasks on Amazon ECS Managed Instances](#).

**Note**

This endpoint is only available for tasks running as a Managed Daemon Service on Amazon ECS Managed Instances.

`${ECS_CONTAINER_METADATA_URI_V4}/tasks/stats`

This path returns Docker stats for all containers across all tasks running on the container instance. The response is a JSON array where each element contains a map of container IDs to their Docker stats for a given task. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

**Note**

This endpoint is only available for tasks running as a Managed Daemon Service on Amazon ECS Managed Instances.

## Amazon ECS task metadata v4 JSON response for tasks on Amazon ECS Managed Instances

The following metadata is returned in the task metadata endpoint (`${ECS_CONTAINER_METADATA_URI_V4}/task`) JSON response.

## Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

## ServiceName

The name of the service to which the task belongs. ServiceName will appear if the task is associated with a service.

## VPCID

The VPC ID of the container instance.

## TaskARN

The Amazon Resource Name (ARN) of the task to which the container belongs.

## Family

The family of the Amazon ECS task definition for the task.

## Revision

The revision of the Amazon ECS task definition for the task.

## DesiredStatus

The desired status for the task from Amazon ECS.

## KnownStatus

The known status for the task from Amazon ECS.

## Limits

The resource limits specified at the task levels such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

## PullStartedAt

The timestamp for when the first container image pull began.

## PullStoppedAt

The timestamp for when the last container image pull finished.

## AvailabilityZone

The Availability Zone the task is in.

## LaunchType

The launch type the task is using. For tasks running on Amazon ECS Managed Instances, the launch type is `MANAGED_INSTANCES`.

## Containers

A list of container metadata for each container associated with the task.

### DockerId

The Docker ID for the container.

When you use Amazon ECS Managed Instances, the id is a 32-digit hex followed by a 10 digit number.

### Name

The name of the container as specified in the task definition.

### DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

### Image

The image for the container.

### ImageID

The SHA-256 digest of the image manifest. This is the digest that can be used to pull the image using the format `repository-url/image@sha256:digest`.

### Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

### Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

### DesiredStatus

The desired status for the container from Amazon ECS.

### KnownStatus

The known status for the container from Amazon ECS.

## ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

## Limits

The resource limits specified at the container level such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

## CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

## StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.

## FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

## Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

## LogDriver

The log driver the container is using.

## LogOptions

The log driver options defined for the container.

## ContainerARN

The Amazon Resource Name (ARN) of the container.

## Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

## Snapshotter

The snapshotter that was used by containerd to download this container image. Valid values are overlayfs, which is the default, and soci, used when lazy loading with a SOCI index.

## RestartCount

The number of times the container has been restarted.

### Note

The RestartCount metadata is included only if a restart policy is enabled for the container. For more information, see [Restart individual containers in Amazon ECS tasks with container restart policies](#).

## ClockDrift

The information about the difference between the reference time and the system time. This capability uses Amazon Time Sync Service to measure clock accuracy and provide the clock error bound for containers. For more information, see [Set the time for your Linux instance](#) in the *Amazon EC2 User Guide for Linux instances*.

## ReferenceTime

The basis of clock accuracy. Amazon ECS uses the Coordinated Universal Time (UTC) global standard through NTP, for example 2021-09-07T16:57:44Z.

## ClockErrorBound

The measure of clock error, defined as the offset to UTC. This error is the difference in milliseconds between the reference time and the system time.

## ClockSynchronizationStatus

Indicates whether the most recent synchronization attempt between the system time and the reference time was successful.

The valid values are SYNCHRONIZED and NOT\_SYNCHRONIZED.

## ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.

## FaultInjectionEnabled

Indicates whether fault injection is enabled for the task. For more information, see [Use fault injection with your Amazon ECS and Fargate workloads](#).

## Amazon ECS task metadata v4 examples for tasks on Amazon ECS Managed Instances

The following examples show sample outputs from the task metadata endpoints for Amazon ECS tasks run on Amazon ECS Managed Instances.

From the container, you can use curl followed by the task meta data endpoint to query the endpoint for example `curl ${ECS_CONTAINER_METADATA_URI_V4}/task`.

### Example container metadata response

When querying the `${ECS_CONTAINER_METADATA_URI_V4}` endpoint you are returned only metadata about the container itself. The following is an example output.

```

## Task metadata available for Amazon ECS tasks on EC2

The Amazon ECS container agent provides a method to retrieve various task metadata and [Docker stats](#). This is referred to as the task metadata endpoint. The following versions are available:

- Task metadata endpoint version 4 – Provides a variety of metadata and Docker stats to containers. Can also provide network rate data. Available for Amazon ECS tasks launched on Amazon EC2 Linux instances running at least version 1.39.0 of the Amazon ECS container agent. For Amazon EC2 Windows instances that use awsvpc network mode, the Amazon ECS container agent must be at least version 1.54.0. For more information, see [Amazon ECS task metadata endpoint version 4](#).
- Task metadata endpoint version 3 – Provides a variety of metadata and Docker stats to containers. Available for Amazon ECS tasks launched on Amazon EC2 Linux instances running at least version 1.21.0 of the Amazon ECS container agent. For Amazon EC2 Windows instances that use awsvpc network mode, the Amazon ECS container agent must be at least version 1.54.0. For more information, see [Amazon ECS task metadata endpoint version 3](#).
- Task metadata endpoint version 2 – Available for Amazon ECS tasks launched on Amazon EC2 Linux instances running at least version 1.17.0 of the Amazon ECS container agent. For Amazon EC2 Windows instances that use awsvpc network mode, the Amazon ECS container agent must be at least version 1.54.0. For more information, see [Amazon ECS task metadata endpoint version 2](#).

If your Amazon ECS task is hosted on Amazon EC2, or if your task uses the host network mode and is hosted on Amazon ECS Managed Instances, you can also access task host metadata using the [Instance Metadata Service \(IMDS\) endpoint](#). The following command, when run from within the instance hosting the task, lists the ID of the host instance.

```
curl http://169.254.169.254/latest/meta-data/instance-id
```

If your Amazon ECS task is hosted on Amazon EC2 and in an IPv6-only configuration, you can access task host metadata using the IPv6 IMDS endpoint. The following command, when run from within the instance hosting the task, lists the ID of the host instance over IPv6.

```
curl http://[fd00:ec2::254]/latest/meta-data/instance-id
```

To access the IPv6 IMDS endpoint, enable the IPv6 IMDS endpoint on your container instance and also configure the metadata service endpoint mode using the IMDS credential provider for your chosen SDK to IPv6. For more information about enabling the IPv6 IMDS endpoint for your container instance, see [Configure the Instance Metadata Service options](#) in *Amazon EC2 User Guide*. For more information about IMDS credential provider for SDKs, see [IMDS credential provider](#) in the *AWS SDKs and Tools Reference Guide*.

#### Note

The IPv6 IMDS endpoint is not accessible when the `awsvpcTrunking` account setting is enabled. To access container instance IAM role credentials when `awsvpcTrunking` is enabled, you can use a task IAM role instead. For more information about task IAM roles, see [Amazon ECS task IAM role](#).

The information you can obtain from the endpoint is divided into categories such as *instance-id*. For more information about the different categories of host instance metadata you can obtain using the endpoint, see [Instance metadata categories](#).

## Amazon ECS task metadata endpoint version 4

The Amazon ECS container agent injects an environment variable into each container, referred to as the *task metadata endpoint* which provides various task metadata and [Docker stats](#) to the container.

The task metadata and network rate stats are sent to CloudWatch Container Insights and can be viewed in the AWS Management Console. For more information, see [Monitor Amazon ECS containers using Container Insights with enhanced observability](#).

**Note**

Amazon ECS provides earlier versions of the task metadata endpoint. To avoid the need to create new task metadata endpoint versions in the future, additional metadata may be added to the version 4 output. We will not remove any existing metadata or change the metadata field names.

The environment variable is injected by default into the containers of Amazon ECS tasks launched on Amazon EC2 Linux instances that are running at least version 1.39.0 of the Amazon ECS container agent. For Amazon EC2 Windows instances that use awsvpc network mode, the Amazon ECS container agent must be at least version 1.54.0. For more information, see [Amazon ECS Linux container instance management](#).

**Note**

You can add support for this feature on Amazon EC2 instances using older versions of the Amazon ECS container agent by updating the agent to the latest version. For more information, see [Updating the Amazon ECS container agent](#).

For task metadata example output, see [Amazon ECS task metadata v4 examples](#).

### Task metadata endpoint version 4 paths

The following task metadata endpoint paths are available to containers.

`${ECS_CONTAINER_METADATA_URI_V4}`

This path returns metadata for the container.

`${ECS_CONTAINER_METADATA_URI_V4}/task`

This path returns metadata for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see [Amazon ECS task metadata V4 JSON response](#).

## `${ECS_CONTAINER_METADATA_URI_V4}/taskWithTags`

This path returns the metadata for the task included in the `/task` endpoint in addition to the task and container instance tags that can be retrieved using the `ListTagsForResource` API. Any errors received when retrieving the tag metadata will be included in the `Errors` field in the response.

### **Note**

The `Errors` field is only in the response for tasks hosted on Amazon EC2 Linux instances running at least version `1.50.0` of the container agent. For Amazon EC2 Windows instances that use `awsvpc` network mode, the Amazon ECS container agent must be at least version `1.54.0`.

This endpoint requires the `ecs:ListTagsForResource` permission.

### **Important**

When using the `${ECS_CONTAINER_METADATA_URI_V4}/taskWithTags` endpoint, be aware that each call makes up to two API requests to `ecs:ListTagsForResource` (one for container instance tags and one for task tags) and that any sidecar containers in the task may make these calls on your behalf. Frequent endpoint calls can result in API throttling.

Consider implementing caching or batching strategies to reduce the frequency of calls, especially in high-traffic applications, and debugging API throttling issues using AWS CloudTrail. For information about throttling limits for the `ListTagsForResource` API, see [Request throttling for the Amazon ECS API](#) in the *Amazon Elastic Container Service API Reference*. For more information about debugging Amazon ECS API calls using AWS CloudTrail, see [Log Amazon ECS API calls using AWS CloudTrail](#).

## `${ECS_CONTAINER_METADATA_URI_V4}/stats`

This path returns Docker stats for the specific container. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

For Amazon ECS tasks that use the `awsvpc` or `bridge` network modes hosted on Amazon EC2 Linux instances running at least version `1.43.0` of the container agent, there will be additional

network rate stats included in the response. For all other tasks, the response will only include the cumulative network stats.

`${ECS_CONTAINER_METADATA_URI_V4}/task/stats`

This path returns Docker stats for all of the containers associated with the task. This can be used by sidecar containers to extract network metrics. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

For Amazon ECS tasks that use the `awsvpc` or `bridge` network modes hosted on Amazon EC2 Linux instances running at least version `1.43.0` of the container agent, there will be additional network rate stats included in the response. For all other tasks, the response will only include the cumulative network stats.

## Amazon ECS task metadata V4 JSON response

The following information is returned from the task metadata endpoint (`${ECS_CONTAINER_METADATA_URI_V4}/task`) JSON response. This includes metadata associated with the task in addition to the metadata for each container within the task.

`Cluster`

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

`ServiceName`

The name of the service to which the task belongs. `ServiceName` will appear for Amazon EC2 and Amazon ECS Anywhere container instances if the task is associated with a service.

### Note

The `ServiceName` metadata is only included when using Amazon ECS container agent version `1.63.1` or later.

`VPCID`

The VPC ID of the Amazon EC2 container instance. This field only appears for Amazon EC2 instances.

**Note**

The VPCID metadata is only included when using Amazon ECS container agent version 1.63.1 or later.

**TaskARN**

The Amazon Resource Name (ARN) of the task to which the container belongs.

**Family**

The family of the Amazon ECS task definition for the task.

**Revision**

The revision of the Amazon ECS task definition for the task.

**DesiredStatus**

The desired status for the task from Amazon ECS.

**KnownStatus**

The known status for the task from Amazon ECS.

**Limits**

The resource limits specified at the task level, such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

**PullStartedAt**

The timestamp for when the first container image pull began.

**PullStoppedAt**

The timestamp for when the last container image pull finished.

**AvailabilityZone**

The Availability Zone the task is in.

**Note**

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 (Windows).

## LaunchType

The launch type the task is using. When using cluster capacity providers, this indicates whether the task is using Fargate or EC2 infrastructure.

### **Note**

This LaunchType metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later (Linux) or 1.0.0 or later (Windows).

## Containers

A list of container metadata for each container associated with the task.

### DockerId

The Docker ID for the container.

When you use Fargate, the id is a 32-digit hex followed by a 10 digit number.

### Name

The name of the container as specified in the task definition.

### DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

### Image

The image for the container.

### ImageID

The SHA-256 digest of the image manifest. This is the digest that can be used to pull the image using the format `repository-url/image@sha256:digest`.

### Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

### Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

## DesiredStatus

The desired status for the container from Amazon ECS.

## KnownStatus

The known status for the container from Amazon ECS.

## ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

## Limits

The resource limits specified at the container level, such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

## CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

## StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.

## FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

## Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

## LogDriver

The log driver the container is using.

### Note

This LogDriver metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

## LogOptions

The log driver options defined for the container.

### Note

This LogOptions metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

## ContainerARN

The Amazon Resource Name (ARN) of the container.

### Note

This ContainerARN metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

## Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

## RestartCount

The number of times the container has been restarted.

### Note

The RestartCount metadata is included only if a restart policy is enabled for the container. For more information, see [Restart individual containers in Amazon ECS tasks with container restart policies](#).

## ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.

## Amazon ECS task metadata v4 examples

The following examples show example outputs from each of the task metadata endpoints.

### Example container metadata response

When querying the `${ECS_CONTAINER_METADATA_URI_V4}` endpoint you are returned only metadata about the container itself. The following is an example output from a task that runs as part of a service (MyService).

```

### Example task with tags with an error metadata response

When querying the `${ECS_CONTAINER_METADATA_URI_V4}/taskWithTags` endpoint you are returned metadata about the task, including the task and container instance tags. If there is an error retrieving the tagging data, the error is returned in the response. The following is an example output for when the IAM role associated with the container instance doesn't have the `ecs:ListTagsForResource` permission allowed.

```

{

## Example container stats response

When querying the `${ECS_CONTAINER_METADATA_URI_V4}/stats` endpoint you are returned network metrics for the container. For Amazon ECS tasks that use the `awsvpc` or `bridge` network modes hosted on Amazon EC2 instances running at least version `1.43.0` of the container agent, there will be additional network rate stats included in the response. For all other tasks, the response will only include the cumulative network stats.

The following is an example output from an Amazon ECS task on Amazon EC2 that uses the `bridge` network mode.

```

{

## Amazon ECS task metadata endpoint version 3

### Important

The task metadata version 3 endpoint is no longer being actively maintained. We recommend that you update the task metadata version 4 endpoint to get the latest metadata endpoint information. For more information, see [the section called “Task metadata endpoint version 4”](#).

If you are using Amazon ECS tasks hosted on AWS Fargate, see [Amazon ECS task metadata endpoint version 3 for tasks on Fargate](#).

Beginning with version 1.21.0 of the Amazon ECS container agent, the agent injects an environment variable called `ECS_CONTAINER_METADATA_URI` into each container in a task. When you query the task metadata version 3 endpoint, various task metadata and [Docker stats](#) are available to tasks. For tasks that use the bridge network mode, network metrics are available when querying the `/stats` endpoints.

The task metadata endpoint version 3 feature is enabled by default for tasks that use Fargate on platform version v1.3.0 or later and tasks that use EC2 and are launched on Amazon EC2 Linux infrastructure running at least version 1.21.0 of the Amazon ECS container agent or on Amazon EC2 Windows infrastructure running at least version 1.54.0 of the Amazon ECS container agent and use `awsvpc` network mode. For more information, see [Amazon ECS Linux container instance management](#).

You can add support for this feature on older container instances by updating the agent to the latest version. For more information, see [Updating the Amazon ECS container agent](#).

**⚠ Important**

For tasks using Fargate and platform versions prior to v1.3.0, the task metadata version 2 endpoint is supported. For more information, see [Amazon ECS task metadata endpoint version 2](#).

**Task Metadata endpoint version 3 paths**

The following task metadata endpoints are available to containers:

`${ECS_CONTAINER_METADATA_URI}`

This path returns metadata JSON for the container.

`${ECS_CONTAINER_METADATA_URI}/task`

This path returns metadata JSON for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see [Amazon ECS task metadata v3 JSON response](#).

`${ECS_CONTAINER_METADATA_URI}/taskWithTags`

This path returns the metadata for the task included in the `/task` endpoint in addition to the task and container instance tags that can be retrieved using the `ListTagsForResource` API.

`${ECS_CONTAINER_METADATA_URI}/stats`

This path returns Docker stats JSON for the specific Docker container. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

`${ECS_CONTAINER_METADATA_URI}/task/stats`

This path returns Docker stats JSON for all of the containers associated with the task. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

**Amazon ECS task metadata v3 JSON response**

The following information is returned from the task metadata endpoint (`${ECS_CONTAINER_METADATA_URI}/task`) JSON response.

## Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

## TaskARN

The Amazon Resource Name (ARN) of the task to which the container belongs.

## Family

The family of the Amazon ECS task definition for the task.

## Revision

The revision of the Amazon ECS task definition for the task.

## DesiredStatus

The desired status for the task from Amazon ECS.

## KnownStatus

The known status for the task from Amazon ECS.

## Limits

The resource limits specified at the task level, such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

## PullStartedAt

The timestamp for when the first container image pull began.

## PullStoppedAt

The timestamp for when the last container image pull finished.

## AvailabilityZone

The Availability Zone the task is in.

### Note

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 or later (Windows).

## Containers

A list of container metadata for each container associated with the task.

### DockerId

The Docker ID for the container.

### Name

The name of the container as specified in the task definition.

### DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

### Image

The image for the container.

### ImageID

The SHA-256 digest of the image manifest. This is the digest that can be used to pull the image using the format `repository-url/image@sha256:digest`.

### Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

### Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

### DesiredStatus

The desired status for the container from Amazon ECS.

### KnownStatus

The known status for the container from Amazon ECS.

### ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

### Limits

The resource limits specified at the container level, such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

## CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

## StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.

## FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

## Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

## Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

## ClockDrift

The information about the difference between the reference time and the system time. This applies to the Linux operating system. This capability uses Amazon Time Sync Service to measure clock accuracy and provide the clock error bound for containers. For more information, see [Set the time for your Linux instance](#) in the *Amazon EC2 User Guide for Linux instances*.

## ReferenceTime

The basis of clock accuracy. Amazon ECS uses the Coordinated Universal Time (UTC) global standard through NTP, for example 2021-09-07T16:57:44Z.

## ClockErrorBound

The measure of clock error, defined as the offset to UTC. This error is the difference in milliseconds between the reference time and the system time.

## ClockSynchronizationStatus

Indicates whether the most recent synchronization attempt between the system time and the reference time was successful.

The valid values are SYNCHRONIZED and NOT\_SYNCHRONIZED.

## ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.

## Amazon ECS task metadata v3 examples

The following examples show sample outputs from the task metadata endpoints.

### Example Container Metadata Response

When querying the `${ECS_CONTAINER_METADATA_URI}` endpoint you are returned only metadata about the container itself. The following is an example output.

```
{
  "DockerId": "43481a6ce4842eec8fe72fc28500c6b52edcc0917f105b83379f88cac1ff3946",
  "Name": "nginx-curl",
  "DockerName": "ecs-nginx-5-nginx-curl-ccccb9f49db0dfe0d901",
  "Image": "nrdlgr/nginx-curl",
  "ImageID":
    "sha256:2e00ae64383cfc865ba0a2ba37f61b50a120d2d9378559dcd458dc0de47bc165",
  "Labels": {
    "com.amazonaws.ecs.cluster": "default",
    "com.amazonaws.ecs.container-name": "nginx-curl",
    "com.amazonaws.ecs.task-arn": "arn:aws:ecs:us-

## Amazon ECS task metadata endpoint version 2

### Important

The task metadata version 2 endpoint is no longer being actively maintained. We recommend that you update the task metadata version 4 endpoint to get the latest metadata endpoint information. For more information, see [the section called “Task metadata endpoint version 4”](#).

Beginning with version 1.17.0 of the Amazon ECS container agent, various task metadata and [Docker stats](#) are available to tasks that use the awsvpc network mode at an HTTP endpoint that is provided by the Amazon ECS container agent.

All containers belonging to tasks that are launched with the awsvpc network mode receive a local IPv4 address within a predefined link-local address range. When a container queries the metadata endpoint, the Amazon ECS container agent can determine which task the container belongs to based on its unique IP address, and metadata and stats for that task are returned.

### Enabling task metadata

### Important

The task metadata version 2 endpoint is no longer being actively maintained. We recommend that you update the task metadata version 4 endpoint to get the latest metadata endpoint information. For more information, see [the section called “Task metadata endpoint version 4”](#).

Beginning with version 1.17.0 of the Amazon ECS container agent, various task metadata and [Docker stats](#) are available to tasks that use the awsvpc network mode at an HTTP endpoint that is provided by the Amazon ECS container agent.

All containers belonging to tasks that are launched with the `awsvpc` network mode receive a local IPv4 address within a predefined link-local address range. When a container queries the metadata endpoint, the Amazon ECS container agent can determine which task the container belongs to based on its unique IP address, and metadata and stats for that task are returned.

## Enabling task metadata

The task metadata version 2 feature is enabled by default for the following:

- Tasks using Fargate that use platform version v1.1.0 or later. For more information, see [Fargate platform versions for Amazon ECS](#).
- Tasks using EC2 that also use the `awsvpc` network mode and are launched on Amazon EC2 Linux infrastructure running at least version 1.17.0 of the Amazon ECS container agent or on Amazon EC2 Windows infrastructure running at least version 1.54.0 of the Amazon ECS container agent. For more information, see [Amazon ECS Linux container instance management](#).

You can add support for this feature on older container instances by updating the agent to the latest version. For more information, see [Updating the Amazon ECS container agent](#).

## Task metadata endpoint paths

The following API endpoints are available to containers:

`169.254.170.2/v2/metadata`

This endpoint returns metadata JSON for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see [Task metadata JSON response](#).

`169.254.170.2/v2/metadata/<container-id>`

This endpoint returns metadata JSON for the specified Docker container ID.

`169.254.170.2/v2/metadata/taskWithTags`

This path returns the metadata for the task included in the `/task` endpoint in addition to the task and container instance tags that can be retrieved using the `ListTagsForResource` API.

`169.254.170.2/v2/stats`

This endpoint returns Docker stats JSON for all of the containers associated with the task. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

169.254.170.2/v2/stats/<container-id>

This endpoint returns Docker stats JSON for the specified Docker container ID. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

## Task metadata JSON response

The following information is returned from the task metadata endpoint (169.254.170.2/v2/metadata) JSON response.

### Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

### TaskARN

The Amazon Resource Name (ARN) of the task to which the container belongs.

### Family

The family of the Amazon ECS task definition for the task.

### Revision

The revision of the Amazon ECS task definition for the task.

### DesiredStatus

The desired status for the task from Amazon ECS.

### KnownStatus

The known status for the task from Amazon ECS.

### Limits

The resource limits specified at the task level, such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

### PullStartedAt

The timestamp for when the first container image pull began.

### PullStoppedAt

The timestamp for when the last container image pull finished.

## AvailabilityZone

The Availability Zone the task is in.

### Note

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 or later (Windows).

## Containers

A list of container metadata for each container associated with the task.

### DockerId

The Docker ID for the container.

### Name

The name of the container as specified in the task definition.

### DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

### Image

The image for the container.

### ImageID

The SHA-256 digest of the image manifest. This is the digest that can be used to pull the image using the format `repository-url/image@sha256:digest`.

### Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

### Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

### DesiredStatus

The desired status for the container from Amazon ECS.

## KnownStatus

The known status for the container from Amazon ECS.

## ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

## Limits

The resource limits specified at the container level, such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

## CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

## StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.

## FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

## Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

## Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

## ClockDrift

The information about the difference between the reference time and the system time. This applies to the Linux operating system. This capability uses Amazon Time Sync Service to measure clock accuracy and provide the clock error bound for containers. For more information, see [Set the time for your Linux instance](#) in the *Amazon EC2 User Guide for Linux instances*.

## ReferenceTime

The basis of clock accuracy. Amazon ECS uses the Coordinated Universal Time (UTC) global standard through NTP, for example 2021-09-07T16:57:44Z.

## ClockErrorBound

The measure of clock error, defined as the offset to UTC. This error is the difference in milliseconds between the reference time and the system time.

## ClockSynchronizationStatus

Indicates whether the most recent synchronization attempt between the system time and the reference time was successful.

The valid values are SYNCHRONIZED and NOT\_SYNCHRONIZED.

## ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.

## Example task metadata response

The following JSON response is for a single-container task.

```

## Amazon ECS task metadata available for tasks on Fargate

Amazon ECS on Fargate provides a method to retrieve various metadata, network metrics, and [Docker stats](#) about your containers and the tasks they are a part of. This is referred to as the *task metadata endpoint*. The following task metadata endpoint versions are available for Amazon ECS on Fargate tasks:

- Task metadata endpoint version 4 – Available for tasks that use platform version 1.4.0 or later.
- Task metadata endpoint version 3 – Available for tasks that use platform version 1.1.0 or later.

All containers belonging to tasks that are launched with the `awsvpc` network mode receive a local IPv4 address within a predefined link-local address range. When a container queries the metadata endpoint, the container agent can determine which task the container belongs to based on its unique IP address, and metadata and stats for that task are returned.

### Topics

- [Amazon ECS task metadata endpoint version 4 for tasks on Fargate](#)
- [Amazon ECS task metadata endpoint version 3 for tasks on Fargate](#)

## Amazon ECS task metadata endpoint version 4 for tasks on Fargate

### Important

If you are using Amazon ECS tasks hosted on Amazon EC2 instances, see [Amazon ECS task metadata endpoint](#).

Beginning with Fargate platform version 1.4.0, an environment variable named `ECS_CONTAINER_METADATA_URI_V4` is injected into each container in a task. When you query the task metadata endpoint version 4, various task metadata and [Docker stats](#) are available to tasks.

The task metadata endpoint version 4 functions like the version 3 endpoint but provides additional network metadata for your containers and tasks. Additional network metrics are available when querying the `/stats` endpoints as well.

The task metadata endpoint is on by default for all Amazon ECS tasks run on AWS Fargate that use platform version 1.4.0 or later.

### Note

To avoid the need to create new task metadata endpoint versions in the future, additional metadata may be added to the version 4 output. We will not remove any existing metadata or change the metadata field names.

### Fargate task metadata endpoint version 4 paths

The following task metadata endpoints are available to containers:

`${ECS_CONTAINER_METADATA_URI_V4}`

This path returns metadata for the container.

`${ECS_CONTAINER_METADATA_URI_V4}/task`

This path returns metadata for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see [Amazon ECS task metadata v4 JSON response for tasks on Fargate](#).

`${ECS_CONTAINER_METADATA_URI_V4}/stats`

This path returns Docker stats for the Docker container. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

**Note**

Amazon ECS tasks on AWS Fargate require that the container run for ~1 second prior to returning the container stats.

`${ECS_CONTAINER_METADATA_URI_V4}/task/stats`

This path returns Docker stats for all of the containers associated with the task. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

**Note**

Amazon ECS tasks on AWS Fargate require that the container run for ~1 second prior to returning the container stats.

## Amazon ECS task metadata v4 JSON response for tasks on Fargate

The following metadata is returned in the task metadata endpoint (`${ECS_CONTAINER_METADATA_URI_V4}/task`) JSON response.

### Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

### ServiceName

The name of the service to which the task belongs. `ServiceName` will appear for Fargate tasks is associated with a service.

### VPCID

The VPC ID of the Amazon EC2 container instance. This field only appears for Amazon EC2 instances.

**Note**

The VPCID metadata is only included when using Amazon ECS container agent version 1.63.1 or later.

**TaskARN**

The Amazon Resource Name (ARN) of the task to which the container belongs.

**Family**

The family of the Amazon ECS task definition for the task.

**Revision**

The revision of the Amazon ECS task definition for the task.

**DesiredStatus**

The desired status for the task from Amazon ECS.

**KnownStatus**

The known status for the task from Amazon ECS.

**Limits**

The resource limits specified at the task levels such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

**PullStartedAt**

The timestamp for when the first container image pull began.

**PullStoppedAt**

The timestamp for when the last container image pull finished.

**AvailabilityZone**

The Availability Zone the task is in.

**Note**

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 (Windows).

## LaunchType

The launch type the task is using. When using cluster capacity providers, this indicates whether the task is using Fargate or EC2 infrastructure.

### Note

This LaunchType metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later (Linux) or 1.0.0 or later (Windows).

## EphemeralStorageMetrics

The reserved size and current usage of the ephemeral storage of this task.

### Note

Fargate reserves space on disk. It is only used by Fargate. You aren't billed for it. It isn't shown in these metrics. However, you can see this additional storage in other tools such as `df`.

## Utilized

The current ephemeral storage usage (in MiB) of this task.

## Reserved

The reserved ephemeral storage (in MiB) of this task. The size of the ephemeral storage can't be changed in a running task. You can specify the `ephemeralStorage` object in your task definition to change the amount of ephemeral storage. The `ephemeralStorage` is specified in GiB, not MiB. The `ephemeralStorage` and the `EphemeralStorageMetrics` are only available on Fargate Linux platform version 1.4.0 or later.

## Containers

A list of container metadata for each container associated with the task.

## DockerId

The Docker ID for the container.

When you use Fargate, the id is a 32-digit hex followed by a 10 digit number.

## Name

The name of the container as specified in the task definition.

## DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

## Image

The image for the container.

## ImageID

The SHA-256 digest of the image manifest. This is the digest that can be used to pull the image using the format `repository-url/image@sha256:digest`.

## Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

## Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

## DesiredStatus

The desired status for the container from Amazon ECS.

## KnownStatus

The known status for the container from Amazon ECS.

## ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

## Limits

The resource limits specified at the container level such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

## CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

## StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.

## FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

## Type

The type of the container. Containers that are specified in your task definition are of type `NORMAL`. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

## LogDriver

The log driver the container is using.

### **Note**

This `LogDriver` metadata is only included when using Amazon ECS Linux container agent version `1.45.0` or later.

## LogOptions

The log driver options defined for the container.

### **Note**

This `LogOptions` metadata is only included when using Amazon ECS Linux container agent version `1.45.0` or later.

## ContainerARN

The Amazon Resource Name (ARN) of the container.

**Note**

This ContainerARN metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

## Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

## Snapshotter

The snapshotter that was used by containerd to download this container image. Valid values are overlayfs, which is the default, and soci, used when lazy loading with a SOCI index. This parameter is only available for tasks that run on Linux platform version 1.4.0.

## RestartCount

The number of times the container has been restarted.

**Note**

The RestartCount metadata is included only if a restart policy is enabled for the container. For more information, see [Restart individual containers in Amazon ECS tasks with container restart policies](#).

## ClockDrift

The information about the difference between the reference time and the system time. This capability uses Amazon Time Sync Service to measure clock accuracy and provide the clock error bound for containers. For more information, see [Set the time for your Linux instance](#) in the *Amazon EC2 User Guide for Linux instances*.

## ReferenceTime

The basis of clock accuracy. Amazon ECS uses the Coordinated Universal Time (UTC) global standard through NTP, for example 2021-09-07T16:57:44Z.

## ClockErrorBound

The measure of clock error, defined as the offset to UTC. This error is the difference in milliseconds between the reference time and the system time.

## ClockSynchronizationStatus

Indicates whether the most recent synchronization attempt between the system time and the reference time was successful.

The valid values are SYNCHRONIZED and NOT\_SYNCHRONIZED.

## ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.

## Amazon ECS task metadata v4 examples for tasks on Fargate

The following examples show sample outputs from the task metadata endpoints for Amazon ECS tasks run on AWS Fargate.

From the container, you can use curl followed by the task meta data endpoint to query the endpoint for example `curl ${ECS_CONTAINER_METADATA_URI_V4}/task`.

### Example container metadata response

When querying the `${ECS_CONTAINER_METADATA_URI_V4}` endpoint you are returned only metadata about the container itself. The following is an example output.

```

## Amazon ECS task metadata endpoint version 3 for tasks on Fargate

### Important

The task metadata version 3 endpoint is no longer being actively maintained. We recommend that you update the task metadata version 4 endpoint to get the latest metadata endpoint information. For more information, see [the section called “Task metadata endpoint version 4 for tasks on Fargate”](#).

Beginning with Fargate platform version 1.1.0, an environment variable named `ECS_CONTAINER_METADATA_URI` is injected into each container in a task. When you query the task metadata version 3 endpoint, various task metadata and [Docker stats](#) are available to tasks.

The task metadata endpoint feature is enabled by default for Amazon ECS tasks hosted on Fargate that use platform version 1.1.0 or later. For more information, see [Fargate platform versions for Amazon ECS](#).

### Task metadata endpoint paths for tasks on Fargate

The following API endpoints are available to containers:

`${ECS_CONTAINER_METADATA_URI}`

This path returns metadata JSON for the container.

`${ECS_CONTAINER_METADATA_URI}/task`

This path returns metadata JSON for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see [Amazon ECS task metadata v3 JSON response for tasks on Fargate](#).

`${ECS_CONTAINER_METADATA_URI}/stats`

This path returns Docker stats JSON for the specific Docker container. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

`${ECS_CONTAINER_METADATA_URI}/task/stats`

This path returns Docker stats JSON for all of the containers associated with the task. For more information about each of the returned stats, see [ContainerStats](#) in the Docker API documentation.

## Amazon ECS task metadata v3 JSON response for tasks on Fargate

The following information is returned from the task metadata endpoint (`${ECS_CONTAINER_METADATA_URI}/task`) JSON response.

Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

TaskARN

The Amazon Resource Name (ARN) of the task to which the container belongs.

Family

The family of the Amazon ECS task definition for the task.

Revision

The revision of the Amazon ECS task definition for the task.

DesiredStatus

The desired status for the task from Amazon ECS.

KnownStatus

The known status for the task from Amazon ECS.

## Limits

The resource limits specified at the task level, such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

## PullStartedAt

The timestamp for when the first container image pull began.

## PullStoppedAt

The timestamp for when the last container image pull finished.

## AvailabilityZone

The Availability Zone the task is in.

### Note

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 or later (Windows).

## Containers

A list of container metadata for each container associated with the task.

### DockerId

The Docker ID for the container.

### Name

The name of the container as specified in the task definition.

### DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

### Image

The image for the container.

## ImageID

The SHA-256 digest of the image manifest. This is the digest that can be used to pull the image using the format `repository-url/image@sha256:digest`.

## Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

## Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

## DesiredStatus

The desired status for the container from Amazon ECS.

## KnownStatus

The known status for the container from Amazon ECS.

## ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

## Limits

The resource limits specified at the container level, such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

## CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

## StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.

## FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

## Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

## Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

## ClockDrift

The information about the difference between the reference time and the system time. This applies to the Linux operating system. This capability uses Amazon Time Sync Service to measure clock accuracy and provide the clock error bound for containers. For more information, see [Set the time for your Linux instance](#) in the *Amazon EC2 User Guide for Linux instances*.

## ReferenceTime

The basis of clock accuracy. Amazon ECS uses the Coordinated Universal Time (UTC) global standard through NTP, for example 2021-09-07T16:57:44Z.

## ClockErrorBound

The measure of clock error, defined as the offset to UTC. This error is the difference in milliseconds between the reference time and the system time.

## ClockSynchronizationStatus

Indicates whether the most recent synchronization attempt between the system time and the reference time was successful.

The valid values are SYNCHRONIZED and NOT\_SYNCHRONIZED.

## ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.

## Amazon ECS task metadata v3 examples for tasks on Fargate

The following JSON response is for a single-container task.

```

```

## Amazon ECS container introspection

The Amazon ECS container agent provides an API operation for gathering details about the container instance on which the agent is running and the associated tasks running on that instance. You can use the **curl** command from within the container instance to query the Amazon ECS container agent (port 51678) and return container instance metadata or task information.

**⚠ Important**

Your container instance must have an IAM role that allows access to Amazon ECS in order to retrieve the metadata. For more information, see [Amazon ECS container instance IAM role](#).

To view container instance metadata, log in to your container instance via SSH and run the following command. Metadata includes the container instance ID, the Amazon ECS cluster in which the container instance is registered, and the Amazon ECS container agent version information.

```
curl -s http://localhost:51678/v1/metadata | python3 -mjson.tool
```

Output:

```
{
  "Cluster": "cluster_name",
  "ContainerInstanceArn": "arn:aws:ecs:region:aws_account_id:container-
instance/cluster_name/container_instance_id",
  "Version": "Amazon ECS Agent - v1.30.0 (02ff320c)"
}
```

To view information about all of the tasks that are running on a container instance, log in to your container instance via SSH and run the following command:

```
curl http://localhost:51678/v1/tasks
```

Output:

```
{
  "Tasks": [
    {
      "Arn": "arn:aws:ecs:us-west-2:012345678910:task/default/example5-58ff-46c9-
ae05-543f8example",
      "DesiredStatus": "RUNNING",
      "KnownStatus": "RUNNING",
      "Family": "hello_world",
      "Version": "8",
    }
  ]
}
```

```

    "Containers": [
      {
        "DockerId":
"9581a69a761a557fbfce1d0f6745e4af5b9dbfb86b6b2c5c4df156f1a5932ff1",
        "DockerName": "ecs-hello_world-8-mysql-fcae8ac8f9f1d89d8301",
        "Name": "mysql",
        "CreatedAt": "2023-10-08T20:09:11.44527186Z",
        "StartedAt": "2023-10-08T20:09:11.44527186Z",
        "ImageID":
"sha256:2ae34abc2ed0a22e280d17e13f9c01aaf725688b09b7a1525d1a2750e2c0d1de"
      },
      {
        "DockerId":
"bf25c5c5b2d4dba68846c7236e75b6915e1e778d31611e3c6a06831e39814a15",
        "DockerName": "ecs-hello_world-8-wordpress-e8bfddf9b488dff36c00",
        "Name": "wordpress"
      }
    ]
  }
}

```

You can view information for a particular task that is running on a container instance. To specify a specific task or container, append one of the following to the request:

- The task ARN (?taskarn=*task\_arn*)
- The Docker ID for a container (?dockerid=*docker\_id*)

To get task information with a container's Docker ID, log in to your container instance via SSH and run the following command.

#### Note

Amazon ECS container agents before version 1.14.2 require full Docker container IDs for the introspection API, not the short version that is shown with **docker ps**. You can get the full Docker ID for a container by running the **docker ps --no-trunc** command on the container instance.

```
curl http://localhost:51678/v1/tasks?dockerid=79c796ed2a7f
```

**Output:**

```
{
  "Arn": "arn:aws:ecs:us-west-2:012345678910:task/default/e01d58a8-151b-40e8-
bc01-22647b9ecfec",
  "Containers": [
    {
      "DockerId":
"79c796ed2a7f864f485c76f83f3165488097279d296a7c05bd5201a1c69b2920",
      "DockerName": "ecs-nginx-efs-2-nginx-9ac0808dd0afa495f001",
      "Name": "nginx",
      "CreatedAt": "2023-10-08T20:09:11.44527186Z",
      "StartedAt": "2023-10-08T20:09:11.44527186Z",
      "ImageID":
"sha256:2ae34abc2ed0a22e280d17e13f9c01aaf725688b09b7a1525d1a2750e2c0d1de"
    }
  ],
  "DesiredStatus": "RUNNING",
  "Family": "nginx-efs",
  "KnownStatus": "RUNNING",
  "Version": "2"
}
```

## Identify unauthorized behavior using Runtime Monitoring

Amazon GuardDuty is a threat detection service that helps protect your accounts, containers, workloads, and the data within your AWS environment. Using machine learning (ML) models, and anomaly and threat detection capabilities, GuardDuty continuously monitors different log sources and runtime activity to identify and prioritize potential security risks and malicious activities in your environment.

Runtime Monitoring in GuardDuty protects workloads running on Fargate and EC2 container instances by continuously monitoring AWS log and networking activity to identify malicious or unauthorized behavior. Runtime Monitoring uses a lightweight, fully managed GuardDuty security agent that analyzes on-host behavior, such as file access, process execution, and network connections. This covers issues including escalation of privileges, use of exposed credentials, or communication with malicious IP addresses, domains, and the presence of malware on your Amazon EC2 instances and container workloads. For more information, see [GuardDuty Runtime Monitoring](#) in the *GuardDuty User Guide*.

Your security administrator enables Runtime Monitoring for a single or multiple accounts in AWS Organizations for GuardDuty. They also select whether GuardDuty automatically deploys the GuardDuty security agent when you use Fargate. All your clusters are automatically protected, and GuardDuty manages the security agent on your behalf.

You can also manually configure the GuardDuty security agent in the following cases:

- You use EC2 container instances
- You need granular control to enable Runtime Monitoring at the cluster level

To use Runtime Monitoring, you must configure the clusters that are protected, and install and manage the GuardDuty security agent on your EC2 container instances.

## How Runtime Monitoring works with Amazon ECS

Runtime Monitoring uses a lightweight GuardDuty security agent that monitors Amazon ECS workload activity for how applications are requesting, gaining access and consuming underlying system resources.

For Fargate tasks, the GuardDuty security agent runs as a sidecar container for each task.

For EC2 container instances, the GuardDuty security agent runs as a process on the instance.

The GuardDuty security agent collects data from the following resources, and then sends the data to GuardDuty to process. You can view the findings in the GuardDuty console. You can also send them to other AWS services such as AWS Security Hub CSPM, or a third-party security vendor for aggregation and remediation. For information about how to view and manage findings, see [Managing Amazon GuardDuty findings](#) in the *Amazon GuardDuty User Guide*.

- Responses from the following Amazon ECS API calls:
  - [DescribeClusters](#)

The response parameters include the Runtime Monitoring tag (when the tag is set) when you use the `--include TAGS` option.

- [DescribeTasks](#)

For Fargate, the response parameters include the GuardDuty sidecar container.

- [ListAccountSettings](#)

The response parameters include the Runtime Monitoring account setting, which is set by your security administrator.

- The container agent introspection data. For more information, see [Amazon ECS container introspection](#).
- The task metadata endpoint for the compute option:
  - [Amazon ECS task metadata endpoint version 4](#)
  - [Amazon ECS task metadata endpoint version 4 for tasks on Fargate](#)

## Considerations

Consider the following when using Runtime Monitoring:

- Runtime Monitoring has a cost associated with it. For more information, see [Amazon GuardDuty Pricing](#).
- Runtime Monitoring is not supported on Amazon ECS Anywhere.
- Runtime Monitoring is not supported for the Windows operating system.
- When you use Amazon ECS Exec on Fargate, you must specify the container name because the GuardDuty security agent runs as a sidecar container.
- You cannot use Amazon ECS Exec on the GuardDuty security agent sidecar container.
- The IAM user that controls Runtime Monitoring at the cluster level, must have the appropriate IAM permissions for tagging. For more information, see [IAM tutorial: Define permissions to access AWS resources based on tags](#) in the *IAM User Guide*.
- Fargate tasks must use a task execution role. This role grants the tasks permission to retrieve, update, and manage the GuardDuty security agent, which is stored in an Amazon ECR private repository, on your behalf.
- Runtime Monitoring is not supported for applications running on Amazon ECS Managed Instances.

## Resource utilization

The tag that you add to the cluster counts toward the cluster tag quota.

The GuardDuty agent sidecar container does not count toward the containers per task definition quota.

As with most security software, there is a slight overhead for GuardDuty. For information about the Fargate memory limits, see [CPU and memory limits](#) in the *GuardDuty User Guide*. For information about the Amazon EC2 memory limits, see [CPU and memory limit for GuardDuty agent](#).

## Runtime Monitoring for Amazon ECS Fargate workloads

If you use EC2 container instances, you must manually configure Runtime Monitoring. For more information, see [Runtime Monitoring for EC2 workloads on Amazon ECS](#).

You can have GuardDuty manage the security agent on your container instances. This option is only available for Fargate. This option ( GuardDuty agent management) is available in GuardDuty

When you use GuardDuty agent management, GuardDuty performs the following operations:

- Creates VPC endpoints for GuardDuty for each VPC that hosts a cluster.
- Retrieves, and installs the latest GuardDuty security agent as a sidecar container on all new standalone Fargate tasks, and new service deployments.

A new service deployment happens the first time you launch a service, or when you update an existing service with the **force new deployment** option.

## Turning on Runtime Monitoring for Amazon ECS

You can configure GuardDuty to automatically manage the security agent for all your Fargate clusters.

### Prerequisites

The following are prerequisites for using Runtime Monitoring:

- The Fargate platform version must be 1.4.0 or later for Linux.
- IAM roles and permissions for Amazon ECS:
  - Fargate tasks must use a task execution role. This role grants the tasks permission to retrieve, update, and manage the GuardDuty security agent on your behalf. For more information see [Amazon ECS task execution IAM role](#).
- You control Runtime Monitoring for a cluster with a pre-defined tag. If your access policies restrict access based on tags, you must grant explicit permissions to your IAM users to tag

clusters. For more information, see [IAM tutorial: Define permissions to access AWS resources based on tags](#) in the *IAM User Guide*.

- Connecting to the Amazon ECR repository:

The GuardDuty security agent is stored in an Amazon ECR repository. Each standalone and service task must have access to the repository. You can use one of the following options:

- For tasks in public subnets, you can either use a public IP address for the task, or create a VPC endpoint for Amazon ECR in the subnet where the task runs. For more information, see [Amazon ECR interface VPC endpoints \(AWS PrivateLink\)](#) in the *Amazon Elastic Container Registry User Guide*.
- For tasks in private subnets, you can use a Network Address Translation (NAT) gateway, or create a VPC endpoint for Amazon ECR in the subnet where the task runs.

For more information, see [Private subnet and NAT gateway](#).

- You must have the `AWSServiceRoleForAmazonGuardDuty` role for GuardDuty. For more information, see [Service-linked role permissions for GuardDuty](#) in the *Amazon GuardDuty User Guide*.
- Any files that you want to protect with Runtime Monitoring must be accessible by the root user. If you manually changed the permissions of a file, you must set it to 755.

The following are prerequisites for using Runtime Monitoring on EC2 container instances:

- You must use version 20230929 or later of the Amazon ECS-AMI.
- You must run Amazon ECS agent to version 1.77 or later on the container instances.
- You must use kernel version 5.10 or later.
- For information about the supported Linux operating systems and architectures, see [Which operating models and workloads does GuardDuty Runtime Monitoring support](#).
- You can use Systems Manager to manage your container instances. For more information, see [Setting up Systems Manager for EC2 instances](#) in the *AWS Systems Manager Session Manager User Guide*.

## Procedure

You enable Runtime Monitoring in GuardDuty. For information about how to enable the feature, see [Enabling Runtime Monitoring](#) in the *Amazon GuardDuty User Guide*.

## Adding Runtime Monitoring to existing Amazon ECS Fargate tasks

When you turn on Runtime Monitoring, all new standalone tasks, and new service deployments in the cluster are protected automatically. In order to preserve the immutability constraint, existing tasks are not affected.

### Prerequisites

1. Turn on Runtime Monitoring. For more information, see [Turning on Runtime Monitoring for Amazon ECS](#).
2. Fargate tasks must use a task execution role. This role grants the tasks permission to retrieve, update, and manage the GuardDuty security agent on your behalf. For more information see [Amazon ECS task execution IAM role](#).

### Procedure

- To immediately protect a task, you need to perform one of the following actions:
  - For standalone tasks, stop the tasks, and then start them. For more information, see [Stopping an Amazon ECS task](#) and [Running an application as an Amazon ECS task](#)
  - For tasks that are part of a service, update the service with the "force new deployment" option. For more information, see [Updating an Amazon ECS service](#).

## Removing Runtime Monitoring from an Amazon ECS cluster

You might want to exclude certain clusters from protection, for example clusters that you use for testing. This causes GuardDuty to perform the following operations on resources in the cluster:

- No longer deploy the GuardDuty security agent to new standalone Fargate tasks, or new service deployments.

In order to preserve the immutability constraint, existing tasks and deployments with Runtime Monitoring enabled are not affected.

- Stop billing and no longer accepts run time events for tasks.

### Procedure

Perform the following steps to remove Runtime Monitoring from a cluster.

1. Use the Amazon ECS console or AWS CLI to set the GuardDutyManaged tag key on the cluster to false. For more information, see [Updating a cluster](#) or [Working with tags using the CLI or API](#). Use the following values for the tag.

 **Note**

The Key and Value are case sensitive and must exactly match the strings.

Key = GuardDutyManaged, Value = false

2. Delete the GuardDuty VPC endpoint for the cluster. For more information about how to delete VPC endpoints, see [Delete an interface endpoint](#) in the *AWS PrivateLink User Guide*.

## Removing Runtime Monitoring for Amazon ECS from an account

When you no longer want to use Runtime Monitoring, disable the feature in GuardDuty. For information about how to disable the feature, see [Enabling Runtime Monitoring](#) in the *Amazon GuardDuty User Guide*.

GuardDuty performs the following operations:

- Deletes the VPC endpoints for GuardDuty for each VPC that hosts a cluster.
- No longer deploys the GuardDuty security agent to new standalone Fargate tasks, or new service deployments.

In order to preserve the immutability constraint, existing tasks and deployments are not affected until they are stopped, replicated, or scaled.

- Stops billing and no longer accepts run time events for tasks.

## Runtime Monitoring for EC2 workloads on Amazon ECS

Use this option when you use EC2 instances for your capacity, or when you need granular control of Runtime Monitoring at the cluster-level on Fargate.

You provision the clusters for Runtime Monitoring by adding a pre-defined tag.

For EC2 container instances, you download, install, and manage the GuardDuty security agent.

For Fargate, GuardDuty manages the security agent on your behalf.

## Turning on Runtime Monitoring for Amazon ECS

You can turn on Runtime Monitoring for clusters with EC2 instances, or when you need granular control of Runtime Monitoring at the cluster-level on Fargate.

The following are prerequisites for using Runtime Monitoring:

- The Fargate platform version must be 1.4.0 or later for Linux.
- IAM roles and permissions for Amazon ECS:
  - Fargate tasks must use a task execution role. This role grants the tasks permission to retrieve, update, and manage the GuardDuty security agent on your behalf. For more information see [Amazon ECS task execution IAM role](#).
  - You control Runtime Monitoring for a cluster with a pre-defined tag. If your access policies restrict access based on tags, you must grant explicit permissions to your IAM users to tag clusters. For more information, see [IAM tutorial: Define permissions to access AWS resources based on tags](#) in the *IAM User Guide*.
- Connecting to the Amazon ECR repository:

The GuardDuty security agent is stored in an Amazon ECR repository. Each standalone and service task must have access to the repository. You can use one of the following options:

- For tasks in public subnets, you can either use a public IP address for the task, or create a VPC endpoint for Amazon ECR in the subnet where the task runs. For more information, see [Amazon ECR interface VPC endpoints \(AWS PrivateLink\)](#) in the *Amazon Elastic Container Registry User Guide*.
- For tasks in private subnets, you can use a Network Address Translation (NAT) gateway, or create a VPC endpoint for Amazon ECR in the subnet where the task runs.

For more information, see [Private subnet and NAT gateway](#).

- You must have the `AWSServiceRoleForAmazonGuardDuty` role for GuardDuty. For more information, see [Service-linked role permissions for GuardDuty](#) in the *Amazon GuardDuty User Guide*.
- Any files that you want to protect with Runtime Monitoring must be accessible by the root user. If you manually changed the permissions of a file, you must set it to 755.

The following are prerequisites for using Runtime Monitoring on EC2 container instances:

- You must use version 20230929 or later of the Amazon ECS-AMI.
- You must run Amazon ECS agent to version 1.77 or later on the container instances.
- You must use kernel version 5.10 or later.
- For information about the supported Linux operating systems and architectures, see [Which operating models and workloads does GuardDuty Runtime Monitoring support](#).
- You can use Systems Manager to manage your container instances. For more information, see [Setting up Systems Manager for EC2 instances](#) in the *AWS Systems Manager Session Manager User Guide*.

You turn on Runtime Monitoring in GuardDuty. For information about how to enable the feature, see [Enabling Runtime Monitoring](#) in the *Amazon GuardDuty User Guide*.

## Adding Runtime Monitoring an Amazon ECS cluster

Configure Runtime Monitoring for the cluster, and then install the GuardDuty security agent on your EC2 container instances.

### Prerequisites

1. Turn on Runtime Monitoring. For more information, see [Turning on Runtime Monitoring for Amazon ECS](#).
2. You control Runtime Monitoring for a cluster with a pre-defined tag. If your access policies restrict access based on tags, you must grant explicit permissions to your IAM users to tag clusters. For more information, see [IAM tutorial: Define permissions to access AWS resources based on tags](#) in the *IAM User Guide*.

### Procedure

Perform the following operations to add Runtime Monitoring to a cluster.

1. Create a VPC endpoint for GuardDuty for each cluster VPC. For more information, see [Creating Amazon VPC endpoint manually](#) in the *GuardDuty User Guide*.
2. Configure the EC2 container instances.
  - a. Update the Amazon ECS agent to version 1.77 or later on the EC2 container instances in the cluster. For more information see [Updating the Amazon ECS container agent](#).

- b. Install the GuardDuty security agent on the EC2 container instances in the cluster. For more information, see [Managing the security agent on an Amazon EC2 instance manually](#) in the *GuardDuty User Guide*.

All new and existing tasks, and deployments are immediately protected because the GuardDuty security agent runs as a process on the EC2 container instance.

3. Use the Amazon ECS console or AWS CLI to set the GuardDutyManaged tag key on the cluster to true. For more information, see [Updating a cluster](#) or [Working with tags using the CLI or API](#). Use the following values for the tag.

 **Note**

The Key and Value are case sensitive and must exactly match the strings.

Key = GuardDutyManaged, Value = true

## Adding Runtime Monitoring to existing Amazon ECS tasks

When you turn on Runtime Monitoring, all new standalone tasks, and new service deployments in the cluster are protected automatically. In order to preserve the immutability constraint, existing tasks are not affected.

### Prerequisites

- Turn on Runtime Monitoring. For more information, see [Turning on Runtime Monitoring for Amazon ECS](#).

### Procedure

- To immediately protect a task, you need to perform one of the following actions:
  - For standalone tasks, stop the tasks, and then start them. For more information, see [Stopping an Amazon ECS task](#) and [Running an application as an Amazon ECS task](#).
  - For tasks that are part of a service, update the service with the "force new deployment" option. For more information, see [Updating an Amazon ECS service](#).

## Removing Runtime Monitoring from an Amazon ECS cluster

You can remove Runtime Monitoring from a cluster. This causes GuardDuty to stop monitoring all resources in the cluster.

### To remove Runtime Monitoring from a cluster

1. Use the Amazon ECS console or AWS CLI to set the `GuardDutyManaged` tag key on the cluster to `false`. For more information, see [Updating a cluster](#) or [Working with tags using the CLI or API](#).

#### Note

The Key and Value are case sensitive and must exactly match the strings.

Key = `GuardDutyManaged`, Value = `false`

2. Uninstall the GuardDuty security agent on your EC2 container instances in the cluster.

For more information, see [Uninstalling the security agent manually](#) in the *GuardDuty User Guide*.

3. Delete the GuardDuty VPC endpoint for each cluster VPC. For more information about how to delete VPC endpoints, see [Delete an interface endpoint](#) in the *AWS PrivateLink User Guide*.

## Updating the GuardDuty security agent on your Amazon ECS container instances

For information about how to update the GuardDuty security agent on your EC2 container instances, see [Updating GuardDuty security agent](#) in the *Amazon GuardDuty User Guide*.

## Removing Runtime Monitoring for Amazon ECS from an account

When you no longer want to use Runtime Monitoring, disable the feature in GuardDuty. For information about how to disable the feature, see [Enabling Runtime Monitoring](#) in the *Amazon GuardDuty User Guide*.

Remove Runtime Monitoring from all clusters. For more information, see [Removing Runtime Monitoring from an Amazon ECS cluster](#).

# Runtime Monitoring Troubleshooting

You might need to troubleshoot or verify that Runtime Monitoring is enabled and running on your tasks and containers.

## Topics

- [How can I tell if Runtime Monitoring is active on my account?](#)
- [How can I tell if Runtime Monitoring is active on a cluster?](#)
- [How can I tell if the GuardDuty security agent is running on a Fargate task?](#)
- [How can I tell if the GuardDuty security agent is running on an EC2 container instance?](#)
- [What happens when there is no task execution role for a task running on the cluster?](#)
- [How can I tell if I have the correct permissions to tag clusters for Runtime Monitoring?](#)
- [What happens when there is no connection Amazon ECR?](#)
- [How do I address out of memory errors on my Fargate tasks after enabling Runtime Monitoring?](#)

## How can I tell if Runtime Monitoring is active on my account?

In the Amazon ECS console, the information is in on the **Account Settings** page.

You can also run `list-account-settings` with the `effective-settings` option.

```
aws ecs list-account-settings --effective-settings
```

## Output

The setting with **name** set to `guardDutyActivate` and **value** set to `on` indicates that the account is configured. You must check with your GuardDuty administrator to see if the management is automatic or manual.

```
{
  "setting": {
    "name": "guardDutyActivate",
    "value": "enabled",
    "principalArn": "arn:aws:iam::123456789012:root",
    "type": "aws-managed"
  }
}
```

```
}
```

## How can I tell if Runtime Monitoring is active on a cluster?

You can review the coverage statistics in the GuardDuty console. This includes information for the Amazon ECS resources associated with your own account or your member accounts is the percentage of the healthy clusters over all the clusters in the selected AWS Region. This includes the coverage for clusters that use the Fargate and EC2s. For more information, see [Reviewing coverage statistics](#) in the *Amazon GuardDuty User Guide*.

## How can I tell if the GuardDuty security agent is running on a Fargate task?

The GuardDuty security agent runs as a sidecar container for Fargate tasks.

In the Amazon ECS console, the sidecar is displayed under **Containers** on the **Task details** page.

You can run `describe-tasks` and look for the container with a **name** set to `aws-gd-agent` and the **lastStatus** set to `RUNNING`.

The following example shows the output for the default cluster for task `aws:ecs:us-east-1:123456789012:task/0b69d5c0-d655-4695-98cd-5d2d5EXAMPLE`.

```
aws ecs describe-tasks --cluster default --tasks aws:ecs:us-  
east-1:123456789012:task/0b69d5c0-d655-4695-98cd-5d2d5EXAMPLE
```

### Output

The container named `gd-agent` is in the `RUNNING` state.

```
"containers": [  
  {  
    "containerArn": "arn:aws:ecs:us-east-1:123456789012:container/4df26bb4-  
f057-467b-a079-96167EXAMPLE",  
    "taskArn": "arn:aws:ecs:us-east-1:123456789012:task/0b69d5c0-  
d655-4695-98cd-5d2d5EXAMPLE",  
    "lastStatus": "RUNNING",  
    "healthStatus": "UNKNOWN",  
    "memory": "string",  
    "name": "aws-gd-agent"  
  }  
]
```

## How can I tell if the GuardDuty security agent is running on an EC2 container instance?

Run the following command to view the status:

```
sudo systemctl status amazon-guardduty-agent
```

The log file is in the following location:

```
/var/log/amzn-guardduty-agent
```

## What happens when there is no task execution role for a task running on the cluster?

For Fargate tasks, the task starts without the GuardDuty security agent sidecar container. The GuardDuty dashboard will show that the task is missing protection in the coverage statistics dashboard.

## How can I tell if I have the correct permissions to tag clusters for Runtime Monitoring?

In order to tag a cluster, you must have the `ecs:TagResource` action for both `CreateCluster` and `UpdateCluster`.

The following is a snippet of an example policy.

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:TagResource"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "ecs:CreateAction" : [ "CreateCluster", "UpdateCluster" ]
        }
      }
    }
  ]
}
```

```
]
}
```

## What happens when there is no connection Amazon ECR?

For Fargate tasks, the task starts without the GuardDuty security agent sidecar container. The GuardDuty dashboard will show that the task is missing protection in the coverage statistics dashboard.

## How do I address out of memory errors on my Fargate tasks after enabling Runtime Monitoring?

The GuardDuty security agent is a lightweight process. However, the process still consumes resources according to the size of the workload. We recommend using container resource tracking tooling, such as Amazon CloudWatch Container Insights to stage GuardDuty deployments in your cluster. These tools help you to discover the consumption profile of the GuardDuty security agent for your applications. You can then adjust your Fargate task size, if required, to avoid potential out of memory conditions.

## Monitor Amazon ECS containers with ECS Exec

With Amazon ECS Exec, you can directly interact with containers without needing to first interact with the host container operating system, open inbound ports, or manage SSH keys. You can use ECS Exec to run commands in or get a shell to a container running on an Amazon EC2 instance or on AWS Fargate. This makes it easier to collect diagnostic information and quickly troubleshoot errors. For example, in a development context, you can use ECS Exec to easily interact with various process in your containers and troubleshoot your applications. And in production scenarios, you can use it to gain break-glass access to your containers to debug issues.

You can run commands in a running Linux or Windows container using ECS Exec from the Amazon ECS API, AWS Command Line Interface (AWS CLI), AWS SDKs, or the AWS Copilot CLI. For details on using ECS Exec, as well as a video walkthrough, using the AWS Copilot CLI, see the [Copilot GitHub documentation](#).

You can also use ECS Exec to maintain stricter access control policies. By selectively turning on this feature, you can control who can run commands and on which tasks they can run those commands. With a log of each command and their output, you can use ECS Exec to view which tasks were run and you can use CloudTrail to audit who accessed a container.

## Considerations

Consider the following when using ECS Exec:

- ECS Exec might not work as expected when running on operating systems not supported by Systems Manager. For information about the supported operating systems, see [Operating system types](#) in the *AWS Systems Manager User Guide*.
- ECS Exec is supported for tasks that run on the following infrastructure:
  - Linux containers on Amazon EC2 on any Amazon ECS-optimized AMI, including Bottlerocket
  - Linux and Windows containers on external instances (Amazon ECS Anywhere)
  - Linux and Windows containers on AWS Fargate
  - Windows containers on Amazon EC2 on the following Windows Amazon ECS-optimized AMIs (with the container agent version 1.56 or later):
    - Amazon ECS-optimized Windows Server 2022 Full AMI
    - Amazon ECS-optimized Windows Server 2022 Core AMI
    - Amazon ECS-optimized Windows Server 2019 Full AMI
    - Amazon ECS-optimized Windows Server 2019 Core AMI
    - Amazon ECS-optimized Windows Server 20H2 Core AMI
- If you configured an HTTP proxy for your task, set the NO\_PROXY environment variable to "NO\_PROXY=169.254.169.254,169.254.170.2" in order to bypass the proxy for EC2 instance metadata and IAM role traffic. If you don't configure the NO\_PROXY environment variable, there can be failures when retrieving instance metadata or IAM role credentials from the metadata endpoint within the container. Setting the NO\_PROXY environment variable as recommended filters the metadata and IAM traffic so that requests to 169.254.169.254 and 169.254.170.2 do not go through the HTTP proxy.
- ECS Exec and Amazon VPC
  - If you are using interface Amazon VPC endpoints with Amazon ECS, you must create the interface Amazon VPC endpoints for the Systems Manager Session Manager (ssmmessages). For more information about Systems Manager VPC endpoints, see [Use AWS PrivateLink to set up a VPC endpoint for Session Manager](#) in the *AWS Systems Manager User Guide*.
  - If you are using interface Amazon VPC endpoints with Amazon ECS, and you are using AWS KMS key for encryption, then you must create the interface Amazon VPC endpoint for AWS KMS key. For more information, see [Connecting to AWS KMS key through a VPC endpoint](#) in the *AWS Key Management Service Developer Guide*.

- When you have tasks that run on Amazon EC2 instances, use `awsvpc` networking mode. If you don't have internet access (such as not configured to use a NAT gateway), you must create the interface Amazon VPC endpoints for the Systems Manager Session Manager (`ssmmessages`). For more information about `awsvpc` network mode considerations, see [Considerations](#). For more information about Systems Manager VPC endpoints, see [Use AWS PrivateLink to set up a VPC endpoint for Session Manager](#) in the *AWS Systems Manager User Guide*.
- Amazon ECS Exec isn't supported for tasks running in an IPv6-only configuration. For more information about running tasks in an IPv6-only configuration, see [Amazon ECS task networking options for Fargate](#) and [Amazon ECS task networking options for EC2](#).
- ECS Exec and SSM
  - Your task requires a task IAM role with the required permissions for SSM Session Manager. For tasks on Amazon EC2, if no task role is configured, the instance role of the underlying Amazon EC2 instance is used instead. For more information, see [ECS Exec permissions](#).
  - When a user runs commands on a container using ECS Exec, these commands are run as the root user. The SSM agent and its child processes run as root even when you specify a user ID for the container.
  - The SSM agent requires that the container file system can be written to in order to create the required directories and files. Therefore, making the root file system read-only using the `readonlyRootFilesystem` task definition parameter, or any other method, isn't supported.
  - While starting SSM sessions outside of the `execute-command` action is possible, this results in the sessions not being logged and being counted against the session limit. We recommend limiting this access by denying the `ssm:start-session` action using an IAM policy. For more information, see [Limiting access to the Start Session action](#).
- The following features run as a sidecar container. Therefore, you must specify the container name to run the command on.
  - Runtime Monitoring
  - Service Connect
- Users can run all of the commands that are available within the container context. The following actions might result in orphaned and zombie processes: terminating the main process of the container, terminating the command agent, and deleting dependencies. To cleanup zombie processes, we recommend adding the `initProcessEnabled` flag to your task definition.
- ECS Exec uses some CPU and memory. You'll want to accommodate for that when specifying the CPU and memory resource allocations in your task definition.

- You must be using AWS CLI version 1.22.3 or later or AWS CLI version 2.3.6 or later. For information about how to update the AWS CLI, see [Installing or updating the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide Version 2*.
- You can have only one ECS Exec session per process ID (PID) namespace. If you are [sharing a PID namespace in a task](#), you can only start ECS Exec sessions into one container.
- The ECS Exec session has an idle timeout time of 20 minutes. This value can't be changed.
- You can't turn on ECS Exec for existing tasks. It can only be turned on for new tasks.
- You can't use ECS Exec when you use `run-task` to launch a task on a cluster that uses managed scaling with asynchronous placement (launch a task with no instance).
- You can't run ECS Exec against Microsoft Nano Server containers.

## Architecture

ECS Exec makes use of AWS Systems Manager (SSM) Session Manager to establish a connection with the running container and uses AWS Identity and Access Management (IAM) policies to control access to running commands in a running container. This is made possible by bind-mounting the necessary SSM agent binaries into the container. The Amazon ECS or AWS Fargate agent is responsible for starting the SSM core agent inside the container alongside your application code. For more information, see [Systems Manager Session Manager](#).

You can audit which user accessed the container using the `ExecuteCommand` event in AWS CloudTrail and log each command (and their output) to Amazon S3 or Amazon CloudWatch Logs. To encrypt data between the local client and container with your own encryption key, you must provide the AWS Key Management Service (AWS KMS) key.

## Configuring ECS Exec

To use ECS Exec, you must first turn on the feature for your tasks and services, and then you can run commands in your containers.

### Optional task definition changes

If you set the task definition parameter `initProcessEnabled` to `true`, this starts the `init` process inside the container. This removes any zombie SSM agent child processes found. The following provides an example.

```
{
```

```

"taskRoleArn": "ecsTaskRole",
"networkMode": "awsvpc",
"requiresCompatibilities": [
    "EC2",
    "FARGATE"
],
"executionRoleArn": "ecsTaskExecutionRole",
"memory": ".5 gb",
"cpu": ".25 vcpu",
"containerDefinitions": [
    {
        "name": "amazon-linux",
        "image": "amazonlinux:latest",
        "essential": true,
        "command": ["sleep", "3600"],
        "linuxParameters": {
            "initProcessEnabled": true
        }
    }
],
"family": "ecs-exec-task"
}

```

## Turning on ECS Exec for your tasks and services

You can turn on the ECS Exec feature for your services and standalone tasks by specifying the `--enable-execute-command` flag when using one of the following AWS CLI commands: [create-service](#), [update-service](#), [start-task](#), or [run-task](#).

For example, if you run the following command, the ECS Exec feature is turned on for a newly created service that runs on Fargate. For more information about creating services, see [create-service](#).

```

aws ecs create-service \
  --cluster cluster-name \
  --task-definition task-definition-name \
  --enable-execute-command \
  --service-name service-name \
  --launch-type FARGATE \
  --network-configuration
  "awsvpcConfiguration={subnets=[subnet-12344321],securityGroups=[sg-12344321],assignPublicIp=EN
  \

```

```
--desired-count 1
```

After you turn on ECS Exec for a task, you can run the following command to confirm the task is ready to be used. If the `lastStatus` property of the `ExecuteCommandAgent` is listed as `RUNNING` and the `enableExecuteCommand` property is set to `true`, then your task is ready.

```
aws ecs describe-tasks \  
  --cluster cluster-name \  
  --tasks task-id
```

The following output snippet is an example of what you might see.

```
{  
  "tasks": [  
    {  
      ...  
      "containers": [  
        {  
          ...  
          "managedAgents": [  
            {  
              "lastStartedAt": "2021-03-01T14:49:44.574000-06:00",  
              "name": "ExecuteCommandAgent",  
              "lastStatus": "RUNNING"  
            }  
          ]  
        }  
      ],  
      ...  
      "enableExecuteCommand": true,  
      ...  
    }  
  ]  
}
```

## Running commands using ECS Exec

## Logging using ECS Exec

You can configure logging for ECS Exec sessions to capture commands and their output for auditing and troubleshooting purposes.

## Turning on logging in your tasks and services

### Important

For more information about CloudWatch pricing, see [CloudWatch Pricing](#). Amazon ECS also provides monitoring metrics that are provided at no additional cost. For more information, see [Monitor Amazon ECS using CloudWatch](#).

Amazon ECS provides a default configuration for logging commands run using ECS Exec. The default is to send logs to CloudWatch Logs using the `awslogs` log driver that's configured in your task definition. If you want to provide a custom configuration, the AWS CLI supports a `--configuration` flag for both the `create-cluster` and `update-cluster` commands. The container image requires `script` and `cat` to be installed in order to have command logs uploaded correctly to Amazon S3 or CloudWatch Logs. For more information about creating clusters, see [create-cluster](#).

### Note

This configuration only handles the logging of the `execute-command` session. It doesn't affect logging of your application.

The following example creates a cluster and then logs the output to your CloudWatch Logs LogGroup named `cloudwatch-log-group-name` and your Amazon S3 bucket named `s3-bucket-name`.

You must use an AWS KMS customer managed key to encrypt the log group when you set the `CloudWatchEncryptionEnabled` option to `true`. For information about how to encrypt the log group, see [Encrypt log data in CloudWatch Logs using AWS Key Management Service](#), in the *Amazon CloudWatch Logs User Guide*.

```
aws ecs create-cluster \
  --cluster-name cluster-name \
  --configuration executeCommandConfiguration="{ \
    kmsKeyId=string, \
    logging= OVERRIDE, \
    logConfiguration={ \
      cloudWatchLogGroupName=cloudwatch-log-group-name, \
```

```
cloudWatchEncryptionEnabled=true, \  
s3BucketName=s3-bucket-name, \  
s3EncryptionEnabled=true, \  
s3KeyPrefix=demo \  
} \  
}"
```

The logging property determines the behavior of the logging capability of ECS Exec:

- **NONE:** logging is turned off.
- **DEFAULT:** logs are sent to the configured awslogs driver. If the driver isn't configured, then no log is saved.
- **OVERRIDE:** logs are sent to the provided Amazon CloudWatch Logs LogGroup, Amazon S3 bucket, or both.

## IAM permissions required for Amazon CloudWatch Logs or Amazon S3 Logging

To enable logging, the Amazon ECS task role that's referenced in your task definition needs to have additional permissions. These additional permissions can be added as a policy to the task role. They're different depending on if you direct your logs to Amazon CloudWatch Logs or Amazon S3.

### Amazon CloudWatch Logs

The following example policy adds the required Amazon CloudWatch Logs permissions.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "logs:DescribeLogGroups"  
      ],  
      "Resource": "*"   
    },  
    {  
      "Effect": "Allow",  
      "Action": [  
        "logs:CreateLogStream",  
        "logs:DescribeLogStreams",
```

```

        "logs:PutLogEvents"
    ],
    "Resource": "arn:aws:logs:us-east-1:111122223333:log-group:/aws/
ecs/cloudwatch-log-group-name:"
    }
]
}

```

## Amazon S3

The following example policy adds the required Amazon S3 permissions.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketLocation"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetEncryptionConfiguration"
      ],
      "Resource": "arn:aws:s3:::s3-bucket-name"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::s3-bucket-name/*"
    }
  ]
}

```

## IAM permissions required for encryption using your own AWS KMS key (KMS key)

By default, the data transferred between your local client and the container uses TLS 1.2 encryption that AWS provides. To further encrypt data using your own KMS key, you must create a KMS key and add the `kms:Decrypt` permission to your task IAM role. This permission is used by your container to decrypt the data. For more information about creating a KMS key, see [Creating keys](#).

You add the following inline policy to your task IAM role which requires the AWS KMS permissions. For more information, see [ECS Exec permissions](#).

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt"
      ],
      "Resource": "arn:aws:kms:us-east-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
    }
  ]
}
```

For the data to be encrypted using your own KMS key, the user or group using the `execute-command` action must be granted the `kms:GenerateDataKey` permission.

The following example policy for your user or group contains the required permission to use your own KMS key. You must specify the Amazon Resource Name (ARN) of your KMS key.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
        "Effect": "Allow",
        "Action": [
            "kms:GenerateDataKey"
        ],
        "Resource": "arn:aws:kms:us-
east-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
    }
}
```

## Using IAM policies to limit access to ECS Exec

You limit user access to the `execute-command` API action by using one or more of the following IAM policy condition keys:

- `aws:ResourceTag/clusterTagKey`
- `ecs:ResourceTag/clusterTagKey`
- `aws:ResourceTag/taskTagKey`
- `ecs:ResourceTag/taskTagKey`
- `ecs:container-name`
- `ecs:cluster`
- `ecs:task`
- `ecs:enable-execute-command`

With the following example IAM policy, users can run commands in containers that are running within tasks with a tag that has an `environment` key and `development` value and in a cluster that's named `cluster-name`.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```

```

        "ecs:ExecuteCommand",
        "ecs:DescribeTasks"
    ],
    "Resource": [
        "arn:aws:ecs:us-east-1:111122223333:task/cluster-name/*",
        "arn:aws:ecs:us-east-1:111122223333:cluster/cluster-name"
    ],
    "Condition": {
        "StringEquals": {
            "ecs:ResourceTag/environment": "development"
        }
    }
}
]
}

```

With the following IAM policy example, users can't use the `execute-command` API when the container name is `production-app`.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "ecs:ExecuteCommand"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "ecs:container-name": "production-app"
        }
      }
    }
  ]
}

```

With the following IAM policy, users can only launch tasks when ECS Exec is turned off.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:RunTask",
        "ecs:StartTask",
        "ecs:CreateService",
        "ecs:UpdateService"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "ecs:enable-execute-command": "false"
        }
      }
    }
  ]
}
```

### Note

Because the `execute-command` API action contains only task and cluster resources in a request, only cluster and task tags are evaluated.

For more information about IAM policy condition keys, see [Actions, resources, and condition keys for Amazon Elastic Container Service](#) in the *Service Authorization Reference*.

## Limiting access to the Start Session action

While starting SSM sessions on your container outside of ECS Exec is possible, this could potentially result in the sessions not being logged. Sessions started outside of ECS Exec also count against the session quota. We recommend limiting this access by denying the `ssm:start-session` action directly for your Amazon ECS tasks using an IAM policy. You can deny access to all Amazon ECS tasks or to specific tasks based on the tags used.

The following is an example IAM policy that denies access to the `ssm:start-session` action for tasks in all Regions with a specified cluster name. You can optionally include a wildcard with the *cluster-name*.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ssm:StartSession",
      "Resource": [
        "arn:aws:ecs:us-east-1:111122223333:task/cluster-name/*"
      ]
    }
  ]
}
```

The following is an example IAM policy that denies access to the `ssm:start-session` action on resources in all Regions tagged with tag key `Task-Tag-Key` and tag value `Exec-Task`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ssm:StartSession",
      "Resource": "arn:aws:ecs:*:*:task/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Task-Tag-Key": "Exec-Task"
        }
      }
    }
  ]
}
```

# Troubleshooting ECS Exec

For additional troubleshooting help, see [Troubleshooting issues with Exec](#).

## Running commands using ECS Exec

You can use Amazon ECS Exec to collect diagnostic information related to your containers and troubleshoot errors that are encountered throughout the lifecycle of your containers.

### Prerequisites

Before you start using ECS Exec, make sure that you have completed these actions:

- Review the considerations. For more information, see [Considerations](#)
- Configure ECS Exec for your tasks and services. For more information, see [Configuring ECS Exec](#)
- **Install and configure the AWS CLI.** For more information, see [Get started with the AWS CLI](#).
- **Install Session Manager plugin for the AWS CLI.** For more information, see [Install the Session Manager plugin for the AWS CLI](#).
- **Configure a task role with appropriate permissions.** You must use a task role with the appropriate permissions for ECS Exec. For more information, see [Task IAM role](#).
- **Verify version requirements.** ECS Exec has version requirements depending on whether your tasks are hosted on Amazon EC2 or AWS Fargate:
  - If you're using Amazon EC2, you must use an Amazon ECS optimized AMI that was released after January 20th, 2021, with an agent version of 1.50.2 or greater. For more information, see [Amazon ECS optimized AMIs](#).
  - If you're using AWS Fargate, you must use platform version 1.4.0 or higher (Linux) or 1.0.0 (Windows). For more information, see [AWS Fargate platform versions](#).

### Using the console for service tasks

You can use the console to run commands using ECS Exec.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, choose the service.

The service details page displays.

4. On the service details page, choose **Tasks**. Then, choose the task.
5. Under **Containers**, choose the container where you want to use ECS Exec.
6. To run commands, do one of the following:
  - Choose **Connect**.

A CloudShell session displays where you can run your commands.

- Choose the arrow, and then choose **Copy AWS CLI command**.

You can then run the commands locally.

## Expected results

If the connection is successful, you should see an interactive shell prompt from your container. You can now run commands directly in the container environment. To exit the session, choose **End Session**.

## Using the console for standalone tasks

You can use the console to run commands using ECS Exec.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Tasks** section, choose the task.

The task details page displays.

4. Under **Containers**, choose the container where you want to use ECS Exec.
5. To run commands, do one of the following:
  - Choose **Connect**.

A CloudShell session displays where you can run your commands.

- Choose the arrow, and then choose **Copy AWS CLI command**.

You can then run the commands locally.

## Expected results

If the connection is successful, you should see an interactive shell prompt from your container. You can now run commands directly in the container environment. To exit the session, choose **End Session**.

## Using the command shell

You can use the command shell to run commands using ECS Exec.

After you have confirmed the `ExecuteCommandAgent` is running, you can open an interactive shell on your container using the following command. If your task contains multiple containers, you must specify the container name using the `--container` flag. Amazon ECS only supports initiating interactive sessions, so you must use the `--interactive` flag.

The following command will run an interactive `/bin/sh` command against a container named *container-name* for a task with an ID of *task-id*.

The *task-id* is the Amazon Resource Name (ARN) of the task.

```
aws ecs execute-command --cluster cluster-name \  
  --task task-id \  
  --container container-name \  
  --interactive \  
  --command "/bin/sh"
```

### Expected results

If the command is successful, you should see an interactive shell prompt from your container. You can now run commands directly in the container environment. To exit the session, type `exit` or press `Ctrl+D`.

## AWS Compute Optimizer recommendations for Amazon ECS

AWS Compute Optimizer generates recommendations for Amazon ECS task and container sizes. For more information, see [What is AWS Compute Optimizer?](#) in the *AWS Compute Optimizer User Guide*.

### Task and container size recommendations for Amazon ECS services on AWS Fargate

AWS Compute Optimizer generates recommendations for Amazon ECS services on AWS Fargate. AWS Compute Optimizer recommends task CPU and task memory size and container CPU,

container memory and container memory reservation sizes. These recommendations are displayed on the following pages of the Compute Optimizer console.

- **Recommendations for Amazon ECS services on Fargate** page
- **Amazon ECS services on Fargate details** page

For more information, see [Viewing recommendations for Amazon ECS services on Fargate](#) in the *AWS Compute Optimizer User Guide*.

# Amazon ECS MCP server

The Amazon ECS MCP server is a fully managed service enabling AI-powered experiences for development and operations. [Model Context Protocol \(MCP\)](#) provides a standardized interface that enriches AI agents and applications with real-time, contextual knowledge of your Amazon ECS workloads, enabling more accurate, context-aware responses and AI-powered workflows to inspect, troubleshoot, and optimize your Amazon ECS workloads.

## Note

The Amazon ECS MCP server is in preview release and is subject to change.

## Overview

The Amazon ECS MCP server can be easily integrated with any MCP compatible AI coding assistants, like [Kiro](#), or third-party tools like [Claude Code](#), [Cursor](#), and [Cline](#), to enhance your development workflow.

During deployment, it provides real-time visibility into service deployments and task health status. For development and operations, the server simplifies Amazon ECS management by providing high-level workflows for monitoring container health, analyzing service events, and investigating deployment issues. For debugging and troubleshooting, the server accelerates issue resolution through comprehensive diagnostic tools that analyze task failures, container logs, and network configurations. These capabilities are accessible through natural language interactions, enabling you to perform complex container operations more intuitively and efficiently.

The Amazon ECS MCP server provides several tools that you can use to:

- **Monitor deployments and services**

Check deployment status, track service events, and monitor container health in real-time.

- **Troubleshoot container issues**

Analyze task failures, investigate image pull errors, and examine container logs with customizable time windows.

- **Inspect network configurations**

Review VPC, subnet, and security group configurations for your Amazon ECS services.

- **Resolve resource dependencies**

Identify blockers preventing task definition deletion and understand resource relationships.

- **Assess security posture**

Collect cluster security configuration data for AI-powered analysis against AWS best practices with prioritized remediation steps.

- **Access up-to-date documentation**

Look up current AWS documentation for accurate, timely guidance on Amazon ECS features and configurations.

The fully managed Amazon ECS MCP server is hosted in the AWS cloud, eliminating the need for local installation and maintenance. It provides enterprise-grade capabilities like automatic updates and patching, centralized security through IAM integration, comprehensive audit logging via CloudTrail, and the proven scalability, reliability, and support of AWS.

## Getting started

To get started, see [Getting Started with the Amazon ECS MCP Server](#).

## Getting Started with the Amazon ECS MCP Server

This guide walks you through the steps to set up and use the Amazon ECS MCP Server with your AI code assistants. You'll learn how to configure your environment, connect to the server, and start managing your Amazon ECS clusters through natural language interactions.

### Note

The Amazon ECS MCP server is in preview release and is subject to change.

## Prerequisites

Before you begin, ensure you have:

- [Created an AWS account with access to Amazon ECS](#)
- [Installed and configured the AWS CLI with credentials](#)
- [Installed Python 3.10+](#)
- [Installed uv](#)

## Setup

### Verify prerequisites

Check that your Python version is 3.10 or higher

```
python3 --version
```

Check uv installation

```
uv --version
```

Verify AWS CLI configuration

```
aws configure list
```

### Set up IAM permissions

You will need [IAM](#) permissions to make read-only requests to AWS services and interact with the MCP server. You can either leverage [AWS managed policies](#), or a single custom policy for more granular control.

#### Option 1: Combined managed and custom policy

1. Attach the AWS managed policy **ReadOnlyAccess** for read-only access to all AWS services
2. Create and attach an additional custom policy for MCP permissions (see the following MCP permissions JSON)

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "MCPServerAccess",
```

```

    "Effect": "Allow",
    "Action": [
        "ecs-mcp:InvokeReadOnlyTools",
        "ecs-mcp:UseMcp"
    ],
    "Resource": "*"
  }
]
}

```

## Option 2: Single custom policy (most granular control)

Alternatively, you can create and attach a single custom JSON policy that includes both AWS service permissions and MCP permissions:

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "MCPServerAccess",
      "Effect": "Allow",
      "Action": [
        "ecs-mcp:InvokeReadOnlyTools",
        "ecs-mcp:UseMcp"
      ],
      "Resource": "*"
    },
    {
      "Sid": "ECSReadOnlyAccess",
      "Effect": "Allow",
      "Action": [
        "ecs:ListAccountSettings",
        "ecs:ListClusters",
        "ecs:ListContainerInstances",
        "ecs:ListTaskDefinitions",
        "ecs:ListServices",
        "ecs:ListServiceDeployments",
        "ecs:ListTasks",
        "ecs:DescribeClusters",
        "ecs:DescribeCapacityProviders",
        "ecs:DescribeContainerInstances",
        "ecs:DescribeTaskDefinition",
        "ecs:DescribeServices",

```

```

        "ecs:DescribeServiceDeployments",
        "ecs:DescribeServiceRevisions",
        "ecs:DescribeTaskSets",
        "ecs:DescribeTasks"
    ],
    "Resource": "*"
},
{
    "Sid": "CloudWatchLogsReadOnlyAccess",
    "Effect": "Allow",
    "Action": [
        "logs:DescribeLogGroups",
        "logs:DescribeLogStreams",
        "logs:GetLogEvents",
        "logs:FilterLogEvents"
    ],
    "Resource": "*"
},
{
    "Sid": "ELBReadOnlyAccess",
    "Effect": "Allow",
    "Action": [
        "elasticloadbalancing:DescribeLoadBalancers",
        "elasticloadbalancing:DescribeTargetGroups",
        "elasticloadbalancing:DescribeListeners"
    ],
    "Resource": "*"
},
{
    "Sid": "EC2ReadOnlyAccess",
    "Effect": "Allow",
    "Action": [
        "ec2:DescribeVpcs",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeRouteTables",
        "ec2:DescribeNetworkInterfaces"
    ],
    "Resource": "*"
},
{
    "Sid": "ECRReadOnlyAccess",
    "Effect": "Allow",
    "Action": [

```

```

        "ecr:DescribeRepositories",
        "ecr:DescribeImages"
    ],
    "Resource": "*"
},
{
    "Sid": "IAMReadOnlyAccessForSecurityAnalysis",
    "Effect": "Allow",
    "Action": [
        "iam:GetRole",
        "iam:ListAttachedRolePolicies",
        "iam:GetPolicy",
        "iam:GetPolicyVersion",
        "iam:ListRolePolicies",
        "iam:GetRolePolicy"
    ],
    "Resource": "*"
}
]
}
```

## Choose and configure an AI assistant

Install MCP-compatible AI assistants or any MCP-compatible tool. For instance, you can use [Kiro](#), [Cline](#), [Cursor](#), or [Claude Code](#). Then set up your AI code assistant to use Amazon ECS MCP server through MCP Proxy for AWS, which is required for secure, authenticated access to the Amazon ECS MCP Server. The proxy acts as a client-side bridge, handling AWS SigV4 authentication using your local AWS credentials. The below example uses Kiro CLI. Follow this [link](#) to learn more about setting up MCP in Kiro.

### Locate MCP configuration file

- **macOS/Linux:**

```
~/ .kiro/settings/mcp.json
```

- **Windows:**

```
%USERPROFILE%\ .kiro\settings\mcp.json
```

Create the configuration file if it doesn't exist.

## Add MCP server configuration

Be sure to replace the region (`{region}`) placeholder with your desired region (e.g., `us-west-2`). Refer to the [the section called “Linux containers on AWS Fargate”](#) for a complete list of regions. Also be sure to replace the `{profile}` placeholder with your [AWS CLI profile name](#), e.g. `default`.

### For Mac/Linux:

```
{
  "mcpServers": {
    "ecs-mcp": {
      "disabled": false,
      "type": "stdio",
      "command": "uvx",
      "args": [
        "mcp-proxy-for-aws@latest",
        "https://ecs-mcp.{region}.api.aws/mcp",
        "--service",
        "ecs-mcp",
        "--profile",
        "{profile}",
        "--region",
        "{region}"
      ]
    }
  }
}
```

### For Windows:

```
{
  "mcpServers": {
    "ecs-mcp": {
      "disabled": false,
      "type": "stdio",
      "command": "uvx",
      "args": [
        "--from",
        "mcp-proxy-for-aws@latest",
        "mcp-proxy-for-aws.exe",
        "https://ecs-mcp.{region}.api.aws/mcp",
        "--service",
        "ecs-mcp",
      ]
    }
  }
}
```

```
        "--profile",
        "{profile}",
        "--region",
        "{region}"
    ]
}
}
```

## Verify configuration

Restart Kiro CLI, `kiro-cli`, verify that the MCP server is loaded, `/mcp`, and check available tools / `tools`.

## Verify your setup

### Test connection

Ask your AI assistant a simple question to verify the connection:

```
List all ECS clusters in my AWS account
```

You should see a list of your Amazon ECS clusters.

## Converse with your AI assistant that uses the Amazon ECS MCP server

### Example 1: Monitor deployments

```
Check deployment status for my web-service in production-cluster
Show me the ALB URL for my deployed service
Get service events for the last hour
```

### Example 2: Investigate container health

```
Show me all tasks that failed in the last 2 hours
Why are my containers failing health checks?
Display container logs for my api-service
```

### Example 3: Troubleshoot failures

```
Analyze task failures in my production cluster
```

```
Check for image pull errors in the last 30 minutes
Why is my task definition stuck in DELETE_IN_PROGRESS state?
```

## Example 4: Inspect configurations

```
Show me the network configuration for my web-service
What security groups are attached to my service?
List all VPC and subnet details for my ECS service
```

## Example 5: Assess security posture

```
Are there any security issues with my production cluster?
Analyze IAM roles and policies for my web-service
Check for overly permissive security groups in my ECS cluster
```

# Common configurations and best practices

## Multiple AWS profiles

If you work with multiple AWS accounts, create separate MCP server configurations.

### For Mac/Linux:

```
{
  "mcpServers": {
    "ecs-mcp-prod": {
      "disabled": false,
      "type": "stdio",
      "command": "uvx",
      "args": [
        "mcp-proxy-for-aws@latest",
        "https://ecs-mcp.{region}.api.aws/mcp",
        "--service",
        "ecs-mcp",
        "--profile",
        "production",
        "--region",
        "us-west-2"
      ]
    },
    "ecs-mcp-dev": {
```

```
"disabled": false,
"type": "stdio",
"command": "uvx",
"args": [
  "mcp-proxy-for-aws@latest",
  "https://ecs-mcp.{region}.api.aws/mcp",
  "--service",
  "ecs-mcp",
  "--profile",
  "development",
  "--region",
  "us-east-1"
]
}
}
```

## Security best practices

Do not pass secrets or sensitive information via allowed input mechanisms:

- Do not include secrets or credentials in any configuration files
- Do not pass sensitive information directly in prompts to the model
- Do not include secrets in task definitions or service configurations
- Avoid logging sensitive information in application logs
- Use or Parameter Store to store sensitive information

## Tool configurations

For a complete list of tools and configurations, see [Amazon ECS MCP Server Tool Configurations](#).

## Amazon ECS MCP Server Tool Configurations

This guide shows all the configurations available for the fully managed Amazon ECS MCP Server.

### Note

The Amazon ECS MCP server is in preview release and is subject to change.

## Environment variables

### **AWS\_PROFILE** (optional)

AWS credentials profile name to use; can be overridden by the `--profile` command-line argument.

Example: `export AWS_PROFILE=dev`

### **AWS\_REGION** (optional)

AWS region for SigV4 signing; defaults to `us-west-2` if not set.

Example: `export AWS_REGION=us-west-2`

## Arguments

### **SigV4 MCP endpoint URL** (required)

The MCP endpoint URL to connect to.

Example: `https://ecs-mcp.us-west-2.api.aws/mcp`

### **--service** (optional)

AWS service name for SigV4 signing; auto-detected from the endpoint hostname if not provided.

Example: `--service ecs-mcp`

### **--profile** (optional)

AWS credentials profile to use. Defaults to the `AWS_PROFILE` environment variable if not specified.

Example: `--profile dev`

### **--region**

AWS region to use. Uses `AWS_REGION` environment variable if not set, defaults to `us-east-1`.

Example: `--region us-west-2`

## **--read-only** (optional)

Disable tools which may require write permissions (tools which DO NOT require write permissions are annotated with `readOnlyHint=true`). By default, all tools are enabled.

Example: `--read-only`

For more configuration options, see [Configuration parameters](#).

## **Tools**

The Amazon ECS MCP server exposes the following [MCP tools](#).

### **Read only tools**

#### **get\_deployment\_status**

The tool checks your Amazon ECS deployment status for a particular Amazon ECS cluster and service.

- Required IAM actions:
  - `ecs:DescribeServices`
  - `elasticloadbalancing:DescribeTargetGroups`
  - `elasticloadbalancing:DescribeLoadBalancers`
- Required parameters:
  - `cluster_name` (string): Amazon ECS cluster name
  - `service_name` (string): Amazon ECS service name
- Response: The tool returns deployment status and details associated with the deployment.

#### **fetch\_service\_events**

This tool retrieves Amazon ECS service events for diagnostics with customizable time windows.

- Required IAM actions:
  - `ecs:DescribeServices`
- Required parameters:
  - `cluster_name` (string): Amazon ECS cluster name
  - `service_name` (string): Amazon ECS service name

- Optional parameters:
  - `time_window` (integer): You can mention a time window in seconds (default is 1 hour or 3600 seconds)
  - `start_time` (string): Custom start time in ISO format
  - `end_time` (string): Custom end time in ISO format
- Response: The tool returns list of events for the service with summary.

### **fetch\_task\_failures**

This tool helps you retrieve and analyze Amazon ECS task failures with summaries. Using this tool, you can identify any patterns in task failures.

- Required IAM actions:
  - `ecs:ListTasks`
  - `ecs:DescribeTasks`
- Required parameters:
  - `cluster_name` (string): Amazon ECS cluster name where your task resides
- Optional parameters:
  - `service_name` (string): You can filter by specific service
  - `time_window` (integer): You can mention a time window in seconds (default is 1 hour or 3600 seconds)
  - `start_time` (string): Custom start time in ISO format
  - `end_time` (string): Custom end time in ISO format
- Response: The tool returns TaskFailureResult with failed tasks and summary

### **fetch\_task\_logs**

This tool retrieves CloudWatch logs for Amazon ECS tasks with flexible time range options. You use this tool to troubleshoot runtime issues.

- Required IAM actions:
  - `ecs:DescribeServices`
  - `ecs:DescribeTaskDefinition`
  - `logs:FilterLogEvents`
- Required parameters:
  - `cluster_name` (string): Amazon ECS cluster name

- `service_name` (string): Amazon ECS service name
- Optional parameters:
  - `time_window` (integer): You can mention a time window in seconds (default is 1 hour or 3600 seconds)
  - `start_time` (string): Custom start time in ISO format
  - `end_time` (string): Custom end time in ISO format
  - `log_group_name` (string): Specify CloudWatch log group
- Response: The tool returns TaskLogsResult with log entries

### **get\_task\_definition\_deletion\_blockers**

This tool identifies dependencies that can prevent task definition deletion. The tool is appropriate when you are running cleanup operations and understand what is preventing Amazon ECS resource deletion.

- Required IAM actions:
  - `ecs:ListClusters`
  - `ecs:ListServices`
  - `ecs:DescribeServices`
  - `ecs:ListTasks`
  - `ecs:DescribeTasks`
- Required parameters:
  - `task_definition_arn` (string): Task definition Amazon Resource Name (ARN) to analyze
- Response: The tool returns the blockers and deletion status

### **detect\_image\_pull\_failures**

This tool helps you to detect and categorize container image pull failures.

- Required IAM actions:
  - `ecs:ListTasks`
  - `ecs:DescribeTasks`
- Required parameters:
  - `cluster_name` (string): Amazon ECS cluster name
- Optional parameters:
  - `service_name` (string): You can filter by specific service

- `time_window` (integer): You can mention a time window in seconds (default is 1 hour or 3600 seconds)
- `start_time` (string): Custom start time in ISO format
- `end_time` (string): Custom end time in ISO format
- Response: The tool returns the failures and summary

### **fetch\_network\_configuration**

This tool retrieves Amazon ECS service network configuration details. You can use this tool to understand the Amazon VPC, subnet, security group configuration of your Amazon ECS setup.

- Required IAM actions:
  - `ecs:DescribeServices`
  - `ec2:DescribeSecurityGroups`
  - `ec2:DescribeSubnets`
- Required parameters:
  - `cluster_name` (string): Amazon ECS cluster name
  - `service_name` (string): Amazon ECS service name
- Response: The tool returns a list of `NetworkConfigurationResult` with network details

### **get\_security\_recommendations**

This tool collects Amazon ECS cluster security configuration data for AI-powered security analysis. It gathers IAM roles and policies, network settings (security groups, subnets, public IP), task definition container settings, and cluster-level configuration. Your AI assistant compares this data against AWS security best practices and generates a prioritized findings report with remediation steps.

- Required IAM actions:
  - `ecs:DescribeClusters`
  - `ecs:ListServices`
  - `ecs:DescribeServices`
  - `ecs:DescribeTaskDefinition`
  - `ec2:DescribeSecurityGroups`
  - `ec2:DescribeSubnets`
  - `iam:GetRole`
  - `iam:ListAttachedRolePolicies`

- `iam:GetPolicy`
- `iam:GetPolicyVersion`
- `iam:ListRolePolicies`
- `iam:GetRolePolicy`
- Required parameters:
  - `cluster_name` (string): Amazon ECS cluster name to analyze
- Optional parameters:
  - `service_name` (string): Scope analysis to a single service. If omitted, all services in the cluster are analyzed.
  - `max_services` (integer): Maximum number of services to analyze (default 25, capped at 50)
- Response: The tool returns cluster configuration, service configurations, task definition settings, network security details, IAM role and policy data, and any collection warnings. Your AI assistant uses this data to generate a prioritized security findings report with remediation guidance.

## **fetch\_action\_logs**

Use this tool to fetch Amazon ECS Action Logs and troubleshoot container lifecycle operations. With Action Logs, you gain visibility into service-side operations that Amazon ECS performs on your behalf, including ENI attachments, image pulls, load balancer registrations, throttling retries, and permission errors. Use this tool when tasks fail to start, deployments stall, or you need to understand what Amazon ECS did during an operation. The tool returns action log entries if Action Logs are enabled for the cluster, or a status message if Action Logs are not configured.

- Required IAM actions:
  - `ecs:DescribeClusters`
  - `logs:DescribeDeliverySources`
  - `logs:DescribeDeliveries`
  - `logs:DescribeDeliveryDestinations`
  - `logs:FilterLogEvents`
- Required parameters:
  - `cluster_name`: The name or ARN of the Amazon ECS cluster.
- Optional parameters:

- `service_name`: The Amazon ECS service name to filter action logs by.
- `task_id`: The task ARN or ID to filter action logs by.
- `deployment_id`: The deployment ID to filter action logs by.
- `log_level`: The log level filter. Valid values are ERROR, WARN, or INFO.
- `time_window`: The time window in seconds. The default value is 3,600 seconds.
- `start_time`: The custom start time in ISO format.
- `end_time`: The custom end time in ISO format.
- **Response:**

The tool returns the action logs discovery status for the cluster. If Action Logs are enabled with a CloudWatch Logs destination, the tool also returns matching log entries. Each entry includes a timestamp, log level, event name, resource ARN, and event details. Results are limited to 1,000 entries. To retrieve more targeted data, use narrower time windows or additional filters.

## Knowledge tools

These tools provide access to up-to-date AWS documentation. They are powered by the AWS Knowledge MCP Server and do not require any IAM permissions from the caller — the Amazon ECS MCP service connects to the knowledge endpoint on your behalf.

### `aws_knowledge_aws___search_documentation`

This tool searches AWS documentation for relevant pages matching a query.

- **Required IAM actions:** None
- **Required parameters:**
  - `search_phrase` (string): Search query for AWS documentation
- **Optional parameters:**
  - `topics` (array): Up to 3 topic areas to search across (default `["general"]`)
  - `limit` (integer): Maximum number of results per topic (default 5)
- **Response:** The tool returns matching documentation pages with titles, URLs, and context snippets.

## **aws\_knowledge\_aws\_\_read\_documentation**

This tool reads the content of AWS documentation pages and returns them in markdown format.

- Required IAM actions: None
- Required parameters:
  - `requests` (array): Array of request objects. Each object contains:
    - `url` (string, required): URL of the documentation page to read
    - `max_length` (integer, optional): Maximum characters to return (default 10000)
    - `start_index` (integer, optional): Character position to start reading from (default 0)
- Response: The tool returns the documentation page content in markdown format. Long pages are returned in chunks with navigation support.

# Amazon ECS troubleshooting

You might need to troubleshoot issues with your load balancers, tasks, services, or container instances. This chapter helps you find diagnostic information from the Amazon ECS container agent, the Docker daemon on the container instance, and the service event log in the Amazon ECS console.

For information about stopped tasks, see one of the following.

| Action                                  | Learn more                                                     |  |

## Resolve Amazon ECS stopped task errors

When your task fails to start, you see an error message in the console and in the describe-tasks output parameters (stoppedReason and stopCode).

You can view stopped tasks in the console for one hour. In order to see stopped tasks, you must change the filter option. For more information, see [Viewing Amazon ECS stopped task errors](#).

The following pages provide information about stopped tasks.

- Learn about changes to stopped task error messages.

[Amazon ECS stopped task error messages updates](#)

- View your stopped tasks so you can get information about the cause.

[Viewing Amazon ECS stopped task errors](#)

- Learn about the stopped tasks error messages and possible reasons for the errors.

[Amazon ECS stopped tasks error messages](#)

- Learn how to verify stopped task connectivity and fix the errors.

[Verifying Amazon ECS stopped task connectivity](#)

## Amazon ECS stopped task error messages updates

Beginning June 14, 2024 the Amazon ECS team is changing the stopped task error messages as described in the following tables. The stopCode will not change. If your applications depend on exact error message strings, you must update your applications with the new strings. For help with questions or problems, contact AWS Support.

 **Note**

We recommend that you do not rely on the error messages for your automation, because the error messages are subject to change.

**CannotPullContainerError**

| Old error message                                                                                                                                                                         | New error message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |

## Viewing Amazon ECS stopped task errors

If you have trouble starting a task, your task might be stopping because of application or configuration errors. For example, you run the task and the task displays a PENDING status and then disappears.

If your task was created by an Amazon ECS service, the actions that Amazon ECS takes to maintain the service are published in the service events. You can view the events in the AWS Management Console, AWS CLI, AWS SDKs, the Amazon ECS API, or tools that use the SDKs and API. These events include Amazon ECS stopping and replaces a task because the containers in the task have stopped running, or have failed too many health checks from Elastic Load Balancing.

If your task ran on a container instance on Amazon EC2 or external computers, you can also look at the logs of the container runtime and the Amazon ECS Agent. These logs are on the host Amazon EC2 instance or external computer. For more information, see [Viewing Amazon ECS container agent logs](#).

## Procedure

### Console

#### AWS Management Console

The following steps can be used to check stopped tasks for errors using the console. In order to see stopped tasks, you must change the filter option.

Stopped tasks only appear in the console for 1 hour.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.

3. On the **Clusters** page, choose the cluster.
4. On the **Cluster : *name*** page, choose the **Tasks** tab.
5. Configure the filter to display stopped tasks. For **Filter desired status**, choose **Stopped**.

The **Stopped** option displays your stopped tasks and **Any desired status** displays all of your tasks.

6. Choose the stopped task to inspect.
7. In the row for your stopped task, in the **Last Status** column, choose **Stopped**.

A pop-up window displays the stopped reason.

## AWS CLI

1. List the stopped tasks in a cluster. The output contains the Amazon Resource Name (ARN) of the task, which you need to describe the task.

```
aws ecs list-tasks \
  --cluster cluster_name \
  --desired-status STOPPED \
  --region region
```

2. Describe the stopped task to retrieve the information. For more information, see [describe-tasks](#) in the *AWS Command Line Interface Reference*.

```
aws ecs describe-tasks \
  --cluster cluster_name \
  --tasks arn:aws:ecs:region:account_id:task/cluster_name/task_ID \
  --region region
```

Use the following output parameters.

- **stopCode** - The stop code indicates why a task was stopped, for example `ResourceInitializationError`
- **StoppedReason** - The reason the task stopped.
- **reason** (in the `containers` structure) - The reason provide additional details about the stopped container.

## Next steps

View your stopped tasks so you can get information about the cause. For more information, see [Amazon ECS stopped tasks error messages](#).

## Amazon ECS stopped tasks error messages

The following are the possible error messages you may receive when your task stops unexpectedly.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

**Tip**

You can use the [Amazon ECS MCP server](#) with AI assistants to analyze task failures and container logs using natural language.

Stopped task error codes have a category associated with them, for example "ResourceInitializationError". To get more information about each category, see the following:

| Category                    | Learn more                                                                    |  |

## Troubleshooting Amazon ECS TaskFailedToStart errors

The following are some TaskFailedToStart error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

## Unexpected EC2 error while attempting to Create Network Interface with public IP assignment enabled in subnet '*subnet-id*'

This happens when a Fargate task that uses the awsvpc network mode and runs in a subnet with a public IP address, and the subnet does not have enough IP addresses.

The number of available IP addresses is available on the subnet details page in the Amazon EC2 console, or by using [describe-subnets](#). For more information, see [View your subnet](#) in the *Amazon VPC User Guide*.

To fix this issue, you can create a new subnet to run your task in.

### InternalError: *<reason>*

This error occurs when an ENI attachment is requested. Amazon EC2 asynchronously handles the provisioning of the ENI. The provisioning process takes time. Amazon ECS has a timeout in case there are long wait times or unreported failures. There are times when the ENI is provisioned, but the report comes to Amazon ECS after the failure timeout. In this case, Amazon ECS sees the reported task failure with an in-use ENI.

## The selected task definition is not compatible with the selected compute strategy

This error occurs when you chose a task definition with a launch type that does not match the cluster capacity type. You need to select a task definition that matches the capacity provider assigned to your cluster.

## Unable to attach network interface to unused device index

This error occurs when When using awsvpc networking type and there is not enough CPU/memory for the task. First, check the CPU for the instances. For more information, see [Amazon EC2 instance type specifications](#) in *Amazon EC2 instance types*. Take the CPU value for the instance and multiply it by the number of ENIs for the instance. Use that value e in the task definition.

## AGENT

The container instance that you attempted to launch a task onto has an agent that's currently disconnected. To prevent extended wait times for task placement, the request was rejected.

For information about how to troubleshoot an agent that's disconnected, see [How do I troubleshoot a disconnected Amazon ECS agent](#).

## Troubleshooting Amazon ECS ResourceInitializationError errors

The following are some ResourceInitialization error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

### Errors

- [The task cannot pull registry authentication from Amazon ECR. There is a connection issue between the task and Amazon ECR. Check your task network configuration.](#)
- [The task can't download the environment variable files from Amazon S3. There is a connection issue between the task and Amazon S3. Check your task network configuration.](#)
- [The task cannot pull secrets from AWS Systems Manager Parameter Store. Check your network connection between the task and AWS Systems Manager.](#)
- [The task can't pull secrets from AWS Secrets Manager. There is a connection issue between the task and Secrets Manager. Check your task network configuration.](#)
- [The task can't pull the secret from Secrets Manager. The task can't retrieve the secret with ARN 'secretARN' from Secrets Manager. Check whether the secret exists in the specified Region.](#)
- [pull command failed: unable to pull secrets or registry auth Check your task network configuration.](#)
- [The task cannot find the Amazon CloudWatch log group defined in the task definition. There is a connection issue between the task and Amazon CloudWatch. Check your network configuration.](#)
- [failed to initialize logging driver](#)
- [failed to invoke EFS utils commands to set up EFS volumes](#)

**The task cannot pull registry authentication from Amazon ECR. There is a connection issue between the task and Amazon ECR. Check your task network configuration.**

This error indicates that the task can't connect to Amazon ECR.

Check the connection between the task and Amazon ECR. For information, see [Verifying Amazon ECS stopped task connectivity](#).

**The task can't download the environment variable files from Amazon S3. There is a connection issue between the task and Amazon S3. Check your task network configuration.**

This error occurs when your task can't download your environment file from Amazon S3.

Check the connection between the task and the Amazon S3 VPC endpoint. For information, see [Verifying Amazon ECS stopped task connectivity](#).

**The task cannot pull secrets from AWS Systems Manager Parameter Store. Check your network connection between the task and AWS Systems Manager.**

This error occurs when your task can't pull the image defined in the task definition using the credentials in Systems Manager.

Check the connection between the task and the Systems Manager VPC endpoint. For information, see [Verifying Amazon ECS stopped task connectivity](#).

**The task can't pull secrets from AWS Secrets Manager. There is a connection issue between the task and Secrets Manager. Check your task network configuration.**

This error occurs when your task can't pull the image defined in the task definition using the credentials in Secrets Manager.

The error indicates that there is a network connectivity issue between the Systems Manager VPC endpoint and the task.

For information about how to verify the connectivity between the task and the endpoint, see [Verifying Amazon ECS stopped task connectivity](#).

**The task can't pull the secret from Secrets Manager. The task can't retrieve the secret with ARN '*secretARN*' from Secrets Manager. Check whether the secret exists in the specified Region.**

This error occurs when your task can't pull the image defined in the task definition using the credentials in Secrets Manager.

This issue is caused by one of the following reasons:

| Error cause..                                                                     | Do this...                                                                 |  |
|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------|--|

For information about viewing your images, see <a href="#">Find secrets in Secrets Manager</a> in the <i>Secrets Manager Developer Guide</i>.</p> |  |

**pull command failed: unable to pull secrets or registry auth Check your task network configuration.**

This error occurs when your task can't connect to Amazon ECR, Systems Manager, or Secrets Manager. This is due to a misconfiguration in your network.

To fix this issue, verify the connectivity between the task and Amazon ECR. You also need to check connectivity between your task and the service which stores your secret (Systems Manager, or Secrets Manager). For more information, see [Verifying Amazon ECS stopped task connectivity](#).

**The task cannot find the Amazon CloudWatch log group defined in the task definition. There is a connection issue between the task and Amazon CloudWatch. Check your network configuration.**

This error occurs when your task fails to find the CloudWatch log group you defined in the task definition.

The error indicates that there is a network connectivity issue between the CloudWatch VPC endpoint and the task.

For information about how to verify the connectivity between the task and the endpoint, see [Verifying Amazon ECS stopped task connectivity](#).

**failed to initialize logging driver**

This error occurs when your task fails to find the CloudWatch log group you defined in the task definition.

The error indicates that the CloudWatch group in the task definition does not exist.

Use the following steps to find the missing CloudWatch.

1. Run the following command to get the task definition information.

```
aws ecs describe-task-definition \  
  --task-definition task-def-name
```

Look at the output for each container and note the `awslogs-group` value.

```
"logConfiguration": {  
    "logDriver": "awslogs",  
    "options": {
```

```
    "awslogs-group": "/ecs/example-group",
    "awslogs-create-group": "true",
    "awslogs-region": "us-east-1",
    "awslogs-stream-prefix": "ecs"
  },
```

2. Verify that the group existis in CloudWatch for more information, see [Working with log groups and log streams](#) in the *Amazon CloudWatch Logs User Guide*.

The issue is either that the group specified in the task definition is incorrect, or the log group does not exist.

3. Fix the issue.

| The issue is...                                              | Do this...                                                                                                                                                                                                                                                                                                                                |  |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| The incorrect log group is specified in the task definition. | Update the task definitio n to include the log group configuration in the container definition.For information about updating the task definition, see <a href="#">Updating an Amazon ECS task definition using the console</a> or <a href="#">RegisterT askDefinition</a> in the <i>Amazon Elastic Container Service API Reference</i> . |  |
| The log group does not exist in CloudWatch                   | Create the log group. For more information, see <a href="#">Create a log group in CloudWatch Logs</a> in the <i>Amazon CloudWatch Logs User Guide</i> .                                                                                                                                                                                   |  |

**failed to invoke EFS utils commands to set up EFS volumes**

The following issues might prevent you from mounting your Amazon EFS volumes on your asks:

- The Amazon EFS file system isn't configured correctly.
- The task doesn't have the required permissions.
- There are issues related to network and VPC configurations.

For information about how to debug and fix this issue, see [Why can't I mount my Amazon EFS volumes on my AWS Fargate tasks](#) on AWS re:Post.

## Troubleshooting Amazon ECS ResourceNotFoundException errors

The following are some `ResourceNotFoundException` error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

**The task can't retrieve the secret with ARN '*secretARN*' from AWS Secrets Manager. Check whether the secret exists in the specified Region.**

This error occurs when the task can't retrieve the secret from Secrets Manager. This means that the secret specified in the task definition (and contained in the error message) does not exist in Secrets Manager.

The Region is in the error message.

Fetching secret data from AWS Secrets Manager in region *region*: secret *secretARN*:  
`ResourceNotFoundException: Secrets Manager can't find the specified secret.`

For information about finding a secret, see [Find secrets in AWS Secrets Manager](#) in the *AWS Secrets Manager User Guide*.

Use the following table to determine and address the error.

| Issue                                                             | Actions                                                                                                                                                                               |  |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| The secret is in a different Region from the the task definition. | <ol style="list-style-type: none"><li>Create the secret in the same Region as the task.<br/>For more information, see <a href="#">Create an AWS Secrets Manager secret</a>.</li></ol> |  |

| Issue                                                                                                  | Actions                                                                                                                                                                                                                                                                                                                                                                                                                        |  |
|--------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|                                                                                                        | <p>b. Update the task definition with the new secret.</p> <p>For more information, see <a href="#">Updating an Amazon ECS task definition using the console</a> or <a href="#">RegisterTaskDefinition</a> in the <i>Amazon Elastic Container Service API Reference</i>.</p>                                                                                                                                                    |  |
| <p>The task definition has the incorrect secret ARN. The correct secret exists in Secrets Manager.</p> | <p>Update the task definition with the correct secret.</p> <p>For more information, see <a href="#">Updating an Amazon ECS task definition using the console</a> or <a href="#">RegisterTaskDefinition</a> in the <i>Amazon Elastic Container Service API Reference</i>.</p>                                                                                                                                                   |  |
| <p>The secret no longer exists.</p>                                                                    | <p>a. Create the secret in the same Region as the task.</p> <p>For more information, see <a href="#">Create an AWS Secrets Manager secret</a>.</p> <p>b. Update the task definition with the new secret.</p> <p>For more information, see <a href="#">Updating an Amazon ECS task definition using the console</a> or <a href="#">RegisterTaskDefinition</a> in the <i>Amazon Elastic Container Service API Reference</i>.</p> |  |

## Troubleshooting Amazon ECS SpotInterruption errors

The SpotInterruption error has different reasons for Fargate and EC2s.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

### Fargate

The SpotInterruption error occurs when there is no Fargate Spot capacity or when Fargate takes back Spot capacity.

You can have your tasks run in multiple Availability Zones to allow for more capacity.

### EC2

This error occurs when there are no available Spot Instances or EC2 takes back Spot Instance capacity.

You can have your instances run in multiple Availability Zones to allow for more capacity.

## Troubleshooting Amazon ECS InternalError errors

**Applies to:** Fargate

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

The InternalError error when the agent encounters an unexpected, non-runtime related internal error.

This error only occurs if using platform version 1.4 or later.

For information about how to debug and fix this issue, see [Amazon ECS stopped tasks error messages](#).

## Troubleshooting Amazon ECS OutOfMemoryError errors

The following are some OutOfMemoryError error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

## container killed due to memory usage

This error occurs when a container exits due to processes in the container consuming more memory than was allocated in the task definition, or due to host or operating system constraints.

## Troubleshooting Amazon ECS ContainerRuntimeError errors

The following are some ContainerRuntimeError error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

### ContainerRuntimeError

This error occurs when the agent receives an unexpected error from `containerd` for a runtime-specific operation. This error is usually caused by an internal failure in the agent or the `containerd` runtime.

This error only occurs if you use platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows).

For information about how to debug and fix this issue, see [Why is my Amazon ECS task Stopped](#) on AWS re:Post.

## Troubleshooting Amazon ECS ContainerRuntimeTimeoutError errors

The following are some ContainerRuntimeTimeoutError error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

### Could not transition to running; timed out after waiting 1m or Docker timeout error

This error occurs when a container can't transition to either a RUNNING or STOPPED state within the timeout period. The reason and timeout value is provided in the error message.

## Troubleshooting Amazon ECS CannotStartContainerError errors

The following are some CannotStartContainerError error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

**failed to get container status: *<reason>***

This error occurs when a container can't be started.

If your container attempts to exceed the memory specified here, the container is stopped. Increase the memory presented to the container. This is the memory parameter in the task definition. For more information, see [the section called "Memory"](#).

## Troubleshooting Amazon ECS CannotStopContainerError errors

The following are some CannotStopContainerError error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

### CannotStopContainerError

This error occurs when a container can't be stopped.

For information about how to debug and fix this issue, see [Why is my Amazon ECS task Stopped](#) on AWS re:Post.

## Troubleshooting Amazon ECS CannotInspectContainerError errors

The following are some CannotInspectContainerError error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

### CannotInspectContainerError

This error occurs when the container agent can't describe the container through the container runtime.

When using platform version 1.3 or earlier, the Amazon ECS agent returns the reason from Docker.

When using platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows), the Fargate agent returns the reason from `containerd`.

For information about how to debug and fix this issue, see [Why is my Amazon ECS task Stopped](#) on AWS re:Post.

## Troubleshooting Amazon ECS CannotCreateVolumeError errors

The following are some CannotCreateVolumeError error messages and actions that you can take to fix the errors.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

### CannotCreateVolumeError

This error occurs when the agent can't create the volume mount specified in the task definition.

This error only occurs if you use platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows).

For information about how to debug and fix this issue, see [Why is my Amazon ECS task Stopped](#) on AWS re:Post.

## CannotPullContainer task errors in Amazon ECS

The following errors indicate that the task failed to start because Amazon ECS can't retrieve the specified container image.

### Note

The 1.4 Fargate platform version truncates long error messages.

To check your stopped tasks for an error message using the AWS Management Console, see [Viewing Amazon ECS stopped task errors](#).

### Tip

You can use the [Amazon ECS MCP server](#) with AI assistants to investigate image pull errors using natural language.

## Errors

- [The task can't pull the image. Check that the role has the permissions to pull images from the registry.](#)
- [The task cannot pull 'image-name' from the Amazon ECR repository 'repository URI'. There is a connection issue between the task and Amazon ECR. Check your task network configuration.](#)
- [The task can't pull the image. Check your network configuration](#)
- [CannotPullContainerError: pull image manifest has been retried 5 time\(s\): failed to resolve ref](#)
- [API error \(500\): Get https://111122223333.dkr.ecr.us-east-1.amazonaws.com/v2/: net/http: request canceled while waiting for connection](#)
- [API error](#)
- [write /var/lib/docker/tmp/GetImageBlob111111111: no space left on device](#)
- [ERROR: toomanyrequests: Too Many Requests or You have reached your pull rate limit.](#)
- [Error response from daemon: Get url: net/http: request canceled while waiting for connection](#)
- [ref pull has been retried 1 time\(s\): failed to copy: httpReaderSeeker: failed open: unexpected status code](#)
- [pull access denied](#)
- [pull command failed: panic: runtime error: invalid memory address or nil pointer dereference](#)
- [error pulling image conf/error pulling image configuration](#)
- [Context canceled](#)

**The task can't pull the image. Check that the role has the permissions to pull images from the registry.**

This error indicates that the task can't pull the image specified in the task definition because of permission issues.

To resolve this issue:

1. Check that the image exists in the *repository*. For information about viewing your images, see [Viewing image details in Amazon ECR](#) in the *Amazon Elastic Container Registry User Guide*.
2. Verify that the *role-arn* has the correct permissions to pull the image.

For information about how to update roles, see [Update permissions for a role](#) in the *AWS Identity and Access Management Use Guide*.

The task uses one of the following roles:

- For tasks with the Fargate, this is the task execution role. For information about the additional permissions for Amazon ECR, [Fargate tasks pulling Amazon ECR images over interface endpoints permissions](#).
- For tasks with EC2, this is the container instance role. For information about the additional permissions for Amazon ECR, [Amazon ECR permissions](#).

**The task cannot pull '*image-name*' from the Amazon ECR repository '*repository URI*'. There is a connection issue between the task and Amazon ECR. Check your task network configuration.**

This error indicates that the task can't connect to Amazon ECR. Check the connection to the *repository URI* repository.

For information about how to verify and resolve the issue, see [Verifying Amazon ECS stopped task connectivity](#).

### **The task can't pull the image. Check your network configuration**

This error indicates that the task can't connect to Amazon ECR.

For information about how to verify and resolve the issue, see [Verifying Amazon ECS stopped task connectivity](#).

### **CannotPullContainerError: pull image manifest has been retried 5 time(s): failed to resolve ref**

This error indicates that the task can't pull the image.

To resolve this, you can:

- Verify that the image specified in the task definition matches the image in the repository.
- Amazon ECS forces image version stability. If the original image is no longer available you get this error. The image tag is part of enforcing this behavior. Change the image in the task definition from using :latest as the tag to a specific version. For more information, see [Container image resolution](#).

For information about how to verify and resolve the issue, see [Verifying Amazon ECS stopped task connectivity](#).

## API error (500): Get https://111122223333.dkr.ecr.us-east-1.amazonaws.com/v2/: net/http: request canceled while waiting for connection

This error indicates that a connection timed out, because a route to the internet doesn't exist.

To resolve this issue, you can:

- For tasks in public subnets, specify **ENABLED** for **Auto-assign public IP** when launching the task. For more information, see [Running an application as an Amazon ECS task](#).
- For tasks in private subnets, specify **DISABLED** for **Auto-assign public IP** when launching the task, and configure a NAT gateway in your VPC to route requests to the internet. For more information, see [NAT Gateways](#) in the *Amazon VPC User Guide*.

## API error

This error indicates that there is a connection issue with the Amazon ECR endpoint.

For information about how to resolve this issue, see [How can I resolve the Amazon ECR error "CannotPullContainerError: API error" in Amazon ECS](#) on the Support website.

## write /var/lib/docker/tmp/**GetImageBlob111111111**: no space left on device

This error indicates that there is insufficient disk space.

To resolve this issue, free up disk space.

If you are using the Amazon ECS-optimized AMI, you can use the following command to retrieve the 20 largest files on your file system:

```
du -Sh / | sort -rh | head -20
```

Example output:

```
5.7G    /var/lib/docker/
containers/50501b5f4cbf90b406e0ca60bf4e6d4ec8f773a6c1d2b451ed8e0195418ad0d2
1.2G    /var/log/ecs
594M    /var/lib/docker/devicemapper/mnt/
c8e3010e36ce4c089bf286a623699f5233097ca126ebd5a700af023a5127633d/rootfs/data/logs
...
```

In some cases, the root volume might be filled out by a running container. If the container is using the default `json-file` log driver without a `max-size` limit, it may be that the log file is responsible for most of that space used. You can use the `docker ps` command to verify which container is using the space by mapping the directory name from the output to the container ID. For example:

| CONTAINER ID | IMAGE                          | COMMAND   | CREATED    |
|--------------|--------------------------------|-----------|------------|
| STATUS       | PORTS                          | NAMES     |            |
| 50501b5f4cbf | amazon/amazon-ecs-agent:latest | "/agent"  | 4 days ago |
| Up 4 days    |                                | ecs-agent |            |

By default, when using the `json-file` log driver, Docker captures the standard output (and standard error) of all of your containers and writes them in files using the JSON format. You can set the `max-size` as a log driver option, which prevents the log file from taking up too much space. For more information, see [JSON File logging driver](#) in the Docker documentation.

The following is a container definition snippet showing how to use this option:

```
{
  "log-driver": "json-file",
  "log-opts": {
    "max-size": "256m"
  }
}
```

An alternative, if your container logs are taking up too much disk space, is to use the `awslogs` log driver. The `awslogs` log driver sends the logs to CloudWatch, which frees up the disk space that would otherwise be used for your container logs on the container instance. For more information, see [Send Amazon ECS logs to CloudWatch](#).

You might need to update the disk size that Docker can access.

For more information, see [CannotPullContainerError: no space left on device](#).

**ERROR: toomanyrequests: Too Many Requests or You have reached your pull rate limit.**

This error indicates that there is a Docker Hub rate limiting.

If you receive one of the following errors, you're likely hitting the Docker Hub rate limits:

For more information about the Docker Hub rate limits, see [Understanding Docker Hub rate limiting](#).

If you have increased the Docker Hub rate limit and you need to authenticate your Docker pulls for your container instances, see [Private registry authentication for container instances](#).

### **Error response from daemon: Get *url*: net/http: request canceled while waiting for connection**

This error indicates that a connection timed out, because a route to the internet doesn't exist.

To resolve this issue, you can:

- For tasks in public subnets, specify **ENABLED** for **Auto-assign public IP** when launching the task. For more information, see [Running an application as an Amazon ECS task](#).
- For tasks in private subnets, specify **DISABLED** for **Auto-assign public IP** when launching the task, and configure a NAT gateway in your VPC to route requests to the internet. For more information, see [NAT Gateways](#) in the *Amazon VPC User Guide*.

### **ref pull has been retried 1 time(s): failed to copy: httpReaderSeeker: failed open: unexpected status code**

This error indicates that there was a failure when copying an image.

To resolve this issue, review one of the following articles:

- For Fargate tasks, see [How do I resolve the "cannotpullcontainererror" error for my Amazon ECS tasks on Fargate](#).
- For other tasks, see [How do I resolve the "cannotpullcontainererror" error for my Amazon ECS tasks](#).

### **pull access denied**

This error indicates that there is no access to the image.

To resolve this issue, you might need to authenticate your Docker client with Amazon ECR. For more information, see [Private registry authentication](#) in the *Amazon ECR User Guide*.

### **pull command failed: panic: runtime error: invalid memory address or nil pointer dereference**

This error indicates that there is no access to the image because of an invalid memory address or nil pointer dereference.

To resolve this issue:

- Check that you have the security group rules to reach Amazon S3.
- When you use gateway endpoints, you must add a route in the route table to access the endpoint.

### error pulling image conf/error pulling image configuration

This error indicates a rate limit has been reached or there is a network error:

To resolve this issue, see [How can I resolve the "CannotPullContainerError" error in my Amazon ECS EC2 Launch Type Task.](#)

### Context canceled

This error indicates that the context was cancelled.

The common cause for this error is because the VPC your task is using doesn't have a route to pull the container image from Amazon ECR.

## Verifying Amazon ECS stopped task connectivity

There are times when a task stops because of a network connectivity issue. It might be an intermittent issue, but it is most likely caused because the task cannot connect to an endpoint.

### Testing the task connectivity

You can use `AWSSupport-TroubleshootECSTaskFailedToStart` runbook to test the task connectivity. When you use the runbook, you need the following resource information:

- The task ID  
Use the ID of the most recent failed task.
- The cluster that the task was in

For information about how to use the runbook, see [AWSSupport-TroubleshootECSTaskFailedToStart](#) in the *AWS Systems Manager Automation runbook reference*.

The runbook analyzes the task. You can view the results in the **Output** section for the following issues that can prevent a task from starting:

- Network connectivity to the configured container registry

- VPC endpoint connectivity
- Security group rule configuration

## Fixing VPC endpoint issues

When the `AWSSupport-TroubleshootECSTaskFailedToStart` runbook result indicates the VPC endpoint issue, check the following configuration:

- The VPC where you create the endpoint and the VPC endpoint need to use Private DNS.
- Make sure that you have a AWS PrivateLink endpoint for the service that the task cannot connect to in the same VPC as the task. For more information see one of the following:

| Service         | VPC endpoint information for the service                                                         |  |
|-----------------|--------------------------------------------------------------------------------------------------|--|
| Amazon ECR      | <a href="#">Amazon ECR interface VPC endpoints (AWS PrivateLink)</a>                             |  |
| Systems Manager | <a href="#">Improve the security of EC2 instances by using VPC endpoints for Systems Manager</a> |  |
| Secrets Manager | <a href="#">Using an AWS Secrets Manager VPC endpoint</a>                                        |  |
| CloudWatch      | <a href="#">CloudWatch VPC endpoint</a>                                                          |  |
| Amazon S3       | <a href="#">AWS PrivateLink for Amazon S3</a>                                                    |  |

- Configure an outbound rule for the task subnet which allows HTTPS on port 443 DNS (TCP) traffic. For more information, see [Configure security group rules](#) in the *Amazon Elastic Compute Cloud User Guide*.
- If you use a custom name domain server, then confirm the DNS query's settings. The query must have outbound access on port 53, and use UDP and TCP protocol. Also, it must have HTTPS access on port 443. For more information, see [Configure security group rules](#) in the *Amazon Elastic Compute Cloud User Guide*.

- If the subnet has a network ACL, the following ACL rules are required:
  - An outbound rule that allows traffic that allows traffic on ports 1024-65535.
  - An inbound rule that allows TCP traffic on port 443.

For information about how to configure rules, see [Control traffic to subnets using network ACLs](#) in the *Amazon Virtual Private Cloud User Guide*.

## Fixing network issues

When the `AWSSupport-TroubleshootECSTaskFailedToStart` runbook result indicates a network issue, check the following configuration:

### Tasks that use `awsvpc` network mode in a public subnet

Perform the following configuration based on the runbook:

- For tasks in public subnets, specify **ENABLED** for **Auto-assign public IP** when launching the task. For more information, see [Running an application as an Amazon ECS task](#).
- You need a gateway to handle internet traffic. The route table for the task subnet needs to have a route for traffic to the gateway.

For more information, see [Add and remove routes from a route table](#) in the *Amazon Virtual Private Cloud User Guide*.

| Gateway type     | Route table destination | Route table target  |
|------------------|-------------------------|---------------------|
| NAT              | 0.0.0.0/0               | NAT gateway ID      |
| Internet gateway | 0.0.0.0/0               | Internet gateway ID |

- If the task subnet has a network ACL, the following ACL rules are required:
  - An outbound rule that allows traffic on ports 1024-65535.
  - An inbound rule that allows TCP traffic on port 443.

For information about how to configure rules, see [Control traffic to subnets using network ACLs](#) in the *Amazon Virtual Private Cloud User Guide*.

## Tasks that use awsvpc network mode in a private subnet

Perform the following configuration based on the runbook:

- Choose **DISABLED** for **Auto-assign public IP** when launching the task.
- Configure a NAT gateway in your VPC to route requests to the internet. For more information, see [NAT Gateways](#) in the *Amazon Virtual Private Cloud User Guide*.
- The route table for the task subnet needs to have a route for traffic to the NAT gateway.

For more information, see [Add and remove routes from a route table](#) in the *Amazon Virtual Private Cloud User Guide*.

| Gateway type | Route table destination | Route table target |
|--------------|-------------------------|--------------------|
| NAT          | 0.0.0.0/0               | NAT gateway ID     |

- If the task subnet has a network ACL, the following ACL rules are required:
  - An outbound rule that allows traffic on ports 1024-65535.
  - An inbound rule that allows TCP traffic on port 443.

For information about how to configure rules, see [Control traffic to subnets using network ACLs](#) in the *Amazon Virtual Private Cloud User Guide*.

## Tasks that don't use awsvpc network mode in a public subnet

Perform the following configuration based on the runbook:

- Choose **Turn on** for **Auto assign IP** under **Networking for Amazon EC2 instances** when you create the cluster.

This option assigns a public IP address to the instance primary network interface.

- You need a gateway to handle internet traffic. The route table for the instance subnet needs to have a route for traffic to the gateway.

For more information, see [Add and remove routes from a route table](#) in the *Amazon Virtual Private Cloud User Guide*.

| Gateway type     | Route table destination | Route table target  |
|------------------|-------------------------|---------------------|
| NAT              | 0.0.0.0/0               | NAT gateway ID      |
| Internet gateway | 0.0.0.0/0               | Internet gateway ID |

- If the instance subnet has a network ACL, the following ACL rules are required:
  - An outbound rule that allows traffic on ports 1024-65535.
  - An inbound rule that allows TCP traffic on port 443.

For information about how to configure rules, see [Control traffic to subnets using network ACLs](#) in the *Amazon Virtual Private Cloud User Guide*.

### Tasks that don't use awsvpc network mode in a private subnet

Perform the following configuration based on the runbook:

- Choose **Turn off** for **Auto assign IP** under **Networking for Amazon EC2 instances** when you create the cluster.
- Configure a NAT gateway in your VPC to route requests to the internet. For more information, see [NAT Gateways](#) in the *Amazon VPC User Guide*.
- The route table for the instance subnet needs to have a route for traffic to the NAT gateway.

For more information, see [Add and remove routes from a route table](#) in the *Amazon Virtual Private Cloud User Guide*.

| Gateway type | Route table destination | Route table target |
|--------------|-------------------------|--------------------|
| NAT          | 0.0.0.0/0               | NAT gateway ID     |

- If the task subnet has a network ACL, the following ACL rules are required:
  - An outbound rule that allows traffic on ports 1024-65535.
  - An inbound rule that allows TCP traffic on port 443.

For information about how to configure rules, see [Control traffic to subnets using network ACLs](#) in the *Amazon Virtual Private Cloud User Guide*.

# Viewing IAM role requests for Amazon ECS tasks

When you use a provider for your task credentials in an IAM role, the provider requests saved in an audit log. The audit log inherits the same log rotation settings as the container agent log. The `ECS_LOG_ROLLOVER_TYPE`, `ECS_LOG_MAX_FILE_SIZE_MB`, and `ECS_LOG_MAX_ROLL_COUNT` container agent configuration variables can be set to affect the behavior of the audit log. For more information, see [Amazon ECS container agent log configuration parameters](#).

For container agent version 1.36.0 and later, the audit log is located at `/var/log/ecs/audit.log`. When the log is rotated, a timestamp in `YYYY-MM-DD-HH` format is added to the end of the log file name.

For container agent version 1.35.0 and earlier, the audit log is located at `/var/log/ecs/audit.log.YYYY-MM-DD-HH`.

The log entry format is as follows:

- Timestamp
- HTTP response code
- IP address and port number of request origin
- Relative URI of the credential provider
- The user agent that made the request
- The ARN of the task to which the requesting container belongs
- The `GetCredentials` API name and version number
- The name of the Amazon ECS cluster to which the container instance is registered
- The container instance ARN

You can use the following command to view the log files.

```
cat /var/log/ecs/audit.log.2016-07-13-16
```

Output:

```
2016-07-13T16:11:53Z 200 172.17.0.5:52444 "/v1/credentials" "python-requests/2.7.0  
CPython/2.7.6 Linux/4.4.14-24.50.amzn1.x86_64" TASK_ARN GetCredentials  
1 CLUSTER_NAME CONTAINER_INSTANCE_ARN
```

# Viewing Amazon ECS service event messages

When troubleshooting a problem with a service, the first place you should check for the diagnostic information is the service event log. You can view service events using the `DescribeServices` API, the AWS CLI, or by using the AWS Management Console.

When viewing service event messages using the Amazon ECS API, only the events from the service scheduler are returned. These include the most recent task placement and instance health events. However, the Amazon ECS console displays service events from the following sources.

- Task placement and instance health events from the Amazon ECS service scheduler. These events have a prefix of **service** (*service-name*). To ensure that this event view is helpful, we only show the 100 most recent events. Duplicate event messages are omitted until either the cause is resolved, or six hours passes. If the cause is not resolved within six hours, you receive another service event message for that cause.
- Service Auto Scaling events. These events have a prefix of **Message** and occur only when a service is configured with an Application Auto Scaling scaling policy.

## Tip

You can use the [Amazon ECS MCP server](#) with AI assistants to analyze service events using natural language.

Use the following steps to view your current service event messages.

### Console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster.
4. Choose the service to inspect.
5. On the **Events** tab, view the messages.

### AWS CLI

Use the [describe-services](#) command to view the service event messages for a specified service.

The following AWS CLI example describes the *service-name* service in the *default* cluster, which will provide the latest service event messages.

```
aws ecs describe-services \
  --cluster default \
  --services service-name \
  --region us-west-2
```

## Amazon ECS service event messages

The following are examples of service event messages you may see in the Amazon ECS console.

### **service (*service-name*) has reached a steady state.**

The service scheduler sends a service (*service-name*) has reached a steady state. service event when the service is healthy and at the desired number of tasks, thus reaching a steady state.

The service scheduler reports the status periodically, so you might receive this message multiple times.

### **service (*service-name*) was unable to place a task because no container instance met all of its requirements.**

The service scheduler sends this event message when it couldn't find the available resources to add another task. The possible causes for this are:

Use capacity providers to automatically scale your EC2 instances. For more information, see [Amazon ECS capacity providers for EC2 workloads](#).

If you intended to use a capacity provider, make sure that you're either passing a capacity provider strategy or have a default capacity provider strategy associated with your cluster and are not passing launch type and capacity provider strategy as input

No container instances were found in your cluster

If no container instances are registered in the cluster you attempt to run a task in, you receive this error. You should add container instances to your cluster. For more information, see [Launching an Amazon ECS Linux container instance](#).

## Not enough ports

If your task uses fixed host port mapping (for example, your task uses port 80 on the host for a web server), you must have at least one container instance per task, because only one container can use a single host port at a time. You should add container instances to your cluster or reduce your number of desired tasks.

## Too many ports registered

The closest matching container instance for task placement can't exceed the maximum allowed reserved port limit of 100 host ports per container instance. Using dynamic host port mapping may remediate the issue.

## Port already in-use

The task definition of this task uses the same port in its port mapping as a task already running on the container instance that was chosen. The service event message would have the chosen container instance ID as part of the following message.

```
The closest matching container-instance is already using a port required by your task.
```

## Not enough memory

If your task definition specifies 1000 MiB of memory, and the container instances in your cluster each have 1024 MiB of memory, you can only run one copy of this task per container instance. You can experiment with less memory in your task definition so that you could launch more than one task per container instance, or launch more container instances into your cluster.

### Note

If you're trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see [Reserving Amazon ECS Linux container instance memory](#).

## Not enough CPU

A container instance has 1,024 CPU units for every CPU core. If your task definition specifies 1,000 CPU units, and the container instances in your cluster each have 1,024 CPU units, you can only run one copy of this task per container instance. You can experiment with fewer CPU units

in your task definition so that you could launch more than one task per container instance, or launch more container instances into your cluster.

#### Not enough available ENI attachment points

Tasks that use the `awsvpc` network mode each receive their own elastic network interface (ENI), which is attached to the container instance that hosts it. Amazon EC2 instances have a limit to the number of ENIs that can be attached to them and there are no container instances in the cluster that have ENI capacity available.

The ENI limit for individual container instances depends on the following conditions:

- If you **have not** opted in to the `awsvpcTrunking` account setting, the ENI limit for each container instance depends on the instance type. For more information, see [IP Addresses Per Network Interface Per Instance Type](#) in the *Amazon EC2 User Guide*.
- If you **have** opted in to the `awsvpcTrunking` account setting but you **have not** launched new container instances using a supported instance type after opting in, the ENI limit for each container instance is still at the default value. For more information, see [IP Addresses Per Network Interface Per Instance Type](#) in the *Amazon EC2 User Guide*.
- If you **have** opted in to the `awsvpcTrunking` account setting and you **have** launched new container instances using a supported instance type after opting in, additional ENIs are available. For more information, see [Supported instances for increased Amazon ECS container network interfaces](#).

For more information about opting in to the `awsvpcTrunking` account setting, see [Increasing Amazon ECS Linux container instance network interfaces](#).

You can add container instances to your cluster to provide more available network adapters.

#### Container instance missing required attribute

Some task definition parameters require a specific Docker remote API version to be installed on the container instance. Others, such as the logging driver options, require the container instances to register those log drivers with the `ECS_AVAILABLE_LOGGING_DRIVERS` agent configuration variable. If your task definition contains a parameter that requires a specific container instance attribute, and you don't have any available container instances that can satisfy this requirement, the task can't be placed.

A common cause of this error is if your service is using tasks that use the `awsvpc` network mode and EC2. The cluster you specified doesn't have a container instance registered to it in the same subnet that was specified in the `awsvpcConfiguration` when the service was created.

You can use the `AWSSupport-TroubleshootECSContainerInstance` runbook to troubleshoot. The runbook reviews whether the user data for the instance contains the correct cluster information, whether the instance profile contains the required permissions, and network configuration issues. For more information, see [AWSSupport-TroubleshootECSContainerInstance](#) in the *AWS Systems Manager Automation runbook reference User Guide*.

For more information on which attributes are required for specific task definition parameters and agent configuration variables, see [Amazon ECS task definition parameters for Fargate](#) and [Amazon ECS container agent configuration](#).

**service (*service-name*) was unable to place a task because no container instance met all of its requirements. The closest matching container-instance *container-instance-id* has insufficient CPU units available.**

The closest matching container instance for task placement doesn't contain enough CPU units to meet the requirements in the task definition. Review the CPU requirements in both the task size and container definition parameters of the task definition.

**service (*service-name*) was unable to place a task because no container instance met all of its requirements. The closest matching container-instance *container-instance-id* encountered error "AGENT".**

The Amazon ECS container agent on the closest matching container instance for task placement is disconnected. If you can connect to the container instance with SSH, you can examine the agent logs; for more information, see [Amazon ECS container agent log configuration parameters](#). You should also verify that the agent is running on the instance. If you are using the Amazon ECS-optimized AMI, you can try stopping and restarting the agent with the following command.

- For the Amazon ECS-optimized Amazon Linux 2 AMI and Amazon ECS-optimized Amazon Linux 2023 AMI

```
sudo systemctl restart ecs
```

- For the Amazon ECS-optimized Amazon Linux AMI

```
sudo stop ecs && sudo start ecs
```

**service (*service-name*) (task *task-id*) (instance *instance-id*) is unhealthy in (elb *elb-name*) due to (reason Instance has failed at least the UnhealthyThreshold number of health checks consecutively.)**

This service is registered with a load balancer and the load balancer health checks are failing. The message includes the task ID to help identify which specific task is failing health checks. For more information, see [Troubleshooting service load balancers in Amazon ECS](#).

**service (*service-name*) is unable to consistently start tasks successfully.**

This service contains tasks that have failed to start after consecutive attempts. At this point, the service scheduler begins to incrementally increase the time between retries. You should troubleshoot why your tasks are failing to launch. For more information, see [Amazon ECS service throttle logic](#).

After the service is updated, for example with an updated task definition, the service scheduler resumes normal behavior.

**service (*service-name*) operations are being throttled. Will try again later.**

This service is unable to launch more tasks due to API throttling limits. Once the service scheduler is able to launch more tasks, it will resume.

To request an API rate limit quota increase, open the [AWS Support Center](#) page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.

**service (*service-name*) was unable to stop or start tasks during a deployment because of the service deployment configuration. Update the minimumHealthyPercent or maximumPercent value and try again.**

This service is unable to stop or start tasks during a service deployment due to the deployment configuration. The deployment configuration consists of the minimumHealthyPercent and maximumPercent values, which are defined when the service is created. Those values can also be updated on an existing service.

The minimumHealthyPercent represents the lower limit on the number of tasks that should be running for a service during a deployment or when a container instance is draining. It's a percent of the desired number of tasks for the service. This value is rounded up. For example, if the minimum healthy percent is 50 and the desired task count is four, then the scheduler can stop two existing

tasks before starting two new tasks. Likewise, if the minimum healthy percent is 75% and the desired task count is two, then the scheduler can't stop any tasks due to the resulting value also being two.

The `maximumPercent` represents the upper limit on the number of tasks that should be running for a service during a deployment or when a container instance is draining. It's a percent of the desired number of tasks for a service. This value is rounded down. For example, if the maximum percent is 200 and the desired task count is four, then the scheduler can start four new tasks before stopping four existing tasks. Likewise, if the maximum percent is 125 and the desired task count is three, the scheduler can't start any tasks due to the resulting value also being three.

When setting a minimum healthy percent or a maximum percent, you should ensure that the scheduler can stop or start at least one task when a deployment is triggered.

**service (*service-name*) was unable to place a task. Reason: You've reached the limit on the number of tasks you can run concurrently**

You can request a quota increase for the resource that caused the error. For more information, see [Service quotas](#). To request a quota increase, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

**service (*service-name*) was unable to place a task. Reason: Internal error.**

The following is the possible reason for this error:

The service is unable to start a task due to a subnet being in an unsupported Availability Zone.

For information about the supported Fargate Regions and Availability Zones, see [the section called "AWS Fargate Regions"](#).

For information about how to view the subnet Availability Zone, see [View your subnet](#) in the *Amazon VPC User Guide*.

**service (*service-name*) was unable to place a task. Reason: The requested CPU configuration is above your limit.**

You can request a quota increase for the resource that caused the error. For more information, see [Service quotas](#). To request a quota increase, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

**service (*service-name*) was unable to place a task. Reason: The requested MEMORY configuration is above your limit.**

You can request a quota increase for the resource that caused the error. For more information, see [Service quotas](#). To request a quota increase, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

**service (*service-name*) was unable to place a task. Reason: You've reached the limit on the number of vCPUs you can run concurrently**

AWS Fargate is transitioning from task count-based quotas to vCPU-based quotas.

You can request a quota increase for Fargate vCPU-based quota. For more information, see [Service quotas](#). To request a Fargate quota increase, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

**service (*service-name*) was unable to reach steady state because task set (*taskSet-ID*) was unable to scale in. Reason: The number of protected tasks are more than the desired count of tasks**

The service has more protected tasks than the desired number of tasks. You can do one the following:

- Wait until the protection on the current tasks expire, enabling them to be terminated.
- Determine which tasks can be stopped and use the `UpdateTaskProtection` API with the `protectionEnabled` option set to `false` to unset protection for these tasks.
- Increase the desired task count of the service to more than the number of protected tasks.

**service (*service-name*) was unable to reach steady state. Reason: No Container Instances were found in your capacity provider.**

The service scheduler sends this event message when it couldn't find the available resources to add another task. The possible causes for this are:

There is no capacity provider associated with the cluster

Use `describe-services` to verify that you have a capacity provider associated with the cluster. You can update the capacity provider strategy for the service.

Verify that there is available capacity in the capacity provider. In the case of EC2, make sure that the container instances meet the task definition requirements.

#### No container instances were found in your cluster

If no container instances are registered in the cluster you attempt to run a task in, you receive this error. You should add container instances to your cluster. For more information, see [Launching an Amazon ECS Linux container instance](#).

#### Not enough ports

If your task uses fixed host port mapping (for example, your task uses port 80 on the host for a web server), you must have at least one container instance per task. Only one container can use a single host port at a time. You should add container instances to your cluster or reduce your number of desired tasks.

#### Too many ports registered

The closest matching container instance for task placement can't exceed the maximum allowed reserved port limit of 100 host ports per container instance. Using dynamic host port mapping may remediate the issue.

#### Port already in-use

The task definition of this task uses the same port in its port mapping as a task already running on the container instance that was chosen. The service event message would have the chosen container instance ID as part of the following message.

```
The closest matching container-instance is already using a port required by your task.
```

#### Not enough memory

If your task definition specifies 1000 MiB of memory, and the container instances in your cluster each have 1024 MiB of memory, you can only run one copy of this task per container instance. You can experiment with less memory in your task definition so that you could launch more than one task per container instance, or launch more container instances into your cluster.

**Note**

If you are trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see [Reserving Amazon ECS Linux container instance memory](#).

## Not enough available ENI attachment points

Tasks that use the awsvpc network mode each receive their own elastic network interface (ENI), which is attached to the container instance that hosts it. Amazon EC2 instances have a limit to the number of ENIs that can be attached to them, and there are no container instances in the cluster that have ENI capacity available.

The ENI limit for individual container instances depends on the following conditions:

- If you **have not** opted in to the awsvpcTrunking account setting, the ENI limit for each container instance depends on the instance type. For more information, see [IP Addresses Per Network Interface Per Instance Type](#) in the *Amazon EC2 User Guide*.
- If you **have** opted in to the awsvpcTrunking account setting but you **have not** launched new container instances using a supported instance type after opting in, the ENI limit for each container instance is still at the default value. For more information, see [IP Addresses Per Network Interface Per Instance Type](#) in the *Amazon EC2 User Guide*.
- If you **have** opted in to the awsvpcTrunking account setting and you **have** launched new container instances using a supported instance type after opting in, additional ENIs are available. For more information, see [Supported instances for increased Amazon ECS container network interfaces](#).

For more information about opting in to the awsvpcTrunking account setting, see [Increasing Amazon ECS Linux container instance network interfaces](#).

You can add container instances to your cluster to provide more available network adapters.

## Container instance missing required attribute

Some task definition parameters require a specific Docker remote API version to be installed on the container instance. Others, such as the logging driver options, require the container instances to register those log drivers with the ECS\_AVAILABLE\_LOGGING\_DRIVERS agent configuration variable. If your task definition contains a parameter that requires a specific

container instance attribute, and you don't have any available container instances that can satisfy this requirement, the task cannot be placed.

A common cause of this error is if your service is using tasks that use the `awsvpc` network mode and EC2 and the cluster you specified doesn't have a container instance registered to it in the same subnet that was specified in the `awsvpcConfiguration` when the service was created.

You can use the `AWSSupport-TroubleshootECSContainerInstance` runbook to troubleshoot. The runbook reviews whether the user data for the instance contains the correct cluster information, whether the instance profile contains the required permissions, and network configuration issues. For more information, see [AWSSupport-TroubleshootECSContainerInstance](#) in the *AWS Systems Manager Automation runbook reference User Guide*.

For more information on which attributes are required for specific task definition parameters and agent configuration variables, see [Amazon ECS task definition parameters for Fargate](#) and [Amazon ECS container agent configuration](#).

**service (*service-name*) was unable to place a task. Reason: Capacity is unavailable at this time. Please try again later or in a different availability zone.**

There is currently no available capacity to run your service on.

You can do one the following:

- Wait until the Fargate capacity or EC2 container instances become available.
- Relaunch the service and specify additional subnets.

**service (*service-name*) deployment failed: tasks failed to start.**

The tasks in your service failed to start.

For information about how to debug stopped tasks, see [Amazon ECS stopped tasks error messages](#).

**service (*service-name*) Timed out waiting for Amazon ECS Agent to start. Please check logs at `/var/log/ecs/ecs-agent.log`.**

The Amazon ECS container agent on the closest matching container instance for task placement is disconnected. If you can connect to the container instance with SSH, you can examine the agent

logs. For more information, see [Amazon ECS container agent log configuration parameters](#). You should also verify that the agent is running on the instance. If you are using the Amazon ECS-optimized AMI, you can try stopping and restarting the agent with the following command.

- For the Amazon ECS-optimized Amazon Linux 2 AMI

```
sudo systemctl restart ecs
```

- For the Amazon ECS-optimized Amazon Linux AMI

```
sudo stop ecs && sudo start ecs
```

**service (*service-name*) task set (*taskSet-ID*) (task *task-id*) is not healthy in target-group (*targetGroup-ARN*) due to TARGET GROUP IS NOT FOUND.**

The task set for the service is failing health checks because the target group isn't found. The message includes the task ID to help identify which specific task is failing health checks. You should delete and recreate the service. Don't delete any Elastic Load Balancing target group unless the corresponding Amazon ECS service is already deleted.

**service (*service-name*) task set (*taskSet-ID*) (task *task-id*) is not healthy in target-group (*targetGroup-ARN*) due to TARGET IS NOT FOUND.**

The task set for the service is failing health checks because the target isn't found. The message includes the task ID to help identify which specific task is failing health checks.

**IAM permissions policies have been misconfigured or changed, and ECS can no longer maintain your service**

The service is unable to maintain tasks due to misconfigured or changed IAM permissions policies. The IAM role associated with your ECS service or tasks may be missing required permissions.

To resolve this issue, add the necessary permissions to the IAM role. For more information about managing IAM permissions policies, see [Adding and removing IAM identity permissions](#) in the *IAM User Guide*.

## **IAM trust relationship has been misconfigured or changed, and ECS can no longer maintain your service**

The service is unable to maintain tasks due to a misconfigured or changed IAM trust relationship. The IAM role associated with your ECS service or tasks may have an incorrect trust policy.

To resolve this issue, configure a trust policy for the role used in your task definition. For more information about creating trust policies for custom roles, see [Creating a role for a custom use case](#) in the *IAM User Guide*.

## **service (*service-name*) could not launch *number* tasks for deployment *deployment-id*.**

The service scheduler sends this event message when a deployment workflow successfully starts some tasks but fails to launch all requested tasks due to insufficient capacity errors. This typically occurs when Circuit Breaker is enabled and provides visibility into why deployments may fail or roll back.

The message includes the specific failure reason, such as insufficient CPU, memory, or other resource constraints. This helps you understand what resources need to be addressed to resolve the deployment issue.

For more information, see [service \(\*service-name\*\) was unable to place a task because no container instance met all of its requirements..](#)

## **service (*service-name*) was unable to place tasks in your cluster because the tasks provisioning capacity limit was exceeded.**

The service scheduler sends this event message when your cluster has reached the limit of 500 tasks that can be in the PROVISIONING state simultaneously. This is a cluster-level limit, not a service-specific issue.

This typically occurs when you start a service with a high number of desired tasks with limited pre-provisioned capacity, or when multiple services are started simultaneously causing high task churn.

To resolve this issue:

- Wait for existing tasks to complete provisioning and move to the RUNNING state.
- Consider scaling your services more gradually to avoid hitting the provisioning limit.

- Review your cluster's capacity provider configuration to ensure adequate resources are available.

For more information about Amazon ECS service quotas, see [Amazon Elastic Container Service endpoints and quotas](#) in the *Amazon Web Services General Reference*.

## Amazon ECS service unhealthy event messages

The following are examples of service unhealthy event messages.

**EC2: (service *service-name*) (task *task-id*) (instance *instance-id*) (port *port-number*) is unhealthy in (target-group *target-group-name*) due to (reason *failure-reason*)**

This message indicates that a task running on an EC2 instance is failing health checks. For more information, see the following:

- [How do I get my Amazon ECS tasks that use EC2 to pass the Application Load Balancer health check?](#)

**EC2 with taskSet: (service *service-name*, taskSet *taskSet-id*) (task *task-id*) (instance *instance-id*) (port *port-number*) is unhealthy in (target-group *target-group-name*) due to (reason *failure-reason*)**

This message indicates that a task in a task set running on an EC2 instance is failing health checks. For more information, see the following:

- [How do I get my Amazon ECS tasks that use the EC2 to pass the Application Load Balancer health check?](#)

**Fargate: (service *service-name*) (task *task-id*) (port *port-number*) is unhealthy in (target-group *target-group-name*) due to (reason *failure-reason*)**

This message indicates that a Fargate task is failing health checks.

For more information about troubleshooting health check failures in Fargate tasks, see [How do I troubleshoot health check failures for Amazon ECS tasks on Fargate?](#).

**Fargate with taskSet: (service *service-name*, taskSet *taskSet-id*) (task *task-id*) (port *port-number*) is unhealthy in (target-group *target-group-name*) due to (reason *failure-reason*)**

This message indicates that a task in a task set running on Fargate is failing health checks.

For more information about troubleshooting health check failures in Fargate tasks, see [How do I troubleshoot health check failures for Amazon ECS tasks on Fargate?](#).

## Amazon ECS Availability Zone service rebalancing service event messages

The following are examples of service event messages you might see.

**service (*service-name*) is not AZ balanced with *number-tasks* tasks in *Availability Zone 1*, *number-tasks* in *Availability Zone 2*, and *number-tasks* in *Availability Zone 3*. AZ Rebalancing in progress.**

The service scheduler sends a service (*service-name*) is not AZ balanced service event when the number of tasks is not evenly spread across Availability Zones. There is no action to take. This is an information event.

**service (*service-name*) is AZ balanced with *number-tasks* tasks in *Availability Zone 1*, *number-tasks* tasks in *Availability Zone 2*, and *number-tasks* tasks in *Availability Zone 3*.**

The service scheduler sends a service (*service-name*) is AZ balanced service event when Availability Zone service rebalancing completes. There is no action to take. This is an information event.

***service-name* has started *number-tasks* tasks in *Availability Zone* to AZ Rebalance: *task-ids*.**

The service scheduler sends a *service-name/task-set-name* has started *number* tasks in *Availability Zone* service event when it starts tasks in an Availability Zone because of service rebalancing. There is no action to take. This is an information event.

***service-name* has stopped *number-tasks* running tasks in *Availability Zone* due to AZ rebalancing: *task-id*.**

The service scheduler sends a *service-name/task-set-name* has stopped *number* tasks in *Availability Zone* service event when it stops tasks in an Availability Zone because of service rebalancing. There is no action to take. This is an information event.

**service (*service-name*) is unable to place a task in *Availability Zone* because no container instance met all of its requirements.**

The service scheduler sends a *service-name* is unable to place a task in *Availability Zone* service event because no container instance met all of its requirements. To address the issue, launch instances in the Availability Zone.

**service (*service-name*) is unable to place a task in *Availability Zone*.**

The service scheduler sends a *service-name* is unable to place a task in *Availability Zone* service event when you use the Fargate and there is no available capacity.

You can add additional subnets in the Availability Zone in the error message, or contact Support to get additional capacity.

**service (*service-name*) was unable to AZ Rebalance because *task-set-name* was unable to scale in due to *reason*.**

The service scheduler sends a *service-name* was unable to AZ Rebalance because *task-set-name* was unable to scale in due to *reason* service event when you use task scale-in protection.

You can do one the following:

- Wait until the protection on the current tasks expire, enabling them to be terminated.
- Determine which tasks can be stopped and use the UpdateTaskProtection API with the protectionEnabled option set to false to unset protection for these tasks.
- Increase the desired task count of the service to more than the number of protected tasks.

## service (*service-name*) stopped AZ Rebalancing.

The service scheduler sends a *service-name* stopped AZ Rebalancing service event when the Availability Zone rebalancing operation stopped. This is an information event. Amazon ECS sends additional events which provide more information.

# Troubleshooting service load balancers in Amazon ECS

Amazon ECS services can register tasks with an Elastic Load Balancing load balancer. Load balancer configuration errors are common causes for stopped tasks. If your stopped tasks were started by services that use a load balancer, consider the following possible causes.

## Amazon ECS service-linked role doesn't exist

The Amazon ECS service-linked role allows Amazon ECS services to register container instances with Elastic Load Balancing load balancers. The service-linked role must be created in your account. For more information, see [Using service-linked roles for Amazon ECS](#).

## Container instance security group

If your container is mapped to port 80 on your container instance, your container instance security group must allow inbound traffic on port 80 for the load balancer health checks to pass.

## Elastic Load Balancing load balancer not configured for all Availability Zones

Your load balancer should be configured to use all of the Availability Zones in a Region, or at least all of the Availability Zones where your container instances reside. If a service uses a load balancer and starts a task on a container instance that resides in an Availability Zone that the load balancer isn't configured to use, the task never passes the health check. This results in the task being killed.

## Elastic Load Balancing load balancer health check misconfigured

The load balancer health check parameters can be overly restrictive or point to resources that don't exist. If a container instance is determined to be unhealthy, it's removed from the load balancer. Be sure to verify that the following parameters are configured correctly for your service load balancer.

### Ping Port

The **Ping Port** value for a load balancer health check is the port on the container instances that the load balancer checks to determine if it is healthy. If this port is misconfigured, the

load balancer likely deregisters your container instance from itself. This port should be configured to use the `hostPort` value for the container in your service's task definition that you're using with the health check.

### Ping Path

This is part of the load balancer healthcheck. It is an endpoint on your application that can return a successful status code (for example, 200) when the application is healthy. This value is often set to `index.html`, but if your service doesn't respond to that request, then the health check fails. If your container doesn't have an `index.html` file, you can set this to `/` to target the base URL for the container instance.

### Response Timeout

This is the amount of time that your container has to return a response to the health check ping. If this value is lower than the amount of time required for a response, the health check fails.

### Health Check Interval

This is the amount of time between health check pings. The shorter your health check intervals are, the faster your container instance can reach the **Unhealthy Threshold**.

### Unhealthy Threshold

This is the number of times your health check can fail before your container instance is considered unhealthy. If you have an unhealthy threshold of 2, and a health check interval of 30 seconds, then your task has 60 seconds to respond to the health check ping before it's assumed unhealthy. You can raise the unhealthy threshold or the health check interval to give your tasks more time to respond.

## Unable to update the service *servicename*: Load balancer container name or port changed in task definition

If your service uses a load balancer, you can use the AWS CLI or SDK to modify the load balancer configuration. For information about how to modify the configuration, see [UpdateService](#) in the *Amazon Elastic Container Service API Reference*. If you update the task definition for the service, the container name and container port that are specified in the load balancer configuration must remain in the task definition.

## You've reached the limit on the number of tasks that you can run concurrently.

For a new account, your quotas might be lower than the service quotas. The service quota for your account can be viewed in the Service Quotas console. To request a quota increase, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

## Troubleshooting service auto scaling in Amazon ECS

Application Auto Scaling turns off scale-in processes while Amazon ECS deployments are in progress, and they resume once the deployment has completed. However, scale-out processes continue to occur, unless suspended, during a deployment. For more information, see [Suspending and resuming scaling for Application Auto Scaling](#).

## Amazon ECS event capture in the console

The Amazon ECS console provides event capture functionality that stores Amazon ECS-generated events, such as service actions and task state changes, to Amazon CloudWatch Logs through EventBridge. This feature includes a query interface with filtering capabilities for monitoring and troubleshooting.

Events provide detailed information about how your service deployments, services, tasks, and instances operate. You can use this information to troubleshoot task or service deployment failures.

When you turn on event capture, you have access to all events Amazon ECS generates for a retention period of your choice, extending beyond the native limitations of the last 100 unfiltered events or stopped tasks visible for only 1 hour.

### How it works

Event capture uses EventBridge to store events in a predefined Amazon CloudWatch Logs log group. The Amazon ECS console provides pre-built queries and filtering options, and correlates events to provide task lifecycles in an intuitive format.

You can query and retrieve the following types of events:

- **Service action events** – Help identify provisioning or resource allocation issues
- **Task lifecycle events** – Help identify why tasks or containers fail to launch or stop running

The Amazon ECS console allows you to set up event capture in one click and provides commonly used queries and filtering without requiring you to learn query languages or navigate between multiple consoles.

## Event types

Event capture stores all Amazon ECS generated events in the following categories:

### Task state change events

Container stops and other termination events, which you can use for troubleshooting or to monitor task lifecycle timelines.

### Service actions

Events such as reaching steady state, failed task placement, or resource constraints.

### Service deployment state changes

Events such as in-progress, completed, or failed deployments, triggered by circuit breaker and rollback settings, to monitor the state of a service deployment.

### Container instance state changes

For workloads on EC2 and Amazon ECS Managed Instances, events show connected and disconnected status.

## Log group configuration

When you turn on event capture, Amazon ECS automatically creates the following resources:

- A Amazon CloudWatch Logs log group named `/aws/events/ecs/containerinsights/${clusterName}/performance`
- An EventBridge rule that ingests all events from the `aws.ecs` source and forwards them to the log group

You can specify a retention period for the log group from 1 day to 10 years. The default retention period is 7 days.

## Considerations

Consider the following when using event capture:

- Event capture stores all events for simplicity. You cannot configure rules in the Amazon ECS console to capture only specific events.
- The Amazon ECS console provides predefined query criteria. For advanced queries, use Amazon CloudWatch Logs Logs Insights to query the log group directly.
- Live tail functionality is not available in the Amazon ECS console. Use Amazon CloudWatch Logs directly for live tail.
- When you disable event capture, the EventBridge rule is deleted.
- Event capture incurs additional costs for EventBridge data ingestion, Amazon CloudWatch Logs storage, and query execution.

For information about EventBridge pricing, see [EventBridge pricing](#).

For information about CloudWatch pricing, see [CloudWatch pricing](#).

## Event-based troubleshooting

Use Amazon ECS generated events to answer common troubleshooting questions.

### Task failure analysis

You can review STOPPED task state change events, stop codes, and container exit codes to determine why a task failed to launch or failed while running.

You can review service action events for placement failures and resource constraint information to determine why a task failed to place due to resource constraints

### Common task failure scenarios

The most common abnormal task failures are related to the following issues:

- CI/CD service deployment failures
- Auto scaling failures
- Task rebalancing failures
- Abnormal container exits, such as out-of-memory (OOM) errors

Abnormal task failures produce STOPPED task state change events with an `EssentialContainerExited` or `TaskFailedToStart` stop code. You can filter by these stop codes to examine container execution and stopping behaviors.

## Turn on event capture for an existing Amazon ECS cluster

You can enable event capture on an existing Amazon ECS cluster to store Amazon ECS-generated events in Amazon CloudWatch Logs through EventBridge. This feature helps you monitor and troubleshoot task failures, service deployments, and other cluster activities.

After you enable event capture, Amazon ECS creates the following resources:

- A Amazon CloudWatch Logs log group named `/aws/events/ecs/containerinsights/{clusterName}/performance`
- An EventBridge rule that captures all events from the `aws.ecs` source

A **History** tab displays in the cluster view, allowing you to query task lifecycle events and service actions. Event capture begins immediately and stores all Amazon ECS-generated events according to your specified retention period.

### Prerequisites

- An existing Amazon ECS cluster
- Appropriate IAM permissions to modify cluster settings and create Amazon CloudWatch Logs resources

## Turn on event capture using the console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Clusters**.
3. Select the cluster where you want to enable event capture.

The cluster details page displays.

4. Choose **Configuration**.
5. In the **ECS events** section, choose **Turn on event capture**.

The **Turn on event capture** dialog box displays.

6. For **Expire event**, choose the retention period for the Amazon CloudWatch Logs log group. The default is 7 days.
7. Choose **Turn on**.

## Viewing Amazon ECS service and task state change events

The Amazon ECS console provides event capture functionality that stores Amazon ECS-generated events, such as service actions and task state changes, to Amazon CloudWatch Logs through EventBridge. This feature includes a query interface with filtering capabilities to enhance monitoring and troubleshooting.

Events provide detailed information about how your service deployments, services, tasks, and instances operate. You can use this information to troubleshoot task or service deployment failures.

You can use any of the following criteria to filter the events:

- Deployment ID (This is only available on the service detail page)
- Start time
- End time
- Service name (only applicable on cluster detail page, on service detail page, this will be default to current service)
- Task ID
- Task Last status
- Task definition family
- Task definition revision

## Viewing events at the cluster-level

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. Choose **Clusters**.

The clusters list page displays.

3. Choose the cluster.

The cluster details page displays.

4. Under **History**, determine the events to view.
  - a. To view service action events, choose **Service action events**.
  - b. To view task state change events, choose **Task state change events**.
  - c. (Optional) In **Query criteria**, enter the filters for the events that you want to view.
5. Choose **Run query**.

The events display in a list.

6. To view the full details of the event, choose the event.

## Viewing at the service-level

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster.
3. On the cluster details page, in the **Services** section, choose the service.

The service details page displays.

4. Under **History**, determine the events to view.
  - a. To view service action events, choose **Service action events**.
  - b. To view task state change events, choose **Task state change events**.
  - c. (Optional) In **Query criteria**, enter the filters for the events that you want to view.
5. Choose **Run query**.

The events display in a list.

6. To view the full details of the event, choose the event.

## Troubleshoot Amazon ECS task definition invalid CPU or memory errors

When registering a task definition using the Amazon ECS API or AWS CLI, if you specify an invalid cpu or memory value, the following error is returned.

```
An error occurred (ClientException) when calling the RegisterTaskDefinition operation:  
Invalid 'cpu' setting for task.
```

**Note**

When using Terraform, the following error might be returned.

```
Error: ClientException: No Fargate configuration exists for given values.
```

To resolve this issue, you must specify a supported value for the task CPU and memory in your task definition. The `cpu` value can be expressed in CPU units or vCPUs in a task definition. It's converted to an integer indicating the CPU units when the task definition is registered. The memory value can be expressed in MiB or GB in a task definition. It's converted to an integer indicating the MiB when the task definition is registered.

For task definitions that specify `FARGATE` for the `requiresCompatibilities` parameter (even if `EC2` is also specified), you must use one of the values in the following table. These values determine your range of supported values for the CPU and memory parameter.

For tasks hosted on Fargate, the following table shows the valid CPU and memory combinations. The memory values in the JSON file are specified in MiB. You can convert the GB value to MiB by multiplying the value by 1024. For example 1 GB = 1024 MiB.

| CPU value      | Memory value                               | Operating systems supported for AWS Fargate |
|----------------|--------------------------------------------|---------------------------------------------|
| 256 (.25 vCPU) | 512 MiB, 1 GB, 2 GB                        | Linux                                       |
| 512 (.5 vCPU)  | 1 GB, 2 GB, 3 GB, 4 GB                     | Linux                                       |
| 1024 (1 vCPU)  | 2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB   | Linux, Windows                              |
| 2048 (2 vCPU)  | Between 4 GB and 16 GB in 1 GB increments  | Linux, Windows                              |
| 4096 (4 vCPU)  | Between 8 GB and 30 GB in 1 GB increments  | Linux, Windows                              |
| 8192 (8 vCPU)  | Between 16 GB and 60 GB in 4 GB increments | Linux                                       |

| CPU value                                                                                                                                                                               | Memory value                                | Operating systems supported for AWS Fargate |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|---------------------------------------------|
| <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div>   |                                             |                                             |
| 16384 (16 vCPU)                                                                                                                                                                         | Between 32 GB and 120 GB in 8 GB increments | Linux                                       |
| <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div>   |                                             |                                             |
| 32768 (32 vCPU)                                                                                                                                                                         | 60 GB, 120 GB, 244 GB                       | Linux                                       |
| <div>  <b>Note</b><br/>           This option requires Linux platform 1.4.0 or later.         </div> |                                             |                                             |

For tasks hosted on Amazon EC2, supported task CPU values are between 0.25 vCPUs and 192 vCPUs.

The CPU control mechanism differs between EC2 and Fargate:

- For tasks hosted on Amazon EC2: Amazon ECS uses the CPU period and the CPU quota to control the task size CPU hard limits. When you specify the vCPU in your task definition, Amazon ECS translates the value to the CPU period and CPU quota settings that apply to the cgroup.
- For tasks hosted on Fargate: Amazon ECS uses CPU shares to control CPU allocation. The CPU quota and period values are not used for CPU limiting in Fargate tasks.

For Amazon EC2 tasks, the CPU quota controls the amount of CPU time granted to a cgroup during a given CPU period. Both settings are expressed in terms of microseconds. When the CPU quota equals the CPU period means a cgroup can execute up to 100% on one vCPU (or any other fraction that totals to 100% for multiple vCPUs). The CPU quota has a maximum of 1000000us and the CPU period has a minimum of 1ms. You can use these values to set the limits for your CPU count. When you change the CPU period without changing the CPU quota, you have different effective limits than what you've specified in your task definition.

The 100ms period allows for vCPUs ranging from 0.125 to 10.

 **Note**

Task-level CPU and memory parameters are ignored for Windows containers.

## Viewing Amazon ECS container agent logs

Amazon ECS stores logs in the `/var/log/ecs` folder of your container instances. There are logs available from the Amazon ECS container agent and from the `ecs-init` service that controls the state of the agent (start/stop) on the container instance. You can view these log files by connecting to a container instance using SSH.

 **Note**

If you are not sure how to collect all of the logs on your container instances, you can use the Amazon ECS logs collector. For more information, see [Collecting container logs with Amazon ECS logs collector](#).

### Linux operating system

The `ecs-init` process stores logs at `/var/log/ecs/ecs-init.log`.

The `ecs-init.log` file contains information about the container agent lifecycle management, configuration, and bootstrapping.

You can use the following command to view the log files.

```
cat /var/log/ecs/ecs-init.log
```

## Output:

```
2018-02-16T18:13:54Z [INFO] pre-start
2018-02-16T18:13:56Z [INFO] start
2018-02-16T18:13:56Z [INFO] No existing agent container to remove.
2018-02-16T18:13:56Z [INFO] Starting Amazon Elastic Container Service Agent
```

## Windows operating system

You can use the Amazon ECS logs collector for Windows. For more information, see [Amazon ECS Logs Collector For Windows](#) on Github.

1. Connect to your instance.
2. Open PowerShell and then run the following commands with administrative privileges. The commands download the script and collect the logs.

```
Invoke-WebRequest -OutFile ecs-logs-collector.ps1 https://
raw.githubusercontent.com/awslabs/aws-ecs-logs-collector-for-windows/master/ecs-
logs-collector.ps1
.\ecs-logs-collector.ps1
```

You can turn on debug logging for Amazon ECS agent and the Docker daemon. This option allows the script to collect the logs before turning on debug mode. The script restarts the Docker daemon and Amazon ECS agent, and then terminates all containers running on the instance. Before running the following command, drain the container instance and moving any important tasks to other container instances.

Run the following command to turn on logging.

```
.\ecs-logs-collector.ps1 -RunMode debug
```

## Collecting container logs with Amazon ECS logs collector

### Note

You can't use the Amazon ECS logs collector on Amazon ECS Managed Instances.

If you are unsure how to collect all of the various logs on your container instances, you can use the Amazon ECS logs collector. It is available on GitHub for both [Linux](#) and [Windows](#). The script collects general operating system logs as well as Docker and Amazon ECS container agent logs, which can be helpful for troubleshooting AWS Support cases. It then compresses and archives the collected information into a single file that can easily be shared for diagnostic purposes. It also supports enabling debug mode for the Docker daemon and the Amazon ECS container agent on Amazon Linux variants, such as the Amazon ECS-optimized AMI.

 **Note**

On Amazon Linux Amazon ECS-optimized AMIs version 20250909 and later, the Amazon ECS logs collector is pre-installed at `/opt/amazon/ecs/ecs-logs-collector.sh` and ready to use without downloading from GitHub. For more information, see [ECS Logs Collector](#) in the ECS-optimized AMI documentation.

Currently, the Amazon ECS logs collector supports the following operating systems:

- Amazon Linux
- Red Hat Enterprise Linux
- Ubuntu
- Windows Server

### To run the Amazon ECS logs collector for Linux (ECS-optimized AMI)

1. Connect to your container instance.
2. Run the script to collect the logs and create the archive.

 **Note**

To enable the debug mode for the Docker daemon and the Amazon ECS container agent, add the `--mode=enable-debug` option to the following command. This might restart the Docker daemon, which kills all containers that are running on the instance. Consider draining the container instance and moving any important tasks to other container instances before enabling debug mode. For more information, see [Draining Amazon ECS container instances](#).

```
[ec2-user ~]$ sudo /opt/amazon/ecs/ecs-logs-collector.sh
```

After you have run the script, you can examine the collected logs in the `collect` folder that the script created. The `collect.tar.gz` file is a compressed archive of all of the logs, which you can share with AWS Support for diagnostic help.

### To download and run the Amazon ECS logs collector for Linux

1. Connect to your container instance.
2. Download the Amazon ECS logs collector script.

```
curl -O https://raw.githubusercontent.com/aws-labs/ecs-logs-collector/master/ecs-logs-collector.sh
```

3. Run the script to collect the logs and create the archive.

```
$ sudo bash ./ecs-logs-collector.sh
```

### To download and run the Amazon ECS logs collector for Windows

1. Connect to your container instance. For more information, see [Connect to your Windows instance using RDP](#) in the *Amazon EC2 User Guide*.
2. Download the Amazon ECS logs collector script using PowerShell.

```
Invoke-WebRequest -OutFile ecs-logs-collector.ps1 https://raw.githubusercontent.com/aws-labs/aws-ecs-logs-collector-for-windows/master/ecs-logs-collector.ps1
```

3. Run the script to collect the logs and create the archive.

#### Note

To enable the debug mode for the Docker daemon and the Amazon ECS container agent, add the `-RunMode debug` option to the following command. This restarts the Docker daemon, which kills all containers that are running on the instance. Consider draining the container instance and moving any important tasks to other container

instances before enabling debug mode. For more information, see [Draining Amazon ECS container instances](#).

```
.\ecs-logs-collector.ps1
```

After you have run the script, you can examine the collected logs in the `collect` folder that the script created. The `collect.tgz` file is a compressed archive of all of the logs, which you can share with AWS Support for diagnostic help.

## Retrieve Amazon ECS diagnostic details with agent introspection

The Amazon ECS agent introspection API provides information about the overall state of the Amazon ECS agent and the container instances.

You can use the agent introspection API to get the Docker ID for a container in your task. You can use the agent introspection API by connecting to a container instance using SSH.

### Important

Your container instance must have an IAM role that allows access to Amazon ECS in order to reach the introspection API. For more information, see [Amazon ECS container instance IAM role](#).

The following example shows two tasks, one that is currently running and one that was stopped.

### Note

The following command is piped through the **python -mjson.tool** for greater readability.

```
curl http://localhost:51678/v1/tasks | python -mjson.tool
```

Output:

```

% Total    % Received % Xferd  Average Speed   Time    Time       Time  Current
           Dload  Upload   Total     Spent    Left     Speed
100 1095 100 1095    0    0 117k      0 --:--:-- --:--:-- --:--:-- 133k
{

```

        "DockerName": "ecs-console-sample-app-static-6-
        busybox-92e4b8d0ecd0cce69a01",
        "Name": "busybox"
    }
],
    "DesiredStatus": "RUNNING",
    "Family": "console-sample-app-static",
    "KnownStatus": "RUNNING",
    "Version": "6"
}
]
}

```

In the preceding example, the stopped task (*090eff9b-1ce3-4db6-848a-a8d14064fd24*) has two containers. You can use **docker inspect *container-ID*** to view detailed information on each container. For more information, see [Amazon ECS container introspection](#).

## Docker diagnostics in Amazon ECS

Docker provides several diagnostic tools that help you troubleshoot problems with your containers and tasks. For more information about all of the available Docker command line utilities, see the [Docker CLI reference](#) in the Docker documentation. You can access the Docker command line utilities by connecting to a container instance using SSH.

The exit codes that Docker containers report can also provide some diagnostic information (for example, exit code 137 means that the container received a SIGKILL signal). For more information, see [Exit Status](#) in the Docker documentation.

## List Docker containers in Amazon ECS

You can use the **docker ps** command on your container instance to list the running containers. In the following example, only the Amazon ECS container agent is running. For more information, see [docker ps](#) in the Docker documentation.

```
docker ps
```

Output:

| CONTAINER ID | IMAGE | COMMAND | CREATED |
|--------------|-------|---------|---------|
| STATUS       | PORTS | NAMES   |         |

|              |                                |           |              |
|--------------|--------------------------------|-----------|--------------|
| cee0d6986de0 | amazon/amazon-ecs-agent:latest | "/agent"  | 22 hours ago |
| Up 22 hours  | 127.0.0.1:51678->51678/tcp     | ecs-agent |              |

You can use the **docker ps -a** command to see all containers (even stopped or killed containers). This is helpful for listing containers that are unexpectedly stopping. In the following example, container f7f1f8a7a245 exited 9 seconds ago, so it doesn't show up in a **docker ps** output without the -a flag.

```
docker ps -a
```

Output:

| CONTAINER ID                                                                    | IMAGE                                     | COMMAND                    |       |
|---------------------------------------------------------------------------------|-------------------------------------------|----------------------------|-------|
| CREATED                                                                         | STATUS                                    | PORTS                      | NAMES |
| db4d48e411b1                                                                    | amazon/ecs-emptyvolume-base:autogenerated | "not-applicable"           |       |

## View Docker Logs in Amazon ECS

You can view the STDOUT and STDERR streams for a container with the **docker logs** command. In this example, the logs are displayed for the *dc7240fe892a* container and piped through the **head** command for brevity. For more information, go to [docker logs](#) in the Docker documentation.

### Note

Docker logs are only available on the container instance if you are using the default json log driver. If you have configured your tasks to use the awslogs log driver, then your

container logs are available in CloudWatch Logs. For more information, see [Send Amazon ECS logs to CloudWatch](#).

```
docker logs dc7240fe892a | head
```

Output:

```
AH00558: httpd: Could not reliably determine the server's fully qualified domain name,
using 172.17.0.11. Set the 'ServerName' directive globally to suppress this message

## Inspect Docker Containers in Amazon ECS

If you have the Docker ID of a container, you can inspect it with the **docker inspect** command. Inspecting containers provides the most detailed view of the environment in which a container was launched. For more information, see [docker inspect](#) in the Docker documentation.

```
docker inspect dc7240fe892a
```

Output:

```
[{
```

```

"AppArmorProfile": "",
"Args": [],
"Config": {
  "AttachStderr": false,
  "AttachStdin": false,
  "AttachStdout": false,
  "Cmd": [
    "httpd-foreground"
  ],
  "CpuShares": 10,
  "Cpuset": "",
  "Domainname": "",
  "Entrypoint": null,
  "Env": [
    "PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin:/usr/

    "HTTPD_PREFIX=/usr/local/apache2",
    "HTTPD_VERSION=2.4.12",
    "HTTPD_BZ2_URL=https://www.apache.org/dist/httpd/httpd-2.4.12.tar.bz2"
  ],
  "ExposedPorts": {
    "80/tcp": {}
  },
  "Hostname": "dc7240fe892a",
  ...

```

## Configuring verbose output from the Docker daemon in Amazon ECS

If you're having trouble with Docker containers or images, you can turn on debug mode on your Docker daemon. Using debugging provides more verbose output from the daemon. You can use this to retrieve error messages that are sent from container registries, such as Amazon ECR.

### Important

This procedure is written for the Amazon ECS-optimized Amazon Linux AMI. For other operating systems, see [Enable debugging](#) and [Control and configure Docker with systemd](#) in the Docker documentation.

## To use Docker daemon debug mode on the Amazon ECS-optimized Amazon Linux AMI

1. Connect to your container instance.
2. Open the Docker options file with a text editor, such as **vi**. For the Amazon ECS-optimized Amazon Linux AMI, the Docker options file is at `/etc/sysconfig/docker`.
3. Find the Docker options statement and add the `-D` option to the string, inside the quotes.

### Note

If the Docker options statement begins with a `#`, remove that character to uncomment the statement and enable the options.

For the Amazon ECS-optimized Amazon Linux AMI, the Docker options statement is called `OPTIONS`. For example:

```
# Additional startup options for the Docker daemon, for example:
# OPTIONS="--ip-forward=true --iptables=true"
# By default we limit the number of open files per container
OPTIONS="--D --default-ulimit nofile=1024:4096"
```

4. Save the file and exit your text editor.
5. Restart the Docker daemon.

```
sudo service docker restart
```

The output is as follows:

```
Stopping docker:                                [ OK ]
Starting docker: .                             [ OK ]
```

6. Restart the Amazon ECS agent.

```
sudo service ecs restart
```

Your Docker logs should now show more verbose output.

```
time="2015-12-30T21:48:21.907640838Z" level=debug msg="Unexpected response from
server: \"{\\\"errors\\\": [{\\\"code\\\": \\\"DENIED\\\", \\\"message\\\": \\\"User:
arn:aws:sts::1111:assumed-role/ecrReadOnly/i-abcdefg is not authorized to perform:

\"Content-Length\": []string{\"235\"}}"
```

## Troubleshoot the Docker API error (500): devmapper in Amazon ECS

The following Docker error indicates that the thin pool storage on your container instance is full, and that the Docker daemon cannot create new containers:

```
CannotCreateContainerError: API error (500): devmapper: Thin Pool has 4350 free data
blocks which is less than minimum required 4454 free data blocks. Create more free
space in thin pool or use dm.min_free_space option to change behavior
```

By default, Amazon ECS-optimized Amazon Linux AMIs from version 2015.09.d and later launch with an 8-GiB volume for the operating system that's attached at `/dev/xvda` and mounted as the root of the file system. There's an additional 22-GiB volume that's attached at `/dev/xvdcz` that Docker uses for image and metadata storage. If this storage space is filled up, the Docker daemon cannot create new containers.

The easiest way to add storage to your container instances is to terminate the existing instances and launch new ones with larger data storage volumes. However, if you can't do this, you can add storage to the volume group that Docker uses and extend its logical volume by following the procedures in [Amazon ECS-optimized Linux AMIs](#).

If your container instance storage is filling up too quickly, there are a few actions that you can take to reduce this effect:

- To view the thin pool information, run the following command on your container instance:

```
docker info
```

- (Amazon ECS container agent 1.8.0 and later) You can reduce the amount of time that stopped or exited containers remain on your container instances. The

ECS\_ENGINE\_TASK\_CLEANUP\_WAIT\_DURATION agent configuration variable sets the time duration to wait from when a task is stopped until the Docker container is removed (by default, this value is 3 hours). This removes the Docker container data. If this value is set too low, you might not be able to inspect your stopped containers or view the logs before they are removed. For more information, see [Amazon ECS container agent configuration](#).

- You can remove non-running containers and unused images from your container instances. You can use the following example commands to manually remove stopped containers and unused images. Deleted containers can't be inspected later, and deleted images must be pulled again before starting new containers from them.

To remove non-running containers, run the following command on your container instance:

```
docker rm $(docker ps -aq)
```

To remove unused images, run the following command on your container instance:

```
docker rmi $(docker images -q)
```

- You can remove unused data blocks within containers. You can use the following command to run **fstrim** on any running container and discard any data blocks that are unused by the container file system.

```
sudo sh -c "docker ps -q | xargs docker inspect --format='{{ .State.Pid }}' | xargs -IZ fstrim /proc/Z/root/"
```

## Troubleshoot Amazon ECS Exec issues

The following are troubleshooting notes to help diagnose why you may be getting an error when using ECS Exec.

### Verify using the Exec Checker

The ECS Exec Checker script provides a way to verify and validate that your Amazon ECS cluster and task have met the prerequisites for using the ECS Exec feature. The ECS Exec Checker script verifies both your AWS CLI environment and cluster and tasks are ready for ECS Exec, by calling various APIs on your behalf. The tool requires the latest version of the AWS CLI and that the `jq` is available. For more information, see [ECS Exec Checker](#) on GitHub.

## Error when calling `execute-command`

If a `The execute command failed` error occurs, the following are possible causes.

- The task does not have the required permissions. Verify that the task definition used to launch your task has a task IAM role defined and that the role has the required permissions. For more information, see [ECS Exec permissions](#).
- The SSM agent isn't installed or isn't running.
- There is an interface Amazon VPC endpoint for Amazon ECS, but there isn't one for Systems Manager Session Manager.

## Troubleshoot Amazon ECS Anywhere issues

Amazon ECS Anywhere provides support for registering an *external instance* such as an on-premises server or virtual machine (VM) to your Amazon ECS cluster. The following are common issues that you might encounter and general troubleshooting recommendations for them.

### Topics

- [External instance registration issues](#)
- [External instance network issues](#)
- [Issues running tasks on your external instance](#)

## External instance registration issues

When registering an external instance with your Amazon ECS cluster, the following requirements must be met:

- An AWS Systems Manager activation, which consists of an *activation ID* and *activation code*, must be retrieved. You use it to register the external instance as a Systems Manager managed instance. When a Systems Manager activation is requested, specify a registration limit and expiration date. The registration limit specifies the maximum number of instances that can be registered using the activation. The default value for registration limit is 1 instance. The expiration date specifies when the activation expires. The default value is 24 hours. If the Systems Manager activation that you're using to register your external instance isn't valid, request a new one. For more information, see [Registering an external instance to an Amazon ECS cluster](#).

- An IAM policy is used to provide your external instance the permissions that it needs to communicate with AWS API operations. If this managed policy isn't created properly and doesn't contain the required permissions, external instance registration fails. For more information, see [Amazon ECS Anywhere IAM role](#).
- Amazon ECS provides an installation script that installs Docker, the Amazon ECS container agent, and the Systems Manager Agent on your external instance. If the installation script fails, it's likely that the script can't be run again on the same instance without an error occurring. If this happens, follow the cleanup process to clear AWS resources from the instance so you can run the installation script again. For more information, see [Deregistering an Amazon ECS external instance](#).

**Note**

Be aware that, if the installation script successfully requested and used the Systems Manager activation, running the installation script a second time uses the Systems Manager activation again. This might in turn cause you to reach the registration limit for that activation. If this limit is reached, you must create a new activation.

- When running the installation script on an external instance for GPU workloads, if the NVIDIA driver is not detected or configured properly, an error will occur. The installation script uses the `nvidia-smi` command to confirm the existence of the NVIDIA driver.

## External instance network issues

To communicate any changes, your external instance requires a network connection to AWS. If your external instance loses its network connection to AWS, tasks that are running on your instances continue to run anyway unless stopped manually. After the connection to AWS is restored, the AWS credentials that are used by the Amazon ECS container agent and Systems Manager Agent on the external instance renew automatically. For more information about the AWS domains that are used for communication between your external instance and AWS, see [Networking](#).

## Issues running tasks on your external instance

If your tasks or containers fail to run on your external instance, the most common causes are either network or permission related. If your containers are pulling their images from Amazon ECR or are configured to send container logs to CloudWatch Logs, your task definition must specify a valid

task execution IAM role. Without a valid task execution IAM role, your containers will fail to start. For more information about network related issues, see [External instance network issues](#).

### Important

Amazon ECS provides the Amazon ECS logs collection tool. You can use it to collect logs from your external instances for troubleshooting purposes. For more information, see [Collecting container logs with Amazon ECS logs collector](#).

## Troubleshoot Java class loading issues on Fargate

Java applications running on Fargate may encounter class loading issues after platform updates, particularly when the application relies on non-deterministic class loading behavior. This can manifest as dependency injection errors, Spring Boot failures, or other runtime exceptions that were not present in previous deployments.

### Symptoms

You might experience the following symptoms:

- Spring Boot dependency injection errors
- `ClassNotFoundException` or `NoClassDefFoundError` exceptions
- Applications that previously worked on Fargate now fail intermittently
- The same container image works on Amazon EC2 but fails on Fargate
- Inconsistent behavior across deployments with identical container images

### Causes

These issues typically occur due to:

- **Non-deterministic class loading:** Java applications that depend on the order in which classes are loaded from JAR files may fail when the underlying platform changes how files are accessed or cached.
- **Platform updates:** Fargate platform version updates may change the underlying file system behavior, affecting the order in which classes are discovered and loaded.

- **JAR file ordering dependencies:** Applications that implicitly rely on specific JAR loading sequences without explicit dependency management.

## Resolution

To resolve Java class loading issues on Fargate, implement deterministic class loading practices:

### Immediate fix

If you need an immediate workaround:

1. **Enforce JAR loading order:** Explicitly specify the order in which JAR files should be loaded in your application's classpath configuration.
2. **Use explicit dependency management:** Ensure all dependencies are explicitly declared in your build configuration (Maven, Gradle, etc.) rather than relying on transitive dependencies.

### Long-term best practices

Implement these practices to prevent future class loading issues:

#### 1. Make class loading deterministic:

- Use explicit dependency declarations in your build files
- Avoid relying on classpath scanning order
- Use dependency management tools to resolve version conflicts
- Use the Java Virtual Machine (JVM) options such as `-verbose: class` to get information about classes loaded by JVM.

#### 2. Spring Boot applications:

- Use `@ComponentScan` with explicit base packages
- Avoid auto-configuration conflicts by explicitly configuring beans
- Use `@DependsOn` annotations to control bean initialization order

#### 3. Build configuration:

- Use dependency management sections in Maven or Gradle
- Exclude transitive dependencies that cause conflicts
- Use tools like Maven Enforcer Plugin to detect dependency issues

#### 4. Testing:

- Test your application with different JVM implementations
- Run integration tests that simulate different deployment environments
- Use tools to analyze classpath conflicts during development

## Prevention

To prevent Java class loading issues in future deployments:

- **Follow deterministic class loading practices:** Design your application to not depend on the order in which classes are loaded from the classpath.
- **Use explicit dependency management:** Always explicitly declare all required dependencies and their versions in your build configuration.
- **Test across environments:** Regularly test your applications across different environments and platform versions to identify potential issues early.
- **Monitor platform updates:** Stay informed about Fargate platform updates and test your applications with new platform versions before they affect production workloads.

## AWS Fargate throttling quotas

AWS Fargate limits Amazon ECS tasks and Amazon EKS pods launch rates to quotas (formerly referred to as limits) using a [token bucket algorithm](#) for each AWS account on a per-Region basis. With this algorithm, your account has a bucket that holds a specific number of tokens. The number of tokens in the bucket represents your rate quota at any given second. Each customer account has a tasks and pods token bucket that depletes based on the number of tasks and pods launched by the customer account. This token bucket has a bucket maximum that allows you to periodically make a higher number of requests, and a refill rate that allows you to sustain a steady rate of requests for as long as needed.

For example, the tasks and pods token bucket size for a Fargate customer account is 100 tokens, and the refill rate is 20 tokens per second. Therefore, you can immediately launch up to 100 Amazon ECS tasks and Amazon EKS pods per customer account, with a sustained launch rate of 20 Amazon ECS tasks and Amazon EKS pods per second.

| Actions                                                                                     | Bucket maximum capacity (or Burst rate) | Bucket refill rate (or Sustained rate) |
|---------------------------------------------------------------------------------------------|-----------------------------------------|----------------------------------------|
| Fargate Resource rate quota for On Demand Amazon ECS tasks and Amazon EKS pods <sup>1</sup> | 100                                     | 20                                     |
| Fargate Resource rate quota for Spot Amazon ECS tasks                                       | 100                                     | 20                                     |

<sup>1</sup>Accounts launching only Amazon EKS pods have a burst rate of 20 with a sustained pod launch rate of 20 pod launches per second when using the platform versions called out in the [Amazon EKS platform versions](#).

## Throttling the RunTask API in Fargate

In addition, Fargate limits the request rate when launching tasks using the Amazon ECS RunTask API using a separate quota. Fargate limits Amazon ECS RunTask API requests for each AWS account on a per-Region basis. Each request that you make removes one token from the bucket. We do this to help the performance of the service, and to ensure fair usage for all Fargate customers. API calls are subject to the request quotas whether they originate from the Amazon Elastic Container Service console, a command line tool, or a third-party application. The rate quota for calls to the Amazon ECS RunTask API is 20 calls per second (burst and sustained). Each call to this API can, however, launch up to 10 tasks. This means you can launch 100 tasks in one second by making 10 calls to this API, requesting 10 tasks to be launched in each call. Similarly, you could also make 20 calls to this API, requesting 5 tasks to be launched in each call. For more information on API throttling for Amazon ECS RunTask API, see [API request throttling](#) in the Amazon ECS API Reference.

In practice, task and pod launch rates are also dependent on other considerations such as container images to be downloaded and unpacked, health checks and other integrations enabled, such as registering tasks or pods into a load balancer. Customers see variations in task and pod launch rates compared with the quotas represented earlier based on the features that customers enable.

## Adjusting rate quotas in Fargate

You can request an increase for Fargate rate throttling quotas for your AWS account. For more information, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

## Troubleshooting Amazon ECS Managed Instances

Use the following procedures to troubleshoot Amazon ECS Managed Instances, including common issues, diagnostic techniques, and resolution steps.

### Prerequisites

Before troubleshooting Amazon ECS Managed Instances, ensure that you have the following requirements in place.

- The AWS CLI is installed and configured with appropriate permissions

For more information, see [Installing or updating to the latest version of the AWS Command Line Interface](#) in the *AWS Command Line Interface User Guide*.

- Access to a cluster with Amazon ECS Managed Instances capacity provider. For more information, see [the section called "Creating a cluster for Amazon ECS Managed Instances"](#).

### Common troubleshooting scenarios

#### Viewing Amazon ECS Managed Instances container agent logs

You can view these Amazon ECS log files in Amazon ECS Managed Instances by connecting to a privileged container running in the instance.

#### Diagnostic steps

##### Deploy a debug container with privileges and Linux capabilities as an Amazon ECS task:

Set the following environment variables.

Replace the *user-input* with your values.

```
export ECS_CLUSTER_NAME="your-cluster-name"
export AWS_REGION="your-region"
export ACCOUNT_ID="your-account-id"
```

## Create a task definition using a CLI JSON file called `node-debugger.json`.

```
cat << EOF > node-debugger.json
{
  "family": "node-debugger",
  "taskRoleArn": "arn:aws:iam::${ACCOUNT_ID}:role/ecsTaskExecutionRole",
  "executionRoleArn": "arn:aws:iam::${ACCOUNT_ID}:role/ecsTaskExecutionRole",
  "cpu": "256",
  "memory": "1024",
  "networkMode": "host",
  "pidMode": "host",
  "requiresCompatibilities": ["MANAGED_INSTANCES", "EC2"],
  "containerDefinitions": [
    {
      "name": "node-debugger",
      "image": "public.ecr.aws/amazonlinux/amazonlinux:2023",
      "essential": true,
      "privileged": true,
      "command": ["sleep", "infinity"],
      "healthCheck": {
        "command": ["CMD-SHELL", "echo debugger || exit 1"],
        "interval": 30,
        "retries": 3,
        "timeout": 5
      },
      "linuxParameters": {
        "initProcessEnabled": true
      },
      "mountPoints": [
        {
          "sourceVolume": "host-root",
          "containerPath": "/host",
          "readOnly": false
        }
      ],
      "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
          "awslogs-group": "/aws/ecs/node-debugger",
          "awslogs-create-group": "true",
          "awslogs-region": "${AWS_REGION}",
          "awslogs-stream-prefix": "ecs"
        }
      }
    }
  ]
}
```

```
    }
  ],
  "volumes": [
    {
      "name": "host-root",
      "host": {
        "sourcePath": "/"
      }
    }
  ]
}
EOF
```

Register, and then run the task. Run the following commands.

```
aws ecs register-task-definition --cli-input-json file:///node-debugger.json

TASK_ARN=$(aws ecs run-task \
  --cluster $ECS_CLUSTER_NAME \
  --task-definition node-debugger \
  --enable-execute-command \
  --capacity-provider-strategy capacityProvider=managed-instances-default,weight=1 \
  --query 'tasks[0].taskArn' --output text)

# Wait for task to be running
aws ecs wait tasks-running --cluster $ECS_CLUSTER_NAME --tasks $TASK_ARN
```

Connect to the container. Run the following command.

```
aws ecs execute-command \
  --cluster $ECS_CLUSTER_NAME \
  --task $TASK_ARN \
  --container node-debugger \
  --interactive \
  --command "/bin/sh"
```

### Check the Amazon ECS agent logs:

In the interactive session of the container, run the following commands:

```
# Install required tools
yum install -y util-linux-core
```

```
# View ECS agent logs
nsenter -t 1 -m -p cat /var/log/ecs/ecs-agent.log | tail -50

# Check agent registration
nsenter -t 1 -m -p grep "Registered container instance" /var/log/ecs/ecs-agent.log

Example Output:

{"level":"info","time":"2025-10-16T12:39:37.665","msg":"Registered container instance
with cluster!"}

# Verify capabilities
nsenter -t 1 -m -p grep "Response contained expected value for attribute" /var/log/ecs/
ecs-agent.log
```

## Check agent metrics:

Run the following command to view the logs.

```
# View metrics logs
nsenter -t 1 -m -p cat /var/log/ecs/metrics.log | tail -20
```

## Task placement issues

The following are symptoms of task placement issues:

- Tasks stuck in PENDING state
- Tasks failing to start on Amazon ECS Managed Instances
- Insufficient resources errors

## Diagnostic steps

Run the following commands to diagnose task placement issues and gather information about cluster capacity, container instances, and system services:

```
# Check cluster capacity
aws ecs describe-clusters --clusters cluster-name --include STATISTICS

# Check cluster capacity providers
aws ecs describe-clusters --clusters cluster-name --include STATISTICS --query
'clusters[].capacityProviders'
```

```
# List container instances
aws ecs list-container-instances --cluster cluster-name

# Check container instance details
aws ecs describe-container-instances --cluster cluster-name --container-
instances container-instance-arn

# Check container instance remaining resources CPU/Mem
aws ecs describe-container-instances --cluster $ECS_CLUSTER_NAME --container-
instances container-instance-arn --query 'containerInstances[].remainingResources'

# Check container instance Security Group
aws ecs describe-container-instances --cluster $ECS_CLUSTER_NAME --container-
instances container-instance-arn --query 'containerInstances[].ec2InstanceId' --output
text
aws ec2 describe-instances --instance-ids instance-id --query
'Reservations[0].Instances[0].SecurityGroups'
aws ec2 describe-security-groups --group-ids security-group-id
```

## System service monitoring:

```
# Check Containerd status
nsenter -t 1 -m -p systemctl status containerd.service

# Check Amazon ECS container agent status
nsenter -t 1 -m -p systemctl status ecs
```

## Resolution

To resolve task placement issues, follow these steps to ensure proper configuration and capacity:

- Verify task resource requirements vs available capacity
- Check placement constraints and strategies
- Ensure Amazon ECS Managed Instances capacity provider is configured
- Ensure that the task and container instance security group have an outbound rule that allow traffic for the Amazon ECS agent management endpoints

## Networking issues

The following are symptoms of networking issues:

- Tasks unable to reach external services
- DNS resolution problems

## Diagnostic steps

### Network connectivity tests:

From the debug container, run the following commands:

#### Note

Confirm the security group attached to your capacity provider or Amazon ECS task is permitting the traffic.

```
# Install DNS Utility
yum install bind-utils -y

# Test DNS resolution
nslookup amazon.com

# Test external connectivity
curl -I https://amazon.com
```

## Resource constraints

The following are symptoms of networking issues:

- Tasks killed due to memory limits
- CPU throttling
- Disk space issues

## Diagnostic steps

Run commands to monitor the resources and container limits.

### Resource monitoring:

```
# Check memory usage
```

```
nsenter -t 1 -m -p free -h

# Check disk usage
nsenter -t 1 -m -p lsblk

# Check disk usage
nsenter -t 1 -m -p df -h
```

## Container Limits:

```
# Check OOM kills
nsenter -t 1 -m -p dmesg | grep -i "killed process"
```

## Container instance agent disconnect issue

The following are symptoms of container instance agent disconnect issues:

- Container instances showing as disconnected in the Amazon ECS console
- Tasks failing to be placed on specific instances
- Agent registration failures in logs

## Diagnostic steps

If there is an existing privilege task running on the host that ECS Exec can access, run the following commands to diagnose agent connectivity issues:

```
# check service status
nsenter -t 1 -m -p systemctl status ecs
nsenter -t 1 -m -p systemctl status containerd

# restart stopped services
nsenter -t 1 -m -p systemctl restart ecs
nsenter -t 1 -m -p systemctl restart containerd
```

Otherwise, force deregister the Amazon ECS Managed Instances. Run the following command:

```
# list ECS Managed Instance container
aws ecs list-container-instances --cluster managed-instances-cluster --query
'containerInstanceArns' --output text

# deregister the specific container instance
```

```
aws ecs deregister-container-instance \  
  --cluster $ECS_CLUSTER_NAME \  
  --container-instance container-instance-arn \  
  --force
```

## Resolution

To resolve agent disconnect issues, follow these steps:

- Verify IAM role permissions for the container instance
- Check security group rules allow outbound HTTPS traffic to ECS endpoints
- Ensure network connectivity to AWS services
- Restart the ECS agent service if necessary: `nsenter -t 1 -m -p systemctl restart ecs`
- Verify the `ECS_CLUSTER` configuration in `/etc/ecs/ecs.config` matches your cluster name

## Log Analysis in Amazon ECS Managed Instances

### System logs

Use the following commands to examine system logs and identify potential issues with the managed instance:

```
# Check system messages  
nsenter -t 1 -m -p journalctl --no-pager -n 50  
  
# Check kernel logs  
nsenter -t 1 -m -p dmesg | tail -20  
  
# Check for disk space errors  
nsenter -t 1 -m -p journalctl --no-pager | grep -i "no space\|disk full\|enospc"
```

## Use the EC2 AWS CLI to get the console output from a Amazon ECS Managed Instance

Use the Amazon EC2 instance ID to retrieve the console output.

Replace the *user-input* with your values.

```
aws ec2 get-console-output --instance-id instance-id --latest --output text
```

## Cleanup

Run the following to stop the debug task and deregister the task definition.

```
# Stop debug task
aws ecs stop-task --cluster $ECS_CLUSTER_NAME --task $TASK_ARN

# Deregister task definition (optional)
aws ecs deregister-task-definition --task-definition node-debugger
```

## Additional resources

For more information about troubleshooting Amazon ECS Managed Instances, see the following resources:

- [the section called “Amazon ECS Managed Instances errors”](#)
- [Troubleshooting](#)
- [the section called “Container agent configuration”](#)
- [the section called “Monitor Amazon ECS containers with ECS Exec”](#)

## Troubleshooting Amazon ECS Managed Instances

When launching tasks with Amazon ECS Managed Instances, Amazon ECS first attempts to place tasks on existing capacity and requests additional capacity for tasks that cannot be placed. If instance provisioning fails, the Amazon EC2 request ID is included in the task failure message. You can use this request ID to look up details of the failed request in CloudTrail for further troubleshooting.

### Note

If you choose to apply least-privilege permissions and specify your own permissions for the instance profile instead of using the `AmazonECSInstanceRolePolicyForManagedInstances` managed policy, you can add the following permissions to help with troubleshooting task-related issues with Amazon ECS Managed Instances:

- `ecs:StartTelemetrySession`

- `ecs:PutSystemLogEvents`

## Task definition is incompatible with Amazon ECS Managed Instances

### Common cause

This error occurs when your task definition contains parameters or configurations that are not supported by Amazon ECS Managed Instances. Common incompatibilities include unsupported network modes, task roles, or resource requirements.

### Resolution

1. Verify that your task definition uses `requiresCompatibilities` set to `MANAGED_INSTANCES`.
2. Ensure your task definition uses the `awsvpc` network mode.
3. Check that CPU and memory values are within supported ranges for Amazon ECS Managed Instances.
4. Review the detailed error message for specific incompatibility details.

## Capacity provider not associated with cluster

### Common cause

This error occurs when the capacity provider specified in your capacity provider strategy is not associated with the cluster or does not exist.

### Resolution

1. Verify that the capacity provider exists in your account and region.
2. Associate the capacity provider with your cluster using the Amazon ECS console or CLI.
3. Ensure the capacity provider is in `ACTIVE` status before using it.

## Infrastructure role permission errors

### Common cause

This error occurs when the Amazon ECS infrastructure role lacks the necessary permissions to perform Amazon EC2 operations on your behalf, or when the role cannot be assumed due to trust relationship issues.

## Resolution

1. Verify that your infrastructure role has the proper trust relationship with Amazon ECS.
2. Ensure the role has the required Amazon EC2 permissions including `ec2:RunInstances`, `ec2:DescribeInstances`, and `iam:PassRole`.
3. Check the encoded authorization failure message in CloudTrail for specific permission details.
4. Update the role policy to include missing permissions identified in the error message.

## VcpuLimitExceeded error

### Common cause

This error occurs when you've reached your vCPU service quota for the instance type family in the current region. Amazon ECS Managed Instances cannot launch additional instances until capacity is available.

### Resolution

1. Request a service quota increase for the affected instance type family through the AWS Support Center.
2. Consider using different instance types that fall under a different vCPU quota category.
3. Terminate unused Amazon EC2 instances to free up vCPU capacity.
4. Review your capacity provider configuration to use instance types with lower vCPU requirements.

## InsufficientCapacity and related capacity errors

### Common cause

These errors occur when AWS doesn't have sufficient capacity to fulfill your instance request. This can include insufficient instance capacity, address capacity, or volume capacity in the requested Availability Zone.

### Resolution

1. Try launching instances in different Availability Zones by configuring multiple subnets in your capacity provider.

2. Consider using different instance types that may have more available capacity.
3. Wait and retry the operation as capacity availability changes frequently.
4. For persistent capacity needs, consider using Reserved Instances or Savings Plans.

## UnauthorizedOperation error

### Common cause

This error occurs when the Amazon ECS service doesn't have the necessary permissions to perform Amazon EC2 operations or pass IAM roles. Common scenarios include missing `ec2:RunInstances` permissions or `iam:PassRole` permissions for the instance profile.

### Resolution

1. Verify that your Amazon ECS infrastructure role has the necessary permissions to launch Amazon EC2 instances.
2. Ensure the infrastructure role has `iam:PassRole` permissions for the instance profile used by your Amazon ECS Managed Instances.
3. Check the encoded authorization failure message in CloudTrail for specific permission details.
4. Update the role policy to include the missing permissions identified in the error message.

## Task timed out waiting for capacity

### Common cause

This error occurs when instances take longer than expected to launch and register with the cluster. This can happen due to Amazon EC2 capacity constraints, instance launch failures, or network connectivity issues.

### Resolution

1. Check Amazon EC2 service health in your region for any ongoing issues.
2. Verify that your subnets have sufficient IP addresses available.
3. Ensure your security groups allow the necessary traffic for Amazon ECS agent communication.
4. Consider using multiple Availability Zones to improve capacity availability.
5. Retry the task launch operation as capacity constraints are often temporary.

## Network configuration errors

### Common cause

These errors occur when there are mismatches between your task's network requirements and the capacity provider's network configuration, such as VPC mismatches or missing network configuration.

### Resolution

1. Verify that your capacity provider is configured with the correct VPC and subnets.
2. Ensure that security groups and subnets belong to the same VPC.
3. Check that your task definition's network configuration is compatible with the capacity provider.
4. Update your capacity provider configuration with the correct network settings.

## Capacity provider can't be deleted due to stuck instances

### Common cause

These errors occur when Amazon ECS Managed Instances are stuck in an ACTIVE or DRAINING state but there are no running tasks on the instances.

### Resolution

To allow the deletion of the capacity provider to proceed, you can force deregister the instances that are stuck using the following command.

```
aws ecs deregister-container-instance \
  --cluster arn:aws:ecs:us-east-1:111122223333:cluster/MyCluster \
  --container-instance arn:aws:ecs:us-east-1:111122223333:container-instance/
a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
  --force
```

## Troubleshooting Amazon ECS Amazon ECS Managed Instances errors

The following are some Amazon ECS Managed Instances error messages and actions that you can take to fix the errors.

## **Amazon ECS Managed Instances Provider is not supported without a Cluster Name**

This error occurs when you try to create a capacity provider with a Amazon ECS Managed Instances provider parameter but no cluster field.

To resolve this issue, specify a valid cluster name when creating the capacity provider.

## **The Amazon ECS Managed Instances provider details are required when creating a Amazon ECS Managed Instances capacity provider**

This error appears when you try to create a capacity provider with Amazon ECS Managed Instances provider but do not supply the actual object.

To correct this issue, specify valid Amazon ECS Managed Instances provider details and try again.

## **Amazon ECS Managed Instances capacity provider must specify an instance profile**

You'll see this error when you try to create a capacity provider with Amazon ECS Managed Instances provider but do not provide the `Ec2InstanceProfile`.

To resolve this, specify a valid EC2 instance profile for your Amazon ECS Managed Instances capacity provider. For more information, see [the section called "Amazon ECS Managed Instances instance profile"](#).

## **Amazon ECS Managed Instances capacity provider must specify an InfrastructureRole**

This message appears when you try to create a capacity provider with Amazon ECS Managed Instances provider but do not provide the `InfrastructureRole`.

To correct this, specify a valid infrastructure role for your Amazon ECS Managed Instances capacity provider. For more information, see [the section called "Infrastructure IAM role"](#).

## **Amazon ECS Managed Instances capacity provider must specify a Network Configuration**

You'll encounter this error when you try to create a capacity provider with Amazon ECS Managed Instances provider but do not provide network configuration.

To resolve this, specify a valid network configuration with non-empty subnets for your Amazon ECS Managed Instances capacity provider. For more information, see [the section called “Task networking for Amazon ECS Managed Instances”](#).

## **No instance types satisfy the instance requirements specified in the Amazon ECS Managed Instances capacity provider**

This happens when you try to create a capacity provider with Amazon ECS Managed Instances provider but no EC2 instance type satisfies the instance requirements.

To address this, review and adjust your instance requirements to match available EC2 instance types.

## **The specified infrastructure role arn is invalid**

This error occurs when the InfrastructureRole does not follow the specific ARN format.

Expected format: `arn:partition:iam::account-id:role/role-name`. Specify a valid role ARN and try again. For more information, see [the section called “Infrastructure IAM role”](#).

## **The specified instance profile role arn is invalid**

This error occurs when the instance profile does not follow the specific ARN format.

Expected format: `arn:partition:iam::account-id:instance-profile/profile-name`. Specify a valid role ARN and try again. For more information, see [the section called “Amazon ECS Managed Instances instance profile”](#).

## **The specified security group id is invalid**

This error occurs when the security group ID does not follow the specific format.

Expected format: `sg-xxxxxxxx` or `sg-xxxxxxxxxxxxxxxxxxxxxx` (8 or 17 characters including letters (lowercase), and numbers after 'sg-'). Specify a security group ID and try again.

## **The specified subnet id is invalid**

This error occurs when the subnet ID does not follow the specific format.

Expected format: `subnet-xxxxxxxx` or `subnet-xxxxxxxxxxxxxxxxxxxxxx` (8 or 17 characters including letters (lowercase), and numbers after 'subnet-'). Specify a subnet ID and try again.

## **Amazon ECS Managed Instances capacity provider must specify a Network Configuration with non empty subnets**

This error occurs when you try to create a capacity provider with Amazon ECS Managed Instances provider and network configuration with empty subnets.

To resolve this, specify a valid network configuration with non-empty subnets for your Amazon ECS Managed Instances capacity provider.

## **Amazon ECS Managed Instances capacity provider cannot have number of tags exceeding maximum allowed value**

This error occurs when you try to create a capacity provider with more than the maximum allowed number of tags (45).

To resolve this, reduce the number of tags to 45 or fewer and try again.

## **Invalid value for propagateTags**

This error occurs when you try to create a capacity provider with an invalid propagateTags value.

The value must be one of the valid propagateTags values. Specify a valid value and try again.

## **The specified capacity provider already exists with cluster scope**

This error occurs when you try to create, update, or delete a Amazon ECS Managed Instances capacity provider without a cluster name, but there is an existing cluster-scoped capacity provider.

To change the configuration of or delete the capacity provider, update or delete the capacity provider with the cluster parameter.

## **The specified capacity provider already exists with account or a different cluster**

This error occurs when you try to create, update, or delete a Amazon ECS Managed Instances capacity provider with a cluster field, while there is an existing account-scoped capacity provider or an existing cluster-scoped capacity provider for a different cluster.

To resolve this, use a different capacity provider name or work with the existing capacity provider.

## **Capacity provider active cluster name does not match the cluster name in the request**

This error occurs when the capacity provider's active cluster name does not match the cluster name specified in the request.

Ensure that the cluster name in your request matches the capacity provider's associated cluster.

## **Capacity provider is not Amazon ECS Managed Instances capacity provider**

This error occurs when you try to use a capacity provider that is not a Amazon ECS Managed Instances capacity provider in a context that requires one.

Ensure you are using a valid Amazon ECS Managed Instances capacity provider for your request.

## **CapacityProvider name must not be blank**

This error occurs when you try to create a capacity provider without specifying a capacity provider name.

Specify a valid capacity provider name and try again.

## **A name is required when updating a capacity provider**

This error occurs when you try to update a capacity provider without specifying a capacity provider name.

Specify a valid name and try again.

## **Tags can not be null or have null elements**

This error occurs when you try to tag a capacity provider with null values.

Ensure all tag values are properly specified and not null.

## **Amazon ECS API failure reasons**

When an API action that you have triggered through the Amazon ECS API, console, or the AWS CLI exits with a `failures` error message, the following might assist in troubleshooting the cause. The failure returns a reason and the Amazon Resource Name (ARN) of the resource associated with the failure.

Many resources are Region-specific, so when using the console ensure that you set the correct Region for your resources. When using the AWS CLI, make sure that your AWS CLI commands are being sent to the correct Region with the `--region region` parameter.

For more information about the structure of the `Failure` data type, see [Failure](#) in the *Amazon Elastic Container Service API Reference*.

The following are examples of failure messages that you might receive when running API commands.

| API action                     | Failure reason or Stopped reason                            | Cause                                                                                                                                                                                   |
|--------------------------------|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DescribeClusters</code>  | MISSING                                                     | The specified cluster wasn't found. Verify the spelling of the cluster name.                                                                                                            |
| <code>DescribeInstances</code> | MISSING                                                     | The specified container instance wasn't found. Verify that you specified the cluster the container instance is registered to and that both the container instance ARN or ID is correct. |
| <code>DescribeServices</code>  | MISSING                                                     | The specified service wasn't found. Verify that the correct cluster or Region is specified and that the service ARN or name is valid.                                                   |
| <code>DescribeTasks</code>     | MISSING                                                     | The specified task wasn't found. Verify the correct cluster or Region is specified and that both the task ARN or ID is valid.                                                           |

|            | MISSING                          | The container instance that you attempted to launch the task onto can't be found. Check if the wrong cluster or Region is specified, or the container instance ARN or ID is misspelled.                                                                                                                                                                                                                                                                                                                                                                                                                       |
|            | INACTIVE                         | The container instance that you attempted to launch a task onto was previously deregistered with Amazon ECS and can't be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| API action            | Failure reason or Stopped reason | Cause                                                                                                                                                                                                                             |
|-----------------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| StopServiceDeployment | ECS deployment failed            | A fraud account ran the StopServiceDeployment API.                                                                                                                                                                                |
| TagResource           | InvalidParameterException        | The ARN for the service that you are tagging has the short format. You must migrate to the long format. For information about how to migrate the ARN, see <a href="#">Migrate an Amazon ECS short service ARN to a long ARN</a> . |
| UpdateTaskProtection  | DEPLOYMENT_BLOCKED               | Can't set task protection as one or more protected tasks are preventing the service deployment from reaching a steady state. Unset task protection on existing tasks or wait until task protection expires.                       |
|                       | MISSING                          | The specified task wasn't found. Verify that the cluster name or ARN and the task ARN or ID are valid.                                                                                                                            |
|                       | TASK_NOT_VALID                   | The specified task isn't part of an Amazon ECS service. Only Amazon ECS service-managed tasks can be protected. Verify the task ARN or ID and try again.                                                                          |

 **Note**

Besides the failure scenarios described here, API operations can also fail due to exceptions, resulting in error responses. For a list of such exceptions, see [Common Errors](#).

## Troubleshooting with Amazon Q Developer

You can use [Amazon Q Developer](#) in the Amazon ECS console to help diagnose and resolve issues with your Amazon ECS resources. For certain errors and status messages on containers, tasks, services, deployments, and task definitions, the console shows an **Inspect with Amazon Q Developer** option. When you choose this option, Amazon Q Developer analyzes the issue in context and suggests possible causes and remediation steps.

### Required permissions

- Permissions to view the Amazon ECS resources you want to troubleshoot, such as clusters, services, tasks, and task definitions.
- [Permissions to use Amazon Q Developer](#) in the console.
- (Recommended) Permissions to view related logs and metrics, such as:
  - CloudWatch Logs
  - CloudWatch

### Procedure

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. Determine the resource that you want to troubleshoot.

| Resource | Steps                                                                                                                                                                                                |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tasks    | <ol style="list-style-type: none"><li>1. On the <b>Clusters</b> page, choose the cluster.</li><li>2. Choose the <b>Tasks</b> tab.</li><li>3. Choose the task that you want to investigate.</li></ol> |

| Resource                 | Steps                                                                                                                                                                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Containers               | <ol style="list-style-type: none"><li>1. On the <b>Clusters</b> page, choose the cluster.</li><li>2. Choose the <b>Tasks</b> tab, and then choose the task.</li><li>3. In the <b>Containers</b> section, choose the container you want to investigate.</li></ol> |
| Services and deployments | <ol style="list-style-type: none"><li>1. On the <b>Clusters</b> page, choose the cluster.</li><li>2. Choose the <b>Services</b> tab.</li><li>3. Choose the service, and then review the <b>Deployments</b> section.</li></ol>                                    |
| Task definitions         | <ol style="list-style-type: none"><li>1. In the navigation pane, choose <b>Task definitions</b>.</li><li>2. Choose the task definition family, and then choose the revision that you want to investigate.</li></ol>                                              |

3. On the resource details page, locate the status or health reason that describes the issue.
4. Click the status reason to open the popover.
5. If available, choose **Inspect with Amazon Q Developer**.
6. Review the explanation and suggested remediation steps that Amazon Q Developer provides. Apply configuration or operational changes as appropriate for your environment.

## Considerations

Consider the following when using Amazon Q Developer with Amazon ECS:

- **Button availability** - The "Inspect with Amazon Q Developer" button is only displayed for resources experiencing potential issues. This option is not available for healthy resources.
- **Read-only operations** - The Amazon Q Developer integration performs only read operations. It makes no mutating or write actions.
- **Cross-region processing** - Amazon Q Developer may process data across AWS regions to provide AI-powered analysis. For more information about cross-region processing, see [Cross-region processing in Amazon Q Developer](#).

- **Console only** - This integration is available only through the Console. It is not available through the AWS CLI, AWS APIs, or infrastructure as code tools.

## Learn more

For more information about using Amazon Q Developer, see [Chatting with Amazon Q Developer about AWS](#).

# Security in Amazon Elastic Container Service

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [AWS compliance programs](#). To learn about the compliance programs that apply to Amazon Elastic Container Service, see [AWS Services in Scope by Compliance Program](#).
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon ECS. The following topics show you how to configure Amazon ECS to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon ECS resources.

## Topics

- [Identity and Access Management for Amazon Elastic Container Service](#)

# Identity and Access Management for Amazon Elastic Container Service

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon ECS resources. IAM is an AWS service that you can use with no additional charge.

## Topics

- [Audience](#)
- [Authenticating with identities](#)
- [Managing access using policies](#)
- [How Amazon Elastic Container Service works with IAM](#)
- [Identity-based policy examples for Amazon Elastic Container Service](#)
- [AWS managed policies for Amazon Elastic Container Service](#)
- [Using service-linked roles for Amazon ECS](#)
- [IAM roles for Amazon ECS](#)
- [Permissions required for the Amazon ECS console](#)
- [Permissions required for Lambda functions in Amazon ECS blue/green deployments](#)
- [IAM permissions required for Amazon ECS service auto scaling](#)
- [Grant permission to tag resources on creation](#)
- [Troubleshooting Amazon Elastic Container Service identity and access](#)
- [IAM best practices for Amazon ECS](#)

## Audience

How you use AWS Identity and Access Management (IAM) differs based on your role:

- **Service user** - request permissions from your administrator if you cannot access features (see [Troubleshooting Amazon Elastic Container Service identity and access](#))
- **Service administrator** - determine user access and submit permission requests (see [How Amazon Elastic Container Service works with IAM](#))

- **IAM administrator** - write policies to manage access (see [Identity-based policy examples for Amazon Elastic Container Service](#))

## Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see [How to sign in to your AWS account](#) in the *AWS Sign-In User Guide*.

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see [AWS Signature Version 4 for API requests](#) in the *IAM User Guide*.

### AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see [Tasks that require root user credentials](#) in the *IAM User Guide*.

### Federated identity

As a best practice, require human users to use federation with an identity provider to access AWS services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Directory Service that accesses AWS services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

For centralized access management, we recommend AWS IAM Identity Center. For more information, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

### IAM users and groups

An [IAM user](#) is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more

information, see [Require human users to use federation with an identity provider to access AWS using temporary credentials](#) in the *IAM User Guide*.

An [IAM group](#) specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see [Use cases for IAM users](#) in the *IAM User Guide*.

## IAM roles

An [IAM role](#) is an identity with specific permissions that provides temporary credentials. You can assume a role by [switching from a user to an IAM role \(console\)](#) or by calling an AWS CLI or AWS API operation. For more information, see [Methods to assume a role](#) in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

## Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy defines permissions when associated with an identity or resource. AWS evaluates these policies when a principal makes a request. Most policies are stored in AWS as JSON documents. For more information about JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

## Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Define custom IAM permissions with customer managed policies](#) in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between

managed and inline policies, see [Choose between managed policies and inline policies](#) in the *IAM User Guide*.

## Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. You must [specify a principal](#) in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

## Other policy types

AWS supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in AWS Organizations. For more information, see [Service control policies](#) in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see [Resource control policies \(RCPs\)](#) in the *AWS Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see [Session policies](#) in the *IAM User Guide*.

## Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

# How Amazon Elastic Container Service works with IAM

Before you use IAM to manage access to Amazon ECS, learn what IAM features are available to use with Amazon ECS.

| IAM feature                                   | Amazon ECS support |
|-----------------------------------------------|--------------------|
| <a href="#">Identity-based policies</a>       | Yes                |
| <a href="#">Resource-based policies</a>       | No                 |
| <a href="#">Policy actions</a>                | Yes                |
| <a href="#">Policy resources</a>              | Partial            |
| <a href="#">Policy condition keys</a>         | Yes                |
| <a href="#">ACLs</a>                          | No                 |
| <a href="#">ABAC (tags in policies)</a>       | Yes                |
| <a href="#">Temporary credentials</a>         | Yes                |
| <a href="#">Forward access sessions (FAS)</a> | Yes                |
| <a href="#">Service roles</a>                 | Yes                |
| <a href="#">Service-linked roles</a>          | Yes                |

To get a high-level view of how Amazon ECS and other AWS services work with most IAM features, see [AWS services that work with IAM](#) in the *IAM User Guide*.

## Identity-based policies for Amazon ECS

**Supports identity-based policies:** Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can

perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Define custom IAM permissions with customer managed policies](#) in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

## Identity-based policy examples for Amazon ECS

To view examples of Amazon ECS identity-based policies, see [Identity-based policy examples for Amazon Elastic Container Service](#).

## Resource-based policies within Amazon ECS

### Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

## Policy actions for Amazon ECS

### Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The **Action** element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

To see a list of Amazon ECS actions, see [Actions defined by Amazon Elastic Container Service](#) in the *Service Authorization Reference*.

Policy actions in Amazon ECS use the following prefix before the action:

```
ecs
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [  
    "ecs:action1",  
    "ecs:action2"  
]
```

You can specify multiple actions using wildcards (\*). For example, to specify all actions that begin with the word `Describe`, include the following action:

```
"Action": "ecs:Describe*"
```

To view examples of Amazon ECS identity-based policies, see [Identity-based policy examples for Amazon Elastic Container Service](#).

## Policy resources for Amazon ECS

**Supports policy resources:** Partial

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). For actions that don't support resource-level permissions, use a wildcard (\*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of Amazon ECS resource types and their ARNs, see [Resources defined by Amazon Elastic Container Service](#) in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see [Actions defined by Amazon Elastic Container Service](#).

Some Amazon ECS API actions support multiple resources. For example, multiple clusters can be referenced when calling the `DescribeClusters` API action. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [  
    "EXAMPLE-RESOURCE-1",  
    "EXAMPLE-RESOURCE-2"
```

For example, the Amazon ECS cluster resource has the following ARN:

```
arn:${Partition}:ecs:${Region}:${Account}:cluster/${clusterName}
```

To specify `my-cluster-1` and `my-cluster-2` cluster in your statement, use the following ARNs:

```
"Resource": [  
    "arn:aws:ecs:us-east-1:123456789012:cluster/my-cluster-1",  
    "arn:aws:ecs:us-east-1:123456789012:cluster/my-cluster-2"
```

To specify all clusters that belong to a specific account, use the wildcard (\*):

```
"Resource": "arn:aws:ecs:us-east-1:123456789012:cluster/*"
```

For task definitions, you can specify the latest revision, or a specific revision.

To specify all revisions of the task definition, use the wildcard (\*):

```
"Resource:arn:${Partition}:ecs:${Region}:${Account}:task-definition/  
${TaskDefinitionFamilyName}:*"
```

To specify a specific task definition revision, use `${TaskDefinitionRevisionNumber}`:

```
"Resource:arn:${Partition}:ecs:${Region}:${Account}:task-definition/  
${TaskDefinitionFamilyName}:${TaskDefinitionRevisionNumber}"
```

To view examples of Amazon ECS identity-based policies, see [Identity-based policy examples for Amazon Elastic Container Service](#).

## Policy condition keys for Amazon ECS

### Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

Amazon ECS supports the following service-specific condition keys that you can use to provide fine-grained filtering for your IAM policies:

| Condition Key                 | Description                                                                                                                                                                                                                                                                                                                                                         | Evaluation Types |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| aws:RequestTag/<br>\${TagKey} | <p>The context key is formatted "aws:RequestTag/ <i>tag-key</i>": "<i>tag-value</i> " where <i>tag-key</i> and <i>tag-value</i> are a tag key and value pair.</p> <p>Checks that the tag key–value pair is present in an AWS request. For example, you could check to see that the request includes the tag key "Dept" and that it has the value "Accounting" .</p> | String           |
| aws:ResourceTag/\${TagKey}    | <p>The context key is formatted "aws:ResourceTag/ <i>tag-key</i>": "<i>tag-value</i> " where <i>tag-key</i> and <i>tag-value</i> are a tag key and value pair.</p> <p>Checks that the tag attached to the identity resource (user or role) matches the specified key name and value.</p>                                                                            | String           |
| aws:TagKeys                   | <p>This context key is formatted "aws:TagKeys": " <i>tag-key</i> " where <i>tag-key</i> is a list of tag keys without values (for example, ["Dept", "Cost-Center"] ).</p> <p>Checks the tag keys that are present in an AWS request.</p>                                                                                                                            | String           |

| Condition Key              | Description                                                                                                                                                                                                                                                                              | Evaluation Types |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| ecs:ResourceTag/\${TagKey} | <p>The context key is formatted "ecs:ResourceTag/ <i>tag-key</i>": "<i>tag-value</i> " where <i>tag-key</i> and <i>tag-value</i> are a tag key and value pair.</p> <p>Checks that the tag attached to the identity resource (user or role) matches the specified key name and value.</p> | String           |

| ecs:auto-assign-public-ip  | The context key is formatted "ecs:auto-assign-public-ip": " <i>value</i> " where <i>value</i> is "true" or "false".                                                                                                                                                                      | String           |
| ecs:capacity-provider      | The context key is formatted "ecs:capacity-provider": " <i>capacity-provider-arn</i> " where <i>capacity-provider-arn</i> is the ARN for the capacity provider.                                                                                                                          | ARN, Null        |
| ecs:cluster                | The context key is formatted "ecs:cluster": " <i>cluster-arn</i> " where <i>cluster-arn</i> is the ARN for the Amazon ECS cluster.                                                                                                                                                       | ARN, Null        |
| ecs:compute-compatibility  | The context key is formatted "ecs:compute-compatibility": " <i>compatibility-type</i> " where <i>compatibility-type</i> is "FARGATE", "EC2" or "EXTERNAL".                                                                                                                               | String           |
| ecs:container-instances    | The context key is formatted "ecs:container-instances": " <i>container-instance-arns</i> " where <i>container-instance-arns</i> is one or more container instance ARNs.                                                                                                                  | ARN, Null        |

| Condition Key                         | Description                                                                                                                                                                                  | Evaluation Types |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| ecs:container-name                    | The context key is formatted "ecs:container-name":" <i>container-name</i> " where <i>container-instance-</i> is the name of an Amazon ECS container which is defined in the task definition. | String           |
| ecs:enable-execute-command            | The context key is formatted "ecs:enable-execute-command":" <i>value</i> " where <i>value-</i> is "true" or "false".                                                                         | String           |
| ecs:enable-service-connect            | The context key is formatted "ecs:enable-service-connect":" <i>value</i> " where <i>value</i> is "true" or "false".                                                                          | String           |
| ecs:enable-efs-volumes                | The context key is formatted "ecs:enable-efs-volumes":" <i>value</i> " where <i>value</i> is "true" or "false".                                                                              | String           |
| ecs:enable-managed-tags               | The context key is formatted "ecs:enable-managed-tags":" <i>value</i> " where <i>value</i> is "true" or "false".                                                                             | String           |
| ecs:enable-vpc-lattice                | The context key is formatted "ecs:vpc-lattice":" <i>value</i> " where <i>value</i> is "true" or "false".                                                                                     | String           |
| ecs:fargate-ephemeral-storage-kms-key | The context key is formatted "ecs:fargate-ephemeral-storage-kms-key":" <i>key</i> " where <i>key</i> is the ID of the AWS KMS key.                                                           | String           |
| ecs:namespace                         | The context key is formatted "ecs:namespace":" <i>namespace-arn</i> " where <i>namespace-arn</i> is the ARN for the AWS Cloud Map namespace.                                                 | ARN, Null        |
| ecs:propagate-tags                    | The context key is formatted "ecs:propagate-tags":" <i>value</i> " where <i>value</i> is "TASK_DEFINITION" , "SERVICE" , or "NONE".                                                          | String           |

| Condition Key       | Description                                                                                                                                                        | Evaluation Types |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| ecs:service         | The context key is formatted "ecs:service": " <i>service-arn</i> " where <i>service-arn</i> is the ARN for the Amazon ECS service.                                 | ARN, Null        |
| ecs:task-definition | The context key is formatted "ecs:task-definition": " <i>task-definition-arn</i> " where <i>task-definition-arn</i> is the ARN for the Amazon ECS task definition. | ARN, Null        |
| ecs:subnet          | The context key is formatted "ecs:subnet": " <i>subnets</i> " where <i>subnets</i> are the subnets of a task or service that uses awsvpc mode.                     | String           |
| ecs:task            | The context key is formatted "ecs:task": " <i>task-arn</i> " where <i>task-arn</i> is the ARN for the Amazon ECS service.                                          | ARN, Null        |
| ecs:task-cpu        | The context key is formatted "ecs:task-cpu": " <i>task-cpu</i> " where <i>task-cpu</i> is the task cpu, as an integer with 1024 = 1 vCPU.                          | Integer          |
| ecs:task-memory     | The context key is formatted "ecs:task-memory": " <i>task-memory</i> " where <i>task-memory</i> is the task memory in MiB.                                         | Integer          |

To see a list of Amazon ECS condition keys, see [Condition keys for Amazon Elastic Container Service](#) in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions defined by Amazon Elastic Container Service](#).

To view examples of Amazon ECS identity-based policies, see [Identity-based policy examples for Amazon Elastic Container Service](#).

## Access control lists (ACLs) in Amazon ECS

**Supports ACLs:** No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

## Attribute-based access control (ABAC) with Amazon ECS

### Important

Amazon ECS supports attributes-based access control for all Amazon ECS resources. To determine whether you can use attributes to scope an action, use the [Actions defined by Amazon ECS](#) table in *Service Authorization Reference*. First verify that there is a resource in the **Resource** column. Then, use the **Condition keys** column to see the keys for the action/resource combination.

### Supports ABAC (tags in policies): Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see [Define permissions with ABAC authorization](#) in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#) in the *IAM User Guide*.

For more information about tagging Amazon ECS resources, see [Tagging Amazon ECS resources](#).

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see [Describing Amazon ECS services based on tags](#).

## Using Temporary credentials with Amazon ECS

### Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](#) and [AWS services that work with IAM](#) in the *IAM User Guide*.

## Forward access sessions for Amazon ECS

**Supports forward access sessions (FAS):** Yes

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see [Forward access sessions](#).

## Service roles for Amazon ECS

**Supports service roles:** Yes

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Create a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

### Warning

Changing the permissions for a service role might break Amazon ECS functionality. Edit service roles only when Amazon ECS provides guidance to do so.

## Service-linked roles for Amazon ECS

**Supports service-linked roles:** Yes

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about creating or managing Amazon ECS service-linked roles, see [Using service-linked roles for Amazon ECS](#).

# Identity-based policy examples for Amazon Elastic Container Service

By default, users and roles don't have permission to create or modify Amazon ECS resources. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see [Create IAM policies \(console\)](#) in the *IAM User Guide*.

For details about actions and resource types defined by Amazon ECS, including the format of the ARNs for each of the resource types, see [Actions, resources, and condition keys for Amazon Elastic Container Service](#) in the *Service Authorization Reference*.

## Amazon ECS policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon ECS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies

that are specific to your use cases. For more information, see [AWS managed policies](#) or [AWS managed policies for job functions](#) in the *IAM User Guide*.

- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#) in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as CloudFormation. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [Validate policies with IAM Access Analyzer](#) in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Secure API access with MFA](#) in the *IAM User Guide*.

For more information about best practices in IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

## Allow Amazon ECS users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ViewOwnUserInfo",
```

```

        "Effect": "Allow",
        "Action": [
            "iam:GetUserPolicy",
            "iam:ListGroupsForUser",
            "iam:ListAttachedUserPolicies",
            "iam:ListUserPolicies",
            "iam:GetUser"
        ],
        "Resource": ["arn:aws:iam::*:user/${aws:username}"]
    },
    {
        "Sid": "NavigateInConsole",
        "Effect": "Allow",
        "Action": [
            "iam:GetGroupPolicy",
            "iam:GetPolicyVersion",
            "iam:GetPolicy",
            "iam:ListAttachedGroupPolicies",
            "iam:ListGroupPolicies",
            "iam:ListPolicyVersions",
            "iam:ListPolicies",
            "iam:ListUsers"
        ],
        "Resource": "*"
    }
]
}

```

## Amazon ECS cluster examples

The following IAM policy allows permission to create and list clusters. The `CreateCluster` and `ListClusters` actions do not accept any resources, so the resource definition is set to `*` for all resources.

### JSON

```

{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ecs:CreateCluster",

```

```

        "ecs:ListClusters"
      ],
      "Resource": "*"
    }
  ]
}

```

## JSON

```

{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:DescribeClusters",
        "ecs>DeleteCluster"
      ],
      "Resource": ["arn:aws:ecs:us-east-1:123456789012:cluster/cluster-
name"]
    }
  ]
}

```

The following IAM policy allows permission to describe and delete a specific cluster. The DescribeClusters and DeleteCluster actions accept cluster ARNs as resources.

## JSON

```

{
  "Statement": [
    {
      "Action": [
        "ecs:Describe*",
        "ecs:List*"
      ],
      "Effect": "Allow",
      "Resource": "*"
    },
    {

```

```

        "Action": [
            "ecs:DeleteCluster",
            "ecs:DeregisterContainerInstance",
            "ecs:ListContainerInstances",
            "ecs:RegisterContainerInstance",
            "ecs:SubmitContainerStateChange",
            "ecs:SubmitTaskStateChange"
        ],
        "Effect": "Allow",
        "Resource": "arn:aws:ecs:us-east-1:123456789012:cluster/default"
    },
    {
        "Action": [
            "ecs:DescribeContainerInstances",
            "ecs:DescribeTasks",
            "ecs:ListTasks",
            "ecs:UpdateContainerAgent",
            "ecs:StartTask",
            "ecs:StopTask",
            "ecs:RunTask"
        ],
        "Effect": "Allow",
        "Resource": "*",
        "Condition": {
            "ArnEquals": {"ecs:cluster": "arn:aws:ecs:us-east-1:123456789012:cluster/default"}
        }
    }
]
}

```

The following IAM policy can be attached to a user or group that would only allow that user or group to perform operations on a specific cluster.

## JSON

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [

```

```

        "ecs:Describe*",
        "ecs:List*"
    ],
    "Effect": "Allow",
    "Resource": "*"
},
{
    "Action": [
        "ecs:DeleteCluster",
        "ecs:DeregisterContainerInstance",
        "ecs:ListContainerInstances",
        "ecs:RegisterContainerInstance",
        "ecs:SubmitContainerStateChange",
        "ecs:SubmitTaskStateChange"
    ],
    "Effect": "Allow",
    "Resource": "arn:aws:ecs:us-east-1:111122223333:cluster/default"
},
{
    "Action": [
        "ecs:DescribeContainerInstances",
        "ecs:DescribeTasks",
        "ecs:ListTasks",
        "ecs:UpdateContainerAgent",
        "ecs:StartTask",
        "ecs:StopTask",
        "ecs:RunTask"
    ],
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
        "ArnEquals": {"ecs:cluster": "arn:aws:ecs:us-
east-1:111122223333:cluster/default"}
    }
}
]
}

```

## Amazon ECS container instance examples

Container instance registration is handled by the Amazon ECS agent, but there may be times where you want to allow a user to deregister an instance manually from a cluster. Perhaps the container

instance was accidentally registered to the wrong cluster, or the instance was terminated with tasks still running on it.

The following IAM policy allows a user to list and deregister container instances in a specified cluster:

JSON

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:DeregisterContainerInstance",
        "ecs:ListContainerInstances"
      ],
      "Resource": "arn:aws:ecs:us-east-1:123456789012:cluster/cluster_name"
    }
  ]
}
```

## Amazon ECS task definition examples

Task definition IAM policies do not support resource-level permissions, but the following IAM policy allows a user to register, list, and describe task definitions:

If you use the console, you must add `CloudFormation: CreateStack` as an Action.

JSON

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:RegisterTaskDefinition",
        "ecs:ListTaskDefinitions",
        "ecs:DescribeTaskDefinition"
      ],
      "Resource": "*"
    }
  ]
}
```

```
    }  
  ]  
}
```

## Run Amazon ECS Task Example

The resources for `RunTask` are task definitions. To limit which clusters a user can run task definitions on, you can specify them in the `Condition` block. The advantage is that you don't have to list both task definitions and clusters in your resources to allow the appropriate access. You can apply one, the other, or both.

The following IAM policy allows permission to run any revision of a specific task definition on a specific cluster:

JSON

```
{  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": ["ecs:RunTask"],  
      "Condition": {  
        "ArnEquals": {"ecs:cluster": "arn:aws:ecs:us-east-1:123456789012:cluster/cluster_name"}  
      },  
      "Resource": ["arn:aws:ecs:us-east-1:123456789012:task-definition/task_family:*"]  
    }  
  ]  
}
```

## Start Amazon ECS task example

The resources for `StartTask` are task definitions. To limit which clusters and container instances a user can start task definitions on, you can specify them in the `Condition` block. The advantage is that you don't have to list both task definitions and clusters in your resources to allow the appropriate access. You can apply one, the other, or both.

The following IAM policy allows permission to start any revision of a specific task definition on a specific cluster and specific container instance.

 **Note**

For this example, when you call the `StartTask` API with the AWS CLI or another AWS SDK, you must specify the task definition revision so that the Resource mapping matches.

## JSON

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ecs:StartTask"],
      "Condition": {
        "ArnEquals": {
          "ecs:cluster": "arn:aws:ecs:us-east-1:123456789012:cluster/cluster_name",
          "ecs:container-instances": ["arn:aws:ecs:us-east-1:123456789012:container-instance/cluster_name/container_instance_UUID"]
        }
      },
      "Resource": ["arn:aws:ecs:us-east-1:123456789012:task-definition/task_family:*"]
    }
  ]
}
```

## List and describe Amazon ECS task examples

The following IAM policy allows a user to describe a specified task in a specified cluster:

## JSON

```
{
  "Statement": [
    {
```

```

        "Effect": "Allow",
        "Action": ["ecs:DescribeTasks"],
        "Condition": {
            "ArnEquals": {"ecs:cluster": "arn:aws:ecs:us-
east-1:123456789012:cluster/cluster_name"}
        },
        "Resource": ["arn:aws:ecs:us-
east-1:123456789012:task/cluster_name/task_UUID"]
    }
]
}

```

## Create Amazon ECS service example

The following IAM policy allows a user to create Amazon ECS services in the AWS Management Console:

JSON

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "application-autoscaling:Describe*",
                "application-autoscaling:PutScalingPolicy",
                "application-autoscaling:RegisterScalableTarget",
                "cloudwatch:DescribeAlarms",
                "cloudwatch:PutMetricAlarm",
                "ecs:List*",
                "ecs:Describe*",
                "ecs:CreateService",
                "elasticloadbalancing:Describe*",
                "iam:GetPolicy",
                "iam:GetPolicyVersion",
                "iam:GetRole",
                "iam:ListAttachedRolePolicies",
                "iam:ListRoles",
                "iam:ListGroups",
                "iam:ListUsers"
            ]
        }
    ]
}

```

```

        ],
        "Resource": "*"
    }
]
}

```

## Describing Amazon ECS services based on tags

You can use conditions in your identity-based policy to control access to Amazon ECS resources based on tags. This example shows how you might create a policy that allows describing your services. However, permission is granted only if the service tag `Owner` has the value of that user's user name. This policy also grants the permissions necessary to complete this action on the console.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DescribeServices",
      "Effect": "Allow",
      "Action": "ecs:DescribeServices",
      "Resource": "*"
    },
    {
      "Sid": "ViewServiceIfOwner",
      "Effect": "Allow",
      "Action": "ecs:DescribeServices",
      "Resource": "arn:aws:ecs:*:*:service/*",
      "Condition": {
        "StringEquals": {"ecs:ResourceTag/Owner": "${aws:username}"}
      }
    }
  ]
}

```

You can attach this policy to the IAM users in your account. If a user named `richard-roe` attempts to describe an Amazon ECS service, the service must be tagged `Owner=richard-roe` or

owner=richard-roe. Otherwise he is denied access. The condition tag key Owner matches both Owner and owner because condition key names are not case-sensitive. For more information, see [IAM JSON Policy Elements: Condition](#) in the *IAM User Guide*.

## Deny Amazon ECS Service Connect Namespace Override Example

The following IAM policy denies a user from overriding the default Service Connect namespace in a service configuration. The default namespace is set in the cluster. However, you can override it in a service configuration. For consistency, consider setting all your new services to use the same namespace. Use the following context keys to require services to use a specific namespace. Replace the <region>, <aws\_account\_id>, <cluster\_name> and <namespace\_id> with your own in the following example.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:CreateService",
        "ecs:UpdateService"
      ],
      "Condition": {
        "ArnEquals": {
          "ecs:cluster": "arn:aws:ecs:us-east-1:123456789012:cluster/cluster_name",
          "ecs:namespace": "arn:aws:servicediscovery:us-east-1:123456789012:namespace/namespace_id"
        }
      },
      "Resource": "*"
    }
  ]
}
```

## AWS managed policies for Amazon Elastic Container Service

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to [create IAM customer managed policies](#) that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see [AWS managed policies](#) in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the **ReadOnlyAccess** AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see [AWS managed policies for job functions](#) in the *IAM User Guide*.

Amazon ECS and Amazon ECR provide several managed policies and trust relationships that you can attach to users, groups, roles, Amazon EC2 instances, and Amazon ECS tasks that allow differing levels of control over resources and API operations. You can apply these policies directly, or you can use them as starting points for creating your own policies. For more information about the Amazon ECR managed policies, see [Amazon ECR managed policies](#).

### AmazonECS\_FullAccess

You can attach the AmazonECS\_FullAccess policy to your IAM identities. This policy grants administrative access to Amazon ECS resources and grants an IAM identity (such as a user, group, or role) access to the AWS services that Amazon ECS is integrated with to use all of Amazon ECS features. Using this policy allows access to all of Amazon ECS features that are available in the AWS Management Console.

To view the permissions for this policy, see [AmazonECS\\_FullAccess](#) in the *AWS Managed Policy Reference*.

## AmazonECSInfrastructureRolePolicyForVolumes

You can attach the AmazonECSInfrastructureRolePolicyForVolumes managed policy to your IAM entities.

The policy grants the permissions that are needed by Amazon ECS to make AWS API calls on your behalf. You can attach this policy to the IAM role that you provide with your volume configuration when you launch Amazon ECS tasks and services. The role allows Amazon ECS to manage volumes attached to your tasks. For more information, see [Amazon ECS infrastructure IAM role](#).

To view the permissions for this policy, see [AmazonECSInfrastructureRolePolicyForVolumes](#) in the *AWS Managed Policy Reference*.

## AmazonEC2ContainerServiceforEC2Role

You can attach the AmazonEC2ContainerServiceforEC2Role policy to your IAM identities. This policy grants administrative permissions that allow Amazon ECS container instances to make calls to AWS on your behalf. For more information, see [Amazon ECS container instance IAM role](#).

Amazon ECS attaches this policy to a service role that allows Amazon ECS to perform actions on your behalf against Amazon EC2 instances or external instances.

To view the permissions for this policy, see [AmazonEC2ContainerServiceforEC2Role](#) in the *AWS Managed Policy Reference*.

## Considerations

You should consider the following recommendations and considerations when using the AmazonEC2ContainerServiceforEC2Role managed IAM policy.

- Following the standard security advice of granting least privilege, you can modify the AmazonEC2ContainerServiceforEC2Role managed policy to fit your specific needs. If any of the permissions granted in the managed policy aren't needed for your use case, create a custom policy and add only the permissions that you require. For example, the UpdateContainerInstancesState permission is provided for Spot Instance draining. If that permission isn't needed for your use case, exclude it using a custom policy.
- Containers that are running on your container instances have access to all of the permissions that are supplied to the container instance role through [instance metadata](#). We recommend that you limit the permissions in your container instance role to the minimal list of permissions that are

provided in the managed `AmazonEC2ContainerServiceforEC2Role` policy. If the containers in your tasks need extra permissions that aren't listed, we recommend providing those tasks with their own IAM roles. For more information, see [Amazon ECS task IAM role](#).

You can prevent containers on the `docker0` bridge from accessing the permissions supplied to the container instance role. You can do this while still allowing the permissions that are provided by [Amazon ECS task IAM role](#) by running the following **iptables** command on your container instances. Containers can't query instance metadata with this rule in effect. This command assumes the default Docker bridge configuration and it doesn't work with containers that use the host network mode. For more information, see [Network mode](#).

```
sudo yum install -y iptables-services; sudo iptables --insert DOCKER USER 1 --in-interface docker+ --destination 169.254.169.254/32 --jump DROP
```

You must save this **iptables** rule on your container instance for it to survive a reboot. For the Amazon ECS-optimized AMI, use the following command. For other operating systems, consult the documentation for that OS.

- For the Amazon ECS-optimized Amazon Linux 2 AMI:

```
sudo iptables-save | sudo tee /etc/sysconfig/iptables && sudo systemctl enable --now iptables
```

- For the Amazon ECS-optimized Amazon Linux AMI:

```
sudo service iptables save
```

## AmazonEC2ContainerServiceEventsRole

You can attach the `AmazonEC2ContainerServiceEventsRole` policy to your IAM identities. This policy grants permissions that allow Amazon EventBridge (formerly CloudWatch Events) to run tasks on your behalf. This policy can be attached to the IAM role that's specified when you create scheduled tasks. For more information, see [Amazon ECS EventBridge IAM Role](#).

To view the permissions for this policy, see [AmazonEC2ContainerServiceEventsRole](#) in the *AWS Managed Policy Reference*.

## AmazonECSTaskExecutionRolePolicy

The AmazonECSTaskExecutionRolePolicy managed IAM policy grants the permissions that are needed by the Amazon ECS container agent and AWS Fargate container agents to make AWS API calls on your behalf. This policy can be added to your task execution IAM role. For more information, see [Amazon ECS task execution IAM role](#).

To view the permissions for this policy, see [AmazonECSTaskExecutionRolePolicy](#) in the *AWS Managed Policy Reference*.

## AmazonECSServiceRolePolicy

The AmazonECSServiceRolePolicy managed IAM policy enables Amazon Elastic Container Service to manage your cluster. This policy can be added to your [AWSServiceRoleForECS](#) service-linked role.

To view the permissions for this policy, see [AmazonECSServiceRolePolicy](#) in the *AWS Managed Policy Reference*.

## AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity

You can attach the AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity policy to your IAM entities. This policy grants administrative access to AWS Private Certificate Authority, Secrets Manager and other AWS Services required to manage Amazon ECS Service Connect TLS features on your behalf.

To view the permissions for this policy, see [AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity](#) in the *AWS Managed Policy Reference*.

## AWSApplicationAutoscalingECSServicePolicy

You can't attach AWSApplicationAutoscalingECSServicePolicy to your IAM entities. This policy is attached to a service-linked role that allows Application Auto Scaling to perform actions on your behalf. For more information, see [Service-linked roles for Application Auto Scaling](#).

To view the permissions for this policy, see [AWSApplicationAutoscalingECSServicePolicy](#) in the *AWS Managed Policy Reference*.

## AWSCodeDeployRoleForECS

You can't attach `AWSCodeDeployRoleForECS` to your IAM entities. This policy is attached to a service-linked role that allows CodeDeploy to perform actions on your behalf. For more information, see [Create a service role for CodeDeploy](#) in the *AWS CodeDeploy User Guide*.

To view the permissions for this policy, see [AWSCodeDeployRoleForECS](#) in the *AWS Managed Policy Reference*.

## AWSCodeDeployRoleForECSLimited

You can't attach `AWSCodeDeployRoleForECSLimited` to your IAM entities. This policy is attached to a service-linked role that allows CodeDeploy to perform actions on your behalf. For more information, see [Create a service role for CodeDeploy](#) in the *AWS CodeDeploy User Guide*.

To view the permissions for this policy, see [AWSCodeDeployRoleForECSLimited](#) in the *AWS Managed Policy Reference*.

## AmazonECSInfrastructureRolePolicyForLoadBalancers

You can attach the `AmazonECSInfrastructureRolePolicyForLoadBalancers` policy to your IAM entities. This policy grants permissions that allow Amazon ECS to manage Elastic Load Balancing resources on your behalf. The policy includes:

- Read-only permissions to describe listeners, rules, target groups, and target health
- Permissions to register and deregister targets with target groups
- Permissions to modify listeners for Application Load Balancers and Network Load Balancers
- Permissions to modify rules for Application Load Balancers

These permissions enable Amazon ECS to automatically manage load balancer configurations when services are created or updated, ensuring proper routing of traffic to your containers.

To view the permissions for this policy, see [AmazonECSInfrastructureRolePolicyForLoadBalancers](#) in the *AWS Managed Policy Reference*.

## AmazonECSInfrastructureRolePolicyForManagedInstances

You can attach the `AmazonECSInfrastructureRolePolicyForManagedInstances` policy to your IAM entities. This policy grants the permissions required by Amazon ECS to create and update Amazon EC2 resources for ECS Managed Instances on your behalf. The policy includes:

- Permissions to create and manage Amazon EC2 launch templates for managed instances
- Permissions to provision Amazon EC2 instances using `CreateFleet` and `RunInstances`
- Permissions to create and manage tags on Amazon EC2 resources created by ECS
- Permissions to pass IAM roles to Amazon EC2 instances for managed instances
- Permissions to create service-linked roles for Amazon EC2 Spot instances
- Read-only permissions to describe Amazon EC2 resources including instances, instance types, launch templates, network interfaces, availability zones, security groups, subnets, VPCs, EC2 Images and capacity reservations
- Read-only permissions to list Amazon ResourceGroups resources, which requires underlying permissions to get tagged resources and list Amazon CloudFormation stack resources

These permissions enable Amazon ECS to automatically provision and manage Amazon EC2 instances for your ECS Managed Instances, ensuring proper configuration and lifecycle management of the underlying compute resources.

To view the permissions for this policy, see

[AmazonECSInfrastructureRolePolicyForManagedInstances](#) in the *AWS Managed Policy Reference*.

## **AmazonECSInfrastructureRolePolicyForVpcLattice**

You can attach the `AmazonECSInfrastructureRolePolicyForVpcLattice` policy to your IAM entities. This policy Provides access to other AWS service resources required to manage VPC Lattice feature in Amazon ECS workloads on your behalf.

To view the permissions for this policy, see [AmazonECSInfrastructureRolePolicyForVpcLattice](#) in the *AWS Managed Policy Reference*.

Provides access to other AWS service resources required to manage VPC Lattice feature in Amazon ECS workloads on your behalf.

## **AmazonECSInfrastructureRoleforExpressGatewayServices**

You can attach the `AmazonECSInfrastructureRoleforExpressGatewayServices` policy to your IAM entities. This policy grants the permissions required by Amazon ECS to create and update web applications using Express Services on your behalf. The policy includes:

- Permissions to create service-linked roles for Amazon ECS Application Auto Scaling

- Permissions to create, modify, and delete Application Load Balancers, listeners, rules, and target groups
- Permissions to create, modify, and delete VPC security groups for ECS-managed resources
- Permissions to request, manage, and delete SSL/TLS certificates through ACM
- Permissions to configure Application Auto Scaling policies and targets for Amazon ECS services
- Permissions to create and manage CloudWatch alarms for auto scaling triggers
- Read-only permissions to describe load balancers, VPC resources, certificates, auto scaling configurations, and CloudWatch alarms

These permissions enable Amazon ECS to automatically provision and manage the infrastructure components required for Express Services web applications, including load balancing, security groups, SSL certificates, and auto scaling configurations.

To view the permissions for this policy, see

[AmazonECSInfrastructureRoleforExpressGatewayServices](#) in the *AWS Managed Policy Reference*.

## **AmazonECSComputeServiceRolePolicy**

The AmazonECSComputeServiceRolePolicy policy is attached to the AmazonECSComputeServiceRole service-linked role. For more information, see [Using roles to manage Amazon ECS Managed Instances](#).

This policy includes permissions that allow Amazon ECS to complete the following tasks:

- Amazon ECS can describe and delete launch templates.
- Amazon ECS can describe and delete launch template versions.
- Amazon ECS can terminate instances.
- Amazon ECS can describe the following instance data parameters:
  - Instance
  - Instance network interfaces: Amazon ECS can describe the the to manage the EC2 instance lifecycle.
  - Instance event window: Amazon ECS can describe the event window information in order to determine if the workflow can be interrupted for patching the instance.
  - Instance status: Amazon ECS can describe the instance status in order to monitor the instance health.

To view the permissions for this policy, see [AmazonECSComputeServiceRolePolicy](#) in the *AWS Managed Policy Reference*.

## AmazonECSInstanceRolePolicyForManagedInstances

The AmazonECSInstanceRolePolicyForManagedInstances policy provides permissions for Amazon ECS managed instances to register with Amazon ECS clusters and communicate with the Amazon ECS service.

This policy includes permissions that allow Amazon ECS managed instances to complete the following tasks:

- Register and deregister with Amazon ECS clusters.
- Submit container instance state changes.
- Submit task state changes.
- Discover polling endpoints for the Amazon ECS agent.

To view the permissions for this policy, see [AmazonECSInstanceRolePolicyForManagedInstances](#) in the *AWS Managed Policy Reference*.

## Amazon ECS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon ECS since this service started tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon ECS Document history page.

| Change                                                    | Description                                                                                                                                                                                                           | Date              |

| Update AmazonECSInfrastructureRolePolicyForManagedInstances policy | <p>The AmazonECSInfrastructureRolePolicyForManagedInstances policy has been updated to modify the CreateFleet permissions. The resource-based conditions for subnets, security groups and EC2 images have been removed because:</p> <ul style="list-style-type: none"><li>• Subnets and security groups are not created or managed by Amazon ECS, so they do not contain the required AmazonECSManaged tags.</li><li>• While Amazon ECS owns and manages EC2 images, the tags are not visible to customers, preventing the application of resource-based policies.</li></ul> <p>This change ensures that the policy functions correctly with resources that lack the expected ECS management tags.</p> | December 15, 2025 |

| Change                                                          | Description                                                                                                                                                                                                     | Date              |
|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Add permissions to <a href="#">AmazonECSServiceRolePolicy</a> . | The AmazonECSServiceRolePolicy managed IAM policy was updated with new Amazon EC2 permissions which allow Amazon ECS to fetch Amazon EC2 Event Windows for services and clusters associated with Event Windows. | November 20, 2025 |
| Add permissions to <a href="#">AmazonECSServiceRolePolicy</a> . | The AmazonECSServiceRolePolicy managed IAM policy was updated with new Amazon EC2 permissions which allow Amazon ECS to provision and de-provision Task ENI.                                                    | November 14, 2025 |

| Change                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Date               |
|--------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| Update <a href="#">AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity</a> policy | Updated the AmazonECS InfrastructureRolePolicyForServiceConnectTransportLayerSecurity managed IAM policy to separate the secretsmanager:DescribeSecret permission into its own policy statement. The permission continues to scope Amazon ECS access exclusively to secrets created by Amazon ECS and uses ARN pattern matching instead of resource tags for scoping. This allows Amazon ECS to monitor secret status throughout its lifecycle, including when a secret has been deleted. | November 13, 2025  |
| Add new <a href="#">the section called "AmazonECSInfrastructureRoleforExpressGatewayServices"</a>      | Added new AmazonECS InfrastructureRoleforExpressGatewayServices policy that provides Amazon ECS access to create and manage web applications using Express Services.                                                                                                                                                                                                                                                                                                                      | November 21, 2025  |
| Add new <a href="#">the section called "AmazonECSInstanceRolePolicyForManagedInstances"</a>            | Added new AmazonECS InstanceRolePolicyForManagedInstances policy that provides permissions for Amazon ECS managed instances to register with Amazon ECS clusters.                                                                                                                                                                                                                                                                                                                         | September 30, 2025 |

| Change                                                                                            | Description                                                                                                                                                                                                                                                                                                                         | Date                |
|---------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| Add new <a href="#">the section called "AmazonECSInfrastructureRolePolicyForManagedInstances"</a> | Added new AmazonECSInfrastructureRolePolicyForManagedInstances policy that provides Amazon ECS access to create and manage Amazon EC2 managed resources.                                                                                                                                                                            | September, 30, 2025 |
| Add new <a href="#">AmazonECSComputeServiceRolePolicy</a>                                         | Allows Amazon ECS to manage your Amazon ECS Managed Instances and related resources.                                                                                                                                                                                                                                                | August 31, 2025     |
| Add permissions to <a href="#">the section called "AmazonEC2ContainerServiceforEC2Role"</a>       | The AmazonEC2ContainerServiceforEC2Role managed IAM policy was updated to include the <code>ecs:ListTagsForResource</code> permission. This permission allows the Amazon ECS agent to retrieve task and container instance tags through the task metadata endpoint ( <code>\${ECS_CONTAINER_METADATA_URI_V4}/taskWithTags</code> ). | August 4, 2025      |
| Add permissions to <a href="#">AmazonECSInfrastructureRolePolicyForLoadBalancers.</a>             | The AmazonECSInfrastructureRolePolicyForLoadBalancers managed IAM policy was updated with new permissions for describing, deregistering, and registering target groups.                                                                                                                                                             | July 25, 2025       |

| Change                                                                                                | Description                                                                                                                                                                                         | Date          |
|-------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Add new <a href="#">the section called "AmazonECSTaskDefinitionRolePolicyForLoadBalancers"</a> policy | Added new AmazonECS InfrastructureRolePolicyForLoadBalancers policy that provides access to other AWS service resources required to manage load balancers associated with Amazon ECS workloads.     | July 15, 2025 |
| Add permissions to <a href="#">AmazonECSServiceRolePolicy</a> .                                       | The AmazonECSServiceRolePolicy managed IAM policy was updated with new AWS Cloud Map permissions which Amazon ECS can update AWS Cloud Map service attributes for services that Amazon ECS manages. | July 15, 2025 |
| Add permissions to <a href="#">AmazonECSServiceRolePolicy</a>                                         | The AmazonECSServiceRolePolicy managed IAM policy was updated with new AWS Cloud Map permissions which Amazon ECS can update AWS Cloud Map service attributes for services that Amazon ECS manages. | June 24, 2025 |

| Change                                                                         | Description                                                                                                                                                                                                                                                                                | Date              |
|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Add permissions to <a href="#">AmazonECSInfrastructureRolePolicyForVolumes</a> | The AmazonECSInfrastructureRolePolicyForVolumes policy has been updated to add the <code>ec2:DescribeInstances</code> permission. The permission helps prevent device name collision for Amazon EBS volumes that are attached to Amazon ECS tasks that run on the same container instance. | June 2, 2025      |
| Add new <a href="#">AmazonECSInfrastructureRolePolicyForVpcLattice</a>         | Provides access to other AWS service resources required to manage VPC Lattice feature in Amazon ECS workloads on your behalf.                                                                                                                                                              | November 18, 2024 |
| Add permissions to <a href="#">AmazonECSInfrastructureRolePolicyForVolumes</a> | The AmazonECSInfrastructureRolePolicyForVolumes policy has been updated to allow customers to create an Amazon EBS volume from a snapshot.                                                                                                                                                 | October 10, 2024  |

| Change                                                                                                  | Description                                                                                                                                                                                                                                                                                                                                | Date             |
|---------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Added permissions to <a href="#">the section called “AmazonECS_FullAccess”</a>                          | The AmazonECS_FullAccess policy was updated to add iam:PassRole permissions for IAM roles for a role named ecsInfrastructureRole . This is the default IAM role created by the AWS Management Console that is intended to be used as an ECS infrastructure role that allows Amazon ECS to manage Amazon EBS volumes attached to ECS tasks. | August 13, 2024  |
| Add new <a href="#">AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity</a> policy | Added new AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity policy that provides administrative access to AWS KMS, AWS Private Certificate Authority, Secrets Manager and enables Amazon ECS Service Connect TLS features to work properly.                                                                         | January 22, 2024 |
| Add new policy <a href="#">AmazonECSInfrastructureRolePolicyForVolumes</a>                              | The AmazonECSInfrastructureRolePolicyForVolumes policy was added. The policy grants the permissions that are needed by Amazon ECS to make AWS API calls to manage Amazon EBS volumes associated with Amazon ECS workloads.                                                                                                                 | January 11, 2024 |

| Change                                                                 | Description                                                                                                                                                                                                                              | Date             |
|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Add permissions to <a href="#">AmazonECSServiceRolePolicy</a>          | The AmazonECSServiceRolePolicy managed IAM policy was updated with new events permissions and additional autoscaling and autoscaling-plans permissions.                                                                                  | December 4, 2023 |
| Add permissions to <a href="#">AmazonEC2ContainerServiceEventsRole</a> | The AmazonECSServiceRolePolicy managed IAM policy was updated to allow access to the AWS Cloud Map DiscoverInstancesRevision API operation.                                                                                              | October 4, 2023  |
| Add permissions to <a href="#">AmazonEC2ContainerServiceforEC2Role</a> | The AmazonEC2ContainerServiceforEC2Role policy was modified to add the <code>ecs:TagResource</code> permission, which includes a condition that limits the permission only to newly created clusters and registered container instances. | March 6, 2023    |

| Change                                                                       | Description                                                                                                                                                                                                                                                                                                                                       | Date            |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Add permissions to <a href="#">the section called “AmazonECS_FullAccess”</a> | The AmazonECS_FullAccess policy was modified to add the elasticloadbalancing:AddTags permission, which includes a condition that limits the permission only to newly created load balancers, target groups, rules, and listeners created. This permission doesn't allow tags to be added to any already created Elastic Load Balancing resources. | January 4, 2023 |
| Amazon ECS started tracking changes                                          | Amazon ECS started tracking changes for its AWS managed policies.                                                                                                                                                                                                                                                                                 | June 8, 2021    |

## Phased out AWS managed IAM policies for Amazon Elastic Container Service

The following AWS managed IAM policies are phased out. These policies are now replaced by the updated policies. We recommend that you update your users or roles to use the updated policies.

### AmazonEC2ContainerServiceFullAccess

#### Important

The AmazonEC2ContainerServiceFullAccess managed IAM policy was phased out as of January 29, 2021, in response to a security finding with the `iam:passRole` permission. This permission grants access to all resources including credentials to roles in the account. Now that the policy is phased out, you can't attach the policy to any new users or roles. Any users or roles that already have the policy attached can continue using it. However, we recommend that you update your users or roles to use the

AmazonECS\_FullAccess managed policy instead. For more information, see [Migrating to the AmazonECS\\_FullAccess managed policy](#).

## AmazonEC2ContainerServiceRole

### Important

The AmazonEC2ContainerServiceRole managed IAM policy is phased out. It's now replaced by the Amazon ECS service-linked role. For more information, see [Using service-linked roles for Amazon ECS](#).

## AmazonEC2ContainerServiceAutoscaleRole

### Important

The AmazonEC2ContainerServiceAutoscaleRole managed IAM policy is phased out. It's now replaced by the Application Auto Scaling service-linked role for Amazon ECS. For more information, see [Service-linked roles for Application Auto Scaling](#) in the *Application Auto Scaling User Guide*.

## Migrating to the AmazonECS\_FullAccess managed policy

The AmazonEC2ContainerServiceFullAccess managed IAM policy was phased out on January 29, 2021, in response to a security finding with the `iam:passRole` permission. This permission grants access to all resources including credentials to roles in the account. Now that the policy is phased out, you can't attach the policy to any new groups, users, or roles. Any groups, users, or roles that already have the policy attached can continue using it. However, we recommend that you update your groups, users, or roles to use the AmazonECS\_FullAccess managed policy instead.

The permissions that are granted by the AmazonECS\_FullAccess policy include the complete list of permissions that are necessary to use ECS as an administrator. If you currently use permissions that are granted by the AmazonEC2ContainerServiceFullAccess policy that aren't in the AmazonECS\_FullAccess policy, you can add them to an inline policy statement. For more information, see [AWS managed policies for Amazon Elastic Container Service](#).

Use the following steps to determine if you have any groups, users, or roles that are currently using the `AmazonEC2ContainerServiceFullAccess` managed IAM policy. Then, update them to detach the earlier policy and attach the `AmazonECS_FullAccess` policy.

### To update a group, user, or role to use the `AmazonECS_FullAccess` policy (AWS Management Console)

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies** and search for and select the `AmazonEC2ContainerServiceFullAccess` policy.
3. Choose the **Policy usage** tab that displays any IAM role that's currently using this policy.
4. For each IAM role that's currently using the `AmazonEC2ContainerServiceFullAccess` policy, select the role and use the following steps to detach the phased out policy and attach the `AmazonECS_FullAccess` policy.
  - a. On the **Permissions** tab, choose the **X** next to the `AmazonEC2ContainerServiceFullAccess` policy.
  - b. Choose **Add permissions**.
  - c. Choose **Attach existing policies directly**, search for and select the `AmazonECS_FullAccess` policy, and then choose **Next: Review**.
  - d. Review the changes and then choose **Add permissions**.
  - e. Repeat these steps for each group, user, or role that's using the `AmazonEC2ContainerServiceFullAccess` policy.

### To update a group, user, or role to use the `AmazonECS_FullAccess` policy (AWS CLI)

1. Use the [generate-service-last-accessed-details](#) command to generate a report that includes details about when the phased out policy was last used.

```
aws iam generate-service-last-accessed-details \
  --arn arn:aws:iam::aws:policy/AmazonEC2ContainerServiceFullAccess
```

Example output:

```
{
  "JobId": "32bb1fb0-1ee0-b08e-3626-ae83EXAMPLE"
```

```
}
```

2. Use the job ID from the previous output with the [get-service-last-accessed-details](#) command to retrieve the last accessed report of the service. This report displays the Amazon Resource Name (ARN) of the IAM entities that last used the phased out policy.

```
aws iam get-service-last-accessed-details \
    --job-id 32bb1fb0-1ee0-b08e-3626-ae83EXAMPLE
```

3. Use one of the following commands to detach the AmazonEC2ContainerServiceFullAccess policy from a group, user, or role.
  - [detach-group-policy](#)
  - [detach-role-policy](#)
  - [detach-user-policy](#)
4. Use one of the following commands to attach the AmazonECS\_FullAccess policy to a group, user, or role.
  - [attach-group-policy](#)
  - [attach-role-policy](#)
  - [attach-user-policy](#)

## Using service-linked roles for Amazon ECS

Amazon Elastic Container Service uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Amazon ECS. Service-linked roles are predefined by Amazon ECS and include all the permissions that the service requires to call other AWS services on your behalf.

### Topics

- [Using roles to allow Amazon ECS to manage clusters](#)
- [Using roles to manage Amazon ECS Managed Instances](#)

## Using roles to allow Amazon ECS to manage clusters

Amazon Elastic Container Service uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Amazon ECS.

Service-linked roles are predefined by Amazon ECS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon ECS easier because you don't have to manually add the necessary permissions. Amazon ECS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon ECS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon ECS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

### Service-linked role permissions for Amazon ECS

Amazon ECS uses the service-linked role named **AWSServiceRoleForECS** – Role to allow Amazon ECS to manage your cluster.

The AWSServiceRoleForECS service-linked role trusts the following services to assume the role:

- `ecs.amazonaws.com`

The role permissions policy named AmazonECSServiceRolePolicy allows Amazon ECS to complete the following actions on the specified resources:

- Action: When using the `awsvpc` network mode for your Amazon ECS tasks, Amazon ECS manages the lifecycle of the elastic network interfaces associated with the task. This also includes tags that Amazon ECS adds to your elastic network interfaces.
- Action: When using a load balancer with your Amazon ECS service, Amazon ECS manages the registration and deregistration of resources with the load balancer.
- Action: When using Amazon ECS service discovery, Amazon ECS manages the required Route 53 and AWS Cloud Map resources for service discovery to work.
- Action: When using Amazon ECS service auto scaling, Amazon ECS manages the required Auto Scaling resources.

- Action: Amazon ECS creates and manages CloudWatch alarms and log streams that assist in the monitoring of your Amazon ECS resources.
- Action: When using Amazon ECS Exec, Amazon ECS manages the permissions needed to start Amazon ECS Exec sessions to your tasks.
- Action: When using Amazon ECS Service Connect, Amazon ECS manages the required AWS Cloud Map resources to use the feature.
- Action: When using Amazon ECS capacity providers, Amazon ECS manages the permissions required to modify the Auto Scaling group and its Amazon EC2 instances.
- Action: Amazon ECS can update AWS Cloud Map service attributes for services that Amazon ECS manages.
- Action: Amazon ECS can invoke Amazon EC2 provision and de-provision ENI when starting and stopping tasks.
- Action: Amazon ECS can fetch Amazon EC2 Event Windows for services and clusters associated with Event Windows.

You must configure permissions to allow your users, groups, or roles to create, edit, or delete a service-linked role. For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

## Creating a service-linked role for Amazon ECS

You don't need to manually create a service-linked role. When you create a cluster, or create or update a service in the AWS Management Console, the AWS CLI, or the AWS API, Amazon ECS creates the service-linked role for you.

### Important

This service-linked role can appear in your account if you completed an action in another service that uses the features supported by this role. If you were using the Amazon ECS service before January 1, 2017, when it began supporting service-linked roles, then Amazon ECS created the `AWSServiceRoleForECS` role in your account. To learn more, see [A new role appeared in my AWS account](#).

You can also use the IAM console to create a service-linked role with the **AWSServiceRoleForECS** use case. In the AWS CLI or the AWS API, use IAM to create a service-linked role with the `ecs.amazonaws.com` service name. For more information, see [Creating a service-linked role](#) in the

*IAM User Guide*. If you delete this service-linked role, you can use this same process to create the role again.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a cluster, or create or update a service, Amazon ECS creates the service-linked role for you again.

If you delete this service-linked role, you can use the same IAM process to create the role again.

## Editing a service-linked role for Amazon ECS

Amazon ECS does not allow you to edit the `AWSServiceRoleForECS` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

## Deleting a service-linked role for Amazon ECS

You don't need to manually delete the `AWSServiceRoleForECS` role. When you delete clusters in all Regions in the AWS Management Console, the AWS CLI, or the AWS API, Amazon ECS cleans up the resources and deletes the service-linked role for you.

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

## Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

### Note

If the Amazon ECS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

## To delete Amazon ECS resources used by the AWSServiceRoleForECS (console)

1. Scale all Amazon ECS services down to a desired count of 0 in all regions, and then delete the services. For more information, see [Updating an Amazon ECS service](#) and [Deleting an Amazon ECS service using the console](#).
2. Force deregister all container instances from all clusters in all Regions. For more information, see [Deregistering an Amazon ECS container instance](#).
3. Delete all Amazon ECS clusters in all regions. For more information, see [Deleting an Amazon ECS cluster](#).

## To delete Amazon ECS resources used by the AWSServiceRoleForECS (AWS CLI)

1. Scale all Amazon ECS services down to a desired count of 0 in all regions, and then delete the services. For more information, see [update-service](#) and [delete-service](#) in the AWS Command Line Interface Reference.
2. Force deregister all container instances from all clusters in all Regions. For more information, see [deregister-container-instance](#).
3. Delete all Amazon ECS clusters in all Regions. For more information, see [delete-cluster](#).

## To delete Amazon ECS resources used by the AWSServiceRoleForECS (API)

1. Scale all Amazon ECS services down to a desired count of 0 in all regions, and then delete the services. For more information, see [UpdateService](#) and [DeleteService](#) in the *Amazon ECS API Reference*.
2. Force deregister all container instances from all clusters in all Regions. For more information, see [DeregisterContainerInstance](#).
3. Delete all Amazon ECS clusters in all Regions. For more information, see [DeleteCluster](#).

## Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForECS service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

## Supported Regions for Amazon ECS service-linked roles

Amazon ECS supports using service-linked roles in all of the Regions where the service is available. For more information, see [AWS Regions and endpoints](#).

## Using roles to manage Amazon ECS Managed Instances

Amazon Elastic Container Service uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Amazon ECS. Service-linked roles are predefined by Amazon ECS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon ECS easier because you don't have to manually add the necessary permissions. Amazon ECS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon ECS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon ECS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

### Service-linked role permissions for Amazon ECS

Amazon ECS uses the service-linked role named **AWSServiceRoleForECSCompute** – Role to allow Amazon ECS to manage Amazon EC2 managed instances, provisioned by the Amazon ECS Managed Instances capacity provider.

The **AWSServiceRoleForECSCompute** service-linked role trusts the following services to assume the role:

- `ecs-compute.amazonaws.com`

The role permissions policy named [AmazonECSComputeServiceRolePolicy](#) allows Amazon ECS complete the following tasks:

- Amazon ECS can describe and delete launch templates.
- Amazon ECS can describe and delete launch template versions.
- Amazon ECS can terminate instances.
- Amazon ECS can describe the following instance data parameters:

- Instance
- Instance network interfaces: Amazon ECS can describe the the to manage the EC2 instance lifecycle.
- Instance event window: Amazon ECS can describe the event window information in order to determine if the workflow can be interrupted for patching the instance.
- Instance status: Amazon ECS can describe the instance status in order to monitor the instance health.

You must configure permissions to allow your users, groups, or roles to create, edit, or delete a service-linked role. For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

## Creating a service-linked role for Amazon ECS

You don't need to manually create a service-linked role. When you create a capacity provider for Amazon ECS Managed Instances in the AWS Management Console, the AWS CLI, or the AWS API, Amazon ECS creates the service-linked role for you.

### Important

This service-linked role can appear in your account if you completed an action in another service that uses the features supported by this role. If you were using the Amazon ECS service before January 1, 2017, when it began supporting service-linked roles, then Amazon ECS created the AmazonECSComputeServiceRolePolicy role in your account. To learn more, see [A new role appeared in my AWS account](#).

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a capacity provider for Amazon ECS Managed Instances, Amazon ECS creates the service-linked role for you again.

If you delete this service-linked role, you can use the same IAM process to create the role again.

## Editing a service-linked role for Amazon ECS

Amazon ECS does not allow you to edit the AmazonECSComputeServiceRolePolicy service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

## Deleting a service-linked role for Amazon ECS

You don't need to manually delete the `AmazonECSComputeServiceRolePolicy` role. When you delete all Amazon ECS Managed Instances capacity providers in all Regions in the AWS Management Console, the AWS CLI, or the AWS API, Amazon ECS cleans up the resources and deletes the service-linked role for you.

### Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the `AmazonECSComputeServiceRolePolicy` service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

### Supported Regions for Amazon ECS service-linked roles

Amazon ECS supports using service-linked roles in all of the Regions where the service is available. For more information, see [AWS Regions and endpoints](#).

## IAM roles for Amazon ECS

An IAM role is an IAM identity that you can create in your account that has specific permissions. In Amazon ECS, you can create roles to grant permissions to Amazon ECS resource such as containers or services.

The roles Amazon ECS requires depend on the task definition launch type and the features that you use. Use the following table to determine which IAM roles you need for Amazon ECS.

| Role                | Definition                                                            | When required                                                                                                                                                                                                           | More information                                   |
|---------------------|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| Task execution role | This role allows Amazon ECS to use other AWS services on your behalf. | Your task is hosted on AWS Fargate or on external instances and: <ul style="list-style-type: none"><li>pulls a container image from an Amazon ECR private repository.</li><li>pulls a container image from an</li></ul> | <a href="#">Amazon ECS task execution IAM role</a> |

| Role      | Definition                                                                           | When required                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | More information                         |

## Best practices for IAM roles in Amazon ECS

The roles Amazon ECS requires depend on the task definition launch type and the features that you use. We recommend that you create separate roles in the table instead of sharing roles.

| Role                | Definition                                                            | When required                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | More information                                   |
|---------------------|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| Task execution role | This role allows Amazon ECS to use other AWS services on your behalf. | <p>Your task is hosted on AWS Fargate or on external instances and:</p> <ul style="list-style-type: none"><li>pulls a container image from an Amazon ECR private repository.</li><li>pulls a container image from an Amazon ECR private repository in a different account from the account that runs the task.</li><li>sends container logs to CloudWatch Logs using the <code>awslogs</code> log driver.</li></ul> <p>Your task is hosted on either AWS Fargate or Amazon EC2 instances and:</p> | <a href="#">Amazon ECS task execution IAM role</a> |

| Role                       | Definition                                                                              | When required                                                                                                                                                                                                                                                     | More information                                       |

| Task role                  | This role allows your application code (on the container) to use other AWS services.    | Your application accesses other AWS services, such as Amazon S3.                                                                                                                                                                                                  | <a href="#">Amazon ECS task IAM role</a>               |
| Container instance role    | This role allows your EC2 instances or external instances to register with the cluster. | Your task is hosted on Amazon EC2 instances or an external instance.                                                                                                                                                                                              | <a href="#">Amazon ECS container instance IAM role</a> |
| Amazon ECS Anywhere role   | This role allows your external instances to access AWS APIs.                            | Your task is hosted on external instances.                                                                                                                                                                                                                        | <a href="#">Amazon ECS Anywhere IAM role</a>           |
| Amazon ECS CodeDeploy role | This role allows CodeDeploy to make updates to your services.                           | You use the CodeDeploy blue/green deployment type to deploy services.                                                                                                                                                                                             | <a href="#">Amazon ECS CodeDeploy IAM Role</a>         |

| Role                           | Definition                                                                       | When required                                                                                                                                                                                                                                                                                                                                                                                                           | More information                                   |
|--------------------------------|----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| Amazon ECS EventBridge role    | This role allows EventBridge to make updates to your services.                   | You use the EventBridge rules and targets to schedule your tasks.                                                                                                                                                                                                                                                                                                                                                       | <a href="#">Amazon ECS EventBridge IAM Role</a>    |
| Amazon ECS infrastructure role | This role allows Amazon ECS to manage infrastructure resources in your clusters. | <ul style="list-style-type: none"> <li>You want to attach Amazon EBS volumes to your Fargate or EC2 launch type Amazon ECS tasks. The infrastructure role allows Amazon ECS to manage Amazon EBS volumes for your tasks.</li> <li>You want to use Transport Layer Security (TLS) to encrypt traffic between your Amazon ECS Service Connect services.</li> <li>You want to create VPC Lattice target groups.</li> </ul> | <a href="#">Amazon ECS infrastructure IAM role</a> |

## Task role

We recommend that you assign a task role. Its role can be distinguished from the role of the Amazon EC2 instance that it's running on. Assigning each task a role aligns with the principle of least privileged access and allows for greater granular control over actions and resources.

When you add a task role to a task definition, the Amazon ECS container agent automatically creates a token with a unique credential ID (for example, 12345678-90ab-cdef-1234-567890abcdef) for the task. This token and the role credentials are then added to the agent's internal cache. The agent populates the environment variable `AWS_CONTAINER_CREDENTIALS_RELATIVE_URI` in the container with the URI of the credential ID (for example, `/v2/credentials/12345678-90ab-cdef-1234-567890abcdef`).

You can manually retrieve the temporary role credentials from inside a container by appending the environment variable to the IP address of the Amazon ECS container agent and running the `curl` command on the resulting string.

```
curl 169.254.170.2$AWS_CONTAINER_CREDENTIALS_RELATIVE_URI
```

The expected output is as follows:

```
{
  "RoleArn": "arn:aws:iam::123456789012:role/SSMTaskRole-SSMFargateTaskIAMRole-DASWSF2WGD6",
  "AccessKeyId": "AKIAIOSFODNN7EXAMPLE",
  "SecretAccessKey": "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY",
  "Token": "IQoJb3JpZ2luX2VjEEM/Example==",
  "Expiration": "2021-01-16T00:51:53Z"
}
```

Newer versions of the AWS SDKs automatically fetch these credentials from the `AWS_CONTAINER_CREDENTIALS_RELATIVE_URI` environment variable when making AWS API calls. For information about how to renew credentials, see [Renewing AWS credentials](#) on rePost.

The output includes an access key-pair consisting of a secret access key ID and a secret key which your application uses to access AWS resources. It also includes a token that AWS uses to verify that the credentials are valid. By default, credentials assigned to tasks using task roles are valid for six hours. After that, they are automatically rotated by the Amazon ECS container agent.

## Task execution role

The task execution role is used to grant the Amazon ECS container agent permission to call specific AWS API actions on your behalf. For example, when you use AWS Fargate, Fargate needs an IAM role that allows it to pull images from Amazon ECR and write logs to CloudWatch Logs. An IAM role is also required when a task references a secret that's stored in AWS Secrets Manager, such as an image pull secret.

**Note**

If you're pulling images as an authenticated user, you're less likely to be impacted by the changes that occurred to [Docker Hub's pull rate limits](#). For more information see, [Private registry authentication for container instances](#).

By using Amazon ECR and Amazon ECR Public, you can avoid the limits imposed by Docker. If you pull images from Amazon ECR, this also helps shorten network pull times and reduces data transfer charges when traffic leaves your VPC.

**Important**

When you use Fargate, you must authenticate to a private image registry using `repositoryCredentials`. It's not possible to set the Amazon ECS container agent environment variables `ECS_ENGINE_AUTH_TYPE` or `ECS_ENGINE_AUTH_DATA` or modify the `ecs.config` file for tasks hosted on Fargate. For more information, see [Private registry authentication for tasks](#).

## Container instance role

The `AmazonEC2ContainerServiceforEC2Role` managed IAM policy includes the following permissions. Following the standard security advice of granting least privilege, the `AmazonEC2ContainerServiceforEC2Role` managed policy can be used as a guide. If you don't need any of the permissions that are granted in the managed policy for your use case, create a custom policy and add only the permissions that you need.

- `ec2:DescribeTags` – (Optional) Allows a principal to describe the tags that are associated with an Amazon EC2 instance. This permission is used by the Amazon ECS container agent to support resource tag propagation. For more information, see [How resources are tagged](#).
- `ecs:CreateCluster` – (Optional) Allows a principal to create an Amazon ECS cluster. This permission is used by the Amazon ECS container agent to create a default cluster, if one doesn't already exist.
- `ecs:DeregisterContainerInstance` – (Optional) Allows a principal to deregister an Amazon ECS container instance from a cluster. The Amazon ECS container agent doesn't call this API operation, but this permission remains to help ensure backwards compatibility.

- `ecs:DiscoverPollEndpoint` – (Required) This action returns endpoints that the Amazon ECS container agent uses to poll for updates.
- `ecs:Poll` – (Required) Allows the Amazon ECS container agent to communicate with the Amazon ECS control plane to report task state changes.
- `ecs:RegisterContainerInstance` – (Required) Allows a principal to register a container instance with a cluster. This permission is used by the Amazon ECS container agent to register the Amazon EC2 instance with a cluster and to support resource tag propagation.
- `ecs:StartTelemetrySession` – (Optional) Allows the Amazon ECS container agent to communicate with the Amazon ECS control plane to report health information and metrics for each container and task.

Although this permission is not required, we recommend that you add it to allow the container instance metrics to start scale actions and also receive reports related to health check commands.

- `ecs:TagResource` – (Optional) Allows the Amazon ECS container agent to tag cluster on creation and to tag container instances when they are registered to a cluster.
- `ecs:UpdateContainerInstancesState` – Allows a principal to modify the status of an Amazon ECS container instance. This permission is used by the Amazon ECS container agent for Spot Instance draining.
- `ecs:Submit*` – (Required) This includes the `SubmitAttachmentStateChanges`, `SubmitContainerStateChange`, and `SubmitTaskStateChange` API actions. They're used by the Amazon ECS container agent to report state changes for each resource to the Amazon ECS control plane. The `SubmitContainerStateChange` permission is no longer used by the Amazon ECS container agent but remains to help ensure backwards compatibility.
- `ecr:GetAuthorizationToken` – (Optional) Allows a principal to retrieve an authorization token. The authorization token represents your IAM authentication credentials and can be used to access any Amazon ECR registry that the IAM principal has access to. The authorization token received is valid for 12 hours.
- `ecr:BatchCheckLayerAvailability` – (Optional) When a container image is pushed to an Amazon ECR private repository, each image layer is checked to verify if it's already pushed. If it is, then the image layer is skipped.
- `ecr:GetDownloadUrlForLayer` – (Optional) When a container image is pulled from an Amazon ECR private repository, this API is called once for each image layer that's not already cached.

- `ecr:BatchGetImage` – (Optional) When a container image is pulled from an Amazon ECR private repository, this API is called once to retrieve the image manifest.
- `logs:CreateLogStream` – (Optional) Allows a principal to create a CloudWatch Logs log stream for a specified log group.
- `logs:PutLogEvents` – (Optional) Allows a principal to upload a batch of log events to a specified log stream.

## Service-linked roles

You can use the service-linked role for Amazon ECS to grant the Amazon ECS service permission to call other service APIs on your behalf. Amazon ECS needs the permissions to create and delete network interfaces, register, and de-register targets with a target group. It also needs the necessary permissions to create and delete scaling policies. These permissions are granted through the service-linked role. This role is created on your behalf the first time that you use the service.

### Note

If you inadvertently delete the service-linked role, you can recreate it. For instructions, see [Create the service-linked role](#).

## Roles recommendations

We recommend that you do the following when setting up your task IAM roles and policies.

### Block access to Amazon EC2 metadata

When you run your tasks on Amazon EC2 instances, we strongly recommend that you block container access to the Amazon EC2 Instance Metadata Service (IMDS) to prevent your containers from accessing sensitive instance-level data, including the instance profile credentials of the instance. If your applications have to call an AWS API action, use IAM roles for tasks instead.

To prevent tasks running in **bridge** mode from accessing Amazon EC2 metadata, run the following command or update the instance's user data. For more instruction on updating the user data of an instance, see this [AWS Support Article](#). For more information about the task definition bridge mode, see [task definition network mode](#).

```
sudo yum install -y iptables-services; sudo iptables --insert FORWARD 1 --in-interface docker+ --destination 169.254.169.254/32 --jump DROP
```

For this change to persist after a reboot, run the following command that's specific for your Amazon Machine Image (AMI):

- Amazon Linux 2

```
sudo iptables-save | sudo tee /etc/sysconfig/iptables && sudo systemctl enable --now iptables
```

- Amazon Linux

```
sudo service iptables save
```

For tasks that use `awsvpc` network mode, set the environment variable `ECS_AWSVPC_BLOCK_IMDS` to `true` in the `/etc/ecs/ecs.config` file.

You should set the `ECS_ENABLE_TASK_IAM_ROLE_NETWORK_HOST` variable to `false` in the `ecs-agent config` file to prevent the containers that are running within the host network from accessing the Amazon EC2 metadata.

## Use the `awsvpc` network mode

Use the network `awsvpc` network mode to restrict the flow of traffic between different tasks or between your tasks and other services that run within your Amazon VPC. This adds an additional layer of security. The `awsvpc` network mode provides task-level network isolation for tasks that run on Amazon EC2. It is the default mode on AWS Fargate. It's the only network mode that you can use to assign a security group to tasks.

## Use last accessed information to refine roles

We recommend that you remove any actions that were never used or haven't been used for some time. This prevents unwanted access from happening. To do this, review last accessed information provided by IAM, and then remove actions that were never used or haven't been used recently. You can do this by following the following steps.

Run the following command to generate a report showing the last access information for the referenced policy:

```
aws iam generate-service-last-accessed-details --arn arn:aws:iam::123456789012:policy/ExamplePolicy1
```

use the JobId that was in the output to run the following command. After you do this, you can view the results of the report.

```
aws iam get-service-last-accessed-details --job-id 98a765b4-3cde-2101-2345-example678f9
```

For more information, see [Refine permissions in AWS using last accessed information](#).

## Monitor AWS CloudTrail for suspicious activity

You can monitor AWS CloudTrail for any suspicious activity. Most AWS API calls are logged to AWS CloudTrail as events. They are analyzed by AWS CloudTrail Insights, and you're alerted of any suspicious behavior that's associated with write API calls. This might include a spike in call volume. These alerts include such information as the time the unusual activity occurred and the top identity ARN that contributed to the APIs.

You can identify actions that are performed by tasks with an IAM role in AWS CloudTrail by looking at the event's `userIdentity` property. In the following example, the `arn` includes of the name of the assumed role, `s3-write-go-bucket-role`, followed by the name of the task, `7e9894e088ad416eb5cab92afExample`.

```
"userIdentity": {  
  "type": "AssumedRole",  
  "principalId": "ARO36C6WWEJ2YEXAMPLE:7e9894e088ad416eb5cab92afExample",  
  "arn": "arn:aws:sts::123456789012:assumed-role/s3-write-go-bucket-  
role/7e9894e088ad416eb5cab92afExample",  
  ...  
}
```

### Note

When tasks that assume a role are run on Amazon EC2 container instances, a request is logged by Amazon ECS container agent to the audit log of the agent that's located at an address in the `/var/log/ecs/audit.log.YYYY-MM-DD-HH` format. For more information, see [Task IAM Roles Log](#) and [Logging Insights Events for Trails](#).

## Amazon ECS task execution IAM role

The task execution role grants the Amazon ECS container and Fargate agents permission to make AWS API calls on your behalf. The task execution IAM role is required depending on the

requirements of your task. You can have multiple task execution roles for different purposes and services associated with your account.

**Note**

These permissions are made available to the agent running on your instance by Amazon ECS periodically sending it the role's temporary credentials, but they aren't directly accessible by the containers in the task. For the IAM permissions that your application code inside the container needs to run, see [Amazon ECS task IAM role](#).

The following are common use cases for a task execution IAM role:

- Your task is hosted on AWS Fargate, Amazon ECS Managed Instances, or an external instance and:
  - pulls a container image from an Amazon ECR private repository.
  - pulls a container image from an Amazon ECR private repository in a different account from the account that runs the task.
  - sends container logs to CloudWatch Logs using the `awslogs` log driver. For more information, see [Send Amazon ECS logs to CloudWatch](#).
- Your tasks are hosted on either AWS Fargate or Amazon EC2 instances and:
  - uses private registry authentication. For more information, see [Private registry authentication permissions](#).
  - uses Runtime Monitoring.
  - the task definition references sensitive data using Secrets Manager secrets or AWS Systems Manager Parameter Store parameters. For more information, see [Secrets Manager or Systems Manager permissions](#).

**Note**

The task execution role is supported by Amazon ECS container agent version 1.16.0 and later.

Amazon ECS provides the managed policy named `AmazonECSTaskExecutionRolePolicy` which contains the permissions the common use cases previously described require. For more

information, see [AmazonECSTaskExecutionRolePolicy](#) in the *AWS Managed Policy Reference Guide*. It might be necessary to add inline policies to your task execution role for special use cases

The Amazon ECS console creates a task execution role. You can manually attach the managed IAM policy for tasks to allow Amazon ECS to add permissions for future features and enhancements as they are introduced. You can use IAM console search to search for `ecsTaskExecutionRole` and see if your account already has the task execution role. For more information, see [IAM console search](#) in the *IAM user guide*.

If you pull images as an authenticated user, you're less likely to be impacted by the changes that occurred to [Docker Hub usage and limits](#). For more information see, [Private registry authentication for container instances](#).

By using Amazon ECR and Amazon ECR Public, you can avoid the limits imposed by Docker. If you pull images from Amazon ECR, this also helps shorten network pull times and reduces data transfer changes when traffic leaves your VPC.

When you use Fargate, you must authenticate to a private image registry using `repositoryCredentials`. It's not possible to set the Amazon ECS container agent environment variables `ECS_ENGINE_AUTH_TYPE` or `ECS_ENGINE_AUTH_DATA` or modify the `ecs.config` file for tasks hosted on Fargate. For more information, see [Private registry authentication for tasks](#).

## Creating the task execution role

If your account doesn't already have a task execution role, use the following steps to create the role.

### AWS Management Console

#### To create the service role for Elastic Container Service (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Service or use case**, choose **Elastic Container Service**, and then choose the **Elastic Container Service Task** use case.
5. Choose **Next**.

6. In the **Add permissions** section, search for **AmazonECSTaskExecutionRolePolicy**, then select the policy.
7. Choose **Next**.
8. For **Role name**, enter **ecsTaskExecutionRole**.
9. Review the role, and then choose **Create role**.

## AWS CLI

Replace all *user input* with your own information.

1. Create a file named `ecs-tasks-trust-policy.json` that contains the trust policy to use for the IAM role. The file should contain the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "ecs-tasks.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Create an IAM role named `ecsTaskExecutionRole` using the trust policy created in the previous step.

```
aws iam create-role \
  --role-name ecsTaskExecutionRole \
  --assume-role-policy-document file://ecs-tasks-trust-policy.json
```

3. Attach the AWS managed `AmazonECSTaskExecutionRolePolicy` policy to the `ecsTaskExecutionRole` role.

```
aws iam attach-role-policy \
  --role-name ecsTaskExecutionRole \
  --policy-arn arn:aws:iam::aws:policy/service-role/
AmazonECSTaskExecutionRolePolicy
```

After you create the role, add additional permissions to the role for the following features.

| Feature                                                                                                                                                    | Additional permissions                                                                              |
|------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Pull container images from private registries outside of AWS (such as Docker Hub, Quay.io, or your own private registry) using Secrets Manager credentials | <a href="#">Private registry authentication permissions</a>                                         |
| Pass sensitive data with Systems Manager or Secrets Manager                                                                                                | <a href="#">Secrets Manager or Systems Manager permissions</a>                                      |
| Have Fargate tasks pull Amazon ECR images over interface endpoints                                                                                         | <a href="#">Fargate tasks pulling Amazon ECR images over interface endpoints permissions</a>        |
| Host configuration files in an Amazon S3 bucket                                                                                                            | <a href="#">Amazon S3 file storage permissions</a>                                                  |
| Configure Container Insights to view Amazon ECS lifecycle events                                                                                           | <a href="#">Permissions required for enabling Amazon ECS lifecycle events in Container Insights</a> |
| View Amazon ECS lifecycle events in Container Insights                                                                                                     | <a href="#">Permissions required to view Amazon ECS lifecycle events in Container Insights</a>      |

## Private registry authentication permissions

Private registry authentication allows your Amazon ECS tasks to pull container images from private registries outside of AWS (such as Docker Hub, Quay.io, or your own private registry) that require authentication credentials. This feature uses Secrets Manager to securely store your registry credentials, which are then referenced in your task definition using the `repositoryCredentials` parameter.

For more information about configuring private registry authentication, see [Using non-AWS container images in Amazon ECS](#).

To provide access to the secrets that contain your private registry credentials, add the following permissions as an inline policy to the task execution role. For more information, see [Adding and Removing IAM Policies](#).

- `secretsmanager:GetSecretValue`—Required to retrieve the private registry credentials from Secrets Manager.
- `kms:Decrypt`—Required only if your secret uses a custom KMS key and not the default key. The Amazon Resource Name (ARN) for your custom key must be added as a resource.

The following is an example inline policy that adds the permissions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt",
        "secretsmanager:GetSecretValue"
      ],
      "Resource": [
        "arn:aws:secretsmanager:us-east-1:111122223333:secret:secret_name",
        "arn:aws:kms:us-east-1:111122223333:key/key_id"
      ]
    }
  ]
}
```

## Secrets Manager or Systems Manager permissions

The permission to allow the container agent to pull the necessary AWS Systems Manager or Secrets Manager resources. For more information, see [Pass sensitive data to an Amazon ECS container](#).

## Using Secrets Manager

To provide access to the Secrets Manager secrets that you create, manually add the following permission to the task execution role. For information about how to manage permissions, see [Adding and Removing IAM identity permissions](#) in the *IAM User Guide*.

- `secretsmanager:GetSecretValue`– Required if you are referencing a Secrets Manager secret. Adds the permission to retrieve the secret from Secrets Manager.

The following example policy adds the required permissions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue"
      ],
      "Resource": [
        "arn:aws:secretsmanager:us-east-1:111122223333:secret:secret_name"
      ]
    }
  ]
}
```

## Using Systems Manager

### Important

For tasks that use the EC2 launch type, you must use the ECS agent configuration variable `ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE=true` to use this feature. You can add it to the `./etc/ecs/ecs.config` file during container instance creation or you can add it to an existing instance and then restart the ECS agent. For more information, see [Amazon ECS container agent configuration](#).

To provide access to the Systems Manager Parameter Store parameters that you create, manually add the following permissions as a policy to the task execution role. For information about how to manage permissions, see [Adding and Removing IAM identity permissions](#) in the *IAM User Guide*.

- `ssm:GetParameters` — Required if you are referencing a Systems Manager Parameter Store parameter in a task definition. Adds the permission to retrieve Systems Manager parameters.
- `secretsmanager:GetSecretValue` — Required if you are referencing a Secrets Manager secret either directly or if your Systems Manager Parameter Store parameter is referencing a Secrets Manager secret in a task definition. Adds the permission to retrieve the secret from Secrets Manager.
- `kms:Decrypt` — Required only if your secret uses a customer managed key and not the default key. The ARN for your custom key should be added as a resource. Adds the permission to decrypt the customer managed key .

The following example policy adds the required permissions:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetParameters",
        "secretsmanager:GetSecretValue",
        "kms:Decrypt"
      ],
      "Resource": [
        "arn:aws:ssm:us-east-1:111122223333:parameter/parameter_name",
        "arn:aws:secretsmanager:us-east-1:111122223333:secret:secret_name",
        "arn:aws:kms:us-east-1:111122223333:key/key_id"
      ]
    }
  ]
}
```

## Fargate tasks pulling Amazon ECR images over interface endpoints permissions

When launching tasks that use Fargate that pull images from Amazon ECR when Amazon ECR is configured to use an interface VPC endpoint, you can restrict the tasks access to a specific VPC or VPC endpoint. Do this by creating a task execution role for the tasks to use that use IAM condition keys.

Use the following IAM global condition keys to restrict access to a specific VPC or VPC endpoint. For more information, see [AWS Global Condition Context Keys](#).

- `aws:SourceVpc`—Restricts access to a specific VPC. You can restrict the VPC to the VPC that hosts the task and endpoint.
- `aws:SourceVpce`—Restricts access to a specific VPC endpoint.

The following task execution role policy provides an example for adding condition keys:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecr:GetAuthorizationToken",
        "logs:CreateLogStream",
        "logs:PutLogEvents"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "arn:aws:ecr:*:*:repository/*",
      "Condition": {
        "StringEquals": {
          "aws:sourceVpce": "vpce-0123456789abcdef0"
        }
      }
    }
  ]
}
```

```
}
    }
  }
}
```

## Amazon ECR permissions

The following permissions are required when you need to pull container images from Amazon ECR private repositories. The task execution role should have these permissions to allow the Amazon ECS container and Fargate agents to pull container images on your behalf. For basic ECS implementations, these permissions should be added to the task execution role rather than the task IAM role.

The Amazon ECS task execution role managed policy (AmazonECSTaskExecutionRolePolicy) includes the necessary permissions for pulling images from Amazon ECR. If you're using the managed policy, you don't need to add these permissions separately.

If you're creating a custom policy, include the following permissions to allow pulling images from Amazon ECR:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecr:BatchGetImage",
        "ecr:GetDownloadUrlForLayer",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*"
    }
  ]
}
```

Note that these permissions are different from the permissions that might be required in the task IAM role if your application code needs to interact with Amazon ECR APIs directly. For information about task IAM role permissions for Amazon ECR, see [Amazon ECR permissions](#).

## Amazon S3 file storage permissions

When you specify a configuration file that's hosted in Amazon S3, the task execution role must include the `s3:GetObject` permission for the configuration file and the `s3:GetBucketLocation` permission on the Amazon S3 bucket that the file is in. For more information, see [Policy actions for Amazon S3](#) in the *Amazon Simple Storage Service User Guide*.

The following example policy adds the required permissions for retrieving a file from Amazon S3. Specify the name of your Amazon S3 bucket and configuration file name.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/folder_name/config_file_name"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketLocation"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket"
      ]
    }
  ]
}
```

## Important Security Consideration

When using Amazon ECS features that integrate with Amazon S3 buckets, implement bucket ownership validation to prevent bucket takeover attacks. Without proper validation, if an Amazon S3 bucket is deleted and recreated by a malicious actor with the same name, your tasks may unknowingly load malicious configurations or send sensitive data to attacker-controlled buckets.

### Recommended IAM Policy Condition:

```
"Condition": {
  "StringEquals": {
    "aws:ResourceAccount": "TRUSTED-ACCOUNT-ID"
  }
}
```

Replace *TRUSTED-ACCOUNT-ID* with the AWS account ID that owns the S3 bucket.

This condition ensures your task execution role can only access Amazon S3 buckets owned by the specified trusted account.

## Amazon ECS task IAM role

Your Amazon ECS tasks can have an IAM role associated with them. The permissions granted in the IAM role are vended to containers running in the task. This role allows your application code (running in the container) to use other AWS services. The task role is required when your application accesses other AWS services, such as Amazon S3.

### Note

These permissions aren't accessed by the Amazon ECS container and Fargate agents. For the IAM permissions that Amazon ECS needs to pull container images and run the task, see [Amazon ECS task execution IAM role](#).

The following are the benefits of using task roles:

- **Separation of concerns:** If you're using EC2, task IAM roles allow you to specify IAM permissions for your containers without requiring these permissions to be specified using EC2 instance

profiles (for more information, see [Using instance profiles](#) in the *AWS Identity and Access Management User Guide*). Therefore, you can deploy your applications independently and uniformly on ECS container instances without needing to modify IAM permissions associated with EC2 instances.

- **Auditability:** Access and event logging are available through CloudTrail to ensure retrospective auditing. Task credentials have a context of 'taskArn' that is attached to the session, so CloudTrail logs show which task the role credentials were vended for.
- **Uniform credentials delivery:** ECS delivers IAM role credentials to your containers and makes them accessible through a well-defined interface irrespective of the compute option associated with your tasks. On ECS Fargate, EC2 instance profiles are not available for containers in your tasks. Task IAM roles enable you to associate IAM permissions to your containers irrespective of the compute option when you use AWS SDK or AWS CLI in your containers. For more information about how the AWS SDK accesses these credentials, see [Container credential provider](#).

### Important

Containers are not a security boundary and the use of task IAM roles does not change this. Each task running on Fargate has its own isolation boundary and does not share the underlying kernel, CPU resources, memory resources, or elastic network interface with another task. For workloads with strict isolation requirements, use Fargate. For EC2, ECS Managed Instances, and ECS Anywhere container instances, there is no task isolation and containers can potentially access credentials for other tasks on the same container instance. They can also access permissions assigned to the [ECS container instance role](#) and other sensitive data such as instance metadata and IAM role credentials accessible through the Amazon EC2 Instance Metadata Service (IMDS), as well as data from co-located tasks. Follow the recommendations in [Roles recommendations](#) to prevent containers from accessing the Amazon EC2 Instance Metadata Service on your container instances (For more information, see [Use the Instance Metadata Service to access instance metadata](#) in the *Amazon EC2 User Guide*).

Note that when you specify an IAM role for a task, the AWS CLI or other SDKs in the containers for that task use the AWS credentials provided by the task role exclusively and they do not inherit any IAM permissions from the Amazon EC2 or external instance they are running on.

## Creating the task IAM role

When creating an IAM policy for your tasks to use, the policy must include the permissions that you want the containers in your tasks to assume. You can use an existing AWS managed policy, or you can create a custom policy from scratch that meets your specific needs. For more information, see [Creating IAM policies](#) in the *IAM User Guide*.

### Important

For Amazon ECS tasks (for all launch types), we recommend that you use the IAM policy and role for your tasks. These credentials allow your task to make AWS API requests without calling `sts:AssumeRole` to assume the same role that is already associated with the task. If your task requires that a role assumes itself, you must create a trust policy that explicitly allows that role to assume itself. For more information, see [Updating a role trust policy](#) in the *IAM User Guide*.

After the IAM policy is created, you can create an IAM role which includes that policy which you reference in your Amazon ECS task definition. You can create the role using the **Elastic Container Service Task** use case in the IAM console. Then, you can attach your specific IAM policy to the role that gives the containers in your task the permissions you desire. The following procedures describe how to do this.

If you have multiple task definitions or services that require IAM permissions, you should consider creating a role for each specific task definition or service with the minimum required permissions for the tasks to operate so that you can minimize the access that you provide for each task.

For information about the service endpoint for your Region, see [Service endpoints](#) in the *Amazon Web Services General Reference Guide*.

The IAM task role must have a trust policy that specifies the `ecs-tasks.amazonaws.com` service. The `sts:AssumeRole` permission allows your tasks to assume an IAM role that's different from the one that the Amazon EC2 instance uses. This way, your task doesn't inherit the role associated with the Amazon EC2 instance. The following is an example trust policy. Replace the Region identifier and specify the AWS account number that you use when launching tasks.

**⚠ Important**

When creating your task IAM role, we recommend that you use the `aws:SourceAccount` or `aws:SourceArn` condition keys in the trust relationship policy associated with the role to scope the permissions further to prevent the confused deputy security issue. Using the `aws:SourceArn` condition key to specify a specific cluster is not currently supported, you should use the wildcard to specify all clusters. To learn more about the confused deputy problem and how to protect your AWS account, see [The confused deputy problem](#) in the *IAM User Guide*.

**JSON**

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "ecs-tasks.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:ecs:us-west-2:111122223333:*"
        },
        "StringEquals": {
          "aws:SourceAccount": "111122223333"
        }
      }
    }
  ]
}
```

Use the following procedure to create a policy to retrieve objects from Amazon S3 with an example policy. Replace all *user input* with your own values.

## AWS Management Console

### To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.

If this is your first time choosing **Policies**, the **Welcome to Managed Policies** page appears. Choose **Get Started**.

3. At the top of the page, choose **Create policy**.
4. In the **Policy editor** section, choose the **JSON** option.
5. Enter the following JSON policy document:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::my-task-secrets-bucket/*"
      ]
    }
  ]
}
```

6. Choose **Next**.

#### Note

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#) in the *IAM User Guide*.

7. On the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.
8. Choose **Create policy** to save your new policy.

## AWS CLI

Replace all *user input* with your own values.

1. Create a file called `s3-policy.json` with the following content.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::my-task-secrets-bucket/*"
      ]
    }
  ]
}
```

2. Use the following command to create the IAM policy using the JSON policy document file. Replace all *user input* with your own values.

```
aws iam create-policy \
  --policy-name taskRolePolicy \
  --policy-document file://s3-policy.json
```

Use the following procedure to create the service role.

## AWS Management Console

### To create the service role for Elastic Container Service (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Service or use case**, choose **Elastic Container Service**, and then choose the **Elastic Container Service Task** use case.
5. Choose **Next**.
6. For **Add permissions**, search for and choose the policy you created.
7. Choose **Next**.
8. For **Role name**, enter a name for your role. For this example, type `AmazonECSTaskS3BucketRole` to name the role.
9. Review the role, and then choose **Create role**.

## AWS CLI

1. Create a file named `ecs-tasks-trust-policy.json` that contains the trust policy to use for the task IAM role. The file should contain the following. Replace the Region identifier and specify the AWS account number that you use when launching tasks.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "ecs-tasks.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {
```

```

    "ArnLike":{
      "aws:SourceArn":"arn:aws:ecs:us-west-2:111122223333:*"
    },
    "StringEquals":{
      "aws:SourceAccount":"111122223333"
    }
  }
}
]
}

```

2. Create an IAM role named `ecsTaskRole` using the trust policy created in the previous step.

```

aws iam create-role \
  --role-name ecsTaskRole \
  --assume-role-policy-document file://ecs-tasks-trust-policy.json

```

3. Retrieve the ARN of the IAM policy you created using the following command. Replace *taskRolePolicy* with the name of the policy you created.

```

aws iam list-policies --scope Local --query 'Policies[?
PolicyName==`taskRolePolicy`].Arn'

```

4. Attach the IAM policy you created to the `ecsTaskRole` role. Replace the `policy-arn` with the ARN of the policy that you created.

```

aws iam attach-role-policy \
  --role-name ecsTaskRole \
  --policy-arn arn:aws:iam:111122223333:aws:policy/taskRolePolicy

```

After you create the role, add additional permissions to the role for the following features.

| Feature                                           | Additional permissions                 |
|---------------------------------------------------|----------------------------------------|
| Use ECS Exec                                      | <a href="#">ECS Exec permissions</a>   |
| Use an image from a private Amazon ECR repository | <a href="#">Amazon ECR permissions</a> |

| Feature                               | Additional permissions                                               |
|---------------------------------------|----------------------------------------------------------------------|
| Use EC2 instances (Windows and Linux) | <a href="#">Amazon EC2 instances additional configuration</a>        |
| Use external instances                | <a href="#">External instance additional configuration</a>           |
| Use Windows EC2 instances             | <a href="#">Amazon EC2 Windows instance additional configuration</a> |

## Amazon ECR permissions

The following permissions are required when your application code needs to interact with Amazon ECR repositories directly. Note that for basic implementation where you only need to pull images from Amazon ECR, these permissions are not required at the task IAM role level. Instead, the Amazon ECS task execution role should have these permissions. For more information about the task execution role, see [Amazon ECS task execution IAM role](#).

If your application code running in the container needs to interact with Amazon ECR APIs directly, you should add the following permissions to a task IAM role and include the task IAM role in your task definition. For more information, see [Adding and Removing IAM Policies](#) in the *IAM User Guide*.

Use the following policy for your task IAM role to add the required Amazon ECR permissions for container applications that need to interact with Amazon ECR directly:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecr:BatchGetImage",
        "ecr:GetDownloadUrlForLayer",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*"
    }
  ]
}
```

```
}
```

## ECS Exec permissions

The [ECS Exec](#) feature requires a task IAM role to grant containers the permissions needed for communication between the managed SSM agent (execute-command agent) and the SSM service. You should add the following permissions to a task IAM role and include the task IAM role in your task definition. For more information, see [Adding and Removing IAM Policies](#) in the *IAM User Guide*.

Use the following policy for your task IAM role to add the required SSM permissions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssmmessages:CreateControlChannel",
        "ssmmessages:CreateDataChannel",
        "ssmmessages:OpenControlChannel",
        "ssmmessages:OpenDataChannel"
      ],
      "Resource": "*"
    }
  ]
}
```

## Amazon EC2 instances additional configuration

We recommend that you limit the permissions in your container instance role to the minimal list of permissions used in the `AmazonEC2ContainerServiceforEC2Role` managed IAM policy.

Your Amazon EC2 instances require at least version `1.11.0` of the container agent to use task role; however, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see [Updating the Amazon ECS container agent](#). If you use an Amazon ECS-optimized AMI, your instance needs at least `1.11.0-1` of the `ecs-init` package. If your instances are using the latest Amazon ECS-optimized AMI, then they

contain the required versions of the container agent and `ecs-init`. For more information, see [Amazon ECS-optimized Linux AMIs](#).

If you are not using the Amazon ECS-optimized AMI for your container instances, add the `--net=host` option to your **docker run** command that starts the agent and the following agent configuration variables for your desired configuration (for more information, see [Amazon ECS container agent configuration](#)):

```
ECS_ENABLE_TASK_IAM_ROLE=true
```

Uses IAM roles for tasks for containers with the bridge and default network modes.

```
ECS_ENABLE_TASK_IAM_ROLE_NETWORK_HOST=true
```

Uses IAM roles for tasks for containers with the host network mode. This variable is only supported on agent versions 1.12.0 and later.

For an example run command, see [Manually updating the Amazon ECS container agent \(for non-Amazon ECS-Optimized AMIs\)](#). You will also need to set the following networking commands on your container instance so that the containers in your tasks can retrieve their AWS credentials:

```
sudo sysctl -w net.ipv4.conf.all.route_localnet=1
sudo iptables -t nat -A PREROUTING -p tcp -d 169.254.170.2 --dport 80 -j DNAT --to-destination 127.0.0.1:51679
sudo iptables -t nat -A OUTPUT -d 169.254.170.2 -p tcp -m tcp --dport 80 -j REDIRECT --to-ports 51679
```

You must save these **iptables** rules on your container instance for them to survive a reboot. You can use the **iptables-save** and **iptables-restore** commands to save your **iptables** rules and restore them at boot. For more information, consult your specific operating system documentation.

To prevent containers run by tasks that use the `awsvpc` network mode from accessing the credential information supplied to the Amazon EC2 instance profile, while still allowing the permissions that are provided by the task role, set the `ECS_AWSVPC_BLOCK_IMDS` agent configuration variable to `true` in the agent configuration file and restart the agent. For more information, see [Amazon ECS container agent configuration](#).

To prevent containers run by tasks that use the `bridge` network mode from accessing the credential information supplied to the Amazon EC2 instance profile, while still allowing the

permissions that are provided by the task role, by running the following **iptables** command on your Amazon EC2 instances. This command doesn't affect containers in tasks that use the host or awsvpc network modes. For more information, see [Network mode](#).

- ```
sudo yum install -y iptables-services; sudo iptables --insert DOCKER-USER 1 --in-interface docker+ --destination 169.254.169.254/32 --jump DROP
```

You must save this **iptables** rule on your Amazon EC2 instance for it to survive a reboot. When using the Amazon ECS-optimized AMI, you can use the following command. For other operating systems, consult the documentation for that operating system.

```
sudo iptables-save | sudo tee /etc/sysconfig/iptables && sudo systemctl enable --now iptables
```

## External instance additional configuration

Your external instances require at least version 1.11.0 of the container agent to use task IAM roles; however, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see [Updating the Amazon ECS container agent](#). If you are using an Amazon ECS-optimized AMI, your instance needs at least 1.11.0-1 of the `ecs-init` package. If your instances are using the latest Amazon ECS-optimized AMI, then they contain the required versions of the container agent and `ecs-init`. For more information, see [Amazon ECS-optimized Linux AMIs](#).

If you are not using the Amazon ECS-optimized AMI for your container instances, add the `--net=host` option to your **docker run** command that starts the agent and the following agent configuration variables for your desired configuration (for more information, see [Amazon ECS container agent configuration](#)):

`ECS_ENABLE_TASK_IAM_ROLE=true`

Uses IAM roles for tasks for containers with the bridge and default network modes.

`ECS_ENABLE_TASK_IAM_ROLE_NETWORK_HOST=true`

Uses IAM roles for tasks for containers with the host network mode. This variable is only supported on agent versions 1.12.0 and later.

For an example run command, see [Manually updating the Amazon ECS container agent \(for non-Amazon ECS-Optimized AMIs\)](#). You will also need to set the following networking commands on your container instance so that the containers in your tasks can retrieve their AWS credentials:

```
sudo sysctl -w net.ipv4.conf.all.route_localnet=1
sudo iptables -t nat -A PREROUTING -p tcp -d 169.254.170.2 --dport 80 -j DNAT --to-destination 127.0.0.1:51679
sudo iptables -t nat -A OUTPUT -d 169.254.170.2 -p tcp -m tcp --dport 80 -j REDIRECT --to-ports 51679
```

You must save these **iptables** rules on your container instance for them to survive a reboot. You can use the **iptables-save** and **iptables-restore** commands to save your **iptables** rules and restore them at boot. For more information, consult your specific operating system documentation.

## Amazon EC2 Windows instance additional configuration

### Important

This applies only to Windows containers on EC2 that use task roles.

The task role with Windows features requires additional configuration on EC2.

- When you launch your container instances, you must set the `-EnableTaskIAMRole` option in the container instances user data script. The `EnableTaskIAMRole` turns on the Task IAM roles feature for the tasks. For example:

```
<powershell>
Import-Module ECSTools
Initialize-ECSAgent -Cluster 'windows' -EnableTaskIAMRole
</powershell>
```

- You must bootstrap your container with the networking commands that are provided in [Amazon ECS container bootstrap script](#).
- You must create an IAM role and policy for your tasks. For more information, see [Creating the task IAM role](#).
- The IAM roles for the task credential provider use port 80 on the container instance. Therefore, if you configure IAM roles for tasks on your container instance, your containers can't use port 80 for the host port in any port mappings. To expose your containers on port 80, we recommend

configuring a service for them that uses load balancing. You can use port 80 on the load balancer. By doing so, traffic can be routed to another host port on your container instances. For more information, see [Use load balancing to distribute Amazon ECS service traffic](#).

- If your Windows instance is restarted, you must delete the proxy interface and initialize the Amazon ECS container agent again to bring the credential proxy back up.

## Amazon ECS container bootstrap script

Before containers can access the credential proxy on the container instance to get credentials, the container must be bootstrapped with the required networking commands. The following code example script should be run on your containers when they start.

### Note

You do not need to run this script when you use awsvpc network mode on Windows.

If you run Windows containers which include Powershell, then use the following script:

```
# Copyright Amazon.com Inc. or its affiliates. All Rights Reserved.
#
# Licensed under the Apache License, Version 2.0 (the "License"). You may
# not use this file except in compliance with the License. A copy of the
# License is located at
#
# http://aws.amazon.com/apache2.0/
#
# or in the "license" file accompanying this file. This file is distributed
# on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either
# express or implied. See the License for the specific language governing
# permissions and limitations under the License.

$gateway = (Get-NetRoute | Where { $_.DestinationPrefix -eq '0.0.0.0/0' } | Sort-Object
  RouteMetric | Select NextHop).NextHop
$ifIndex = (Get-NetAdapter -InterfaceDescription "Hyper-V Virtual Ethernet*" | Sort-
  Object | Select ifIndex).ifIndex
New-NetRoute -DestinationPrefix 169.254.170.2/32 -InterfaceIndex $ifIndex -NextHop
  $gateway -PolicyStore ActiveStore # credentials API
New-NetRoute -DestinationPrefix 169.254.169.254/32 -InterfaceIndex $ifIndex -NextHop
  $gateway -PolicyStore ActiveStore # metadata API
```

If you run Windows containers that only have the Command shell, then use the following script:

```
# Copyright Amazon.com Inc. or its affiliates. All Rights Reserved.
#
# Licensed under the Apache License, Version 2.0 (the "License"). You may
# not use this file except in compliance with the License. A copy of the

nexthop="%gateway%" store=active # metadata API
```

## Amazon ECS container instance IAM role

Amazon ECS container instances, including both Amazon EC2 and external instances, run the Amazon ECS container agent and require an IAM role for the service to know that the agent belongs to you. Before you launch container instances and register them to a cluster, you must create an IAM role for your container instances to use. The role is created in the account that you use to log into the console or run the AWS CLI commands.

### Important

If you are registering external instances to your cluster, the IAM role you use requires Systems Manager permissions as well. For more information, see [Amazon ECS Anywhere IAM role](#).

Amazon ECS provides the `AmazonEC2ContainerServiceforEC2Role` managed IAM policy which contains the permissions needed to use the full Amazon ECS feature set. This managed

policy can be attached to an IAM role and associated with your container instances. Alternatively, you can use the managed policy as a guide when creating a custom policy to use. The container instance role provides permissions needed for the Amazon ECS container agent and Docker daemon to call AWS APIs on your behalf. For more information on the managed policy, see [AmazonEC2ContainerServiceforEC2Role](#).

## Create the container instance role

### Important

If you are registering external instances to your cluster, see [Amazon ECS Anywhere IAM role](#).

You can manually create the role and attach the managed IAM policy for container instances to allow Amazon ECS to add permissions for future features and enhancements as they are introduced. Use the following procedure to attach the managed IAM policy if needed.

### AWS Management Console

#### To create the service role for Elastic Container Service (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Service or use case**, choose **Elastic Container Service**, and then choose the **EC2 Role for Elastic Container Service** use case.
5. Choose **Next**.
6. In the **Permissions policies** section, verify that the **AmazonEC2ContainerServiceforEC2Role** policy is selected.

### Important

The **AmazonEC2ContainerServiceforEC2Role** managed policy should be attached to the container instance IAM role, otherwise you will receive an error using the AWS Management Console to create clusters.

7. Choose **Next**.
8. For **Role name**, enter **ecsInstanceRole**
9. Review the role, and then choose **Create role**.

## AWS CLI

Replace all *user input* with your own values.

1. Create a file called `instance-role-trust-policy.json` with the following contents.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": { "Service": "ec2.amazonaws.com" },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Use the following command to create the instance IAM role using the trust policy document.

```
aws iam create-role \
  --role-name ecsInstanceRole \
  --assume-role-policy-document file://instance-role-trust-policy.json
```

3. Create an instance profile named `ecsInstanceRole-profile` using the [create-instance-profile](#) command.

```
aws iam create-instance-profile --instance-profile-name ecsInstanceRole-profile
```

## Example response

```
{
  "InstanceProfile": {
    "InstanceProfileId": "AIPAJTLPJLEGREXAMPLE",
    "Roles": [],
    "CreateDate": "2022-04-12T23:53:34.093Z",
```

```
    "InstanceProfileName": "ecsInstanceRole-profile",
    "Path": "/",
    "Arn": "arn:aws:iam::123456789012:instance-profile/ecsInstanceRole-profile"
  }
}
```

4. Add the *ecsInstanceRole* role to the *ecsInstanceRole-profile* instance profile.

```
aws iam add-role-to-instance-profile \
  --instance-profile-name ecsInstanceRole-profile \
  --role-name ecsInstanceRole
```

5. Attach the AmazonEC2ContainerServiceForEC2Role managed policy to the role using the following command.

```
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::aws:policy/service-role/AmazonEC2ContainerServiceforEC2Role \
  --role-name ecsInstanceRole
```

After you create the role, add additional permissions to the role for the following features.

| Feature                                          | Additional permissions                                     |
|--------------------------------------------------|------------------------------------------------------------|
| Amazon ECR has the container image               | <a href="#">Amazon ECR permissions</a>                     |
| Have CloudWatch Logs monitor container instances | <a href="#">Monitoring container instances permissions</a> |
| Host configuration files in an Amazon S3 bucket  | <a href="#">Amazon S3 read-only access</a>                 |

Amazon ECR permissions

The Amazon ECS container instance role that you use with your container instances must have the following IAM policy permissions for Amazon ECR.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecr:BatchCheckLayerAvailability",
        "ecr:BatchGetImage",
        "ecr:GetDownloadUrlForLayer",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*"
    }
  ]
}
```

If you use the `AmazonEC2ContainerServiceforEC2Role` managed policy for your container instances, then your role has the proper permissions.

### Permissions required for setting the `awsvpcTrunking` account setting

Amazon ECS supports launching container instances with increased ENI density using supported Amazon EC2 instance types. When you use this feature, we recommend that you create 2 container instance roles. Enable the `awsvpcTrunking` account setting for one role and use that role for tasks that require ENI trunking. For information about the `awsvpcTrunking` account setting, see [Access Amazon ECS features with account settings](#).

The container instance role that you use with your container instances must have the following IAM policy permissions for setting the account setting

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```
        "Action": [
            "ecs:ListAccountSettings",
            "ecs:ListAttributes",
            "ecs:PutAccountSetting"
        ],
        "Resource": "*"
    }
}
```

In order to use the container instance role, add the following to instance user data:

```
#!/bin/bash
aws ecs put-account-setting --name awsvpcTrunking --value enabled --region region
ECS_CLUSTER=MyCluster>> /etc/ecs/ecs.config
EOF
```

For more information about adding user data to your EC2 instances, see [Run commands on your Linux instance at launch](#) in the *Amazon EC2 User Guide*.

## Amazon S3 read-only access

Storing configuration information in a private bucket in Amazon S3 and granting read-only access to your container instance IAM role is a secure and convenient way to allow container instance configuration at launch time. You can store a copy of your `ecs.config` file in a private bucket, use Amazon EC2 user data to install the AWS CLI and then copy your configuration information to `/etc/ecs/ecs.config` when the instance launches.

For more information about creating an `ecs.config` file, storing it in Amazon S3, and launching instances with this configuration, see [Storing Amazon ECS container instance configuration in Amazon S3](#).

You can use the following AWS CLI command to allow Amazon S3 read-only access for your container instance role. Replace *ecsInstanceRole* with the name of the role that you created.

```
aws iam attach-role-policy \
    --role-name ecsInstanceRole \
    --policy-arn arn:aws:iam::aws:policy/AmazonS3ReadOnlyAccess
```

You can also use the IAM console to add Amazon S3 read-only access (AmazonS3ReadOnlyAccess) to your role. For more information, see [Updating permissions for a role](#) in the *AWS Identity and Access Management User Guide*.

## Monitoring container instances permissions

Before your container instances can send log data to CloudWatch Logs, you must create an IAM policy to allow the Amazon ECS agent to write the customer's application logs to CloudWatch (normally handled through the `awslogs` driver). After you create the policy, attach that policy to `ecsInstanceRole`.

### AWS Management Console

#### To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.

If this is your first time choosing **Policies**, the **Welcome to Managed Policies** page appears. Choose **Get Started**.

3. At the top of the page, choose **Create policy**.
4. In the **Policy editor** section, choose the **JSON** option.
5. Enter the following JSON policy document:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:DescribeLogStreams"
      ],
      "Resource": ["arn:aws:logs:*:*:*"]
    }
  ]
}
```

6. Choose **Next**.

 **Note**

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#) in the *IAM User Guide*.

7. On the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.
8. Choose **Create policy** to save your new policy.

After you create the policy, attach the policy to the container instance role. For information about how to attach the policy to the role, see [Updating permissions for a role](#) in the *AWS Identity and Access Management User Guide*.

## AWS CLI

1. Create a file called `instance-cw-logs.json` with the following content.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:DescribeLogStreams"
      ],
      "Resource": ["arn:aws:logs:*:*:*"]
    }
  ]
}
```

2. Use the following command to create the IAM policy using the JSON policy document file.

```
aws iam create-policy \  
  --policy-name cwlogspolicy \  
  --policy-document file://instance-cw-logs.json
```

3. Retrieve the ARN of the IAM policy you created using the following command. Replace *cwlogspolicy* with the name of the policy you created.

```
aws iam list-policies --scope Local --query 'Policies[?  
PolicyName==`cwlogspolicy`].Arn'
```

4. Use the following command to attach the policy to the container instance IAM role using the policy ARN.

```
aws iam attach-role-policy \  
  --role-name ecsInstanceRole \  
  --policy-arn arn:aws:iam:111122223333:aws:policy/cwlogspolicy
```

## Amazon ECS Anywhere IAM role

When you register an on-premises server or virtual machine (VM) to your cluster, the server or VM requires an IAM role to communicate with AWS APIs. You only need to create this IAM role once for each AWS account. However, this IAM role must be associated with each server or VM that you register to a cluster. This role is the `ECSAnywhereRole`. You can create this role manually. Alternatively, Amazon ECS can create the role on your behalf when you register an external instance in the AWS Management Console. You can use IAM console search to search for `ecsAnywhereRole` and see if your account already has the role. For more information, see [IAM console search](#) in the *IAM user guide*.

AWS provides two managed IAM policies that can be used when creating the ECS Anywhere IAM role, the `AmazonSSMManagedInstanceCore` and `AmazonEC2ContainerServiceforEC2Role` policies. The `AmazonEC2ContainerServiceforEC2Role` policy includes permissions that likely provide more access than you need. Therefore, depending on your specific use case, we recommend that you create a custom policy adding only the permissions from that policy that you require in it. For more information, see [Amazon ECS container instance IAM role](#).

The task execution IAM role grants the Amazon ECS container agent permission to make AWS API calls on your behalf. When a task execution IAM role is used, it must be specified in your task definition. For more information, see [Amazon ECS task execution IAM role](#).

The task execution role is required if any of the following conditions apply:

- You're sending container logs to CloudWatch Logs using the `awslogs` log driver.
- Your task definition specifies a container image that's hosted in an Amazon ECR private repository. However, if the `ECSAnywhereRole` role that's associated with your external instance also includes the permissions necessary to pull images from Amazon ECR then your task execution role doesn't need to include them.

## Creating the Amazon ECS Anywhere role

Replace all *user input* with your own information.

1. Create a local file named `ssm-trust-policy.json` with the following trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": { "Service": [
      "ssm.amazonaws.com"
    ] },
    "Action": "sts:AssumeRole"
  }
}
```

2. Create the role and attach the trust policy by using the following AWS CLI command.

```
aws iam create-role --role-name ecsAnywhereRole --assume-role-policy-document
file://ssm-trust-policy.json
```

3. Attach the AWS managed policies by using the following command.

```
aws iam attach-role-policy --role-name ecsAnywhereRole --policy-arn
arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

```
aws iam attach-role-policy --role-name ecsAnywhereRole --policy-arn
arn:aws:iam::aws:policy/service-role/AmazonEC2ContainerServiceforEC2Role
```

You can also use the IAM custom trust policy workflow to create the role. For more information, see [Creating a role using custom trust policies \(console\)](#) in the *IAM User Guide*.

## Amazon ECS infrastructure IAM role

An Amazon ECS infrastructure IAM role allows Amazon ECS to manage infrastructure resources in your clusters on your behalf, and is used when:

- You want to attach Amazon EBS volumes to your Fargate or EC2 launch type Amazon ECS tasks. The infrastructure role allows Amazon ECS to manage Amazon EBS volumes for your tasks.

You can use the `AmazonECSInfrastructureRolePolicyForVolumes` managed policy.

- You want to use Transport Layer Security (TLS) to encrypt traffic between your Amazon ECS Service Connect services.

You can use the

`AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity` managed policy.

- You want to create Amazon VPC Lattice target groups.

You can use the `AmazonECSInfrastructureRolePolicyForVpcLattice` managed policy.

- You want to use Amazon ECS Managed Instances in your Amazon ECS clusters. The infrastructure role allows Amazon ECS to manage the lifecycle of managed instances.

You can use the `AmazonECSInfrastructureRolePolicyForManagedInstances` managed policy.

- You want to use Express Mode. The infrastructure role allows Amazon ECS to provision and manage the infrastructure components required for Express Mode services, including load balancing, security groups, SSL certificates, and auto scaling configurations.

You can use the `AmazonECSInfrastructureRoleforExpressGatewayServices` managed policy.

When Amazon ECS assumes this role to take actions on your behalf, the events will be visible in AWS CloudTrail. If Amazon ECS uses the role to manage Amazon EBS volumes attached to your

tasks, the CloudTrail log `roleSessionName` will be `ECSTaskVolumesForEBS`. If the role is used to encrypt traffic between your Service Connect services, the CloudTrail log `roleSessionName` will be `ECSServiceConnectForTLS`. If the role is used to create target groups for VPC Lattice, the CloudTrail log `roleSessionName` will be `ECSNetworkingWithVPCLattice`. If the role is used to manage Amazon ECS Managed Instances, the CloudTrail log `roleSessionName` will be `ECSManagedInstancesForCompute`. You can use this name to search events in the CloudTrail console by filtering for **User name**.

Amazon ECS provides managed policies which contain the permissions required for volume attachment, TLS, VPC Lattice, and managed instances.

For more information see, [AmazonECSInfrastructureRolePolicyForVolumes](#), [AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity](#), [AmazonECSInfrastructureRolePolicyForVpcLattice](#), [AmazonECSInfrastructureRolePolicyForManagedInstances](#), and [AmazonECSInfrastructureRoleforExpressGatewayServices](#) in the *AWS Managed Policy Reference Guide*.

## Creating the Amazon ECS infrastructure role

Replace all *user input* with your own information.

1. Create a file named `ecs-infrastructure-trust-policy.json` that contains the trust policy to use for the IAM role. The file should contain the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToECSForInfrastructureManagement",
      "Effect": "Allow",
      "Principal": {
        "Service": "ecs.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Use the following AWS CLI command to create a role named `ecsInfrastructureRole` by using the trust policy that you created in the previous step.

```
aws iam create-role \
    --role-name ecsInfrastructureRole \
    --assume-role-policy-document file://ecs-infrastructure-trust-policy.json
```

3. Depending on your use case, attach the managed policy to the `ecsInfrastructureRole` role.
  - To attach Amazon EBS volumes to your Fargate or EC2 launch type Amazon ECS tasks, attach the `AmazonECSInfrastructureRolePolicyForVolumes` managed policy.
  - To use Transport Layer Security (TLS) to encrypt traffic between your Amazon ECS Service Connect services, attach the `AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity` managed policy.
  - To create Amazon VPC Lattice target groups, attach the `AmazonECSInfrastructureRolePolicyForVpcLattice` managed policy.
  - You want to use Amazon ECS Managed Instances in your Amazon ECS clusters, attach the `AmazonECSInfrastructureRolePolicyForManagedInstances` managed policy.

```
aws iam attach-role-policy \
    --role-name ecsInfrastructureRole \
    --policy-arn arn:aws:iam::aws:policy/service-role/
AmazonECSInfrastructureRolePolicyForVolumes
```

```
aws iam attach-role-policy \
    --role-name ecsInfrastructureRole \
    --policy-arn arn:aws:iam::aws:policy/service-role/
AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity
```

```
aws iam attach-role-policy \
    --role-name ecsInfrastructureRole \
    --policy-arn arn:aws:iam::aws:policy/
AmazonECSInfrastructureRolePolicyForManagedInstances
```

You can also use the IAM console's **Custom trust policy** workflow to create the role. For more information, see [Creating a role using custom trust policies \(console\)](#) in the *IAM User Guide*.

### Important

If the infrastructure role is being used by Amazon ECS to manage Amazon EBS volumes attached to your tasks, ensure the following before you stop tasks that use Amazon EBS volumes.

- The role isn't deleted.
- The trust policy for the role isn't modified to remove Amazon ECS access (`ecs.amazonaws.com`).
- The managed policy `AmazonECSInfrastructureRolePolicyForVolumes` isn't removed. If you must modify the role's permissions, retain at least `ec2:DetachVolume`, `ec2:DeleteVolume`, and `ec2:DescribeVolumes` for volume deletion.

Deleting or modifying the role before stopping tasks with attached Amazon EBS volumes will result in the tasks getting stuck in `DEPROVISIONING` and the associated Amazon EBS volumes failing to delete. Amazon ECS will automatically retry at regular intervals to stop the task and delete the volume until the necessary permissions are restored. You can view a task's volume attachment status and associated status reason by using the [DescribeTasks](#) API.

After you create the file, you must grant your user permission to pass the role to Amazon ECS.

### Permission to pass the infrastructure role to Amazon ECS

To use an ECS infrastructure IAM role, you must grant your user permission to pass the role to Amazon ECS. Attach the following `iam:PassRole` permission to your user. Replace *`ecsInfrastructureRole`* with the name of the infrastructure role that you created.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{
  "Action": "iam:PassRole",
  "Effect": "Allow",
  "Resource": ["arn:aws:iam::*:role/ecsInfrastructureRole"],
  "Condition": {
    "StringEquals": {"iam:PassedToService": "ecs.amazonaws.com"}
  }
}
```

For more information about `iam:PassRole` and updating permissions for your user, see [Granting a user permissions to pass a role to an AWS service](#) and [Changing permissions for an IAM user](#) in the *AWS Identity and Access Management User Guide*.

## Amazon ECS Managed Instances instance profile

An instance profile is an IAM container that holds exactly one IAM role and allows Amazon ECS Managed Instances to assume that role securely. The instance profile contains an instance role that the ECS agent assumes to register instances with clusters and communicate with the ECS service.

### Important

If you use Amazon ECS Managed Instances with the `AmazonECSInfrastructureRolePolicyForManagedInstances` managed policy, the instance role name must start with `ecsInstanceRole`. The policy scopes `iam:PassRole` to `arn:aws:iam::*:role/ecsInstanceRole*`, so a mismatched name causes an authorization error at task launch. This is common with CloudFormation when you omit `RoleName`, because CloudFormation auto-generates names like `MyStack-InstanceRole-ABC123`.

If you use a custom infrastructure role policy instead, the instance role can have any name as long as your policy includes an `iam:PassRole` grant targeting the instance role ARN.

## Create the role with the trust policy

Replace all *user input* with your own information.

1. Create a file named `ecsInstanceRole-trust-policy.json` that contains the trust policy to use for the IAM role. The file should contain the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": { "Service": "ec2.amazonaws.com" },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Use the following AWS CLI command to create a role named `ecsInstanceRole` by using the trust policy that you created in the previous step.

```
aws iam create-role \
  --role-name ecsInstanceRole \
  --assume-role-policy-document file://ecsInstanceRole-trust-policy.json
```

3. Attach the AWS managed `AmazonECSInstanceRolePolicyForManagedInstances` policy to the `ecsInstanceRole` role.

```
aws iam attach-role-policy \
  --role-name ecsInstanceRole \
  --policy-arn arn:aws:iam::aws:policy/
AmazonECSInstanceRolePolicyForManagedInstances
```

#### Note

If you choose to apply least-privilege permissions and specify your own permissions instead, you can add the following permissions to help with troubleshooting task-related issues with Amazon ECS Managed Instances:

- `ecs:StartTelemetrySession`
- `ecs:PutSystemLogEvents`

You can also use the IAM console's **Custom trust policy** workflow to create the role. For more information, see [Creating a role using custom trust policies \(console\)](#) in the *IAM User Guide*.

After you create the file, you must grant your user permission to pass the role to Amazon ECS.

### Create the instance profile using the AWS CLI

After creating the role, create the instance profile using the AWS CLI:

```
aws iam create-instance-profile --instance-profile-name ecsInstanceRole
```

Add the role to the instance profile:

```
aws iam add-role-to-instance-profile \  
  --instance-profile-name ecsInstanceRole \  
  --role-name ecsInstanceRole
```

Verify the profile was created successfully:

```
aws iam get-instance-profile --instance-profile-name ecsInstanceRole
```

### Create the instance profile using CloudFormation

You can use AWS CloudFormation to create the instance role and instance profile. Choose one of the following options based on whether you use the AWS-managed infrastructure policy or a custom policy.

#### Option 1: Use the `ecsInstanceRole` naming convention (recommended)

When you use the AWS-managed infrastructure policy, you must explicitly set `RoleName` to a value that starts with `ecsInstanceRole`. If you omit `RoleName`, CloudFormation auto-generates a name that does not match the managed policy's `iam:PassRole` condition, and tasks fail to launch.

```
Resources:  
  EcsInstanceRole:  
    Type: AWS::IAM::Role  
    Properties:  
      RoleName: ecsInstanceRole  
      AssumeRolePolicyDocument:
```

```

    Version: "2012-10-17"
    Statement:
      - Effect: Allow
        Principal:
          Service: ec2.amazonaws.com
        Action: sts:AssumeRole
    ManagedPolicyArns:
      - arn:aws:iam::aws:policy/AmazonECSInstanceRolePolicyForManagedInstances

EcsInstanceProfile:
  Type: AWS::IAM::InstanceProfile
  Properties:
    InstanceProfileName: ecsInstanceRole
    Roles:
      - !Ref EcsInstanceRole

```

## Option 2: Use a custom role name

If you prefer to let CloudFormation generate the role name, or you use a custom name that does not start with `ecsInstanceRole`, you must add an inline policy on your infrastructure role that grants `iam:PassRole` for the instance role.

```

Resources:
  EcsInstanceRole:
    Type: AWS::IAM::Role
    Properties:
      # No RoleName – CFN auto-generates
      AssumeRolePolicyDocument:
        Version: "2012-10-17"
        Statement:
          - Effect: Allow
            Principal:
              Service: ec2.amazonaws.com
            Action: sts:AssumeRole
      ManagedPolicyArns:
        - arn:aws:iam::aws:policy/AmazonECSInstanceRolePolicyForManagedInstances

  EcsInstanceProfile:
    Type: AWS::IAM::InstanceProfile
    Properties:
      Roles:
        - !Ref EcsInstanceRole

```

```
EcsInfrastructureRole:
  Type: AWS::IAM::Role
  Properties:
    AssumeRolePolicyDocument:
      Version: "2012-10-17"
      Statement:
        - Effect: Allow
          Principal:
            Service: ecs.amazonaws.com
          Action: sts:AssumeRole
    ManagedPolicyArns:
      - arn:aws:iam::aws:policy/AmazonECSInfrastructureRolePolicyForManagedInstances
    Policies:
      - PolicyName: PassInstanceRoleToEC2
        PolicyDocument:
          Version: "2012-10-17"
          Statement:
            - Effect: Allow
              Action: iam:PassRole
              Resource: !GetAtt EcsInstanceRole.Arn
              Condition:
                StringLike:
                  iam:PassedToService: "ec2.*"
```

## Troubleshooting

### Tasks fail with iam:PassRole authorization error

If your tasks fail with a `ResourceInitializationError` that mentions `iam:PassRole`, verify that your instance role name starts with `ecsInstanceRole`. You can check the auto-generated name in the CloudFormation console under your stack's **Resources** tab. If the name does not match, either:

- Add `RoleName: ecsInstanceRole` to your `AWS::IAM::Role` resource.
- Add an explicit `iam:PassRole` inline policy to your infrastructure role. For more information, see [the section called "Option 2: Use a custom role name"](#).

## Amazon ECS infrastructure IAM role for load balancers

An Amazon ECS infrastructure IAM role for load balancers allows Amazon ECS to manage load balancer resources in your clusters on your behalf, and is used when:

- You want to use blue/green deployments with Amazon ECS. The infrastructure role allows Amazon ECS to manage load balancer resources for your deployments.
- You need Amazon ECS to create, modify, or delete load balancer resources such as target groups and listeners during deployment operations.

When Amazon ECS assumes this role to take actions on your behalf, the events will be visible in AWS CloudTrail. If Amazon ECS uses the role to manage load balancer resources for your blue/green deployments, the CloudTrail log `roleSessionName` will be `ECSNetworkingWithELB` or `ecs-service-scheduler`. You can use this name to search events in the CloudTrail console by filtering for **User name**.

Amazon ECS provides a managed policy which contains the permissions required for load balancer management. For more information see, [AmazonECSInfrastructureRolePolicyForLoadBalancers](#) in the *AWS Managed Policy Reference Guide*.

## Creating the Amazon ECS infrastructure role for load balancers

Replace all *user input* with your own information.

1. Create a file named `ecs-infrastructure-trust-policy.json` that contains the trust policy to use for the IAM role. The file should contain the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToECSForInfrastructureManagement",
      "Effect": "Allow",
      "Principal": {
        "Service": "ecs.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Use the following AWS CLI command to create a role named `ecsInfrastructureRoleForLoadBalancers` by using the trust policy that you created in the previous step.

```
aws iam create-role \  
    --role-name ecsInfrastructureRoleForLoadBalancers \  
    --assume-role-policy-document file://ecs-infrastructure-trust-policy.json
```

3. Attach the AWS managed `AmazonECSInfrastructureRolePolicyForLoadBalancers` policy to the `ecsInfrastructureRoleForLoadBalancers` role.

```
aws iam attach-role-policy \  
    --role-name ecsInfrastructureRoleForLoadBalancers \  
    --policy-arn arn:aws:iam::aws:policy/  
AmazonECSInfrastructureRolePolicyForLoadBalancers
```

You can also use the IAM console's **Custom trust policy** workflow to create the role. For more information, see [Creating a role using custom trust policies \(console\)](#) in the *IAM User Guide*.

### Important

If the infrastructure role is being used by Amazon ECS to manage load balancer resources for your blue/green deployments, ensure the following before you delete or modify the role:

- The role isn't deleted while active deployments are in progress.
- The trust policy for the role isn't modified to remove Amazon ECS access (`ecs.amazonaws.com`).
- The managed policy `AmazonECSInfrastructureRolePolicyForLoadBalancers` isn't removed while active deployments are in progress.

Deleting or modifying the role during active blue/green deployments may result in deployment failures and could leave your services in an inconsistent state.

After you create the file, you must grant your user permission to pass the role to Amazon ECS.

## Permission to pass the infrastructure role to Amazon ECS

To use an ECS infrastructure IAM role for load balancers, you must grant your user permission to pass the role to Amazon ECS. Attach the following `iam:PassRole` permission to your user. Replace *`ecsInfrastructureRoleForLoadBalancers`* with the name of the infrastructure role that you created.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "iam:PassRole",
      "Effect": "Allow",
      "Resource":
[ "arn:aws:iam::*:role/ecsInfrastructureRoleForLoadBalancers" ],
      "Condition": {
        "StringEquals": { "iam:PassedToService": "ecs.amazonaws.com" }
      }
    }
  ]
}
```

For more information about `iam:PassRole` and updating permissions for your user, see [Granting a user permissions to pass a role to an AWS service](#) and [Changing permissions for an IAM user](#) in the *AWS Identity and Access Management User Guide*.

## Amazon ECS CodeDeploy IAM Role

Before you can use the CodeDeploy blue/green deployment type with Amazon ECS, the CodeDeploy service needs permissions to update your Amazon ECS service on your behalf. These permissions are provided by the CodeDeploy IAM role (`ecsCodeDeployRole`).

### Note

Users also require permissions to use CodeDeploy; these permissions are described in [Required IAM permissions](#).

There are two managed policies provided. For more information, see one of the following in the *AWS Managed Policy Reference Guide*:

- [AWSCodeDeployRoleForECS](#) - gives CodeDeploy permission to update any resource using the associated action.
- [AWSCodeDeployRoleForECSLimited](#) - gives CodeDeploy more limited permissions.

## Creating the CodeDeploy role

You can use the following procedures to create a CodeDeploy role for Amazon ECS

### AWS Management Console

#### To create the service role for CodeDeploy (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Service or use case**, choose **CodeDeploy**, and then choose the **CodeDeploy - ECS** use case.
5. Choose **Next**.
6. In the **Attach permissions policy** section, ensure that the **AWSCodeDeployRoleForECS** policy is selected.
7. Choose **Next**.
8. For **Role name**, enter **ecsCodeDeployRole**.
9. Review the role, and then choose **Create role**.

### AWS CLI

Replace all *user input* with your own information.

1. Create a file named `codedeploy-trust-policy.json` that contains the trust policy to use for the CodeDeploy IAM role.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": ["codedeploy.amazonaws.com"]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Create an IAM role named `ecsCodedeployRole` using the trust policy created in the previous step.

```
aws iam create-role \
  --role-name ecsCodedeployRole \
  --assume-role-policy-document file://codedeploy-trust-policy.json
```

3. Attach the `AWSCodeDeployRoleForECS` or `AWSCodeDeployRoleForECSLimited` managed policy to the `ecsTaskRole` role.

```
aws iam attach-role-policy \
  --role-name ecsCodedeployRole \
  --policy-arn arn:aws:iam::aws:policy/AWSCodeDeployRoleForECS
```

```
aws iam attach-role-policy \
  --role-name ecsCodedeployRole \
  --policy-arn arn:aws:iam::aws:policy/AWSCodeDeployRoleForECSLimited
```

When the tasks in your service need a task execution role, you must add the `iam:PassRole` permission for each task execution role or task role override to the CodeDeploy role as a policy.

## Task execution role permissions

When the tasks in your service need a task execution role, you must add the `iam:PassRole` permission for each task execution role or task role override to the CodeDeploy role as a policy. For more information, see [Amazon ECS task execution IAM role](#) and [Amazon ECS task IAM role](#). Then, you attach that policy to the CodeDeploy role.

### Create the policy

#### AWS Management Console

##### To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.

If this is your first time choosing **Policies**, the **Welcome to Managed Policies** page appears. Choose **Get Started**.

3. At the top of the page, choose **Create policy**.
4. In the **Policy editor** section, choose the **JSON** option.
5. Enter the following JSON policy document:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": ["arn:aws:iam::<aws_account_id>:role/
<ecsCodeDeployRole>"]
    }
  ]
}
```

6. Choose **Next**.

**Note**

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#) in the *IAM User Guide*.

7. On the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.
8. Choose **Create policy** to save your new policy.

After you create the policy, attach the policy to the CodeDeploy role. For information about how to attach the policy to the role, see [Update permissions for a role](#) in the *AWS Identity and Access Management User Guide*.

## AWS CLI

Replace all *user input* with your own information.

1. Create a file called `blue-green-iam-passrole.json` with the following content.

### JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": ["arn:aws:iam::*:role/code-deploy-role"],
      "Condition": {
        "StringEquals": {"iam:PassedToService":
"ecs.amazonaws.com"}
      }
    }
  ]
}
```

2. Use the following command to create the IAM policy using the JSON policy document file.

```
aws iam create-policy \  
  --policy-name cdTaskExecutionPolicy \  
  --policy-document file://blue-green-iam-passrole.json
```

3. Retrieve the ARN of the IAM policy you created using the following command.

```
aws iam list-policies --scope Local --query 'Policies[?  
PolicyName==`cdTaskExecutionPolicy`].Arn'
```

4. Use the following command to attach the policy to the CodeDeploy IAM role.

```
aws iam attach-role-policy \  
  --role-name ecsCodedeployRole \  
  --policy-arn arn:aws:iam:111122223333:aws:policy/cdTaskExecutionPolicy
```

## Amazon ECS EventBridge IAM Role

Before you can use Amazon ECS scheduled tasks with EventBridge rules and targets, the EventBridge service needs permissions to run Amazon ECS tasks on your behalf. These permissions come from the EventBridge IAM role (ecsEventsRole).

The AmazonEC2ContainerServiceEventsRole policy is the following.

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": ["ecs:RunTask"],  
      "Resource": ["*"]  
    },  
    {  
      "Effect": "Allow",  
      "Action": "iam:PassRole",  
      "Resource": ["*"],  
      "Condition": {
```

```

        "StringLike": {"iam:PassedToService": "ecs-tasks.amazonaws.com"}
    },
    {
        "Effect": "Allow",
        "Action": "ecs:TagResource",
        "Resource": "*",
        "Condition": {
            "StringEquals": {
                "ecs:CreateAction": ["RunTask"]
            }
        }
    }
]
}

```

If your scheduled tasks require the use of the task execution role, a task role, or a task role override, then you must add `iam:PassRole` permissions for each task execution role, task role, or task role override to the EventBridge IAM role. For more information about the task execution role, see [Amazon ECS task execution IAM role](#).

#### Note

Specify the full ARN of your task execution role or task role override.

## JSON

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": [
                "arn:aws:iam::111122223333:role/ecsTaskExecutionRole_or_TaskRole_name"
            ]
        }
    ]
}

```

```
}
```

You can choose to let the AWS Management Console create the EventBridge role for you when you configure a scheduled task. For more information, see [Using Amazon EventBridge Scheduler to schedule Amazon ECS tasks](#).

## Creating the EventBridge role

Replace all *user input* with your own information.

1. Create a file named `eventbridge-trust-policy.json` that contains the trust policy to use for the IAM role. The file should contain the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "events.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Use the following command to create an IAM role named `ecsEventsRole` by using the trust policy that you created in the previous step.

```
aws iam create-role \
  --role-name ecsEventsRole \
  --assume-role-policy-document file://eventbridge-trust-policy.json
```

3. Attach the AWS managed `AmazonEC2ContainerServiceEventsRole` to the `ecsEventsRole` role using the following command.

```
aws iam attach-role-policy \
```

```
--role-name ecsEventsRole \  
--policy-arn arn:aws:iam::aws:policy/service-role/  
AmazonEC2ContainerServiceEventsRole
```

You can also use the IAM console's **Custom trust policy** workflow (<https://console.aws.amazon.com/iam/>) to create the role. For more information, see [Creating a role using custom trust policies \(console\)](#) in the *IAM User Guide*.

## Attaching a policy to the `ecsEventsRole` role

You can use the following procedures to add permissions for the task execution role to the EventBridge IAM role.

### AWS Management Console

#### To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.

If this is your first time choosing **Policies**, the **Welcome to Managed Policies** page appears. Choose **Get Started**.

3. At the top of the page, choose **Create policy**.
4. In the **Policy editor** section, choose the **JSON** option.
5. Enter the following JSON policy document:

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": "iam:PassRole",  
      "Resource": ["arn:aws:iam::111122223333:role/  
<ecsTaskExecutionRole_or_TaskRole_name>"]  
    }  
  ]  
}
```

6. Choose **Next**.

**Note**

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#) in the *IAM User Guide*.

7. On the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.
8. Choose **Create policy** to save your new policy.

After you create the policy, attach the policy to the EventBridge role. For information about how to attach the policy to the role, see [Update permissions for a role](#) in the *AWS Identity and Access Management User Guide*.

**AWS CLI**

Replace all *user input* with your own information.

1. Create a file called `ev-iam-passrole.json` with the following content.

**JSON**

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": [
        "arn:aws:iam::111122223333:role/ecsTaskExecutionRole_or_TaskRole_name"
      ]
    }
  ]
}
```

2. Use the following AWS CLI command to create the IAM policy using the JSON policy document file.

```
aws iam create-policy \  
  --policy-name eventsTaskExecutionPolicy \  
  --policy-document file://ev-iam-passrole.json
```

3. Retrieve the ARN of the IAM policy you created using the following command.

```
aws iam list-policies --scope Local --query 'Policies[?  
PolicyName==`eventsTaskExecutionPolicy`].Arn'
```

4. Use the following command to attach the policy to the EventBridge IAM role by using the policy ARN.

```
aws iam attach-role-policy \  
  --role-name ecsEventsRole \  
  --policy-arn arn:aws:iam:111122223333:aws:policy/eventsTaskExecutionPolicy
```

## Permissions required for the Amazon ECS console

Following the best practice of granting least privilege, you can use the `AmazonECS_FullAccess` managed policy as a template for creating your own custom policy. That way, you can take away or add permissions to and from the managed policy based on your specific requirements. For more information, see [AmazonECS\\_FullAccess](#) in the *AWS Managed Policy Reference*.

### Permissions for creating IAM roles

The following actions require additional permissions in order to complete the operation:

- Registering an external instance - for more information, see [Amazon ECS Anywhere IAM role](#)
- Registering a task definition - for more information, see [Amazon ECS task execution IAM role](#)
- Creating an EventBridge rule to use for scheduling tasks - for more information, see [Amazon ECS EventBridge IAM Role](#)

You can add these permissions by creating a role in IAM before you use them in the Amazon ECS console. If you do not create the roles, the Amazon ECS console creates them on your behalf.

## Permissions required for registering an external instance to a cluster

You need additional permissions when you register an external instance to a cluster and you want to create a new external instance (`ecsExternalInstanceRole`) role.

The following additional permissions are required:

- `iam` – Allows principals to create and list IAM roles and their attached policies.
  - `iam:AttachRolePolicy`
  - `iam:CreateRole`
  - `iam:CreateInstanceProfile`
  - `iam:AddRoleToInstanceProfile`
  - `iam:ListInstanceProfilesForRole`
  - `iam:GetRole`
- `ssm` – Allows principals to register the external instance with Systems Manager.

### Note

In order to choose an existing `ecsExternalInstanceRole`, you must have the `iam:GetRole` and `iam:PassRole` permissions.

The following policy contains the required permissions, and limits the actions to the `ecsExternalInstanceRole` role.

JSON

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:AttachRolePolicy",
        "iam:CreateRole",
        "iam:CreateInstanceProfile",
        "iam:AddRoleToInstanceProfile",
        "iam:ListInstanceProfilesForRole",
```

```
        "iam:GetRole"
      ],
      "Resource": "arn:aws:iam::*:role/ecsExternalInstanceRole"
    },
    {
      "Effect": "Allow",
      "Action": ["iam:PassRole", "ssm:CreateActivation"],
      "Resource": "arn:aws:iam::*:role/ecsExternalInstanceRole"
    }
  ]
}
```

## Permissions required for registering a task definition

You need additional permissions when you register a task definition and you want to create a new task execution (`ecsTaskExecutionRole`) role.

The following additional permissions are required:

- `iam`– Allows principals to create and list IAM roles and their attached policies.
  - `iam:AttachRolePolicy`
  - `iam:CreateRole`
  - `iam:GetRole`

### Note

In order to choose an existing `ecsTaskExecutionRole`, you must have the `iam:GetRole` permission.

The following policy contains the required permissions, and limits the actions to the `ecsTaskExecutionRole` role.

JSON

```
{
  "Statement": [
    {
```

```

    "Effect": "Allow",
    "Action": [
        "iam:AttachRolePolicy",
        "iam:CreateRole",
        "iam:GetRole"
    ],
    "Resource": "arn:aws:iam::*:role/ecsTaskExecutionRole"
}
]
}

```

## Permissions required for using Amazon Q Developer to provide recommendations in the console

For Amazon Q Developer to provide recommendations in the Amazon ECS; console, you must enable the correct IAM permissions for either your IAM user or role. You must add the `codewhisperer:GenerateRecommendations` permission.

JSON

```

{
  "Statement": [
    {
      "Sid": "AmazonQDeveloperPermissions",
      "Effect": "Allow",
      "Action": ["codewhisperer:GenerateRecommendations"],
      "Resource": "*"
    }
  ]
}

```

To use inline chat in the Amazon ECS; console, you must enable the correct IAM permissions for either your IAM user or role. You must add the `q:SendMessage` permission.:

JSON

```

{
  "Statement": [

```

```
{
  "Sid": "AmazonQDeveloperInlineChatPermissions",
  "Effect": "Allow",
  "Action": ["q:SendMessage"],
  "Resource": "*"
}
```

## Permissions required for creating an EventBridge rule for scheduled tasks

You need additional permissions when you schedule a task and you want to create a new CloudWatch Events role (`ecsEventsRole`) role.

The following additional permissions are required:

- `iam`– Allows principals to create and list IAM roles and their attached policies, and to allow Amazon ECS to pass the role to other services to assume the role.

### Note

In order to choose an existing `ecsEventsRole`, you must have the `iam:GetRole` and `iam:PassRole` permissions.

The following policy contains the required permissions, and limits the actions to the `ecsEventsRole` role.

JSON

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:AttachRolePolicy",
        "iam:CreateRole",
        "iam:GetRole",
        "iam:PassRole"
      ]
    }
  ]
}
```

```
    ],  
    "Resource": "arn:aws:iam::*:role/ecsEventsRole"  
  }  
]  
}
```

## Permissions required for viewing service deployments

When you follow the best practice of granting least privilege, you need to add additional permissions in order to view service deployments in the console.

You need access to the following actions:

- `ListServiceDeployments`
- `DescribeServiceDeployments`
- `DescribeServiceRevisions`

You need access to the following resources:

- Service
- Service deployment
- Service revision

The following example policy contains the required permissions, and limits the actions to a specified service.

Replace the account, cluster-name, and service-name with your values.

JSON

```
{  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "ecs:ListServiceDeployments",  
        "ecs:DescribeServiceDeployments",
```

```

        "ecs:DescribeServiceRevisions"
    ],
    "Resource": [
        "arn:aws:ecs:us-east-1:123456789012:service/cluster-name/service-
name",
        "arn:aws:ecs:us-east-1:123456789012:service-deployment/cluster-name/
service-name/*",
        "arn:aws:ecs:us-east-1:123456789012:service-revision/cluster-name/
service-name/*"
    ]
}
]
}

```

## Permissions required to view Amazon ECS lifecycle events in Container Insights

The following permissions are required to view the lifecycle events. Add the following permissions as an inline policy to the role. For more information, see [Adding and Removing IAM Policies](#)

- events:DescribeRule
- events:ListTargetsByRule
- logs:DescribeLogGroups

### JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "events:DescribeRule",
        "events:ListTargetsByRule",
        "logs:DescribeLogGroups"
      ],
      "Resource": "*"
    }
  ]
}

```

## Permissions required for enabling Amazon ECS lifecycle events in Container Insights

The following permissions are required to configure the lifecycle events:

- events:PutRule
- events:PutTargets
- logs:CreateLogGroup

### JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "events:PutRule",
        "events:PutTargets",
        "logs:CreateLogGroup"
      ],
      "Resource": "*"
    }
  ]
}
```

## Permissions required for the Amazon ECS console with CloudFormation

Before using the AWS Management Console to create your resources, you'll need to make sure to have the correct IAM permissions. For information on how to set up permissions for the Amazon ECS console in general first, see [Permissions required for the Amazon ECS console](#).

The Amazon ECS console is powered by AWS CloudFormation and requires additional IAM permissions in the following cases:

- Creating a cluster
- Creating a service
- Creating a capacity provider

You can create a policy for the additional permissions, and then attach them to the IAM role you use to access the console. For more information, see [Creating IAM policies](#) in the *IAM User Guide*.

## Permissions required for creating a cluster

When you create a cluster in the console, you need additional permissions that grant you permissions to manage CloudFormation stacks.

The following additional permissions are required:

- `cloudformation` – Allows principals to create and manage CloudFormation stacks. This is required when creating Amazon ECS clusters using the AWS Management Console and the subsequent managing of those clusters.
- `ssm` – Allows CloudFormation to reference latest Amazon ECS-optimized AMI. This is required when creating Amazon ECS clusters using the AWS Management Console.

The following policy contains the required CloudFormation permissions, and limits the actions to resources created in the Amazon ECS console.

JSON

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudformation:CreateStack",
        "cloudformation>DeleteStack",
        "cloudformation:DescribeStack*",
        "cloudformation:UpdateStack"
      ],
      "Resource": [
        "arn:*:cloudformation:*:*:stack/Infra-ECS-Cluster-*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": "ssm:GetParameters",
      "Resource": [
        "arn:aws:ssm:*:*:parameter/aws/service/ecs/optimized-ami/amazon-
linux-2*/*",

```

```

        "arn:aws:ssm:*:*:parameter/aws/service/ecs/optimized-ami/amazon-
linux-2023*/**"
    ]
}
]
}

```

If you have not created the Amazon ECS container instance role (`ecsInstanceRole`), and you are creating a cluster that uses Amazon EC2 instances, then the console will create the role on your behalf.

In addition, if you use Auto Scaling groups, then you need additional permissions so that the console can add tags to the auto scaling groups when using the cluster auto scaling feature.

The following additional permissions are required:

- `autoscaling` – Allows the console to tag Amazon EC2 Auto Scaling group. This is required when managing Amazon EC2 auto scaling groups when using the cluster auto scaling feature. The tag is the ECS-managed tag that the console automatically adds to the group to indicate it was created in the console.
- `iam` – Allows principals to list IAM roles and their attached policies. Principals can also list instance profiles available to your Amazon EC2 instances.

The following policy contains the required IAM permissions, and limits the actions to the `ecsInstanceRole` role.

The Auto Scaling permissions are not limited.

JSON

```

{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:AttachRolePolicy",
        "iam:CreateRole",
        "iam:CreateInstanceProfile",
        "iam:AddRoleToInstanceProfile",

```

```

        "iam:ListInstanceProfilesForRole",
        "iam:GetRole"
    ],
    "Resource": "arn:aws:iam::*:role/ecsInstanceRole"
},
{
    "Effect": "Allow",
    "Action": "autoscaling:CreateOrUpdateTags",
    "Resource": "*"
}
]
}

```

## Permissions required for creating a service

When you create a service in the console, you need additional permissions that grant you permissions to manage CloudFormation stacks. The following additional permissions are required:

- **cloudformation** – Allows principals to create and manage CloudFormation stacks. This is required when creating Amazon ECS services using the AWS Management Console and the subsequent managing of those services.

The following policy contains the required permissions, and limits the actions to resources created in the Amazon ECS console.

JSON

```

{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudformation:CreateStack",
        "cloudformation:DeleteStack",
        "cloudformation:DescribeStack*",
        "cloudformation:UpdateStack"
      ],
      "Resource": [
        "arn:*:cloudformation:*:*:stack/ECS-Console-V2-Service-*"
      ]
    }
  ]
}

```

```
}  
]  
}
```

## Permissions required for Lambda functions in Amazon ECS blue/green deployments

When you use Lambda functions as deployment lifecycle hooks in Amazon ECS blue/green deployments, you need to create an IAM role with specific permissions. This role allows Amazon ECS to invoke your Lambda functions at various stages of the deployment lifecycle.

The following additional permissions are required:

- `lambda:InvokeFunction` – Allows Amazon ECS to invoke Lambda functions configured as lifecycle hooks during the deployment process.

For the trust policy, you need to allow the service to assume this role:

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Principal": {  
        "Service": [  
          "ecs.amazonaws.com"  
        ]  
      },  
      "Action": "sts:AssumeRole"  
    }  
  ]  
}
```

## IAM permissions required for Amazon ECS service auto scaling

Service Auto Scaling is made possible by a combination of the Amazon ECS, CloudWatch, and Application Auto Scaling APIs. Services are created and updated with Amazon ECS, alarms are created with CloudWatch, and scaling policies are created with Application Auto Scaling.

In addition to the standard IAM permissions for creating and updating services, the following permissions are required to interact with Service Auto Scaling settings.

- `application-autoscaling:*`
- `ecs:DescribeServices`
- `ecs:UpdateService`
- `cloudwatch:DescribeAlarms`
- `cloudwatch:PutMetricAlarm`
- `cloudwatch>DeleteAlarms`
- `cloudwatch:DescribeAlarmHistory`
- `cloudwatch:DescribeAlarmsForMetric`
- `cloudwatch:GetMetricStatistics`
- `cloudwatch:ListMetrics`
- `cloudwatch:DisableAlarmActions`
- `cloudwatch:EnableAlarmActions`
- `iam:CreateServiceLinkedRole`
- `sns:CreateTopic`
- `sns:Subscribe`
- `sns:Get*`
- `sns:List*`

The Application Auto Scaling service also needs permission to describe your Amazon ECS services and CloudWatch alarms, and permissions to modify your service's desired count on your behalf. The `sns:` permissions are for the notifications that CloudWatch sends to an Amazon SNS topic when a threshold has been exceeded. If you use automatic scaling for your Amazon ECS services, it creates a service-linked role named `AWSServiceRoleForApplicationAutoScaling_ECSService`. This service-linked role grants Application Auto Scaling permission to describe the alarms for your policies, to monitor the current running task count of the service, and to modify the desired

count of the service. The original managed Amazon ECS role for Application Auto Scaling was `ecsAutoscaleRole`, but it is no longer required. The service-linked role is the default role for Application Auto Scaling. For more information, see [Service-linked roles for Application Auto Scaling](#) in the *Application Auto Scaling User Guide*.

If you created your Amazon ECS container instance role before CloudWatch metrics are available for Amazon ECS, you might need to add the `ecs:StartTelemetrySession` permission. For more information, see [Considerations](#).

## Grant permission to tag resources on creation

The following tag-on create Amazon ECS API actions allow you to specify tags when you create the resource. If tags are specified in the resource-creating action, AWS performs additional authorization to verify that the correct permissions are assigned to create tags.

- `CreateCapacityProvider`
- `CreateCluster`
- `CreateService`
- `CreateTaskSet`
- `RegisterContainerInstance`
- `RegisterTaskDefinition`
- `RunTask`
- `StartTask`

You can use resource tags to implement attribute-based control (ABAC). For more information, see [the section called “Control access to Amazon ECS resources using resource tags”](#) and [Tagging resources](#).

To allow tagging on creation, create or modify a policy to include both the permissions to use the action that creates the resource, such as `ecs:CreateCluster` or `ecs:RunTask` and the `ecs:TagResource` action.

The following example demonstrates a policy that allows users to create clusters and add tags during the cluster creation. Users are not permitted to tag any existing resources (they cannot call the `ecs:TagResource` action directly).

```
{
```

```

"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "ecs:CreateCluster"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": [
      "ecs:TagResource"
    ],
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "ecs:CreateAction": [
          "CreateCluster",
          "CreateCapacityProvider",
          "CreateService",
          "CreateTaskSet",
          "RegisterContainerInstance",
          "RegisterTaskDefinition",
          "RunTask",
          "StartTask"
        ]
      }
    }
  }
]
}

```

The `ecs:TagResource` action is only evaluated if tags are applied during the resource-creating action. Therefore, a user that has permissions to create a resource (assuming there are no tagging conditions) does not require permissions to use the `ecs:TagResource` action if no tags are specified in the request. However, if the user attempts to create a resource with tags, the request fails if the user does not have permissions to use the `ecs:TagResource` action.

## Amazon ECS control access to specific tags

You can use additional conditions in the `Condition` element of your IAM policies to control the tag keys and values that can be applied to resources.

The following condition keys can be used with the examples in the preceding section:

- `aws:RequestTag`: To indicate that a particular tag key or tag key and value must be present in a request. Other tags can also be specified in the request.
- Use with the `StringEquals` condition operator to enforce a specific tag key and value combination, for example, to enforce the tag `cost-center=cc123`:

```
"StringEquals": { "aws:RequestTag/cost-center": "cc123" }
```

- Use with the `StringLike` condition operator to enforce a specific tag key in the request; for example, to enforce the tag key `purpose`:

```
"StringLike": { "aws:RequestTag/purpose": "*" }
```

- `aws:TagKeys`: To enforce the tag keys that are used in the request.
- Use with the `ForAllValues` modifier to enforce specific tag keys if they are provided in the request (if tags are specified in the request, only specific tag keys are allowed; no other tags are allowed). For example, the tag keys `environment` or `cost-center` are allowed:

```
"ForAllValues:StringEquals": { "aws:TagKeys": ["environment","cost-center"] }
```

- Use with the `ForAnyValue` modifier to enforce the presence of at least one of the specified tag keys in the request. For example, at least one of the tag keys `environment` or `webserver` must be present in the request:

```
"ForAnyValue:StringEquals": { "aws:TagKeys": ["environment","webserver"] }
```

These condition keys can be applied to resource-creating actions that support tagging, as well as the `ecs:TagResource` action. To learn whether an Amazon ECS API action supports tagging, see [Actions, resources, and condition keys for Amazon ECS](#).

To force users to specify tags when they create a resource, you must use the `aws:RequestTag` condition key or the `aws:TagKeys` condition key with the `ForAnyValue` modifier on the resource-creating action. The `ecs:TagResource` action is not evaluated if a user does not specify tags for the resource-creating action.

For conditions, the condition key is not case-sensitive and the condition value is case-sensitive. Therefore, to enforce the case-sensitivity of a tag key, use the `aws:TagKeys` condition key, where the tag key is specified as a value in the condition.

For more information about multi-value conditions, see [Conditions with multiple context keys or values](#) in the *IAM User Guide*.

## Control access to Amazon ECS resources using resource tags

When you create an IAM policy that grants users permission to use Amazon ECS resources, you can include tag information in the `Condition` element of the policy to control access based on tags. This is known as attribute-based access control (ABAC). ABAC provides better control over which resources a user can modify, use, or delete. For more information, see [What is ABAC for AWS?](#)

For example, you can create a policy that allows users to delete a cluster, but denies the action if the cluster has the tag `environment=production`. To do this, you use the `aws:ResourceTag` condition key to allow or deny access to the resource based on the tags that are attached to the resource.

```
"StringEquals": { "aws:ResourceTag/environment": "production" }
```

To learn whether an Amazon ECS API action supports controlling access using the `aws:ResourceTag` condition key, see [Actions, resources, and condition keys for Amazon ECS](#). Note that the `Describe` actions do not support resource-level permissions, so you must specify them in a separate statement without conditions.

For example IAM policies, see [Amazon ECS Example policies](#).

If you allow or deny users access to resources based on tags, you must consider explicitly denying users the ability to add those tags to or remove them from the same resources. Otherwise, it's possible for a user to circumvent your restrictions and gain access to a resource by modifying its tags.

## Amazon ECS Example policies

You can use IAM policies to grant users permissions to view and work with specific resources in the Amazon ECS console. You can use the example policies in the previous section; however, they are designed for requests that are made with the AWS CLI or an AWS SDK.

## Example: Allow users to delete an Amazon ECS cluster based on tags

The following policy allows users to delete clusters when the tag has a key/value pair of "Purpose/Testing".

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ecs:DeleteCluster"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:ecs:us-east-1:111122223333:cluster/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Purpose": "Testing"
        }
      }
    }
  ]
}
```

## Troubleshooting Amazon Elastic Container Service identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon ECS and IAM.

### Topics

- [I am not authorized to perform an action in Amazon ECS](#)
- [I am not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my AWS account to access my Amazon ECS resources](#)
- [I am having issues with my Amazon ECS Managed Instances instance profile](#)
- [Additional troubleshooting resources](#)

## I am not authorized to perform an action in Amazon ECS

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional `my-example-widget` resource but doesn't have the fictional `ecs:GetWidget` permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
ecs:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the `my-example-widget` resource by using the `ecs:GetWidget` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

## I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Amazon ECS.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Amazon ECS. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

If you use Amazon ECS Managed Instances and receive this error, your instance role name might not match the naming convention required by the managed policy. For more information, see [I am having issues with my Amazon ECS Managed Instances instance profile](#).

## I want to allow people outside of my AWS account to access my Amazon ECS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon ECS supports these features, see [How Amazon Elastic Container Service works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

## I am having issues with my Amazon ECS Managed Instances instance profile

If you use the `AmazonECSInfrastructureRolePolicyForManagedInstances` managed policy, the instance role name must start with `ecsInstanceRole`. The policy scopes `iam:PassRole` to `arn:aws:iam::*:role/ecsInstanceRole*`, so a mismatched name causes an authorization error at task launch.

This is common with CloudFormation when you omit `RoleName` from your `AWS::IAM::Role` resource, because CloudFormation auto-generates names like `MyStack-InstanceRole-ABC123` that do not match the policy condition.

To resolve this issue, do one of the following:

- Add `RoleName: ecsInstanceRole` to your `AWS::IAM::Role` resource so the name matches the managed policy.
- Add an explicit `iam:PassRole` inline policy to your infrastructure role that targets the instance role ARN.

For CloudFormation templates and detailed steps, see [Create the instance profile using CloudFormation](#).

## Additional troubleshooting resources

The following pages provide information about error codes:

- [Amazon ECS stopped tasks error messages](#)
- [Viewing Amazon ECS service event messages](#)

## IAM best practices for Amazon ECS

You can use AWS Identity and Access Management (IAM) to manage and control access to your AWS services and resources through rule-based policies for authentication and authorization purposes. More specifically, through this service, you control access to your AWS resources by using policies that are applied to users, groups, or roles. Among these three, users are accounts that can have access to your resources. And, an IAM role is a set of permissions that can be assumed by an authenticated identity, which isn't associated with a particular identity outside of IAM. For more information, see [Amazon ECS overview of access management: Permissions and policies](#).

### Follow the policy of least privileged access

Create policies that are scoped to allow users to perform their prescribed jobs. For example, if a developer needs to periodically stop a task, create a policy that only permits that particular action. The following example only allows a user to stop a task that belongs to a particular `task_family` on a cluster with a specific Amazon Resource Name (ARN). Referring to an ARN in a condition is also an example of using resource-level permissions. You can use resource-level permissions to specify the resource that you want an action to apply to. For more information, see [Policy resources for Amazon ECS](#).

## Have cluster resources serve as the administrative boundary

Policies that are too narrowly scoped can cause a proliferation of roles and increase administrative overhead. Rather than creating roles that are scoped to particular tasks or services only, create roles that are scoped to clusters and use the cluster as your primary administrative boundary.

## Create automated pipelines to isolate end-users from the API

You can limit the actions that users can use by creating pipelines that automatically package and deploy applications onto Amazon ECS clusters. This effectively delegates the job of creating, updating, and deleting tasks to the pipeline. For more information, see [Tutorial: Amazon ECS standard deployment with CodePipeline](#) in the *AWS CodePipeline User Guide*.

## Use policy conditions for an added layer of security

When you need an added layer of security, add a condition to your policy. This can be useful if you're performing a privileged operation or when you need to restrict the set of actions that can be performed against particular resources. The following example policy requires multi-factor authorization when deleting a cluster.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:DeleteCluster"
      ],
      "Condition": {
        "Bool": {
          "aws:MultiFactorAuthPresent": "true"
        }
      },
      "Resource": ["*"]
    }
  ]
}
```

Tags applied to services are propagated to all the tasks that are part of that service. Because of this, you can create roles that are scoped to Amazon ECS resources with specific tags. In the following policy, an IAM principal starts and stops all tasks with a tag-key of Department and a tag-value of Accounting.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:StartTask",
        "ecs:StopTask",
        "ecs:RunTask"
      ],
      "Resource": "arn:aws:ecs:us-east-1:123456789012:cluster/my-cluster",
      "Condition": {
        "StringEquals": {"ecs:ResourceTag/Department": "Accounting"}
      }
    }
  ]
}
```

## Periodically audit access to the APIs

A user might change roles. After they change roles, the permissions that were previously granted to them might no longer apply. Make sure that you audit who has access to the Amazon ECS APIs and whether that access is still warranted. Consider integrating IAM with a user lifecycle management solution that automatically revokes access when a user leaves the organization. For more information, see [AWS security audit guidelines](#) in the *AWS Identity and Access Management User Guide*.

## Logging and Monitoring in Amazon Elastic Container Service

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Elastic Container Service and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one

occurs. AWS provides several tools for monitoring your Amazon ECS resources and responding to potential incidents:

## Amazon CloudWatch Alarms

Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see [Monitor Amazon ECS using CloudWatch](#).

For services with tasks that use Fargate, you can use CloudWatch alarms to scale in and scale out the tasks in your service based on CloudWatch metrics, such as CPU and memory utilization. For more information, see [Automatically scale your Amazon ECS service](#).

For clusters with tasks or services using EC2, you can use CloudWatch alarms to scale in and scale out the container instances based on CloudWatch metrics, such as cluster memory reservation.

## Amazon CloudWatch Logs

Monitor, store, and access the log files from the containers in your Amazon ECS tasks by specifying the `awslogs` log driver in your task definitions. For more information, see [Using the awslogs driver](#).

You can also monitor, store, and access the operating system and Amazon ECS container agent log files from your Amazon ECS container instances. This method for accessing logs can be used for containers using EC2..

## Amazon CloudWatch Events

Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see [Automate responses to Amazon ECS errors using EventBridge](#) in this guide and [EventBridge is the evolution of Amazon CloudWatch Events](#) in the *Amazon EventBridge User Guide*.

## AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon ECS. Using the information collected by CloudTrail, you can determine the request that was made to Amazon ECS, the IP address from which the request was made, who made the request, when

it was made, and additional details. For more information, see [Log Amazon ECS API calls using AWS CloudTrail](#).

## AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

For more information, see [AWS Trusted Advisor](#) in the *Support User Guide*.

## AWS Compute Optimizer

AWS Compute Optimizer is a service that analyzes the configuration and utilization metrics of your AWS resources. It reports whether your resources are optimal, and generates optimization recommendations to reduce the cost and improve the performance of your workloads.

For more information, see [AWS Compute Optimizer recommendations for Amazon ECS](#).

Another important part of monitoring Amazon ECS involves manually monitoring those items that the CloudWatch alarms don't cover. The CloudWatch, Trusted Advisor, and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your container instances and the containers in your tasks.

# Compliance validation for Amazon Elastic Container Service

Our new AWS sign-up experience is not designed for regulated workloads. If you're using our new AWS sign-up experience, but you want to use AWS for regulated workloads, you can [sign up for AWS \(advanced\)](#) or [activate advanced features](#) for your AWS environment.

To learn whether an AWS service is within the scope of specific compliance programs, see [AWS services in Scope by Compliance Program](#) and choose the compliance program that you are interested in. For general information, see [AWS Compliance Programs](#).

You can download third-party audit reports using AWS Artifact. For more information, see [Downloading Reports in AWS Artifact](#).

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. For more

information about your compliance responsibility when using AWS services, see [AWS Security Documentation](#).

## Compliance and security best practices for Amazon ECS

Your compliance responsibility when using Amazon ECS is determined by the sensitivity of your data, the compliance objectives of your company, and applicable laws and regulations.

### Payment Card Industry Data Security Standards (PCI DSS)

It's important that you understand the complete flow of cardholder data (CHD) within the environment when adhering to PCI DSS. The CHD flow determines the applicability of the PCI DSS, defines the boundaries and components of a cardholder data environment (CDE), and therefore the scope of a PCI DSS assessment. Accurate determination of the PCI DSS scope is key to defining the security posture and ultimately a successful assessment. Customers must have a procedure for scope determination that assures its completeness and detects changes or deviations from the scope.

The temporary nature of containerized applications provides additional complexities when auditing configurations. As a result, customers need to maintain an awareness of all container configuration parameters to ensure compliance requirements are addressed throughout all phases of a container lifecycle.

For additional information on achieving PCI DSS compliance on Amazon ECS, refer to the following whitepapers.

- [Architecting on Amazon ECS for PCI DSS compliance](#)

### HIPAA (U.S. Health Insurance Portability and Accountability Act)

Using Amazon ECS with workloads that process protected health information (PHI) requires no additional configuration. Amazon ECS acts as an orchestration service that coordinates the launch of containers on Amazon EC2. It doesn't operate with or upon data within the workload being orchestrated. Consistent with HIPAA regulations and the AWS Business Associate Addendum, PHI should be encrypted in transit and at-rest when accessed by containers launched with Amazon ECS.

Various mechanisms for encrypting at-rest are available with each AWS storage option, such as Amazon S3, Amazon EBS, and AWS KMS. You can deploy an overlay network (such as VNS3 or Weave Net) to ensure complete encryption of PHI transferred between containers or to provide a redundant layer of encryption. You should also use complete logging, and direct all container logs

to Amazon CloudWatch. For information about using the best practices for infrastructure security, see [Infrastructure Protection](#) in *Security Pillar AWS Well-Architected Framework*.

## AWS Security Hub CSPM

Use AWS Security Hub CSPM. This AWS service provides a comprehensive view of your security state within AWS. Security Hub CSPM uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see [Security Hub CSPM controls reference](#).

## Amazon GuardDuty with Amazon ECS Runtime Monitoring

Amazon GuardDuty is a threat detection service that helps protect your accounts, containers, workloads, and the data within your AWS environment. Using machine learning (ML) models, and anomaly and threat detection capabilities, GuardDuty continuously monitors different log sources and runtime activity to identify and prioritize potential security risks and malicious activities in your environment.

Use Runtime Monitoring in GuardDuty to identify malicious or unauthorized behavior. Runtime Monitoring protects workloads running on Fargate and EC2 by continuously monitoring AWS log and networking activity to identify malicious or unauthorized behavior. Runtime Monitoring uses a lightweight, fully managed GuardDuty security agent that analyzes on-host behavior, such as file access, process execution, and network connections. This covers issues including escalation of privileges, use of exposed credentials, or communication with malicious IP addresses, domains, and the presence of malware on your Amazon EC2 instances and container workloads. For more information, see [GuardDuty Runtime Monitoring](#) in the *GuardDuty User Guide*.

## Compliance recommendations

We recommend that you engage the compliance program owners within your business early and use the AWS shared responsibility model to identify compliance control ownership for success with the relevant compliance programs. For more information, see [AWS shared responsibility model for Amazon ECS](#).

## AWS Fargate Federal Information Processing Standard (FIPS-140)

Federal Information Processing Standard (FIPS-140) is a U.S. and Canadian government standard that specifies the security requirements for cryptographic modules that protect sensitive

information. FIPS-140 defines a set of validated cryptography functions that can be used to encrypt data in transit and data at rest.

When you turn on FIPS-140 compliance, you can run workloads on Fargate in a manner that is compliant with FIPS-140. For more information about FIPS-140 compliance, see [Federal Information Processing Standard \(FIPS\) 140-3](#).

## AWS Fargate FIPS-140 Considerations

Consider the following when using FIPS-140 compliance on Fargate:

- FIPS-140 compliance is only available in the AWS GovCloud (US) Regions.
- Fargate supports FIPS-140 version 140.3
- FIPS-140 compliance is turned off by default. You must turn it on.
- Amazon CloudWatch doesn't support a dualstack FIPS endpoint that can be used to monitor Amazon ECS tasks in IPv6-only configuration that use FIPS-140 compliance.
- Your tasks must use the following configuration for FIPS-140 compliance:
  - The `operatingSystemFamily` must be `LINUX`.
  - The `cpuArchitecture` must be `X86_64`.
  - The Fargate platform version must be `1.4.0` or later.

## Use FIPS on Fargate

Use the following procedure to use FIPS-140 compliance on Fargate.

1. Turn on FIPS-140 compliance. For more information, see [the section called “AWS Fargate Federal Information Processing Standard \(FIPS-140\) compliance”](#).
2. You can optionally use ECS Exec to run the following command to verify the FIPS-140 compliance status for a cluster.

Replace *cluster-name* with the name of your cluster, *task-id* with the ID or ARN of your task, and *container-name* with the name of the container in your task you want to run the command against.

A return value of "1" indicates that you are using FIPS.

```
aws ecs execute-command \
```

```
--cluster cluster-name \  
--task task-id \  
--container container-name \  
--interactive \  
--command "cat /proc/sys/crypto/fips_enabled"
```

## Use CloudTrail for Fargate FIPS-140 auditing

CloudTrail is turned on in your AWS account when you create the account. When API and console activity occurs in Amazon ECS, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for Amazon ECS, create a trail which CloudTrail uses to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see [the section called “Log Amazon ECS API calls using AWS CloudTrail”](#).

The following example shows a CloudTrail log entry that demonstrates the PutAccountSettingDefault API action:

```
{  
  "eventVersion": "1.08",  
  "userIdentity": {  
    "type": "IAMUser",  
    "principalId": "AIDAIIV5AJI5LXF5EXAMPLE",  
    "arn": "arn:aws:iam::123456789012:user/jdoe",  
    "accountId": "123456789012",  
    "accessKeyId": "AKIAIPWIOFC3EXAMPLE",  
  },  
  "eventTime": "2023-03-01T21:45:18Z",  
  "eventSource": "ecs.amazonaws.com",  
  "eventName": "PutAccountSettingDefault",  
  "awsRegion": "us-gov-east-1",  
  "sourceIPAddress": "52.94.133.131",  
  "userAgent": "aws-cli/2.9.8 Python/3.9.11 Windows/10 exe/AMD64 prompt/off command/  
ecs.put-account-setting",  
}
```

```

    "requestParameters": {
      "name": "fargateFIPSMODE",
      "value": "enabled"
    },
    "responseElements": {
      "setting": {
        "name": "fargateFIPSMODE",
        "value": "enabled",
        "principalArn": "arn:aws:iam::123456789012:user/jdoe"
      }
    },
    "requestID": "acdc731e-e506-447c-965d-f5f75EXAMPLE",
    "eventID": "6afced68-75cd-4d44-8076-0beEXAMPLE",
    "readOnly": false,
    "eventType": "AwsApiCall",
    "managementEvent": true,
    "recipientAccountId": "123456789012",
    "eventCategory": "Management",
    "tlsDetails": {
      "tlsVersion": "TLSv1.2",
      "cipherSuite": "ECDHE-RSA-AES128-GCM-SHA256",
      "clientProvidedHostHeader": "ecs-fips.us-gov-east-1.amazonaws.com"
    }
  }
}

```

## Infrastructure Security in Amazon Elastic Container Service

As a managed service, Amazon Elastic Container Service is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see [AWS Cloud Security](#). To design your AWS environment using the best practices for infrastructure security, see [Infrastructure Protection](#) in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access Amazon ECS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

You can call these API operations from any network location. Amazon ECS supports resource-based access policies, which can include restrictions based on the source IP address, so make sure that the policies account for the IP address for the network location. You can also use Amazon ECS policies to control access from specific Amazon Virtual Private Cloud endpoints or specific VPCs. Effectively, this isolates network access to a given Amazon ECS resource from only the specific VPC within the AWS network. For more information, see [Amazon ECS interface VPC endpoints \(AWS PrivateLink\)](#).

## Amazon ECS interface VPC endpoints (AWS PrivateLink)

You can improve the security posture of your VPC by configuring Amazon ECS to use an interface VPC endpoint. Interface endpoints are powered by AWS PrivateLink, a technology that allows you to privately access Amazon ECS APIs by using private IP addresses. AWS PrivateLink restricts all network traffic between your VPC and Amazon ECS to the Amazon network. You don't need an internet gateway, a NAT device, or a virtual private gateway.

For more information about AWS PrivateLink and VPC endpoints, see [VPC endpoints](#) in the *Amazon VPC User Guide*.

## Considerations

### Considerations for endpoints in Regions introduced starting on December 23, 2023

Before you set up interface VPC endpoints for Amazon ECS, be aware of the following considerations:

- You must have the following Region-specific VPC endpoints:

#### Note

If you do not configure all of the endpoints, your traffic will go over the public endpoints, not your VPC endpoint.

- `com.amazonaws.region.ecs-agent`
- `com.amazonaws.region.ecs-telemetry`
- `com.amazonaws.region.ecs`

For example, the Canada West (Calgary) (ca-west-1) Region needs the following VPC endpoints:

- `com.amazonaws.ca-west-1.ecs-agent`

- `com.amazonaws.ca-west-1.ecs-telemetry`
- `com.amazonaws.ca-west-1.ecs`
- When you use a template to create AWS resources in the new Region and the template was copied from a Region introduced before December 23, 2023, depending on the copy-from Region, perform one of the following operations.

For example, the copy-from Region is US East (N. Virginia) (`us-east-1`). The copy-to Region is Canada West (Calgary) (`ca-west-1`).

| Configuration                                                  | Action                                                                                                                                                                                                                                                                                               |  |
|----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| The copied-from Region does not have any VPC endpoints.        | Create all three VPC endpoints for the new Region (for example, <code>com.amazonaws.ca-west-1.ecs-agent</code> ).                                                                                                                                                                                    |  |

## Considerations for Amazon ECS VPC endpoints for Fargate

When there is an VPC endpoint for `ecr.dkr` and `ecr.api` in the same VPC where a Fargate task is deployed into, it will use the VPC endpoint. If there is no VPC endpoint, it will use the Fargate interface.

Before you set up interface VPC endpoints for Amazon ECS, be aware of the following considerations:

- Tasks using Fargate don't require the interface VPC endpoints for Amazon ECS, but you might need interface VPC endpoints for Amazon ECR, Secrets Manager, or Amazon CloudWatch Logs described in the following points.
- To allow your tasks to pull private images from Amazon ECR, you must create the interface VPC endpoints for Amazon ECR. For more information, see [Interface VPC Endpoints \(AWS PrivateLink\)](#) in the *Amazon Elastic Container Registry User Guide*.

** Important**

- If you configure Amazon ECR to use an interface VPC endpoint, you can create a task execution role that includes condition keys to restrict access to a specific VPC or VPC endpoint. For more information, see [Fargate tasks pulling Amazon ECR images over interface endpoints permissions](#).
  - If your tasks are in an IPv6-only configuration and use an Amazon ECR dualstack image URI, note that Amazon ECR doesn't support dualstack interface VPC endpoints. For more information, see [Getting started with making requests over IPv6](#) in the *Amazon Elastic Container Registry User Guide*.
- To allow your tasks to pull sensitive data from Secrets Manager, you must create the interface VPC endpoints for Secrets Manager. For more information, see [Using Secrets Manager with VPC Endpoints](#) in the *AWS Secrets Manager User Guide*.
  - If your VPC doesn't have an internet gateway and your tasks use the `awslogs` log driver to send log information to CloudWatch Logs, you must create an interface VPC endpoint for CloudWatch Logs. For more information, see [Using CloudWatch Logs with Interface VPC Endpoints](#) in the *Amazon CloudWatch Logs User Guide*.
  - VPC endpoints currently don't support cross-Region requests. Ensure that you create your endpoint in the same Region where you plan to issue your API calls to Amazon ECS. For example, assume that you want to run tasks in US East (N. Virginia). Then, you must create the Amazon ECS VPC endpoint in US East (N. Virginia). An Amazon ECS VPC endpoint created in any other region can't run tasks in US East (N. Virginia).
  - VPC endpoints only support Amazon-provided DNS through Amazon Route 53. If you want to use your own DNS, you can use conditional DNS forwarding. For more information, see [DHCP Options Sets](#) in the *Amazon VPC User Guide*.
  - The security group attached to the VPC endpoint must allow incoming connections on TCP port 443 from the private subnet of the VPC.

- Service Connect management of the Envoy proxy uses the `com.amazonaws.region.ecs-agent` VPC endpoint. When you don't use the VPC endpoints, Service Connect management of the Envoy proxy uses the `ecs-sc` endpoint in that Region. For a list of the Amazon ECS endpoints in each Region, see [Amazon ECS endpoints and quotas](#).

## Considerations for Amazon ECS VPC endpoints for EC2

Before you set up interface VPC endpoints for Amazon ECS, be aware of the following considerations:

- Tasks using EC2 require that the container instances that they're launched on to run version 1.25.1 or later of the Amazon ECS container agent. For more information, see [Amazon ECS Linux container instance management](#).
- To allow your tasks to pull sensitive data from Secrets Manager, you must create the interface VPC endpoints for Secrets Manager. For more information, see [Using Secrets Manager with VPC Endpoints](#) in the *AWS Secrets Manager User Guide*.
- If your VPC doesn't have an internet gateway and your tasks use the `awslogs` log driver to send log information to CloudWatch Logs, you must create an interface VPC endpoint for CloudWatch Logs. For more information, see [Using CloudWatch Logs with Interface VPC Endpoints](#) in the *Amazon CloudWatch Logs User Guide*.
- VPC endpoints currently don't support cross-Region requests. Ensure that you create your endpoint in the same Region where you plan to issue your API calls to Amazon ECS. For example, assume that you want to run tasks in US East (N. Virginia). Then, you must create the Amazon ECS VPC endpoint in US East (N. Virginia). An Amazon ECS VPC endpoint created in any other Region can't run tasks in US East (N. Virginia).
- VPC endpoints only support Amazon-provided DNS through Amazon Route 53. If you want to use your own DNS, you can use conditional DNS forwarding. For more information, see [DHCP Options Sets](#) in the *Amazon VPC User Guide*.
- The security group attached to the VPC endpoint must allow incoming connections on TCP port 443 from the private subnet of the VPC.

## Understanding Amazon ECS endpoint naming patterns

The Amazon ECS container agent uses the [DiscoverPollEndpoint](#) API to find the agent and telemetry endpoints to connect to. The returned hostnames depend on whether the call uses the `com.amazonaws.region.ecs` interface VPC endpoint.

- When the call goes through the ecs interface VPC endpoint, the returned endpoints use the base private DNS names `ecs-a.region.amazonaws.com` and `ecs-t.region.amazonaws.com`. A numeric identifier appears in the URL path, for example `https://ecs-a.region.amazonaws.com/acs/1/`.
- When the call doesn't go through the ecs interface VPC endpoint, the returned endpoints can use numbered hostnames, such as `ecs-a-1.region.amazonaws.com` and `ecs-t-1.region.amazonaws.com`. These hostnames resolve to public endpoints.

You don't need to create DNS records for numbered hostnames. If you use your own Route 53 private hosted zones instead of the endpoint's private DNS, create hosted zones only for the following domains:

- `ecs.region.amazonaws.com`
- `ecs-a.region.amazonaws.com`
- `ecs-t.region.amazonaws.com`

## Troubleshooting agent connectivity through VPC endpoints

If your container instances connect to numbered hostnames such as `ecs-a-1.region.amazonaws.com`, the agent's `DiscoverPollEndpoint` call isn't going through the ecs interface VPC endpoint. Check the following from the container instance:

- `ecs.region.amazonaws.com` resolves to the private IP addresses of your ecs endpoint.
- If the agent uses an HTTP proxy, either the proxy resolves `ecs.region.amazonaws.com` to your ecs endpoint, or the hostname is in `NO_PROXY`. Otherwise the proxy can send the call over the public path even when DNS on the instance is correct. For more information, see [Using an HTTP proxy for Amazon ECS Linux container instances](#).

After the call goes through the ecs endpoint, the agent connects to `ecs-a.region.amazonaws.com` and `ecs-t.region.amazonaws.com`. Make sure that you also created the `ecs-agent` and `ecs-telemetry` interface VPC endpoints and that those hostnames resolve to their private IP addresses. For more information, see [Creating the VPC Endpoints for Amazon ECS](#).

## Creating the VPC Endpoints for Amazon ECS

To create the VPC endpoint for the Amazon ECS service, use the [Access an AWS service using an interface VPC endpoint](#) procedure in the *Amazon VPC User Guide* to create the following endpoints. If you have existing container instances within your VPC, you should create the endpoints in the order that they're listed. If you plan on creating your container instances after your VPC endpoint is created, the order doesn't matter.

### Note

If you do not configure all of the endpoints, your traffic will go over the public endpoints, not your VPC endpoint.

When you create endpoints, Amazon ECS also creates a private DNS name for the endpoint. For example, `ecs-a.region.amazonaws.com` for `ecs-agent` and `ecs-t.region.amazonaws.com` for `ecs-telemetry`.

- `com.amazonaws.region.ecs-agent`
- `com.amazonaws.region.ecs-telemetry`
- `com.amazonaws.region.ecs`

### Note

**region** represents the Region identifier for an AWS Region supported by Amazon ECS, such as `us-east-2` for the US East (Ohio) Region.

The `ecs-agent` endpoint uses the `ecs:poll` API, and the `ecs-telemetry` endpoint uses the `ecs:poll` and `ecs:StartTelemetrySession` API.

If you have existing tasks that are using the EC2 launch type, after you have created the VPC endpoints, each container instance needs to pick up the new configuration. For this to happen, you must either reboot each container instance or restart the Amazon ECS container agent on each container instance. To restart the container agent, do the following.

### To restart the Amazon ECS container agent

1. Log in to your container instance via SSH.

## 2. Stop the container agent.

```
sudo docker stop ecs-agent
```

## 3. Start the container agent.

```
sudo docker start ecs-agent
```

After you have created the VPC endpoints and restarted the Amazon ECS container agent on each container instance, all newly launched tasks pick up the new configuration.

## Creating a VPC endpoint policy for Amazon ECS

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon ECS. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

### Example: VPC endpoint policy for Amazon ECS actions

The following is an example of an endpoint policy for Amazon ECS. When attached to an endpoint, this policy grants access to permission to create and list clusters. The `CreateCluster` and `ListClusters` actions do not accept any resources, so the resource definition is set to `*` for all resources.

```
{
  "Statement": [
    {
      "Principal": "*",
      "Effect": "Allow",
      "Action": [
        "ecs:CreateCluster",
        "ecs:ListClusters"
      ],
      "Resource": "*"
    }
  ]
}
```

```
    "Resource": [
      "*"
    ]
  }
]
```

## AWS shared responsibility model for Amazon ECS

Security and Compliance is a shared responsibility between AWS and the customer. This shared model can help relieve the customer's operational burden as AWS operates, manages and controls the components from the host operating system and virtualization layer down to the physical security of the facilities in which the service operates. The customer assumes responsibility and management of the guest operating system (including updates and security patches), other associated application software as well as the configuration of the AWS provided security group firewall. Customers should carefully consider the services they choose as their responsibilities vary depending on the services used, the integration of those services into their IT environment, and applicable laws and regulations. The nature of this shared responsibility also provides the flexibility and customer control that permits the deployment.

### Fargate

The following illustration shows the shared responsibility model for the Fargate launch type. Fargate runs each workload in an isolated hardware virtualized environment. As a result, each task gets dedicated infrastructure capacity. Containerized workloads running on Fargate do not share an operating system, Linux kernel, network interface, ephemeral storage, CPU, or memory with other tasks. When using Fargate, customers are not responsible for securing the compute infrastructure that runs their containers. Fargate will provision and patch the infrastructure upon which customer workloads run. For more information, see [Task retirement and maintenance for AWS Fargate on Amazon ECS](#).

You are responsible for managing the following resources:

- Network configuration including VPC, NACLs, security groups, and route tables
- Client and service storage encryption. For more information, see [Storage options for Amazon ECS tasks](#).
- Container images. For more information, see [Amazon ECS task and container security best practices](#).

- IAM permissions for the applications by using the task role. For more information, see [Amazon ECS task IAM role](#).

#### AWS Shared Responsibility Model for Amazon ECS with Fargate

## EC2

The following illustration shows the shared responsibility for EC2. When you run tasks on EC2 instances you are responsible for maintaining your EC2 instances in addition to the following resources:

- The Amazon ECS agent.
- The EC2 instance AMI, including patching and hardening.
- Network configuration including VPC, NACLs, security groups, and route tables.
- Client and service storage encryption. For more information, see [Storage options for Amazon ECS tasks](#).
- Container images. For more information, see [Amazon ECS task and container security best practices](#).
- IAM permissions for the applications by using the task role. For more information, see [Amazon ECS task IAM role](#).
- Configuring container instances to block container access to the Amazon EC2 Instance Metadata Service (IMDS). For more information, see [Roles recommendations](#).

- Security considerations for co-located workloads. Unlike Fargate, there is no task isolation on EC2 container instances. Containers can potentially access credentials, environment variables, and temporary files from other tasks on the same instance, including data left behind by previously running tasks. For sensitive applications, configure your environment so that each application runs on dedicated instances.

The following diagram illustrates the shared responsibility model for EC2, showing which security responsibilities are managed by AWS and which are yours.

#### AWS Shared Responsibility Model for Amazon ECS

## Shared responsibility model for Amazon ECS Managed Instances

Amazon ECS Managed Instances provides a managed solution for containerized workloads that combines the operational simplicity of Fargate with access to the full range of Amazon EC2 instance types and capabilities. AWS handles infrastructure provisioning, patching, scaling, and maintenance while customers retain control over their applications and specific configurations.

Unlike Fargate, containerized workloads running on Amazon ECS Managed Instances share the operating system, Linux kernel, network interface, ephemeral storage, CPU, memory, and GPU resources with other tasks on the same instance. Amazon ECS optimizes infrastructure utilization by placing multiple tasks on larger instances to minimize unused capacity.

## AWS responsibilities

When using Amazon ECS Managed Instances, AWS is responsible for:

- Instance provisioning and lifecycle management
- Operating system patching and security updates
- Infrastructure scaling and optimization
- Instance replacement and maintenance (maximum 21-day instance lifetime)
- Access control restrictions (no SSH access, no SSM Session Manager access)
- Amazon EC2 Instance Storage encryption, which is storage directly attached to the instance. For more information, see [Data protection in Amazon EC2](#).
- Amazon ECS manages the volumes attached to Amazon EC2 instances at creation time, including root and data volumes.
- Amazon ECS uses Amazon EC2 managed instances under-the-hood. For more information about Amazon EC2 managed instances, see [Security in Amazon EC2](#).

## Customer responsibilities

You are responsible for managing the following resources:

- Network configuration including VPC, NACLs, security groups, and route tables
- Client and service storage encryption. For more information, see [Storage options for Amazon ECS tasks](#).
- Container images. For more information, see [Amazon ECS task and container security best practices](#).
- IAM permissions for the applications by using the task role. For more information, see [Amazon ECS task IAM role](#).
- Application-level configuration and monitoring
- Security monitoring of your containers
- Task and service definitions
- Security considerations for co-located workloads. Unlike Fargate, there is no task isolation on Amazon ECS Managed Instances. Containers can potentially access credentials, environment variables, and temporary files from other tasks on the same instance, including data left behind by previously running tasks.

- Privileged container configurations and enhanced Linux capabilities (CAP\_NET\_ADMIN, CAP\_BPF, CAP\_PERFMON, etc.) when enabled
- Management operations through Amazon ECS API (direct instance access via SSH or SSM is not available)

For information about AWS and customer responsibilities for Amazon ECS Managed Instances security, see [Security considerations for Amazon ECS Managed Instances](#).

The following diagram illustrates the shared responsibility model for Amazon ECS Managed Instances, showing which security responsibilities are managed by AWS and which are yours.

**AWS Shared Responsibility Model for Amazon ECS with Managed Instances**

## Network security best practices for Amazon ECS

Network security is a broad topic that encompasses several subtopics. These include encryption-in-transit, network segmentation and isolation, firewalling, traffic routing, and observability.

### Encryption in transit

Encrypting network traffic prevents unauthorized users from intercepting and reading data when that data is transmitted across a network. With Amazon ECS, network encryption can be implemented in any of the following ways.

- **Using Nitro instances:**

By default, traffic is automatically encrypted between the following Nitro instance types: C5n, G4, I3en, M5dn, M5n, P3dn, R5dn, and R5n. Traffic isn't encrypted when it's routed through a transit gateway, load balancer, or similar intermediary.

- [Encryption in transit](#)
- [What's new announcement from 2019](#)
- [This talk from re:Inforce 2019](#)
- **Using Server Name Indication (SNI) with an Application Load Balancer:**

The Application Load Balancer (ALB) and Network Load Balancer (NLB) support Server Name Indication (SNI). By using SNI, you can put multiple secure applications behind a single listener. For this, each has its own TLS certificate. We recommend that you provision certificates for the load balancer using AWS Certificate Manager (ACM) and then add them to the listener's certificate list. The AWS load balancer uses a smart certificate selection algorithm with SNI. If the hostname that's provided by a client matches a single certificate in the certificate list, the load balancer chooses that certificate. If a hostname that's provided by a client matches multiple certificates in the list, the load balancer selects a certificate that the client can support. Examples include self-signed certificate or a certificate generated through the ACM.

- [SNI with Application Load Balancer](#)
- [SNI with Network Load Balancer](#)
- **End-to-end encryption with TLS certificates:**

This involves deploying a TLS certificate with the task. This can either be a self-signed certificate or a certificate from a trusted certificate authority. You can obtain the certificate by referencing a secret for the certificate. Otherwise, you can choose to run a container that issues a Certificate Signing Request (CSR) to ACM and then mounts the resulting secret to a shared volume.

- [Maintaining transport layer security all the way to your containers using the Network Load Balancer with Amazon ECS part 1](#)
- [Maintaining Transport Layer Security \(TLS\) all the way to your container part 2: Using AWS Private Certificate Authority](#)

## Task networking

The following recommendations are in consideration of how Amazon ECS works. Amazon ECS doesn't use an overlay network. Instead, tasks are configured to operate in different network

modes. For example, tasks that are configured to use bridge mode acquire a non-routable IP address from a Docker network that runs on each host. Tasks that are configured to use the awsvpc network mode acquire an IP address from the subnet of the host. Tasks that are configured with host networking use the host's network interface. awsvpc is the preferred network mode. This is because it's the only mode that you can use to assign security groups to tasks. It's also the only mode that's available for AWS Fargate tasks on Amazon ECS.

## Security groups for tasks

We recommend that you configure your tasks to use the awsvpc network mode. After you configure your task to use this mode, the Amazon ECS agent automatically provisions and attaches an Elastic Network Interface (ENI) to the task. When the ENI is provisioned, the task is enrolled in an AWS security group. The security group acts as a virtual firewall that you can use to control inbound and outbound traffic.

If you use a custom firewall with tasks or services, add an outbound rule to allow traffic for the Amazon ECS agent management endpoints ("ecs-a-\*.*region*.amazonaws.com"), telemetry endpoints ("ecs-t-\*.*region*.amazonaws.com"), and the Service Connect Envoy management endpoints ("ecs-sc.*region*.api.aws").

If you use Amazon ECS Managed Instances, also add an outbound rule to allow traffic for the data plane endpoints ("ecs-d-\*.*region*.api.aws"). Your managed instances use these endpoints for system log delivery and other data plane operations.

## AWS PrivateLink and Amazon ECS

AWS PrivateLink is a networking technology that allows you to create private endpoints for different AWS services, including Amazon ECS. The endpoints are required in sandboxed environments where there is no Internet Gateway (IGW) attached to the Amazon VPC and no alternative routes to the Internet. Using AWS PrivateLink ensures that calls to the Amazon ECS service stay within the Amazon VPC and do not traverse the internet. For instructions on how to create AWS PrivateLink endpoints for Amazon ECS and other related services, see [Amazon ECS interface Amazon VPC endpoints](#).

### Important

AWS Fargate tasks don't require an AWS PrivateLink endpoint for Amazon ECS.

Amazon ECR and Amazon ECS both support endpoint policies. These policies allow you to refine access to a service's APIs. For example, you could create an endpoint policy for Amazon ECR that only allows images to be pushed to registries in particular AWS accounts. A policy like this could be used to prevent data from being exfiltrated through container images while still allowing users to push to authorized Amazon ECR registries. For more information, see [Use VPC endpoint policies](#).

The following policy allows all AWS principals in your account to perform all actions against only your Amazon ECR repositories:

```
{
  "Statement": [
    {
      "Sid": "LimitECRAccess",
      "Principal": "*",
      "Action": "*",
      "Effect": "Allow",
      "Resource": "arn:aws:ecr:region:account_id:repository/*"
    }
  ]
}
```

You can enhance this further by setting a condition that uses the new `PrincipalOrgID` property. This prevents pushing and pulling of images by an IAM principal that isn't part of your AWS Organizations. For more information, see [aws:PrincipalOrgID](#).

We recommended applying the same policy to both the `com.amazonaws.region.ecr.dkr` and the `com.amazonaws.region.ecr.api` endpoints.

## Container agent settings

The Amazon ECS container agent configuration file includes several environment variables that relate to network security. `ECS_AWSVPC_BLOCK_IMDS` and `ECS_ENABLE_TASK_IAM_ROLE_NETWORK_HOST` are used to block a task's access to Amazon EC2 metadata. `HTTP_PROXY` is used to configure the agent to route through a HTTP proxy to connect to the internet. For instructions on configuring the agent and the Docker runtime to route through a proxy, see [HTTP Proxy Configuration](#).

### Important

These settings aren't available when you use AWS Fargate.

## Network security recommendations

We recommend that you do the following when setting up your Amazon VPC, load balancers, and network.

### Use network encryption where applicable with Amazon ECS

You should use network encryption where applicable. Certain compliance programs, such as PCI DSS, require that you encrypt data in transit if the data contains cardholder data. If your workload has similar requirements, configure network encryption.

Modern browsers warn users when connecting to insecure sites. If your service is fronted by a public facing load balancer, use TLS/SSL to encrypt the traffic from the client's browser to the load balancer and re-encrypt to the backend if warranted.

### Use awsvpc network mode and security groups to control traffic between tasks and other resources in Amazon ECS

You should use awsvpc network mode and security groups when you need to control traffic between tasks and between tasks and other network resources. If your service is behind an ALB, use security groups to only allow inbound traffic from other network resources using the same security group as your ALB. If your application is behind an NLB, configure the task's security group to only allow inbound traffic from the Amazon VPC CIDR range and the static IP addresses assigned to the NLB.

Security groups should also be used to control traffic between tasks and other resources within the Amazon VPC such as Amazon RDS databases.

### Create Amazon ECS clusters in separate Amazon VPCs when network traffic needs to be strictly isolated

You should create clusters in separate Amazon VPCs when network traffic needs to be strictly isolated. Avoid running workloads that have strict security requirements on clusters with workloads that don't have to adhere to those requirements. When strict network isolation is mandatory, create clusters in separate Amazon VPCs and selectively expose services to other Amazon VPCs using Amazon VPC endpoints. For more information, see [VPC endpoints](#).

## Configure AWS PrivateLink endpoints when warranted for Amazon ECS

You should configure AWS PrivateLink endpoints when warranted. If your security policy prevents you from attaching an Internet Gateway (IGW) to your Amazon VPCs, configure AWS PrivateLink endpoints for Amazon ECS and other services such as Amazon ECR, AWS Secrets Manager, and Amazon CloudWatch.

## Use Amazon VPC Flow Logs to analyze the traffic to and from long-running tasks in Amazon ECS

You should use Amazon VPC Flow Logs to analyze the traffic to and from long-running tasks. Tasks that use `awsvpc` network mode get their own ENI. Doing this, you can monitor traffic that goes to and from individual tasks using Amazon VPC Flow Logs. A recent update to Amazon VPC Flow Logs (v3), enriches the logs with traffic metadata including the vpc ID, subnet ID, and the instance ID. This metadata can be used to help narrow an investigation. For more information, see [Amazon VPC Flow Logs](#).

### Note

Because of the temporary nature of containers, flow logs might not always be an effective way to analyze traffic patterns between different containers or containers and other network resources.

## Amazon ECS task and container security best practices

You should consider the container image as your first line of defense against an attack. An insecure, poorly constructed image can allow an attacker to escape the bounds of the container and gain access to the host. You should do the following to mitigate the risk of this happening.

We recommend that you do the following when setting up your tasks and containers.

### Create minimal or use distroless images

Start by removing all extraneous binaries from the container image. If you're using an unfamiliar image from Amazon ECR Public Gallery, inspect the image to refer to the contents of each of the container's layers. You can use an application such as [Dive](#) to do this.

Alternatively, you can use **distroless** images that only include your application and its runtime dependencies. They don't contain package managers or shells. Distroless images improve the "signal to noise of scanners and reduces the burden of establishing provenance to just what you need." For more information, see the GitHub documentation on [distroless](#).

Docker has a mechanism for creating images from a reserved, minimal image known as **scratch**. For more information, see [Creating a simple parent image using scratch](#) in the Docker documentation. With languages like Go, you can create a static linked binary and reference it in your Dockerfile. The following example shows how you can accomplish this.

```
#####
# STEP 1 build executable binary
#####
FROM golang:alpine AS builder
# Install git.
# Git is required for fetching the dependencies.
RUN apk update && apk add --no-cache git
WORKDIR $GOPATH/src/mypackage/myapp/
COPY . .
# Fetch dependencies.
# Using go get.
RUN go get -d -v
# Build the binary.
RUN go build -o /go/bin/hello
#####
# STEP 2 build a small image
#####
FROM scratch
# Copy our static executable.
COPY --from=builder /go/bin/hello /go/bin/hello
# Run the hello binary.
ENTRYPOINT ["/go/bin/hello"]
This creates a container image that consists of your application and nothing else,
making it extremely secure.
```

The previous example is also an example of a multi-stage build. These types of builds are attractive from a security standpoint because you can use them to minimize the size of the final image pushed to your container registry. Container images devoid of build tools and other extraneous binaries improves your security posture by reducing the attack surface of the image. For more information about multi-stage builds, see [Multi-stage builds](#) in the Docker documentation.

## Scan your images for vulnerabilities

Similar to their virtual machine counterparts, container images can contain binaries and application libraries with vulnerabilities or develop vulnerabilities over time. The best way to safeguard against exploits is by regularly scanning your images with an image scanner.

Amazon ECR provides two versions of basic scanning that use the Common Vulnerabilities and Exposures (CVEs) database:

- **AWS native basic scanning** – Uses AWS native technology, which is now GA and recommended. This improved basic scanning is designed to provide customers with better scanning results and vulnerability detection across a broad set of popular operating systems. This allows customers to further strengthen the security of their container images. All new customer registries are opted into this improved version by default.
- **Clair basic scanning** – The previous basic scanning version which uses the open-source Clair project and is deprecated. For more information about Clair, see [Clair](#) on GitHub.

Both AWS native and Clair basic scanning are supported in all regions listed in [AWS Services by Region](#), except for those that were added after September, 2024. Because Clair support is deprecated, Clair will not be supported in new regions as they are added and will no longer be supported in all regions as of October 1, 2025.

Amazon ECR uses the severity for a CVE from the upstream distribution source if available. Otherwise, the Common Vulnerability Scoring System (CVSS) score is used. The CVSS score can be used to obtain the NVD vulnerability severity rating. For more information, see [NVD Vulnerability Severity Ratings](#).

You can also see the results of a scan from within the Amazon ECR console or by calling the [DescribeImageScanFindings](#) API. Images with a HIGH or CRITICAL vulnerability should be deleted or rebuilt. If an image that has been deployed develops a vulnerability, it should be replaced as soon as possible.

[Docker Desktop Edge version 2.3.6.0](#) or later can [scan](#) local images. The scans are powered by [Snyk](#), an application security service. When vulnerabilities are discovered, Snyk identifies the layers and dependencies with the vulnerability in the Dockerfile. It also recommends safe alternatives like using a slimmer base image with fewer vulnerabilities or upgrading a particular package to a newer version. By using Docker scan, developers can resolve potential security issues before pushing their images to the registry.

- [Automating image compliance using Amazon ECR and AWS Security Hub CSPM](#) explains how to surface vulnerability information from Amazon ECR in AWS Security Hub CSPM and automate remediation by blocking access to vulnerable images.

## Remove special permissions from your images

The access rights flags `setuid` and `setgid` allow running an executable with the permissions of the owner or group of the executable. Remove all binaries with these access rights from your image as these binaries can be used to escalate privileges. Consider removing all shells and utilities like `nc` and `curl` that can be used for malicious purposes. You can find the files with `setuid` and `setgid` access rights by using the following command.

```
find / -perm /6000 -type f -exec ls -ld {} \;
```

To remove these special permissions from these files, add the following directive to your container image.

```
RUN find / -xdev -perm /6000 -type f -exec chmod a-s {} \; || true
```

## Create a set of curated images

Rather than allowing developers to create their own images, create a set of vetted images for the different application stacks in your organization. By doing so, developers can forego learning how to compose Dockerfiles and concentrate on writing code. As changes are merged into your codebase, a CI/CD pipeline can automatically compile the asset and then store it in an artifact repository. And, last, copy the artifact into the appropriate image before pushing it to a Docker registry such as Amazon ECR. At the very least you should create a set of base images that developers can create their own Dockerfiles from. You should avoid pulling images from Docker Hub. You don't always know what is in the image and the images can have vulnerabilities.

## Scan application packages and libraries for vulnerabilities

Use of open source libraries is now common. As with operating systems and OS packages, these libraries can have vulnerabilities. As part of the development lifecycle these libraries should be scanned and updated when critical vulnerabilities are found.

Docker Desktop performs local scans using Snyk. It can also be used to find vulnerabilities and potential licensing issues in open source libraries. It can be integrated directly into developer workflows giving you the ability to mitigate risks posed by open source libraries. For more information, see the following topics:

- [Open Source Application Security Tools](#) includes a list of tools for detecting vulnerabilities in applications.

## Perform static code analysis

You should perform static code analysis before building a container image. It's performed against your source code and is used to identify coding errors and code that could be exploited by a malicious actor, such as fault injections. You can use Amazon Inspector. For more information, see [Scanning Amazon ECR container images with Amazon Inspector](#) in the *Amazon Inspector User Guide*.

## Run containers as a non-root user

You should run containers as a non-root user. By default, containers run as the `root` user unless the `USER` directive is included in your Dockerfile. The default Linux capabilities that are assigned by Docker restrict the actions that can be run as `root`, but only marginally. For example, a container running as `root` is still not allowed to access devices.

As part of your CI/CD pipeline you should lint Dockerfiles to look for the `USER` directive and fail the build if it's missing. For more information, see the following topics:

- [Dockerfile-lint](#) is an open-source tool from RedHat that can be used to check if the file conforms to best practices.
- [Hadolint](#) is another tool for building Docker images that conform to best practices.

## Use a read-only root file system

You should use a read-only root file system. A container's root file system is writable by default. When you configure a container with a RO (read-only) root file system it forces you to explicitly define where data can be persisted. This reduces your attack surface because the container's file system can't be written to unless permissions are specifically granted.

**Note**

Having a read-only root file system can cause issues with certain OS packages that expect to be able to write to the filesystem. If you're planning to use read-only root file systems, thoroughly test beforehand.

## Configure tasks with CPU and Memory limits (Amazon EC2)

You should configure tasks with CPU and memory limits to minimize the following risk. A task's resource limits set an upper bound for the amount of CPU and memory that can be reserved by all the containers within a task. If no limits are set, tasks have access to the host's CPU and memory. This can cause issues where tasks deployed on a shared host can starve other tasks of system resources.

**Note**

Amazon ECS on AWS Fargate tasks require you to specify CPU and memory limits because it uses these values for billing purposes. One task hogging all of the system resources isn't an issue for Amazon ECS Fargate because each task is run on its own dedicated instance. If you don't specify a memory limit, Amazon ECS allocates a minimum of 4MB to each container. Similarly, if no CPU limit is set for the task, the Amazon ECS container agent assigns it a minimum of 2 CPUs.

## Use immutable tags with Amazon ECR

With Amazon ECR, you can and should use configure images with immutable tags. This prevents pushing an altered or updated version of an image to your image repository with an identical tag. This protects against an attacker pushing a compromised version of an image over your image with the same tag. By using immutable tags, you effectively force yourself to push a new image with a different tag for each change.

## Avoid running containers as privileged (Amazon EC2)

You should avoid running containers as privileged. For background, containers run as `privileged` are run with extended privileges on the host. This means the container inherits all of the Linux

capabilities assigned to root on the host. Its use should be severely restricted or forbidden. We advise setting the Amazon ECS container agent environment variable `ECS_DISABLE_PRIVILEGED` to true to prevent containers from running as privileged on particular hosts if privileged isn't needed. Alternatively you can use AWS Lambda to scan your task definitions for the use of the `privileged` parameter.

#### Note

Running a container as `privileged` isn't supported on Amazon ECS on AWS Fargate.

## Remove unnecessary Linux capabilities from the container

The following is a list of the default Linux capabilities assigned to Docker containers. For more information about each capability, see [Overview of Linux Capabilities](#).

```
CAP_CHOWN, CAP_DAC_OVERRIDE, CAP_FOWNER, CAP_FSETID, CAP_KILL,  
CAP_SETGID, CAP_SETUID, CAP_SETPCAP, CAP_NET_BIND_SERVICE,  
CAP_NET_RAW, CAP_SYS_CHROOT, CAP_MKNOD, CAP_AUDIT_WRITE,  
CAP_SETFCAP
```

If a container doesn't require all of the Docker kernel capabilities listed above, consider dropping them from the container. For more information about each Docker kernel capability, see [KernelCapabilities](#). You can find out which capabilities are in use by doing the following:

- Install the OS package [libcap-ng](#) and run the `pscap` utility to list the capabilities that each process is using.
- You can also use [capsh](#) to decipher which capabilities a process is using.

## Use a customer managed key (CMK) to encrypt images pushed to Amazon ECR

You should use a customer managed key (CMK) to encrypt images that are pushed to Amazon ECR. Images that are pushed to Amazon ECR are automatically encrypted at rest with a AWS Key Management Service (AWS KMS) managed key. If you would rather use your own key, Amazon ECR now supports AWS KMS encryption with customer managed keys (CMK). Before enabling server

side encryption with a CMK, review the Considerations listed in the documentation on [encryption at rest](#).

# Tutorials for Amazon ECS

The following tutorials show you how to perform common tasks when using Amazon ECS.

You can use any of the following tutorials to learn more about getting started with Amazon ECS.

| Tutorial overview                               | Learn more                                                                 |  |
|-------------------------------------------------|----------------------------------------------------------------------------|--|
| Get started with Amazon ECS on Fargate.         | <a href="#">Learn how to create an Amazon ECS Linux task for Fargate</a>   |  |
| Get started with Windows containers on Fargate. | <a href="#">Learn how to create an Amazon ECS Windows task for Fargate</a> |  |
| Get started with Windows containers for EC2.    | <a href="#">Learn how to create an Amazon ECS Windows task for EC2</a>     |  |

You can use any of the following tutorials to deploy tasks on Amazon ECS using the AWS CLI

| Tutorial overview                      | Learn more                                                                           |  |

## Creating an Amazon ECS Linux task for the Fargate with the AWS CLI

The following steps help you set up a cluster, register a task definition, run a Linux task, and perform other common scenarios in Amazon ECS with the AWS CLI. Use the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing or updating to the latest version of the AWS CLI](#).

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

## Topics

- [Prerequisites](#)
- [Step 1: Create a Cluster](#)
- [Step 2: Register a Linux Task Definition](#)
- [Step 3: List Task Definitions](#)
- [Step 4: Create a Service](#)
- [Step 5: List Services](#)
- [Step 6: Describe the Running Service](#)
- [Step 7: Test](#)
- [Step 8: Clean Up](#)

## Prerequisites

This tutorial assumes that the following prerequisites have been completed.

- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading your AWS CLI, [Installing or updating to the latest version of the AWS CLI](#).
- The steps in [Set up to use Amazon ECS](#) have been completed.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.
- You have a VPC and security group created to use. This tutorial uses a container image hosted on Amazon ECR Public so your task must have internet access. To give your task a route to the internet, use one of the following options.
  - Use a private subnet with a NAT gateway that has an elastic IP address.
  - Use a public subnet and assign a public IP address to the task.

For more information, see [the section called "Create a virtual private cloud"](#).

For information about security groups and rules, see, [Default security groups for your VPCs](#) and [Example rules](#) in the *Amazon Virtual Private Cloud User Guide*.

- If you follow this tutorial using a private subnet, you can use Amazon ECS Exec to directly interact with your container and test the deployment. You will need to create a task IAM role to use ECS Exec. For more information on the task IAM role and other prerequisites, see [Monitor Amazon ECS containers with Amazon ECS Exec](#).

- (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see [What is AWS CloudShell?](#) in the *AWS CloudShell User Guide*.

## Step 1: Create a Cluster

By default, your account receives a default cluster.

### Note

The benefit of using the default cluster that is provided for you is that you don't have to specify the `--cluster` *cluster\_name* option in the subsequent commands. If you do create your own, non-default, cluster, you must specify `--cluster` *cluster\_name* for each command that you intend to use with that cluster.

Create your own cluster with a unique name with the following command:

```
aws ecs create-cluster --cluster-name fargate-cluster
```

Output:

```
{
  "cluster": {
    "status": "ACTIVE",
    "defaultCapacityProviderStrategy": [],
    "statistics": [],
    "capacityProviders": [],
    "tags": [],
    "clusterName": "fargate-cluster",
    "settings": [
      {
        "name": "containerInsights",
        "value": "disabled"
      }
    ],
    "registeredContainerInstancesCount": 0,
    "pendingTasksCount": 0,
    "runningTasksCount": 0,
    "activeServicesCount": 0,
  }
}
```

```

    "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/fargate-cluster"
  }
}

```

## Step 2: Register a Linux Task Definition

Before you can run a task on your ECS cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that creates a PHP web app using the httpd container image hosted on Docker Hub. For more information about the available task definition parameters, see [Amazon ECS task definitions](#). For this tutorial, the `taskRoleArn` is only needed if you are deploying the task in a private subnet and wish to test the deployment. Replace the `taskRoleArn` with the IAM task role you created to use ECS Exec as mentioned in [Prerequisites](#).

```

{
  "family": "sample-fargate",
  "networkMode": "awsvpc",
  "taskRoleArn": "arn:aws:iam::aws_account_id:role/execCommandRole",
  "containerDefinitions": [
    {
      "name": "fargate-app",
      "image": "public.ecr.aws/docker/library/httpd:latest",
      "portMappings": [
        {
          "containerPort": 80,
          "hostPort": 80,
          "protocol": "tcp"
        }
      ],
      "essential": true,
      "entryPoint": [
        "sh",
        "-c"
      ],
      "command": [
        "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample
App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </
head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1>
<h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon
ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-
foreground\""
      ]
    }
  ]
}

```

```
    }
  ],
  "requiresCompatibilities": [
    "FARGATE"
  ],
  "cpu": "256",
  "memory": "512"
}
```

Save the task definition JSON as a file and pass it with the `--cli-input-json file://path_to_file.json` option.

To use a JSON file for container definitions:

```
aws ecs register-task-definition --cli-input-json file://$HOME/tasks/fargate-task.json
```

The **register-task-definition** command returns a description of the task definition after it completes its registration.

## Step 3: List Task Definitions

You can list the task definitions for your account at any time with the **list-task-definitions** command. The output of this command shows the family and revision values that you can use together when calling **run-task** or **start-task**.

```
aws ecs list-task-definitions
```

Output:

```
{
  "taskDefinitionArns": [
    "arn:aws:ecs:region:aws_account_id:task-definition/sample-fargate:1"
  ]
}
```

## Step 4: Create a Service

After you have registered a task for your account, you can create a service for the registered task in your cluster. For this example, you create a service with one instance of the `sample-fargate:1`

task definition running in your cluster. The task requires a route to the internet, so there are two ways you can achieve this. One way is to use a private subnet configured with a NAT gateway with an elastic IP address in a public subnet. Another way is to use a public subnet and assign a public IP address to your task. We provide both examples in the following sections.

Example using a private subnet. The `enable-execute-command` option is needed to use Amazon ECS Exec.

```
aws ecs create-service --cluster fargate-cluster --service-name fargate-service --  
task-definition sample-fargate:1 --desired-count 1 --launch-type "FARGATE" --network-  
configuration "awsvpcConfiguration={subnets=[subnet-abcd1234],securityGroups=[sg-  
abcd1234]}" --enable-execute-command
```

Example using a public subnet.

```
aws ecs create-service --cluster fargate-cluster --service-name fargate-service --  
task-definition sample-fargate:1 --desired-count 1 --launch-type "FARGATE" --network-  
configuration "awsvpcConfiguration={subnets=[subnet-abcd1234],securityGroups=[sg-  
abcd1234],assignPublicIp=ENABLED}"
```

The `create-service` command returns a description of the task definition after it completes its registration.

## Step 5: List Services

List the services for your cluster. You should see the service that you created in the previous section. You can take the service name or the full ARN that is returned from this command and use it to describe the service later.

```
aws ecs list-services --cluster fargate-cluster
```

Output:

```
{  
  "serviceArns": [  
    "arn:aws:ecs:region:aws_account_id:service/fargate-cluster/fargate-service"  
  ]  
}
```

## Step 6: Describe the Running Service

Describe the service using the service name retrieved earlier to get more information about the task.

```
aws ecs describe-services --cluster fargate-cluster --services fargate-service
```

If successful, this will return a description of the service failures and services. For example, in the `services` section, you will find information on deployments, such as the status of the tasks as running or pending. You may also find information on the task definition, the network configuration and time-stamped events. In the failures section, you will find information on failures, if any, associated with the call. For troubleshooting, see [Service Event Messages](#). For more information about the service description, see [Describe Services](#).

```
{
  "services": [
    {
      "networkConfiguration": {
        "awsvpcConfiguration": {
          "subnets": [
            "subnet-abcd1234"
          ],
          "securityGroups": [
            "sg-abcd1234"
          ],
          "assignPublicIp": "ENABLED"
        }
      },
      "launchType": "FARGATE",
      "enableECSManagedTags": false,
      "loadBalancers": [],
      "deploymentController": {
        "type": "ECS"
      },
      "desiredCount": 1,
      "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/fargate-cluster",
      "serviceArn": "arn:aws:ecs:region:aws_account_id:service/fargate-cluster/fargate-service",
      "deploymentConfiguration": {
        "maximumPercent": 200,
        "minimumHealthyPercent": 100
      },
    }
  ],
}
```

```

    "createdAt": 1692283199.771,
    "schedulingStrategy": "REPLICA",
    "placementConstraints": [],
    "deployments": [
      {
        "status": "PRIMARY",

"taskDefinition": "arn:aws:ecs:region:aws_account_id:task-definition/
sample-fargate:1"
}
],
"failures": []
}

```

## Step 7: Test

### Testing task deployed using public subnet

Describe the task in the service so that you can get the Elastic Network Interface (ENI) for the task.

First, get the task ARN.

```
aws ecs list-tasks --cluster fargate-cluster --service fargate-service
```

The output contains the task ARN.

```

{
  "taskArns": [
    "arn:aws:ecs:us-east-1:123456789012:task/fargate-service/EXAMPLE"
  ]
}

```

Describe the task and locate the ENI ID. Use the task ARN for the tasks parameter.

```
aws ecs describe-tasks --cluster fargate-cluster --tasks arn:aws:ecs:us-east-1:123456789012:task/service/EXAMPLE
```

The attachment information is listed in the output.

```
{
  "tasks": [
    {
      "attachments": [
        {
          "id": "d9e7735a-16aa-4128-bc7a-b2d5115029e9",
          "type": "ElasticNetworkInterface",
          "status": "ATTACHED",
          "details": [
            {
              "name": "subnetId",
              "value": "subnetabcd1234"
            },
            {
              "name": "networkInterfaceId",
              "value": "eni-0fa40520aeEXAMPLE"
            }
          ]
        }
      ]
    }
  ]
}
```

Describe the ENI to get the public IP address.

```
aws ec2 describe-network-interfaces --network-interface-id eni-0fa40520aeEXAMPLE
```

The public IP address is in the output.

```
{
  "NetworkInterfaces": [
    {
      "Association": {
        "IpOwnerId": "amazon",
        "PublicDnsName": "ec2-34-229-42-222.compute-1.amazonaws.com",
        "PublicIp": "198.51.100.2"
      }
    }
  ]
}
```

```
...
}
```

Enter the public IP address in your web browser and you should see a webpage that displays the **Amazon ECS** sample application.

## Testing task deployed using private subnet

Describe the task and locate managedAgents to verify that the ExecuteCommandAgent is running. Note the privateIPv4Address for later use.

```
aws ecs describe-tasks --cluster fargate-cluster --tasks arn:aws:ecs:us-east-1:123456789012:task/fargate-service/EXAMPLE
```

The managed agent information is listed in the output.

```
{
  "tasks": [
    {
      "attachments": [
        {
          "id": "d9e7735a-16aa-4128-bc7a-b2d5115029e9",
          "type": "ElasticNetworkInterface",
          "status": "ATTACHED",
          "details": [
            {
              "name": "subnetId",
              "value": "subnetabcd1234"
            },
            {
              "name": "networkInterfaceId",
              "value": "eni-0fa40520aeEXAMPLE"
            },
            {
              "name": "privateIPv4Address",
              "value": "10.0.143.156"
            }
          ]
        }
      ],
      ...
      "containers": [
```

```
{
  ...
  "managedAgents": [
    {
      "lastStartedAt": "2023-08-01T16:10:13.002000+00:00",
      "name": "ExecuteCommandAgent",
      "lastStatus": "RUNNING"
    }
  ],
  ...
}
```

After verifying that the `ExecuteCommandAgent` is running, you can run the following command to run an interactive shell on the container in the task.

```
aws ecs execute-command --cluster fargate-cluster \
  --task arn:aws:ecs:us-east-1:123456789012:task/fargate-service/EXAMPLE \
  --container fargate-app \
  --interactive \
  --command "/bin/sh"
```

After the interactive shell is running, run the following commands to install cURL.

```
apt update
```

```
apt install curl
```

After installing cURL, run the following command using the private IP address you obtained earlier.

```
curl 10.0.143.156
```

You should see the HTML equivalent of the **Amazon ECS** sample application webpage.

```
<html>
  <head>
    <title>Amazon ECS Sample App</title>
    <style>body {margin-top: 40px; background-color: #333;} </style>
  </head>
  <body>
    <div style=color:white;text-align:center>
```

```
<h1>Amazon ECS Sample App</h1>
<h2>Congratulations!</h2> <p>Your application is now running on a container in
Amazon ECS.</p>
</div>
</body>
</html>
```

## Step 8: Clean Up

When you are finished with this tutorial, you should clean up the associated resources to avoid incurring charges for unused resources.

Delete the service.

```
aws ecs delete-service --cluster fargate-cluster --service fargate-service --force
```

Delete the cluster.

```
aws ecs delete-cluster --cluster fargate-cluster
```

## Creating an Amazon ECS Windows task for the Fargate with the AWS CLI

The following steps help you set up a cluster, register a task definition, run a Windows task, and perform other common scenarios in Amazon ECS with the AWS CLI. Ensure that you are using the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing or updating to the latest version of the AWS CLI](#).

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

## Topics

- [Prerequisites](#)

- [Step 1: Create a Cluster](#)
- [Step 2: Register a Windows Task Definition](#)
- [Step 3: List task definitions](#)
- [Step 4: Create a service](#)
- [Step 5: List services](#)
- [Step 6: Describe the Running Service](#)
- [Step 7: Clean Up](#)

## Prerequisites

This tutorial assumes that the following prerequisites have been completed.

- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading your AWS CLI, see [Installing or updating to the latest version of the AWS CLI](#).
- The steps in [Set up to use Amazon ECS](#) have been completed.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.
- You have a VPC and security group created to use. This tutorial uses a container image hosted on Docker Hub so your task must have internet access. To give your task a route to the internet, use one of the following options.
  - Use a private subnet with a NAT gateway that has an elastic IP address.
  - Use a public subnet and assign a public IP address to the task.

For more information, see [the section called “Create a virtual private cloud”](#).

For information about security groups and rules, see, [Default security groups for your VPCs](#) and [Example rules](#) in the *Amazon Virtual Private Cloud User Guide*.

- (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see [What is AWS CloudShell?](#) in the *AWS CloudShell User Guide*.

## Step 1: Create a Cluster

By default, your account receives a default cluster.

**Note**

The benefit of using the default cluster that is provided for you is that you don't have to specify the `--cluster` *cluster\_name* option in the subsequent commands. If you do create your own, non-default, cluster, you must specify `--cluster` *cluster\_name* for each command that you intend to use with that cluster.

Create your own cluster with a unique name with the following command:

```
aws ecs create-cluster --cluster-name fargate-cluster
```

Output:

```
{
  "cluster": {
    "status": "ACTIVE",
    "statistics": [],
    "clusterName": "fargate-cluster",
    "registeredContainerInstancesCount": 0,
    "pendingTasksCount": 0,
    "runningTasksCount": 0,
    "activeServicesCount": 0,
    "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/fargate-cluster"
  }
}
```

## Step 2: Register a Windows Task Definition

Before you can run a Windows task on your Amazon ECS cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that creates a web app. For more information about the available task definition parameters, see [Amazon ECS task definitions](#).

```
{
  "containerDefinitions": [
    {
      "command": ["New-Item -Path C:\\\\inetpub\\\\wwwroot\\\\index.html -Type file
-Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top:
```

```

40px; background-color: #333;} </style> </head><body> <div style=color:white;text-
align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your
application is now running on a container in Amazon ECS.</p>'; C:\\ServiceMonitor.exe
w3svc"],
    "entryPoint": [
        "powershell",
        "-Command"
    ],
    "essential": true,
    "cpu": 2048,
    "memory": 4096,
    "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-
ltsc2019",
    "name": "sample_windows_app",
    "portMappings": [
        {
            "hostPort": 80,
            "containerPort": 80,
            "protocol": "tcp"
        }
    ]
},
"memory": "4096",
"cpu": "2048",
"networkMode": "awsvpc",
"family": "windows-simple-iis-2019-core",
"executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
"runtimePlatform": {"operatingSystemFamily": "WINDOWS_SERVER_2019_CORE"},
"requiresCompatibilities": ["FARGATE"]
}

```

The preceding example JSON can be passed to the AWS CLI in two ways: You can save the task definition JSON as a file and pass it with the `--cli-input-json file://path_to_file.json` option.

To use a JSON file for container definitions:

```
aws ecs register-task-definition --cli-input-json file://$HOME/tasks/fargate-task.json
```

The **register-task-definition** command returns a description of the task definition after it completes its registration.

## Step 3: List task definitions

You can list the task definitions for your account at any time with the **list-task-definitions** command. The output of this command shows the family and revision values that you can use together when calling **run-task** or **start-task**.

```
aws ecs list-task-definitions
```

Output:

```
{
  "taskDefinitionArns": [
    "arn:aws:ecs:region:aws_account_id:task-definition/sample-fargate-windows:1"
  ]
}
```

## Step 4: Create a service

After you have registered a task for your account, you can create a service for the registered task in your cluster. For this example, you create a service with one instance of the `sample-fargate:1` task definition running in your cluster. The task requires a route to the internet, so there are two ways you can achieve this. One way is to use a private subnet configured with a NAT gateway with an elastic IP address in a public subnet. Another way is to use a public subnet and assign a public IP address to your task. We provide both examples in the following sections.

Example using a private subnet.

```
aws ecs create-service --cluster fargate-cluster --service-name fargate-service
--task-definition sample-fargate-windows:1 --desired-count 1 --launch-type
"FARGATE" --network-configuration "awsvpcConfiguration={subnets=[subnet-
abcd1234],securityGroups=[sg-abcd1234]}"
```

Example using a public subnet.

```
aws ecs create-service --cluster fargate-cluster --service-name fargate-service
--task-definition sample-fargate-windows:1 --desired-count 1 --launch-type
"FARGATE" --network-configuration "awsvpcConfiguration={subnets=[subnet-
abcd1234],securityGroups=[sg-abcd1234],assignPublicIp=ENABLED}"
```

The **create-service** command returns a description of the task definition after it completes its registration.

## Step 5: List services

List the services for your cluster. You should see the service that you created in the previous section. You can take the service name or the full ARN that is returned from this command and use it to describe the service later.

```
aws ecs list-services --cluster fargate-cluster
```

Output:

```
{
  "serviceArns": [
    "arn:aws:ecs:region:aws_account_id:service/fargate-cluster/fargate-service"
  ]
}
```

## Step 6: Describe the Running Service

Describe the service using the service name retrieved earlier to get more information about the task.

```
aws ecs describe-services --cluster fargate-cluster --services fargate-service
```

If successful, this will return a description of the service failures and services. For example, in services section, you will find information on deployments, such as the status of the tasks as running or pending. You may also find information on the task definition, the network configuration and time-stamped events. In the failures section, you will find information on failures, if any, associated with the call. For troubleshooting, see [Service Event Messages](#). For more information about the service description, see [Describe Services](#).

```
{
  "services": [
    {
      "status": "ACTIVE",
      "taskDefinition": "arn:aws:ecs:region:aws_account_id:task-definition/sample-fargate-windows:1",
      "pendingCount": 2,

```

```

    "launchType": "FARGATE",
    "loadBalancers": [],
    "roleArn": "arn:aws:iam::aws_account_id:role/aws-service-role/
ecs.amazonaws.com/AWSServiceRoleForECS",
    "placementConstraints": [],
    "createdAt": 1510811361.128,
    "desiredCount": 2,
    "networkConfiguration": {
      "awsvpcConfiguration": {
        "subnets": [
          "subnet-abcd1234"
        ],
        "securityGroups": [
          "sg-abcd1234"
        ],
        "assignPublicIp": "DISABLED"
      }
    },
    "platformVersion": "LATEST",
    "serviceName": "fargate-service",
    "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/fargate-cluster",
    "serviceArn": "arn:aws:ecs:region:aws_account_id:service/fargate-cluster/
fargate-service",
    "deploymentConfiguration": {
      "maximumPercent": 200,
      "minimumHealthyPercent": 100
    },
    "deployments": [
      {
        "status": "PRIMARY",
        "networkConfiguration": {
          "awsvpcConfiguration": {

            "id": "095703e1-0ca3-4379-a7c8-c0f1b8b95ace",
            "createdAt": 1510811364.691
        }
    ],
    "runningCount": 0,
    "placementStrategy": []
}
],
"failures": []
}

```

## Step 7: Clean Up

When you are finished with this tutorial, you should clean up the associated resources to avoid incurring charges for unused resources.

Delete the service.

```
aws ecs delete-service --cluster fargate-cluster --service fargate-service --force
```

Delete the cluster.

```
aws ecs delete-cluster --cluster fargate-cluster
```

## Creating an Amazon ECS task for EC2 with the AWS CLI

The following steps help you set up a cluster, register a task definition, run a task, and perform other common scenarios in Amazon ECS with the AWS CLI. Use the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing or updating to the latest version of the AWS CLI](#).

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

### Topics

- [Prerequisites](#)
- [Create a cluster](#)
- [Launch a container instance with the Amazon ECS AMI](#)
- [List container instances](#)
- [Describe your container instance](#)
- [Register a task definition](#)
- [List task definitions](#)
- [Create a service](#)
- [List services](#)
- [Describe the service](#)
- [Describe the running task](#)
- [Test the web server](#)
- [Clean up resources](#)

## Prerequisites

This tutorial assumes that the following prerequisites have been completed:

- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading your AWS CLI, see [Installing or updating to the latest version of the AWS CLI](#).
- The steps in [Set up to use Amazon ECS](#) have been completed.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.
- You have a container instance IAM role created to use. For more information, see [Amazon ECS container instance IAM role](#).
- You have a VPC created to use. For more information, see [the section called "Create a virtual private cloud"](#).
- (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see [What is AWS CloudShell?](#) in the *AWS CloudShell User Guide*.

## Create a cluster

By default, your account receives a default cluster when you launch your first container instance.

### Note

The benefit of using the default cluster that is provided for you is that you don't have to specify the `--cluster` *cluster\_name* option in the subsequent commands. If you do create your own, non-default, cluster, you must specify `--cluster` *cluster\_name* for each command that you intend to use with that cluster.

Create your own cluster with a unique name with the following command:

```
aws ecs create-cluster --cluster-name MyCluster
```

Output:

```
{
  "cluster": {
    "clusterName": "MyCluster",
    "status": "ACTIVE",
    "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/MyCluster"
  }
}
```

## Launch a container instance with the Amazon ECS AMI

Container instances are EC2 instances that run the Amazon ECS container agent and have been registered into a cluster. In this section, you'll launch an EC2 instance using the ECS-optimized AMI.

### To launch a container instance with the AWS CLI

1. Retrieve the latest ECS-optimized Amazon Linux 2 AMI ID for your AWS Region using the following command. This command uses AWS Systems Manager Parameter Store to get the latest ECS-optimized AMI ID. The AMI includes the Amazon ECS container agent and Docker runtime pre-installed.

```
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/
recommended --query 'Parameters[0].Value' --output text | jq -r '.image_id'
```

Output:

```
ami-abcd1234
```

2. Create a security group that allows SSH access for managing your container instance and HTTP access for the web server.

```
aws ec2 create-security-group --group-name ecs-tutorial-sg --description "ECS
tutorial security group"
```

Output:

```
{
  "GroupId": "sg-abcd1234"
}
```

3. Add an inbound rule to the security group by running the following command.

```
aws ec2 authorize-security-group-ingress --group-id sg-abcd1234 --protocol tcp --port 80 --cidr 0.0.0.0/0
```

Output:

```
{
  "Return": true,
  "SecurityGroupRules": [
    {
      "SecurityGroupId": "sgr-efgh5678",
      "GroupId": "sg-abcd1234",
      "GroupOwnerId": "123456789012",
      "IsEgress": false,
      "IpProtocol": "tcp",
      "FromPort": 80,
      "ToPort": 80,
      "CidrIpv4": "0.0.0.0/0"
    }
  ]
}
```

The security group now allows SSH access from the specified IP range and HTTP access from anywhere. In a production environment, you should restrict SSH access to your specific IP address and consider limiting HTTP access as needed.

4. Create an EC2 key pair for SSH access to your container instance.

```
aws ec2 create-key-pair --key-name ecs-tutorial-key --query 'KeyMaterial' --output text > ecs-tutorial-key.pem
chmod 400 ecs-tutorial-key.pem
```

The private key is saved to your local machine with appropriate permissions for SSH access.

5. Launch an EC2 instance using the ECS-optimized AMI and configure it to join your cluster.

```
aws ec2 run-instances --image-id ami-abcd1234 --instance-type t3.micro --key-name ecs-tutorial-key --security-group-ids sg-abcd1234 --iam-instance-profile Name=ecsInstanceRole --user-data '#!/bin/bash
echo ECS_CLUSTER=MyCluster >> /etc/ecs/ecs.config'
{
  "Instances": [
```

```
{
  "InstanceId": "i-abcd1234",
  "ImageId": "ami-abcd1234",
  "State": {
    "Code": 0,
    "Name": "pending"
  },
  "PrivateDnsName": "",
  "PublicDnsName": "",
  "StateReason": {
    "Code": "pending",
    "Message": "pending"
  },
  "InstanceType": "t3.micro",
  "KeyName": "ecs-tutorial-key",
  "LaunchTime": "2025-01-13T10:30:00.000Z"
}
```

The user data script configures the Amazon ECS agent to register the instance with your `MyCluster`. The instance uses the `ecsInstanceRole` IAM role, which provides the necessary permissions for the agent.

## List container instances

Within a few minutes of launching your container instance, the Amazon ECS agent registers the instance with your `MyCluster` cluster. You can list the container instances in a cluster by running the following command:

```
aws ecs list-container-instances --cluster MyCluster
```

Output:

```
{
  "containerInstanceArns": [
    "arn:aws:ecs:us-east-1:aws_account_id:container-instance/container_instance_ID"
  ]
}
```

## Describe your container instance

After you have the ARN or ID of a container instance, you can use the **describe-container-instances** command to get valuable information on the instance, such as remaining and registered CPU and memory resources.

```
aws ecs describe-container-instances --cluster MyCluster --container-  
instances container_instance_ID
```

Output:

```
{  
  "failures": [],  
  "containerInstances": [  
    {  
      "status": "ACTIVE",  
      "registeredResources": [  
        {  
          "integerValue": 1024,  
          "longValue": 0,  
          "type": "INTEGER",  
          "name": "CPU",  
          "doubleValue": 0.0  
        },  
        {  
          "integerValue": 995,  
          "longValue": 0,  
          "type": "INTEGER",  
          "name": "MEMORY",  
          "doubleValue": 0.0  
        },  
        {  
          "name": "PORTS",  
          "longValue": 0,  
          "doubleValue": 0.0,  
          "stringSetValue": [  
            "22",  
            "2376",  
            "2375",  
            "51678"  
          ],  
          "type": "STRINGSET",  
        }  
      ]  
    }  
  ]  
}
```

```

        "integerValue": 0
    },
    {
        "name": "PORTS_UDP",
        "longValue": 0,
        "doubleValue": 0.0,
        "stringSetValue": [],
        "type": "STRINGSET",
        "integerValue": 0
    }
],
"ec2InstanceId": "instance_id",
"agentConnected": true,
"containerInstanceArn": "arn:aws:ecs:us-west-2:aws_account_id:container-
instance/container_instance_ID",

            "51678"
        ],
        "type": "STRINGSET",
        "integerValue": 0
    }
],

```

```

        {
            "name": "PORTS_UDP",
            "longValue": 0,
            "doubleValue": 0.0,
            "stringSetValue": [],
            "type": "STRINGSET",
            "integerValue": 0
        }
    ],
    "runningTasksCount": 0,
    "attributes": [
        {
            "name": "com.amazonaws.ecs.capability.privileged-container"
        },
        {
            "name": "com.amazonaws.ecs.capability.docker-remote-api.1.17"
        },
        {
            "name": "com.amazonaws.ecs.capability.docker-remote-api.1.18"
        },
        {
            "name": "com.amazonaws.ecs.capability.docker-remote-api.1.19"
        },
        {
            "name": "com.amazonaws.ecs.capability.logging-driver.json-file"
        },
        {
            "name": "com.amazonaws.ecs.capability.logging-driver.syslog"
        }
    ],
    "versionInfo": {
        "agentVersion": "1.5.0",
        "agentHash": "b197edd",
        "dockerVersion": "DockerVersion: 1.7.1"
    }
}
]
}

```

You can also find the Amazon EC2 instance ID that you can use to monitor the instance in the Amazon EC2 console or with the **aws ec2 describe-instances --instance-id *instance\_id*** command.

## Register a task definition

Before you can run a task on your Amazon ECS cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that uses an nginx image. For more information about the available task definition parameters, see [Amazon ECS task definitions](#).

```
{
  "family": "nginx-task",
  "containerDefinitions": [
    {
      "name": "nginx",
      "image": "public.ecr.aws/ecs-sample-image/amazon-ecs-sample:latest",
      "cpu": 256,
      "memory": 512,
      "essential": true,
      "portMappings": [
        {
          "containerPort": 80,
          "hostPort": 80,
          "protocol": "tcp"
        }
      ]
    }
  ],
  "requiresCompatibilities": ["EC2"],
  "networkMode": "bridge"
}
```

The preceding example JSON can be passed to the AWS CLI in two ways: You can save the task definition JSON as a file and pass it with the `--cli-input-json file://path_to_file.json` option. Or, you can escape the quotation marks in the JSON and pass the JSON container definitions on the command line. If you choose to pass the container definitions on the command line, your command additionally requires a `--family` parameter that is used to keep multiple versions of your task definition associated with each other.

To use a JSON file for container definitions:

```
aws ecs register-task-definition --cli-input-json file://$HOME/tasks/nginx.json
```

The **register-task-definition** returns a description of the task definition after it completes its registration.

```
{
  "taskDefinition": {
    "taskDefinitionArn": "arn:aws:ecs:us-east-1:123456789012:task-definition/nginx-
task:1",
    "family": "nginx-task",
    "revision": 1,
    "status": "ACTIVE",
    "containerDefinitions": [
      {
        "name": "nginx",
        "image": "public.ecr.aws/docker/library/nginx:latest",
        "cpu": 256,
        "memory": 512,
        "essential": true,
        "portMappings": [
          {
            "containerPort": 80,
            "hostPort": 80,
            "protocol": "tcp"
          }
        ],
        "environment": [],
        "mountPoints": [],
        "volumesFrom": []
      }
    ],
    "volumes": [],
    "networkMode": "bridge",
    "compatibilities": [
      "EC2"
    ],
    "requiresCompatibilities": [
      "EC2"
    ]
  }
}
```

## List task definitions

You can list the task definitions for your account at any time with the **list-task-definitions** command. The output of this command shows the family and revision values that you can use together when calling **create-service**.

```
aws ecs list-task-definitions
```

Output:

```
{
  "taskDefinitionArns": [
    "arn:aws:ec2:us-east-1:aws_account_id:task-definition/sleep360:1",
    "arn:aws:ec2:us-east-1:aws_account_id:task-definition/sleep360:2",
    "arn:aws:ec2:us-east-1:aws_account_id:task-definition/nginx-task:1",
    "arn:aws:ec2:us-east-1:aws_account_id:task-definition/wordpress:3",
    "arn:aws:ec2:us-east-1:aws_account_id:task-definition/wordpress:4",
    "arn:aws:ec2:us-east-1:aws_account_id:task-definition/wordpress:5",
    "arn:aws:ec2:us-east-1:aws_account_id:task-definition/wordpress:6"
  ]
}
```

## Create a service

After you have registered a task for your account and have launched a container instance that is registered to your cluster, you can create an Amazon ECS service that runs and maintains a desired number of tasks simultaneously using the task definition that you registered. For this example, you place a single instance of the `nginx:1` task definition in your `MyCluster` cluster.

```
aws ecs create-service --cluster MyCluster --service-name nginx-service --task-
definition nginx-task:1 --desired-count 1
```

Output:

```
{
  "service": {
    "serviceArn": "arn:aws:ecs:us-east-1:aws_account_id:service/MyCluster/nginx-
service",
    "serviceName": "nginx-service",
    "clusterArn": "arn:aws:ecs:us-east-1:aws_account_id:cluster/MyCluster",

```

```
    "taskDefinition": "arn:aws:ecs:us-east-1:aws_account_id:task-definition/nginx-  
task:1",  
    "desiredCount": 1,  
    "runningCount": 0,  
    "pendingCount": 0,  
    "launchType": "EC2",  
    "status": "ACTIVE",  
    "createdAt": "2025-01-13T10:45:00.000Z"  
  }  
}
```

## List services

List the services for your cluster. You should see the service that you created in the previous section. You can note the service ID or the full ARN that is returned from this command and use it to describe the service later.

```
aws ecs list-services --cluster MyCluster
```

Output:

```
{  
  "taskArns": [  
    "arn:aws:ecs:us-east-1:aws_account_id:task/task_ID"  
  ]  
}
```

## Describe the service

Describe the service using the following command to get more information about the service.

```
aws ecs describe-services --cluster MyCluster --services nginx-service
```

Output:

```
{  
  "services": [  
    {  
      "serviceArn": "arn:aws:ecs:us-east-1:aws_account_id:service/MyCluster/  
nginx-service",  
      "serviceName": "nginx-service",  
    }  
  ]  
}
```

```

        "clusterArn": "arn:aws:ecs:us-east-1:aws_account_id:cluster/MyCluster",
        "taskDefinition": "arn:aws:ecs:us-east-1:aws_account_id:task-definition/
nginx-task:1",
        "desiredCount": 1,
        "runningCount": 1,
        "pendingCount": 0,
        "launchType": "EC2",
        "status": "ACTIVE",
        "createdAt": "2025-01-13T10:45:00.000Z",
        "events": [
            {
                "id": "abcd1234-5678-90ab-cdef-1234567890ab",
                "createdAt": "2025-01-13T10:45:30.000Z",
                "message": "(service nginx-service) has started 1 tasks: (task
abcd1234-5678-90ab-cdef-1234567890ab)."
            }
        ]
    }
}

```

## Describe the running task

After describing the service, run the following command to get more information about the task that is running as part of your service.

```
aws ecs list-tasks --cluster MyCluster --service-name nginx-service
```

Output:

```

{
    "tasks": [
        {
            "taskArn": "arn:aws:ecs:us-east-1:aws_account_id:task/MyCluster/
abcd1234-5678-90ab-cdef-1234567890ab",
            "clusterArn": "arn:aws:ecs:us-east-1:aws_account_id:cluster/MyCluster",
            "taskDefinitionArn": "arn:aws:ecs:us-east-1:aws_account_id:task-definition/
nginx-task:1",
            "containerInstanceArn": "arn:aws:ecs:us-east-1:aws_account_id:container-
instance/MyCluster/abcd1234-5678-90ab-cdef-1234567890ab",
            "lastStatus": "RUNNING",
            "desiredStatus": "RUNNING",

```

```

    "containers": [
      {
        "containerArn": "arn:aws:ecs:us-east-1:aws_account_id:container/
MyCluster/abcd1234-5678-90ab-cdef-1234567890ab/abcd1234-5678-90ab-cdef-1234567890ab",
        "taskArn": "arn:aws:ecs:us-east-1:aws_account_id:task/MyCluster/
abcd1234-5678-90ab-cdef-1234567890ab",
        "name": "nginx",
        "lastStatus": "RUNNING",
        "networkBindings": [
          {
            "bindIP": "0.0.0.0",
            "containerPort": 80,
            "hostPort": 80,
            "protocol": "tcp"
          }
        ]
      }
    ],
    "createdAt": "2025-01-13T10:45:00.000Z",
    "startedAt": "2025-01-13T10:45:30.000Z"
  }
]
}

```

## Test the web server

### To test the web server

1. Retrieve the public IP address of your container instance by running the following command.

```
aws ec2 describe-instances --instance-ids i-abcd1234 --query
'Reservations[0].Instances[0].PublicIpAddress' --output text
```

Output:

```
203.0.113.25
```

2. After retrieving the IP address, run the following `curl` command with the IP address.

```
curl http://203.0.113.25
```

## Output:

```
<!DOCTYPE html>
<html>
<head>
<title>Welcome to nginx!</title>
...
</head>
<body>
<h1>Welcome to nginx!</h1>
<p>If you can see this page, the nginx web server is successfully installed and
  working.</p>
...
</body>
</html>
```

The nginx welcome page confirms that your service is running successfully and accessible from the internet.

## Clean up resources

To avoid incurring charges, clean up the resources that you created in this tutorial.

### To clean up resources

1. Update the service to have zero desired tasks, then delete the service.

```
aws ecs update-service --cluster MyCluster --service nginx-service --desired-count
0
{
  "service": {
    "serviceArn": "arn:aws:ecs:us-east-1:123456789012:service/MyCluster/nginx-
service",
    "serviceName": "nginx-service",
    "desiredCount": 0,
    "runningCount": 1,
    "pendingCount": 0,
    "status": "ACTIVE"
  }
}
```

## 2. Wait for the running tasks to stop, then delete the service.

```
aws ecs delete-service --cluster MyCluster --service nginx-service
{
  "service": {
    "serviceArn": "arn:aws:ecs:us-east-1:123456789012:service/MyCluster/nginx-
service",
    "serviceName": "nginx-service",
    "status": "DRAINING"
  }
}
```

## 3. Terminate the container instance you created.

```
aws ec2 terminate-instances --instance-ids i-abcd1234
{
  "TerminatingInstances": [
    {
      "InstanceId": "i-abcd1234",
      "CurrentState": {
        "Code": 32,
        "Name": "shutting-down"
      },
      "PreviousState": {
        "Code": 16,
        "Name": "running"
      }
    }
  ]
}
```

## 4. Clean up the security group and key pair that you created.

```
aws ec2 delete-security-group --group-id sg-abcd1234
aws ec2 delete-key-pair --key-name ecs-tutorial-key
rm ecs-tutorial-key.pem
```

## 5. Delete the Amazon ECS cluster.

```
aws ecs delete-cluster --cluster MyCluster
{
  "cluster": {
    "clusterArn": "arn:aws:ecs:us-east-1:123456789012:cluster/MyCluster",

```

```
        "clusterName": "MyCluster",  
        "status": "INACTIVE"  
    }  
}
```

## Configuring Amazon ECS to listen for CloudWatch Events events

Learn how to set up a simple Lambda function that listens for task events and writes them out to a CloudWatch Logs log stream.

### Prerequisite: Set up a test cluster

If you do not have a running cluster to capture events from, follow the steps in [the section called “Creating a cluster for Fargate workloads”](#) to create one. At the end of this tutorial, you run a task on this cluster to test that you have configured your Lambda function correctly.

### Step 1: Create the Lambda function

In this procedure, you create a simple Lambda function to serve as a target for Amazon ECS event stream messages.

1. Open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. Choose **Create function**.
3. On the **Author from scratch** screen, do the following:
  - a. For **Name**, enter a value.
  - b. For **Runtime**, choose your version of Python, for example, **Python 3.9**.
  - c. For **Role**, choose **Create a new role with basic Lambda permissions**.
4. Choose **Create function**.
5. In the **Function code** section, edit the sample code to match the following example:

```
import json  
  
def lambda_handler(event, context):  
    if event["source"] != "aws.ecs":
```

```
raise ValueError("Function only supports input from events with a source  
type of: aws.ecs")  
  
print('Here is the event:')  
print(json.dumps(event))
```

This is a simple Python 3.9 function that prints the event sent by Amazon ECS. If everything is configured correctly, at the end of this tutorial, you see that the event details appear in the CloudWatch Logs log stream associated with this Lambda function.

6. Choose **Save**.

## Step 2: Register an event rule

Next, you create a CloudWatch Events event rule that captures task events coming from your Amazon ECS clusters. This rule captures all events coming from all clusters within the account where it is defined. The task messages themselves contain information about the event source, including the cluster on which it resides, that you can use to filter and sort events programmatically.

### Note

When you use the AWS Management Console to create an event rule, the console automatically adds the IAM permissions necessary to grant CloudWatch Events permission to call your Lambda function. If you are creating an event rule using the AWS CLI, you need to grant this permission explicitly. For more information, see [Events in Amazon EventBridge](#) and [Amazon EventBridge event patterns](#) in the *Amazon EventBridge User Guide*.

### To route events to your Lambda function

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. On the navigation pane, choose **Events, Rules, Create rule**.
3. For **Event Source**, choose **ECS** as the event source. By default, the rule applies to all Amazon ECS events for all of your Amazon ECS groups. Alternatively, you can select specific events or a specific Amazon ECS group.
4. For **Targets**, choose **Add target**, for **Target type**, choose **Lambda function**, and then select your Lambda function.

5. Choose **Configure details**.
6. For **Rule definition**, type a name and description for your rule and choose **Create rule**.

## Step 3: Create a task definition

Create a task definition.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task Definitions**.
3. Choose **Create new Task Definition, Create new revision with JSON**.
4. Copy and paste the following example task definition into the box and then choose **Save**.

```
{
  "containerDefinitions": [
    {
      "command": [
        "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-foreground\"\"",
      ],
      "entryPoint": [
        "sh",
        "-c"
      ],
      "essential": true,
      "image": "public.ecr.aws/docker/library/httpd:2.4",
      "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
          "awslogs-group" : "/ecs/fargate-task-definition",
          "awslogs-region": "us-east-1",
          "awslogs-stream-prefix": "ecs"
        }
      },
      "name": "sample-fargate-app",
      "portMappings": [
        {
          "containerPort": 80,
```

```
        "hostPort": 80,  
        "protocol": "tcp"  
      }  
    ]  
  },  
  "cpu": "256",  
  "executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",  
  "family": "fargate-task-definition",  
  "memory": "512",  
  "networkMode": "awsvpc",  
  "runtimePlatform": {  
    "operatingSystemFamily": "LINUX"  
  },  
  "requiresCompatibilities": [  
    "FARGATE"  
  ]  
}
```

5. Choose **Create**.

## Step 4: Test your rule

Finally, you create a CloudWatch Events event rule that captures task events coming from your Amazon ECS clusters. This rule captures all events coming from all clusters within the account where it is defined. The task messages themselves contain information about the event source, including the cluster on which it resides, that you can use to filter and sort events programmatically.

### To test your rule

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. Choose **Task definitions**.
3. Choose **console-sample-app-static**, and then choose **Deploy, Run new task**.
4. For **Cluster**, choose default, and then choose **Deploy**.
5. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
6. On the navigation pane, choose **Logs** and select the log group for your Lambda function (for example, **/aws/lambda/my-function**).
7. Select a log stream to view the event data.

# Sending Amazon Simple Notification Service alerts for Amazon ECS task stopped events

Configure an Amazon EventBridge event rule that only captures task events where the task has stopped running because one of its essential containers has terminated. The event sends only task events with a specific `stoppedReason` property to the designated Amazon SNS topic.

## Prerequisite: Set up a test cluster

If you do not have a running cluster to capture events from, follow the steps in [Getting started with the console using Linux containers on AWS Fargate](#) to create one. At the end of this tutorial, you run a task on this cluster to test that you have configured your Amazon SNS topic and EventBridge rule correctly.

## Prerequisite: Configure permissions for Amazon SNS

To allow EventBridge to publish to an Amazon SNS topic, use the `aws sns get-topic-attributes` and the `aws sns set-topic-attributes` commands.

For information about how to add the permission, see [Amazon SNS permissions](#) in the *Amazon Simple Notification Service Developer Guide*

Add the following permissions:

```
{
  "Sid": "PublishEventsToMyTopic",
  "Effect": "Allow",
  "Principal": {
    "Service": "events.amazonaws.com"
  },
  "Action": "sns: Publish",
  "Resource": "arn:aws:sns:region:account-id:TaskStoppedAlert",
}
```

## Step 1: Create and subscribe to an Amazon SNS topic

For this tutorial, you configure an Amazon SNS topic to serve as an event target for your new event rule.

For information about how to create and subscribe to an Amazon SNS topic , see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide* and use the following table to determine what options to select.

| Option   | Value                                               |  |
|----------|-----------------------------------------------------|--|
| Type     | Standard                                            |  |
| Name     | TaskStoppedAlert                                    |  |
| Protocol | Email                                               |  |
| Endpoint | An email address to which you currently have access |  |

## Step 2: Register an event rule

Next, you register an event rule that captures only task-stopped events for tasks with stopped containers.

For information about how to create and subscribe to an Amazon SNS topic , see [Create a rule in Amazon EventBridge](#) in the *Amazon EventBridge User Guide* and use the following table to determine what options to select.

| Option        | Value                                                            |  |
|---------------|------------------------------------------------------------------|--|
| Rule type     | Rule with an event pattern                                       |  |
| Event source  | AWS events or EventBridge partner events                         |  |
| Event pattern | Custom pattern (JSON editor)                                     |  |
| Event pattern | <pre>{   "source": [     "aws.ecs"   ],   "detail-type": [</pre> |  |

| Option      | Value                                                                                                                                                      |  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|             | <pre>"ECS Task State Change" ], "detail":{   "lastStatus":[     "STOPPED"   ],   "stoppedReason":[     "Essentia l container in task exited"   ] } }</pre> |  |
| Target type | AWS service                                                                                                                                                |  |
| Target      | SNS topic                                                                                                                                                  |  |
| Topic       | TaskStoppedAlert (The topic you created in Step 1)                                                                                                         |  |

### Step 3: Test your rule

Verify that the rule is working by running a task that exits shortly after it starts. If your event rule is configured correctly, you receive an email message within a few minutes with the event text. If you have an existing task definition that can satisfy the rule requirements, run a task using it. If you do not, the following steps will walk you through registering a Fargate task definition and running it that will.

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. In the navigation pane, choose **Task definitions**.
3. Choose **Create new task definition**, **Create new task definition with JSON**.
4. In the JSON editor box, edit your JSON file, copy the following into the editor.

```
{
  "containerDefinitions":[
```

```
{
  "command":[
    "sh",
    "-c",
    "sleep 5"
  ],
  "essential":true,
  "image":"public.ecr.aws/amazonlinux/amazonlinux:latest",
  "name":"test-sleep"
}
],
"cpu":"256",
"executionRoleArn":"arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
"family":"fargate-task-definition",
"memory":"512",
"networkMode":"awsvpc",
"requiresCompatibilities":[
  "FARGATE"
]
}
```

5. Choose **Create**.

### To run a task from the console

1. Open the console at <https://console.aws.amazon.com/ecs/v2>.
2. On the **Clusters** page, choose the cluster you created in the prerequisites.
3. From the **Tasks** tab, choose **Run new task**.
4. For **Application type**, choose **Task**.
5. For **Task definition**, choose **fargate-task-definition**.
6. For **Desired tasks**, enter the number of tasks to launch.
7. Choose **Create**.

## Concatenating multiline or stack-trace Amazon ECS log messages

Beginning with AWS for Fluent Bit version 2.22.0, a multiline filter is included. The multiline filter helps concatenate log messages that originally belong to one context but were split across

multiple records or log lines. For more information about the multiline filter, see the [Fluent Bit documentation](#).

Common examples of split log messages are:

- Stack traces.
- Applications that print logs on multiple lines.
- Log messages that were split because they were longer than the specified runtime max buffer size. You can concatenate log messages split by the container runtime by following the example on GitHub: [FireLens Example: Concatenate Partial/Split Container Logs](#).

## Required IAM permissions

You have the necessary IAM permissions for the container agent to pull the container images from Amazon ECR and for the container to route logs to CloudWatch Logs.

For these permissions, you must have the following roles:

- A task IAM role.
- A task execution IAM role.

You need the following permissions:

- `logs:CreateLogStream`
- `logs:CreateLogGroup`
- `logs:PutLogEvents`

## Determine when to use the multiline log setting

The following are example log snippets that you see in the CloudWatch Logs console with the default log setting. You can look at the line that starts with `log` to determine if you need the multiline filter. When the context is the same, you can use the multiline log setting. In this example, the context is `"com.myproject.model.MyProject"`.

```
2022-09-20T15:47:56:595-05-00 {"container_id":  
  "82ba37cada1d44d389b03e78caf74faa-EXAMPLE", "container_name": "example-
```

```
app", "source": "stdout", "log": ": "      at com.myproject.modele.
(MyProject.badMethod.java:22)",
{
  "container_id": "82ba37cada1d44d389b03e78caf74faa-EXAMPLE",
  "container_name": ": "example-app",
  "source": "stdout",
  "log": ": "      at com.myproject.model.MyProject.badMethod(MyProject.java:22)",
  "ecs_cluster": "default",
  "ecs_task_arn": "arn:aws:region:123456789012:task/default/
b23c940d29ed4714971cba72cEXAMPLE",
  "ecs_task_definition": "firelense-example-multiline:3"
}
```

```
2022-09-20T15:47:56:595-05-00 {"container_id":
"82ba37cada1d44d389b03e78caf74faa-EXAMPLE", "container_name": "example-app", "stdout",
"log": ": "      at com.myproject.modele.(MyProject.oneMoreMethod.java:18)",
{
  "container_id": "82ba37cada1d44d389b03e78caf74faa-EXAMPLE",
  "container_name": ": "example-app",
  "source": "stdout",
  "log": ": "      at
com.myproject.model.MyProject.oneMoreMethod(MyProject.java:18)",
  "ecs_cluster": "default",
  "ecs_task_arn": "arn:aws:region:123456789012:task/default/
b23c940d29ed4714971cba72cEXAMPLE",
  "ecs_task_definition": "firelense-example-multiline:3"
}
```

After you use the multiline log setting, the output will look similar to the example.

```
2022-09-20T15:47:56:595-05-00 {"container_id":
"82ba37cada1d44d389b03e78caf74faa-EXAMPLE", "container_name": "example-app",
"stdout",...
{
  "container_id": "82ba37cada1d44d389b03e78caf74faa-EXAMPLE",
  "container_name": ": "example-app",
  "source": "stdout",
  "log": "September 20, 2022 06:41:48 Exception in thread \"main\"
java.lang.RuntimeException: Something has gone wrong, aborting!\n
at com.myproject.module.MyProject.badMethod(MyProject.java:22)\n      at
```

```
at com.myproject.model.MyProject.oneMoreMethod(MyProject.java:18)
com.myproject.module.MyProject.main(MyProject.java:6)",
  "ecs_cluster": "default",
  "ecs_task_arn": "arn:aws:region:123456789012:task/default/
b23c940d29ed4714971cba72cEXAMPLE",
  "ecs_task_definition": "firelense-example-multiline:2"
}
```

## Parse and concatenate options

To parse logs and concatenate lines that were split because of newlines, you can use either of these two options.

- Use your own parser file that contains the rules to parse and concatenate lines that belong to the same message.
- Use a Fluent Bit built-in parser. For a list of languages supported by the Fluent Bit built-in parsers, see [Fluent Bit documentation](#).

The following tutorial walks you through the steps for each use case. The steps show you how to concatenate multilines and send the logs to Amazon CloudWatch. You can specify a different destination for your logs.

### Example: Use a parser that you create

In this example, you will complete the following steps:

1. Build and upload the image for a Fluent Bit container.
2. Build and upload the image for a demo multiline application that runs, fails, and generates a multiline stack trace.
3. Create the task definition and run the task.
4. View the logs to verify that messages that span multiple lines appear concatenated.

### Build and upload the image for a Fluent Bit container

This image will include the parser file where you specify the regular expression and a configuration file that references the parser file.

1. Create a folder with the name `FluentBitDockerImage`.

2. Within the folder, create a parser file that contains the rules to parse the log and concatenate lines that belong in the same message.
  - a. Paste the following contents in the parser file:

```
[MULTILINE_PARSER]
    name          multiline-regex-test
    type           regex
    flush_timeout 1000
    #
    # Regex rules for multiline parsing
    # -----
    #
    # configuration hints:
    #
    # - first state always has the name: start_state
    # - every field in the rule must be inside double quotes
    #
    # rules |   state name   | regex pattern                               | next state
    # -----|-----|-----|-----
    rule     "start_state"  "/(Dec \d+ \d+\:\d+\:\d+)(.*)/"  "cont"
    rule     "cont"         "/^\s+at.*/"                      "cont"
```

As you customize your regex pattern, we recommend you use a regular expression editor to test the expression.

- b. Save the file as `parsers_multiline.conf`.
3. Within the `FluentBitDockerImage` folder, create a custom configuration file that references the parser file that you created in the previous step.

For more information about the custom configuration file, see [Specifying a custom configuration file](#) in the *Amazon Elastic Container Service Developer Guide*

- a. Paste the following contents in the file:

```
[SERVICE]
    flush          1
    log_level      info
    parsers_file    /parsers_multiline.conf

[FILTER]
    name           multiline
```

```
match *
multiline.key_content log
multiline.parser multiline-regex-test
```

**Note**

You must use the absolute path of the parser.

- b. Save the file as `extra.conf`.
4. Within the `FluentBitDockerImage` folder, create the `Dockerfile` with the Fluent Bit image and the parser and configuration files that you created.
  - a. Paste the following contents in the file:

```
FROM public.ecr.aws/aws-observability/aws-for-fluent-bit:latest

ADD parsers_multiline.conf /parsers_multiline.conf
ADD extra.conf /extra.conf
```

- b. Save the file as `Dockerfile`.
5. Using the `Dockerfile`, build a custom Fluent Bit image with the parser and custom configuration files included.

**Note**

You can place the parser file and configuration file anywhere in the Docker image except `/fluent-bit/etc/fluent-bit.conf` as this file path is used by FireLens.

- a. Build the image: `docker build -t fluent-bit-multiline-image`.

Where: `fluent-bit-multiline-image` is the name for the image in this example.

- b. Verify that the image was created correctly: `docker images --filter reference=fluent-bit-multiline-image`

If successful, the output shows the image and the latest tag.

6. Upload the custom Fluent Bit image to Amazon Elastic Container Registry.

- a. Create an Amazon ECR repository to store the image: `aws ecr create-repository --repository-name fluent-bit-multiline-repo --region us-east-1`

Where: `fluent-bit-multiline-repo` is the name for the repository and `us-east-1` is the region in this example.

The output gives you the details of the new repository.

- b. Tag your image with the `repositoryUri` value from the previous output: `docker tag fluent-bit-multiline-image repositoryUri`

Example: `docker tag fluent-bit-multiline-image  
xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-  
repo`

- c. Run the docker image to verify it ran correctly: `docker images --filter reference=repositoryUri`

In the output, the repository name changes from `fluent-bit-multiline-repo` to the `repositoryUri`.

- d. Authenticate to Amazon ECR by running the `aws ecr get-login-password` command and specifying the registry ID you want to authenticate to: `aws ecr get-login-password | docker login --username AWS --password-stdin registry ID.dkr.ecr.region.amazonaws.com`

Example: `ecr get-login-password | docker login --username AWS --  
password-stdin xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com`

A successful login message appears.

- e. Push the image to Amazon ECR: `docker push registry ID.dkr.ecr.region.amazonaws.com/repository name`

Example: `docker push xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/  
fluent-bit-multiline-repo`

## Build and upload the image for a demo multiline application

This image will include a Python script file that runs the application and a sample log file.

When you run the task, the application simulates runs, then fails and creates a stack trace.

1. Create a folder named `multiline-app`: `mkdir multiline-app`
2. Create a Python script file.
  - a. Within the `multiline-app` folder, create a file and name it `main.py`.
  - b. Paste the following contents in the file:

```
import os
import time
file1 = open('/test.log', 'r')
Lines = file1.readlines()

count = 0

for i in range(10):
    print("app running normally...")
    time.sleep(1)

# Strips the newline character
for line in Lines:
    count += 1
    print(line.rstrip())
print(count)
print("app terminated.")
```

- c. Save the `main.py` file.
3. Create a sample log file.
  - a. Within the `multiline-app` folder, create a file and name it `test.log`.
  - b. Paste the following contents in the file:

```
single line...
Dec 14 06:41:08 Exception in thread "main" java.lang.RuntimeException:
Something has gone wrong, aborting!
    at com.myproject.module.MyProject.badMethod(MyProject.java:22)
    at com.myproject.module.MyProject.oneMoreMethod(MyProject.java:18)
    at com.myproject.module.MyProject.anotherMethod(MyProject.java:14)
    at com.myproject.module.MyProject.someMethod(MyProject.java:10)
    at com.myproject.module.MyProject.main(MyProject.java:6)
another line...
```

- c. Save the `test.log` file.
4. Within the `multiline-app` folder, create the `Dockerfile`.
  - a. Paste the following contents in the file:

```
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
ADD test.log /test.log

RUN yum upgrade -y && yum install -y python3

WORKDIR /usr/local/bin

COPY main.py .

CMD ["python3", "main.py"]
```

- b. Save the `Dockerfile` file.
5. Using the `Dockerfile`, build an image.
  - a. Build the image: `docker build -t multiline-app-image`  
  
Where: `multiline-app-image` is the name for the image in this example.
  - b. Verify that the image was created correctly: `docker images --filter reference=multiline-app-image`

If successful, the output shows the image and the latest tag.

6. Upload the image to Amazon Elastic Container Registry.
  - a. Create an Amazon ECR repository to store the image: `aws ecr create-repository --repository-name multiline-app-repo --region us-east-1`

Where: `multiline-app-repo` is the name for the repository and `us-east-1` is the region in this example.

The output gives you the details of the new repository. Note the `repositoryUri` value as you will need it in the next steps.

- b. Tag your image with the `repositoryUri` value from the previous output: `docker tag multiline-app-image repositoryUri`

Example: `docker tag multiline-app-image xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/multiline-app-repo`

- c. Run the docker image to verify it ran correctly: `docker images --filter reference=repositoryUri`

In the output, the repository name changes from `multiline-app-repo` to the `repositoryUri` value.

- d. Push the image to Amazon ECR: `docker push aws_account_id.dkr.ecr.region.amazonaws.com/repository name`

Example: `docker push xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/multiline-app-repo`

## Create the task definition and run the task

1. Create a task definition file with the file name `multiline-task-definition.json`.
2. Paste the following contents in the `multiline-task-definition.json` file:

```
{
  "family": "firelens-example-multiline",
  "taskRoleArn": "task role ARN",
  "executionRoleArn": "execution role ARN",
  "containerDefinitions": [
    {
      "essential": true,
      "image": "aws_account_id.dkr.ecr.us-east-1.amazonaws.com/fluently-bit-multiline-image:latest",
      "name": "log_router",
      "firelensConfiguration": {
        "type": "fluentbit",
        "options": {
          "config-file-type": "file",
          "config-file-value": "/extra.conf"
        }
      },
      "memoryReservation": 50
    },
    {
      "essential": true,
```

```

        "image": "aws_account_id.dkr.ecr.us-east-1.amazonaws.com/multiline-app-
image:latest",
        "name": "app",
        "logConfiguration": {
            "logDriver": "awsfirelens",
            "options": {
                "Name": "cloudwatch_logs",
                "region": "us-east-1",
                "log_group_name": "multiline-test/application",
                "auto_create_group": "true",
                "log_stream_prefix": "multiline-"
            }
        },
        "memoryReservation": 100
    }
],
"requiresCompatibilities": ["FARGATE"],
"networkMode": "awsvpc",
"cpu": "256",
"memory": "512"
}

```

Replace the following in the `multiline-task-definition.json` task definition:

a. *task role ARN*

To find the task role ARN, go to the IAM console. Choose **Roles** and find the `ecs-task-role-for-firelens` task role that you created. Choose the role and copy the **ARN** that appears in the **Summary** section.

b. *execution role ARN*

To find the execution role ARN, go to the IAM console. Choose **Roles** and find the `ecsTaskExecutionRole` role. Choose the role and copy the **ARN** that appears in the **Summary** section.

c. *aws\_account\_id*

To find your `aws_account_id`, log into the AWS Management Console. Choose your user name and copy your Account ID.

d. *us-east-1*

Replace the region if necessary.

3. Register the task definition file: `aws ecs register-task-definition --cli-input-json file://multiline-task-definition.json --region region`
4. Open the console at <https://console.aws.amazon.com/ecs/v2>.
5. In the navigation pane, choose **Task Definitions** and then choose the `firelens-example-multiline` family because we registered the task definition to this family in the first line of the preceding task definition.
6. Choose the latest version.
7. Choose the **Deploy, Run task**.
8. On the **Run Task** page, For **Cluster**, choose the cluster, and then under **Networking**, for **Subnets**, choose the available subnets for your task.
9. Choose **Create**.

### Verify that multiline log messages in Amazon CloudWatch appear concatenated

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. From the navigation pane, expand **Logs** and choose **Log groups**.
3. Choose the `multiline-test/application` log group.
4. Choose the log. View messages. Lines that matched the rules in the parser file are concatenated and appear as a single message.

The following log snippet shows lines concatenated in a single Java stack trace event:

```
{
  "container_id": "xxxxxx",
  "container_name": "app",
  "source": "stdout",
  "log": "Dec 14 06:41:08 Exception in thread \"main\"
java.lang.RuntimeException: Something has gone wrong, aborting!\\n
at com.myproject.module.MyProject.badMethod(MyProject.java:22)\\n      at
com.myproject.module.MyProject.oneMoreMethod(MyProject.java:18)\\n
at com.myproject.module.MyProject.anotherMethod(MyProject.java:14)\\n
at com.myproject.module.MyProject.someMethod(MyProject.java:10)\\n      at
com.myproject.module.MyProject.main(MyProject.java:6)\",
  "ecs_cluster": "default",
  "ecs_task_arn": "arn:aws:ecs:us-east-1:xxxxxxxxxxxx:task/default/xxxxxx",
  "ecs_task_definition": "firelens-example-multiline:2"
}
```

The following log snippet shows how the same message appears with just a single line if you run an Amazon ECS container that is not configured to concatenate multiline log messages.

```
{
  "log": "Dec 14 06:41:08 Exception in thread \"main\"
java.lang.RuntimeException: Something has gone wrong, aborting!",
  "container_id": "xxxxxx-xxxxxx",
  "container_name": "app",
  "source": "stdout",
  "ecs_cluster": "default",
  "ecs_task_arn": "arn:aws:ecs:us-east-1:xxxxxxxxxxxx:task/default/xxxxxx",
  "ecs_task_definition": "firelens-example-multiline:3"
}
```

## Example: Use a Fluent Bit built-in parser

In this example, you will complete the following steps:

1. Build and upload the image for a Fluent Bit container.
2. Build and upload the image for a demo multiline application that runs, fails, and generates a multiline stack trace.
3. Create the task definition and run the task.
4. View the logs to verify that messages that span multiple lines appear concatenated.

### Build and upload the image for a Fluent Bit container

This image will include a configuration file that references the Fluent Bit parser.

1. Create a folder with the name `FluentBitDockerImage`.
2. Within the `FluentBitDockerImage` folder, create a custom configuration file that references the Fluent Bit built-in parser file.

For more information about the custom configuration file, see [Specifying a custom configuration file](#) in the *Amazon Elastic Container Service Developer Guide*

- a. Paste the following contents in the file:

```
[FILTER]
```

```
name          multiline
match         *
multiline.key_content log
multiline.parser go
```

- b. Save the file as `extra.conf`.
3. Within the `FluentBitDockerImage` folder, create the `Dockerfile` with the Fluent Bit image and the parser and configuration files that you created.
  - a. Paste the following contents in the file:

```
FROM public.ecr.aws/aws-observability/aws-for-fluent-bit:latest
ADD extra.conf /extra.conf
```

- b. Save the file as `Dockerfile`.
4. Using the `Dockerfile`, build a custom Fluent Bit image with the custom configuration file included.

 **Note**

You can place the configuration file anywhere in the Docker image except `/fluent-bit/etc/fluent-bit.conf` as this file path is used by FireLens.

- a. Build the image: `docker build -t fluent-bit-multiline-image`.  
  
Where: `fluent-bit-multiline-image` is the name for the image in this example.
  - b. Verify that the image was created correctly: `docker images --filter reference=fluent-bit-multiline-image`  
  
If successful, the output shows the image and the latest tag.
5. Upload the custom Fluent Bit image to Amazon Elastic Container Registry.
  - a. Create an Amazon ECR repository to store the image: `aws ecr create-repository --repository-name fluent-bit-multiline-repo --region us-east-1`  
  
Where: `fluent-bit-multiline-repo` is the name for the repository and `us-east-1` is the region in this example.  
  
The output gives you the details of the new repository.

- b. Tag your image with the repositoryUri value from the previous output: `docker tag fluent-bit-multiline-image repositoryUri`

Example: `docker tag fluent-bit-multiline-image xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-repo`

- c. Run the docker image to verify it ran correctly: `docker images --filter reference=repositoryUri`

In the output, the repository name changes from fluent-bit-multiline-repo to the repositoryUri.

- d. Authenticate to Amazon ECR by running the `aws ecr get-login-password` command and specifying the registry ID you want to authenticate to: `aws ecr get-login-password | docker login --username AWS --password-stdin registryID.dkr.ecr.region.amazonaws.com`

Example: `aws ecr get-login-password | docker login --username AWS --password-stdin xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com`

A successful login message appears.

- e. Push the image to Amazon ECR: `docker push registryID.dkr.ecr.region.amazonaws.com/repository name`

Example: `docker push xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-repo`

## Build and upload the image for a demo multiline application

This image will include a Python script file that runs the application and a sample log file.

1. Create a folder named multiline-app: `mkdir multiline-app`
2. Create a Python script file.
  - a. Within the multiline-app folder, create a file and name it main.py.
  - b. Paste the following contents in the file:

```
import os
import time
```

```

file1 = open('/test.log', 'r')
Lines = file1.readlines()

count = 0

for i in range(10):
    print("app running normally...")
    time.sleep(1)

# Strips the newline character
for line in Lines:
    count += 1
    print(line.rstrip())
print(count)
print("app terminated.")

```

- c. Save the `main.py` file.
3. Create a sample log file.
    - a. Within the `multiline-app` folder, create a file and name it `test.log`.
    - b. Paste the following contents in the file:

```

panic: my panic

goroutine 4 [running]:
panic(0x45cb40, 0x47ad70)

created by runtime.gcenable
/usr/local/go/src/runtime/mgc.go:216 +0x58
one more line, no multiline
```

- c. Save the `test.log` file.
4. Within the `multiline-app` folder, create the `Dockerfile`.
  - a. Paste the following contents in the file:

```
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
ADD test.log /test.log

RUN yum upgrade -y && yum install -y python3

WORKDIR /usr/local/bin

COPY main.py .

CMD ["python3", "main.py"]
```

- b. Save the `Dockerfile` file.
5. Using the `Dockerfile`, build an image.
  - a. Build the image: `docker build -t multiline-app-image`

Where: `multiline-app-image` is the name for the image in this example.

- b. Verify that the image was created correctly: `docker images --filter reference=multiline-app-image`

If successful, the output shows the image and the latest tag.

6. Upload the image to Amazon Elastic Container Registry.
  - a. Create an Amazon ECR repository to store the image: `aws ecr create-repository --repository-name multiline-app-repo --region us-east-1`

Where: `multiline-app-repo` is the name for the repository and `us-east-1` is the region in this example.

The output gives you the details of the new repository. Note the `repositoryUri` value as you will need it in the next steps.

- b. Tag your image with the `repositoryUri` value from the previous output: `docker tag multiline-app-image repositoryUri`

Example: `docker tag multiline-app-image xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/multiline-app-repo`

- c. Run the docker image to verify it ran correctly: `docker images --filter reference=repositoryUri`

In the output, the repository name changes from `multiline-app-repo` to the `repositoryUri` value.

- d. Push the image to Amazon ECR: `docker push aws_account_id.dkr.ecr.region.amazonaws.com/repository name`

Example: `docker push xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/multiline-app-repo`

## Create the task definition and run the task

1. Create a task definition file with the file name `multiline-task-definition.json`.
2. Paste the following contents in the `multiline-task-definition.json` file:

```
{
  "family": "firelens-example-multiline",
  "taskRoleArn": "task role ARN",
  "executionRoleArn": "execution role ARN",
  "containerDefinitions": [
    {
      "essential": true,
      "image": "aws_account_id.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-image:latest",
      "name": "log_router",
      "firelensConfiguration": {
        "type": "fluentbit",
        "options": {
          "config-file-type": "file",
          "config-file-value": "/extra.conf"
        }
      }
    }
  ]
}
```

```

        }
      },
      "memoryReservation": 50
    },
    {
      "essential": true,
      "image": "aws_account_id.dkr.ecr.us-east-1.amazonaws.com/multiline-app-  
image:latest",
      "name": "app",
      "logConfiguration": {
        "logDriver": "awsfirelens",
        "options": {
          "Name": "cloudwatch_logs",
          "region": "us-east-1",
          "log_group_name": "multiline-test/application",
          "auto_create_group": "true",
          "log_stream_prefix": "multiline-"
        }
      },
      "memoryReservation": 100
    }
  ],
  "requiresCompatibilities": ["FARGATE"],
  "networkMode": "awsvpc",
  "cpu": "256",
  "memory": "512"
}

```

Replace the following in the `multiline-task-definition.json` task definition:

a. *task role ARN*

To find the task role ARN, go to the IAM console. Choose **Roles** and find the `ecs-task-role-for-firelens` task role that you created. Choose the role and copy the **ARN** that appears in the **Summary** section.

b. *execution role ARN*

To find the execution role ARN, go to the IAM console. Choose **Roles** and find the `ecsTaskExecutionRole` role. Choose the role and copy the **ARN** that appears in the **Summary** section.

c. *aws\_account\_id*

To find your `aws_account_id`, log into the AWS Management Console. Choose your user name and copy your Account ID.

d. `us-east-1`

Replace the region if necessary.

3. Register the task definition file: `aws ecs register-task-definition --cli-input-json file://multiline-task-definition.json --region us-east-1`
4. Open the console at <https://console.aws.amazon.com/ecs/v2>.
5. In the navigation pane, choose **Task Definitions** and then choose the `firelens-example-multiline` family because we registered the task definition to this family in the first line of the preceding task definition.
6. Choose the latest version.
7. Choose the **Deploy, Run task**.
8. On the **Run Task** page, For **Cluster**, choose the cluster, and then under **Networking**, for **Subnets**, choose the available subnets for your task.
9. Choose **Create**.

### Verify that multiline log messages in Amazon CloudWatch appear concatenated

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. From the navigation pane, expand **Logs** and choose **Log groups**.
3. Choose the `multiline-test/application` log group.
4. Choose the log and view the messages. Lines that matched the rules in the parser file are concatenated and appear as a single message.

The following log snippet shows a Go stack trace that is concatenated into a single event:

```
{
  "log": "panic: my panic\n\nngoroutine 4 [running]:\npanic(0x45cb40,\n0x47ad70)\n /usr/local/go/src/runtime/panic.go:542 +0x46c fp=0xc42003f7b8\nsp=0xc42003f710 pc=0x422f7c\nmain.main.func1(0xc420024120)\n foo.go:6\n+0x39 fp=0xc42003f7d8 sp=0xc42003f7b8 pc=0x451339\nruntime.goexit()\n /usr/\nlocal/go/src/runtime/asm_amd64.s:2337 +0x1 fp=0xc42003f7e0 sp=0xc42003f7d8\npc=0x44b4d1\ncreated by main.main\n foo.go:5 +0x58\n\nngoroutine 1 [chan receive]:\n\nruntime.gopark(0x4739b8, 0xc420024178, 0x46fcd7, 0xc, 0xc420028e17, 0x3)\n /usr/\nlocal/go/src/runtime/proc.go:280 +0x12c fp=0xc420053e30 sp=0xc420053e00 pc=0x42503c

+0xcc fp=0xc42003e7e0 sp=0xc42003e7a8 pc=0x424e5c\nruntime.goexit()\n /usr/
local/go/src/runtime/asm_amd64.s:2337 +0x1 fp=0xc42003e7e8 sp=0xc42003e7e0
pc=0x44b4d1\ncreated by runtime.init.4\n /usr/local/go/src/runtime/proc.go:227
+0x35\n\nngoroutine 3 [GC sweep wait]:\nruntime.gopark(0x4739b8, 0x4ad7e0,
0x46fdd2, 0xd, 0x419914, 0x1)\n /usr/local/go/src/runtime/proc.go:280 +0x12c
fp=0xc42003ef60 sp=0xc42003ef30 pc=0x42503c\nruntime.goparkunlock(0x4ad7e0,
0x46fdd2, 0xd, 0x14, 0x1)\n /usr/local/go/src/runtime/proc.go:286 +0x5e
fp=0xc42003efa0 sp=0xc42003ef60 pc=0x42512e\nruntime.bgsweep(0xc42001e150)\n
 /usr/local/go/src/runtime/mgcsweep.go:52 +0xa3 fp=0xc42003efd8 sp=0xc42003efa0
pc=0x419973\nruntime.goexit()\n /usr/local/go/src/runtime/asm_amd64.s:2337 +0x1
fp=0xc42003efe0 sp=0xc42003efd8 pc=0x44b4d1\ncreated by runtime.gcenable\n /usr/
local/go/src/runtime/mgc.go:216 +0x58",
  "container_id": "xxxxxx-xxxxxx",
  "container_name": "app",
  "source": "stdout",
  "ecs_cluster": "default",
  "ecs_task_arn": "arn:aws:ecs:us-east-1:xxxxxxxxxxxx:task/default/xxxxxx",
  "ecs_task_definition": "firelens-example-multiline:2"
}

```

The following log snippet shows how the same event appears if you run an ECS container that is not configured to concatenate multiline log messages. The log field contains a single line.

```

{
  "log": "panic: my panic",
  "container_id": "xxxxxx-xxxxxx",
  "container_name": "app",
  "source": "stdout",

```

```
"ecs_cluster": "default",  
"ecs_task_arn": "arn:aws:ecs:us-east-1:xxxxxxxxxxxx:task/default/xxxxxx",  
"ecs_task_definition": "firelens-example-multiline:3"
```

### Note

If your logs go to log files instead of the standard output, we recommend specifying the `multiline.parser` and `multiline.key_content` configuration parameters in the [Tail input plugin](#) instead of the Filter.

## Deploying Fluent Bit on Amazon ECS Windows containers

Fluent Bit is a fast and flexible log processor and router supported by various operating systems. It can be used to route logs to various AWS destinations such as Amazon CloudWatch Logs, Firehose Amazon S3, and Amazon OpenSearch Service. Fluent Bit supports common partner solutions such as [Datadog](#), [Splunk](#), and custom HTTP servers. For more information about Fluent Bit, see the [Fluent Bit](#) website.

The **AWS for Fluent Bit** image is available on Amazon ECR on both the Amazon ECR Public Gallery and in an Amazon ECR repository in most Regions for high availability. For more information, see [aws-for-fluent-bit](#) on the GitHub website.

This tutorial walks you through how to deploy Fluent Bit containers on their Windows instances running in Amazon ECS to stream logs generated by the Windows tasks to Amazon CloudWatch for centralized logging.

This tutorial uses the following approach:

- Fluent Bit runs as a service with the Daemon scheduling strategy. This strategy ensures that a single instance of Fluent Bit always runs on the container instances in the cluster.
  - Listens on port 24224 using the forward input plug-in.
  - Expose port 24224 to the host so that the Docker runtime can send logs to Fluent Bit using this exposed port.
  - Has a configuration which allows Fluent Bit to send the logs records to specified destinations.
- Launch all other Amazon ECS task containers using the `fluentd` logging driver. For more information, see [Fluentd logging driver](#) on the Docker documentation website.

- Docker connects to the TCP socket 24224 on localhost inside the host namespace.
- The Amazon ECS agent adds labels to the containers which includes the cluster name, task definition family name, task definition revision number, task ARN, and the container name. The same information is added to the log record using the labels option of the fluentd docker logging driver. For more information, see [labels, labels-regex, env, and env-regex](#) on the Docker documentation website.
- Because the `async` option of the fluentd logging driver is set to `true`, when the Fluent Bit container is restarted, docker buffers the logs until the Fluent Bit container is restarted. You can increase the buffer limit by setting the `fluentd-buffer-limit` option. For more information, see [fluentd-buffer-limit](#) on the Docker documentation website.

The work flow is as follows:

- The Fluent Bit container starts and listens on port 24224 which is exposed to the host.
- Fluent Bit uses the task IAM role credentials specified in its task definition.
- Other tasks launched on the same instance use the fluentd docker logging driver to connect to the Fluent Bit container on port 24224.
- When the application containers generate logs, docker runtime tags those records, adds additional metadata specified in labels, and then forwards them on port 24224 in the host namespace.
- Fluent Bit receives the log record on port 24224 because it is exposed to the host namespace.
- Fluent Bit performs its internal processing and routes the logs as specified.

This tutorial uses the default CloudWatch Fluent Bit configuration which does the following:

- Creates a new log group for each cluster and task definition family.
- Creates a new log stream for each task container in the previously generated log group whenever a new task is launched. Each stream will be marked with the task id to which the container belongs.
- Adds additional metadata including the cluster name, task ARN, task container name, task definition family, and the task definition revision number in each log entry.

For example, if you have `task_1` with `container_1` and `container_2` and `task_2` with `container_3`, then the following are the CloudWatch log streams:

- `/aws/ecs/windows.ecs_task_1`

task-out.*TASK\_ID*.container\_1

task-out.*TASK\_ID*.container\_2

- /aws/ecs/windows.ecs\_task\_2

task-out.*TASK\_ID*.container\_3

### Note

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

## Steps

- [Prerequisites](#)
- [Step 1: Create the IAM access roles](#)
- [Step 2: Create an Amazon ECS Windows container instance](#)
- [Step 3: Configure Fluent Bit](#)
- [Step 4: Register a Windows Fluent Bit task definition which routes the logs to CloudWatch](#)
- [Step 5: Run the ecs-windows-fluent-bit task definition as an Amazon ECS service using the daemon scheduling strategy](#)
- [Step 6: Register a Windows task definition which generates the logs](#)
- [Step 7: Run the windows-app-task task definition](#)
- [Step 8: Verify the logs on CloudWatch](#)
- [Step 9: Clean up](#)

## Prerequisites

This tutorial assumes that the following prerequisites have been completed:

- The latest version of the AWS CLI is installed and configured. For more information, see [Installing or updating to the latest version of the AWS CLI](#).

- The `aws-for-fluent-bit` container image is available for the following Windows operating systems:
  - Windows Server 2019 Core
  - Windows Server 2019 Full
  - Windows Server 2022 Core
  - Windows Server 2022 Full
- The steps in [Set up to use Amazon ECS](#) have been completed.
- You have a cluster. In this tutorial, the cluster name is **FluentBit-cluster**.
- You have a VPC with a public subnet where the EC2 instance will be launched. You can use your default VPC. You can also use a private subnet that allows Amazon CloudWatch endpoints to reach the subnet. For more information about Amazon CloudWatch endpoints, see [Amazon CloudWatch endpoints and quotas](#) in the *AWS General Reference*. For information about how to use the Amazon VPC wizard to create a VPC, see [the section called "Create a virtual private cloud"](#).

## Step 1: Create the IAM access roles

Create the Amazon ECS IAM roles.

1. Create the Amazon ECS container instance role named `ecsInstanceRole`. For more information, see [Amazon ECS container instance IAM role](#).
2. Create an IAM role for the Fluent Bit task named `fluentTaskRole`. For more information, see [the section called "Task IAM role"](#).

The IAM permissions granted in this IAM role are assumed by the task containers. In order to allow Fluent Bit to send logs to CloudWatch, you need to attach the following permissions to the task IAM role.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
```

```
        "logs:CreateLogStream",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "logs:PutLogEvents"
    ],
    "Resource": "*"
}
]
```

3. Attach the policy to the role.

- a. Save the preceding content in a file named `fluent-bit-policy.json`.
- b. Run the following command to attach the inline policy to `fluentTaskRole` IAM role.

```
aws iam put-role-policy --role-name fluentTaskRole --policy-name
fluentTaskPolicy --policy-document file://fluent-bit-policy.json
```

## Step 2: Create an Amazon ECS Windows container instance

Create an Amazon ECS Windows container instance.

### To create an Amazon ECS instance

1. Use the `aws ssm get-parameters` command to retrieve the AMI ID for the Region that hosts your VPC. For more information, see [Retrieving Amazon ECS-Optimized AMI metadata](#).
2. Use the Amazon EC2 console to launch the instance.
  - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
  - b. From the navigation bar, select the Region to use.
  - c. From the **EC2 Dashboard**, choose **Launch instance**.
  - d. For **Name**, enter a unique name.
  - e. For **Application and OS Images (Amazon Machine Image)**, choose the AMI that you retrieved in the first step.
  - f. For **Instance type**, choose `t3.xlarge`.
  - g. For **Key pair (login)**, choose a key pair.

- h. Under **Network settings**, for **Security group**, choose an existing security group, or create a new one.
- i. Under **Network settings**, for **Auto-assign Public IP**, select **Enable**.
- j. Under **Advanced details**, for **IAM instance profile**, choose **ecsInstanceRole**.
- k. Configure your Amazon ECS container instance with the following user data. Under **Advanced Details**, paste the following script into the **User data** field, replacing *cluster\_name* with the name of your cluster.

```
<powershell>
Import-Module ECSTools
Initialize-ECSAgent -Cluster cluster-name -EnableTaskENI -EnableTaskIAMRole -
LoggingDrivers '["awslogs","fluentd"]'
</powershell>
```

- l. When you are ready, select the acknowledgment field, and then choose **Launch Instances**.
- m. A confirmation page lets you know that your instance is launching. Choose **View Instances** to close the confirmation page and return to the console.

## Step 3: Configure Fluent Bit

You can use the following default configuration provided by AWS to get quickly started:

- [Amazon CloudWatch](#) which is based on the Fluent Bit plug-in for [Amazon CloudWatch](#) on the *Fluent Bit Official Manual*.

Alternatively, you can use other default configurations provided by AWS. For more information, see [Overriding the entrypoint for the Windows image](#) on the `aws-for-fluent-bit` the Github website.

The default Amazon CloudWatch Fluent Bit configuration is the following.

Replace the following variables:

- *region* with the Region where you want to send the Amazon CloudWatch logs.

```
[SERVICE]
  Flush      5
```

```
Log_Level      info
Daemon         off
```

#### [INPUT]

```
Name          forward
Listen        0.0.0.0
Port          24224
Buffer_Chunk_Size 1M
Buffer_Max_Size 6M
Tag_Prefix    ecs.
```

# Amazon ECS agent adds the following log keys as labels to the docker container.  
 # We would use fluentd logging driver to add these to log record while sending it to  
 Fluent Bit.

#### [FILTER]

```
Name          modify
Match         ecs.*
Rename        com.amazonaws.ecs.cluster ecs_cluster
Rename        com.amazonaws.ecs.container-name ecs_container_name
Rename        com.amazonaws.ecs.task-arn ecs_task_arn
Rename        com.amazonaws.ecs.task-definition-family
ecs_task_definition_family
Rename        com.amazonaws.ecs.task-definition-version
ecs_task_definition_version
```

#### [FILTER]

```
Name          rewrite_tag
Match         ecs.*
Rule          $ecs_task_arn ^([a-z-:0-9]+)/([a-zA-Z0-9-_]+)/([a-z0-9-9])$
out.$3.$ecs_container_name false
Emitter_Name   re_emitted
```

#### [OUTPUT]

```
Name          cloudwatch_logs
Match         out.*
region        region
log_group_name fallback-group
log_group_template /aws/ecs/$ecs_cluster.$ecs_task_definition_family
log_stream_prefix task-
auto_create_group On
```

Every log which gets into Fluent Bit has a tag which you specify, or is automatically generated when you do not supply one. The tags can be used to route different logs to different destinations. For additional information, see [Tag](#) in the *Fluent Bit Official Manual*.

The preceding Fluent Bit configuration has the following properties:

- The forward input plug-in listens for incoming traffic on TCP port 24224.
- Each log entry received on that port has a tag which the forward input plug-in modifies to prefix the record with `ecs . string`.
- The Fluent Bit internal pipeline routes the log entry to modify the filter using the Match regex. This filter replaces the keys in the log record JSON to the format which Fluent Bit can consume.
- The modified log entry is then consumed by the `rewrite_tag` filter. This filter changes the tag of the log record to the format `out.TASK_ID.CONTAINER_NAME`.
- The new tag will be routed to output `cloudwatch_logs` plug-in which creates the log groups and streams as described earlier by using the `log_group_template` and `log_stream_prefix` options of the CloudWatch output plug-in. For additional information, see [Configuration parameters](#) in the *Fluent Bit Official Manual*.

## Step 4: Register a Windows Fluent Bit task definition which routes the logs to CloudWatch

Register a Windows Fluent Bit task definition which routes the logs to CloudWatch.

### Note

This task definition exposes Fluent Bit container port 24224 to the host port 24224. Verify that this port is not open in your EC2 instance security group to prevent access from outside.

### To register a task definition

1. Create a file named `fluent-bit.json` with the following contents.

Replace the following variables:

- `task-iam-role` with the Amazon Resource Name (ARN) of your task IAM role

- *region* with the Region where your task runs

```
{
  "family": "ecs-windows-fluent-bit",
  "taskRoleArn": "task-iam-role",
  "containerDefinitions": [
    {
      "name": "fluent-bit",
      "image": "public.ecr.aws/aws-observability/aws-for-fluent-bit:windowsservercore-latest",
      "cpu": 512,
      "portMappings": [
        {
          "hostPort": 24224,
          "containerPort": 24224,
          "protocol": "tcp"
        }
      ],
      "entryPoint": [
        "Powershell",
        "-Command"
      ],
      "command": [
        "C:\\\\entrypoint.ps1 -ConfigFile C:\\\\ecs_windows_forward_daemon\\cloudwatch.conf"
      ],
      "environment": [
        {
          "name": "AWS_REGION",
          "value": "region"
        }
      ],
      "memory": 512,
      "essential": true,
      "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
          "awslogs-group": "/ecs/fluent-bit-logs",
          "awslogs-region": "region",
          "awslogs-stream-prefix": "flb",
          "awslogs-create-group": "true"
        }
      }
    }
  ]
}
```

```
    }  
  }  
],  
"memory": "512",  
"cpu": "512"  
}
```

2. Run the following command to register the task definition.

```
aws ecs register-task-definition --cli-input-json file://fluent-bit.json --  
region region
```

You can list the task definitions for your account by running the `list-task-definitions` command. The output of displays the family and revision values that you can use together with `run-task` or `start-task`.

## Step 5: Run the `ecs-windows-fluent-bit` task definition as an Amazon ECS service using the daemon scheduling strategy

After you register a task definition for your account, you can run a task in the cluster. For this tutorial, you run one instance of the `ecs-windows-fluent-bit:1` task definition in your `FluentBit-cluster` cluster. Run the task in a service which uses the daemon scheduling strategy, which ensures that a single instance of Fluent Bit always runs on each of your container instances.

### To run a task

1. Run the following command to start the `ecs-windows-fluent-bit:1` task definition (registered in the previous step) as a service.

#### Note

This task definition uses the `awslogs` logging driver, your container instance need to have the necessary permissions.

Replace the following variables:

- *region* with the Region where your service runs

```
aws ecs create-service \
  --cluster FluentBit-cluster \
  --service-name FluentBitForwardDaemonService \
  --task-definition ecs-windows-fluent-bit:1 \
  --launch-type EC2 \
  --scheduling-strategy DAEMON \
  --region region
```

2. Run the following command to list your tasks.

Replace the following variables:

- *region* with the Region where your service tasks run

```
aws ecs list-tasks --cluster FluentBit-cluster --region region
```

## Step 6: Register a Windows task definition which generates the logs

Register a task definition which generates the logs. This task definition deploys Windows container image which will write an incremental number to stdout every second.

The task definition uses the fluentd logging driver which connects to port 24224 which the Fluent Bit plug-in listens to. The Amazon ECS agent labels each Amazon ECS container with tags including the cluster name, task ARN, task definition family name, task definition revision number and the task container name. These key-value labels are passed to Fluent Bit.

### Note

This task uses the default network mode. However, you can also use the awsvpc network mode with the task.

### To register a task definition

1. Create a file named `windows-app-task.json` with the following contents.

```
{
```

```

"family": "windows-app-task",
"containerDefinitions": [
  {
    "name": "sample-container",
    "image": "mcr.microsoft.com/windows/servercore:ltsc2019",
    "cpu": 512,
    "memory": 512,
    "essential": true,
    "entryPoint": [
      "Powershell",
      "-Command"
    ],
    "command": [
      "$count=1;while(1) { Write-Host $count; sleep 1; $count=$count+1;}"
    ],
    "logConfiguration": {
      "logDriver": "fluentd",
      "options": {
        "fluentd-address": "localhost:24224",
        "tag": "{{ index .ContainerLabels \"com.amazonaws.ecs.task-definition-family\" }}",
        "fluentd-async": "true",
        "labels": "com.amazonaws.ecs.cluster,com.amazonaws.ecs.container-name,com.amazonaws.ecs.task-arn,com.amazonaws.ecs.task-definition-family,com.amazonaws.ecs.task-definition-version"
      }
    }
  }
],
"memory": "512",
"cpu": "512"
}

```

2. Run the following command to register the task definition.

Replace the following variables:

- *region* with the Region where your task runs

```

aws ecs register-task-definition --cli-input-json file://windows-app-task.json --
region region

```

You can list the task definitions for your account by running the `list-task-definitions` command. The output of displays the family and revision values that you can use together with `run-task` or `start-task`.

## Step 7: Run the `windows-app-task` task definition

After you register the `windows-app-task` task definition, run it in your `FluentBit-cluster` cluster.

### To run a task

1. Run the `windows-app-task:1` task definition you registered in the previous step.

Replace the following variables:

- `region` with the Region where your task runs

```
aws ecs run-task --cluster FluentBit-cluster --task-definition windows-app-task:1
--count 2 --region region
```

2. Run the following command to list your tasks.

```
aws ecs list-tasks --cluster FluentBit-cluster
```

## Step 8: Verify the logs on CloudWatch

In order to verify your Fluent Bit setup, check for the following log groups in the CloudWatch console:

- `/ecs/fluent-bit-logs` - This is the log group which corresponds to the Fluent Bit daemon container which is running on the container instance.
- `/aws/ecs/FluentBit-cluster.windows-app-task` - This is the log group which corresponds to all the tasks launched for `windows-app-task` task definition family inside `FluentBit-cluster` cluster.

`task-out.FIRST_TASK_ID.sample-container` - This log stream contains all the logs generated by the first instance of the task in the `sample-container` task container.

task-out.*SECOND\_TASK\_ID*.sample-container - This log stream contains all the logs generated by the second instance of the task in the sample-container task container.

The task-out.*TASK\_ID*.sample-container log stream has fields similar to the following:

```
{
  "source": "stdout",
  "ecs_task_arn": "arn:aws:ecs:region:0123456789012:task/FluentBit-
cluster/13EXAMPLE",
  "container_name": "/ecs-windows-app-task-1-sample-container-cEXAMPLE",
  "ecs_cluster": "FluentBit-cluster",
  "ecs_container_name": "sample-container",
  "ecs_task_definition_version": "1",
  "container_id": "61f5e6EXAMPLE",
  "log": "10",
  "ecs_task_definition_family": "windows-app-task"
}
```

## To verify the Fluent Bit setup

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the navigation pane, choose **Log groups**. Make sure that you're in the Region where you deployed Fluent Bit to your containers.

In the list of log groups in the AWS Region, you should see the following:

- /ecs/fluent-bit-logs
- /aws/ecs/FluentBit-cluster.windows-app-task

If you see these log groups, the Fluent Bit setup is verified.

## Step 9: Clean up

When you have finished this tutorial, clean up the resources associated with it to avoid incurring charges for resources that you aren't using.

## To clean up the tutorial resources

1. Stop the `windows-simple-task` task and the `ecs-fluent-bit` task. For more information, see [the section called “Stopping a task”](#).
2. Run the following command to delete the `/ecs/fluent-bit-logs` log group. For more information, about deleting log groups see [delete-log-group](#) in the *AWS Command Line Interface Reference*.

```
aws logs delete-log-group --log-group-name /ecs/fluent-bit-logs
aws logs delete-log-group --log-group-name /aws/ecs/FluentBit-cluster.windows-app-task
```

3. Run the following command to terminate the instance.

```
aws ec2 terminate-instances --instance-ids instance-id
```

4. Run the following commands to delete the IAM roles.

```
aws iam delete-role --role-name ecsInstanceRole
aws iam delete-role --role-name fluentTaskRole
```

5. Run the following command to delete the Amazon ECS cluster.

```
aws ecs delete-cluster --cluster FluentBit-cluster
```

## Using gMSA for EC2 Linux containers on Amazon ECS

Amazon ECS supports Active Directory authentication for Linux containers on EC2 through a special kind of service account called a *group Managed Service Account* (gMSA).

Linux based network applications, such as .NET Core applications, can use Active Directory to facilitate authentication and authorization management between users and services. You can use this feature by designing applications that integrate with Active Directory and run on domain-joined servers. But, because Linux containers can't be domain-joined, you need to configure a Linux container to run with gMSA.

A Linux container that runs with gMSA relies on the `credentials-fetcher` daemon that runs on the container's host Amazon EC2 instance. That is, the daemon retrieves the gMSA credentials from the Active Directory domain controller and then transfers these credentials to the container

instance. For more information about service accounts, see [Create gMSAs for Windows containers](#) on the Microsoft Learn website.

## Considerations

Consider the following before you use gMSA for Linux containers:

- If your containers run on EC2, you can use gMSA for Windows containers and Linux containers. For information about how to use gMSA for Linux container on Fargate, see [Using gMSA for Linux containers on Fargate](#).
- You might need a Windows computer that's joined to the domain to complete the prerequisites. For example, you might need a Windows computer that's joined to the domain to create the gMSA in Active Directory with PowerShell. The RSAT Active Director PowerShell tools are only available for Windows. For more information, see [Installing the Active Directory administration tools](#).
- You chose between **domainless gMSA** and **joining each instance to a single domain**. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

Then, choose the data storage for the CredSpec and optionally, for the Active Directory user credentials for domainless gMSA.

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the container. You generate the CredSpec file and then store it in one of the CredSpec storage options in the following table, specific to the Operating System of the container instances. To use the domainless method, an optional section in the CredSpec file can specify credentials in one of the *domainless user credentials* storage options in the following table, specific to the Operating System of the container instances.

| Storage location              | Linux                       | Windows                     |
|-------------------------------|-----------------------------|-----------------------------|
| Amazon Simple Storage Service | CredSpec                    | CredSpec                    |
| AWS Secrets Manager           | domainless user credentials | domainless user credentials |

| Storage location                           | Linux    | Windows                               |
|--------------------------------------------|----------|---------------------------------------|
| Amazon EC2 Systems Manager Parameter Store | CredSpec | CredSpec, domainless user credentials |
| Local file                                 | N/A      | CredSpec                              |

## Prerequisites

Before you use the gMSA for Linux containers feature with Amazon ECS, make sure to complete the following:

- You set up an Active Directory domain with the resources that you want your containers to access. Amazon ECS supports the following setups:
  - An Directory Service Active Directory. Directory Service is an AWS managed Active Directory that's hosted on Amazon EC2. For more information, see [Getting Started with AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
  - An on-premises Active Directory. You must ensure that the Amazon ECS Linux container instance can join the domain. For more information, see [AWS Direct Connect](#).
- You have an existing gMSA account in the Active Directory. For more information, see [Using gMSA for EC2 Linux containers on Amazon ECS](#).
- You installed and are running the `credentials-fetcher` daemon on an Amazon ECS Linux container instance. You also added an initial set of credentials to the `credentials-fetcher` daemon to authenticate with the Active Directory.

### Note

The `credentials-fetcher` daemon is only available for Amazon Linux 2023 and Fedora 37 and later. The daemon isn't available for Amazon Linux 2. For more information, see [aws/credentials-fetcher](#) on GitHub.

- You set up the credentials for the `credentials-fetcher` daemon to authenticate with the Active Directory. The credentials must be a member of the Active Directory security group that has access to the gMSA account. There are multiple options in [Decide if you want to join the instances to the domain, or use domainless gMSA..](#)

- You added the required IAM permissions. The permissions that are required depend on the methods that you choose for the initial credentials and for storing the credential specification:
  - If you use *domainless gMSA* for initial credentials, IAM permissions for AWS Secrets Manager are required on the task execution role.
  - If you store the credential specification in SSM Parameter Store, IAM permissions for Amazon EC2 Systems Manager Parameter Store are required on the task execution role.
  - If you store the credential specification in Amazon S3, IAM permissions for Amazon Simple Storage Service are required on the task execution role.

## Setting up gMSA-capable Linux Containers on Amazon ECS

### Prepare the infrastructure

The following steps are considerations and setup that are performed once. After you complete these steps, you can automate creating container instances to reuse this configuration.

Decide how the initial credentials are provided and configure the EC2 user data in a reusable EC2 launch template to install the `credentials-fetcher` daemon.

#### 1. Decide if you want to join the instances to the domain, or use domainless gMSA.

- **Join EC2 instances to the Active Directory domain**

- **Join the instances by user data**

Add the steps to join the Active Directory domain to your EC2 user data in an EC2 launch template. Multiple Amazon EC2 Auto Scaling groups can use the same launch template.

You can use these steps [Joining an Active Directory or FreeIPA domain](#) in the Fedora Docs.

- **Make an Active Directory user for domainless gMSA**

The `credentials-fetcher` daemon has a feature that's called *domainless gMSA*. This feature requires a domain, but the EC2 instance doesn't need to be joined to the domain. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance. Instead, you provide the name of a

secret in AWS Secrets Manager in the CredSpec file. The secret must contain a username, password, and the domain to log in to.

This feature is supported and can be used with Linux and Windows containers.

This feature is similar to the *gMSA support for non-domain-joined container hosts* feature. For more information about the Windows feature, see [gMSA architecture and improvements](#) on the Microsoft Learn website.

- a. Make a user in your Active Directory domain. The user in Active Directory must have permission to access the gMSA service accounts that you use in the tasks.
- b. Create a secret in AWS Secrets Manager, after you made the user in Active Directory. For more information, see [Create an AWS Secrets Manager secret](#).
- c. Enter the user's username, password, and the domain into JSON key-value pairs called username, password and domainName, respectively.

```
{"username": "username", "password": "passw0rd", "domainName": "example.com"}
```

- d. Add configuration to the CredSpec file for the service account. The additional HostAccountConfig contains the Amazon Resource Name (ARN) of the secret in Secrets Manager.

On Windows, the PluginGUID must match the GUID in the following example snippet. On Linux, the PluginGUID is ignored. Replace MySecret with example with the Amazon Resource Name (ARN) of your secret.

```
"ActiveDirectoryConfig": {  
  "HostAccountConfig": {  
    "PortableCcgVersion": "1",  
    "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",  
    "PluginInput": {  
      "CredentialArn": "arn:aws:secretsmanager:aws-  
region:111122223333:secret:MySecret"  
    }  
  }  
}
```

- e. The *domainless gMSA* feature needs additional permissions in the task execution role. Follow the step [\(Optional\) domainless gMSA secret](#).

## 2. Configure instances and install `credentials-fetcher` daemon

You can install the `credentials-fetcher` daemon with a user data script in your EC2 Launch Template. The following examples demonstrate two types of user data, cloud-config YAML or bash script. These examples are for Amazon Linux 2023 (AL2023). Replace `MyCluster` with the name of the Amazon ECS cluster that you want these instances to join.

- **cloud-config YAML**

```
Content-Type: text/cloud-config
package_reboot_if_required: true
packages:
  # prerequisites
  - dotnet
  - realmd
  - oddjob
  - oddjob-mkhomedir
  - sssd
  - adcli
  - krb5-workstation
  - samba-common-tools
  # https://github.com/aws/credentials-fetcher gMSA credentials management for
  # containers
  - credentials-fetcher
write_files:
  # configure the ECS Agent to join your cluster.
  # replace MyCluster with the name of your cluster.
  - path: /etc/ecs/ecs.config
    owner: root:root
    permissions: '0644'
    content: |
      ECS_CLUSTER=MyCluster
      ECS_GMSA_SUPPORTED=true
runcmd:
  # start the credentials-fetcher daemon and if it succeeded, make it start after
  # every reboot
  - "systemctl start credentials-fetcher"
  - "systemctl is-active credentials-fetcher && systemctl enable credentials-
    fetcher"
```

- **bash script**

If you're more comfortable with bash scripts and have multiple variables to write to `/etc/ecs/ecs.config`, use the following heredoc format. This format writes everything between the lines beginning with **cat** and EOF to the configuration file.

```
#!/usr/bin/env bash
set -euxo pipefail

# prerequisites
timeout 30 dnf install -y dotnet realmd oddjob oddjob-mkhomedir sssd adcli
krb5-workstation samba-common-tools
# install https://github.com/aws/credentials-fetcher gMSA credentials
management for containers
timeout 30 dnf install -y credentials-fetcher

# start credentials-fetcher
systemctl start credentials-fetcher
systemctl is-active credentials-fetcher && systemctl enable credentials-fetcher

cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_GMSA_SUPPORTED=true
EOF
```

There are optional configuration variables for the `credentials-fetcher` daemon that you can set in `/etc/ecs/ecs.config`. We recommend that you set the variables in the user data in the YAML block or heredoc similar to the previous examples. Doing so prevents issues with partial configuration that can happen with editing a file multiple times. For more information about the ECS agent configuration, see [Amazon ECS Container Agent](#) on GitHub.

- Optionally, you can use the variable `CREDENTIALS_FETCHER_HOST` if you change the `credentials-fetcher` daemon configuration to move the socket to another location.

## Setting up permissions and secrets

Do the following steps once for each application and each task definition. We recommend that you use the best practice of granting the least privilege and narrow the permissions used in the policy. This way, each task can only read the secrets that it needs.

## 1. (Optional) domainless gMSA secret

If you use the domainless method where the instance isn't joined to the domain, follow this step.

You must add the following permissions as an inline policy to the task execution IAM role. Doing so gives the `credentials-fetcher` daemon access to the Secrets Manager secret. Replace the `MySecret` example with the Amazon Resource Name (ARN) of your secret in the Resource list.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue"
      ],
      "Resource": "arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret-AbCdEf"
    }
  ]
}
```

### Note

If you use your own KMS key to encrypt your secret, you must add the necessary permissions to this role and add this role to the AWS KMS key policy.

## 2. Decide if you're using SSM Parameter Store or S3 to store the CredSpec

Amazon ECS supports the following ways to reference the file path in the `credentialSpecs` field of the task definition.

If you join the instances to a single domain, use the prefix `credentialSpec:` at the start of the ARN in the string. If you use domainless gMSA, then use `credentialSpecdomainless:`.

For more information about the CredSpec, see [Credential specification file](#).

- **Amazon S3 Bucket**

Add the credential spec to an Amazon S3 bucket. Then, reference the Amazon Resource Name (ARN) of the Amazon S3 bucket in the `credentialSpecs` field of the task definition.

```
{
  "family": "",
  "executionRoleArn": "",
  "containerDefinitions": [
    {
      "name": "",
      ...
      "credentialSpecs": [
        "credentialSpecDomainless:arn:aws:s3:::${BucketName}/${ObjectName}"
      ],
      ...
    }
  ],
  ...
}
```

To give your tasks access to the S3 bucket, add the following permissions as an inline policy to the Amazon ECS task execution IAM role.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor",
      "Effect": "Allow",
      "Action": [
        "s3:Get*",
        "s3:List*"
      ],
      "Resource": [
```

```

        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/{object}"
    ]
}

```

- **SSM Parameter Store parameter**

Add the credential spec to an SSM Parameter Store parameter. Then, reference the Amazon Resource Name (ARN) of the SSM Parameter Store parameter in the `credentialSpecs` field of the task definition.

```

{
  "family": "",
  "executionRoleArn": "",
  "containerDefinitions": [
    {
      "name": "",
      ...
      "credentialSpecs": [
        "credentialSpecDomainless:arn:aws:ssm:aws-
        region:111122223333:parameter/parameter_name"
      ],
      ...
    }
  ],
  ...
}

```

To give your tasks access to the SSM Parameter Store parameter, add the following permissions as an inline policy to the Amazon ECS task execution IAM role.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [

```

```

        "ssm:GetParameters"
      ],
      "Resource": "arn:aws:ssm:us-east-1:123456789012:parameter/my-
parameter"
    }
  ]
}

```

## Credential specification file

Amazon ECS uses an Active Directory credential specification file (*CredSpec*). This file contains the gMSA metadata that's used to propagate the gMSA account context to the Linux container. You generate the CredSpec and reference it in the `credentialSpecs` field in your task definition. The CredSpec file doesn't contain any secrets.

The following is an example CredSpec file.

```

{
  "CmsPlugins": [
    "ActiveDirectory"
  ],
  "DomainJoinConfig": {
    "Sid": "S-1-5-21-2554468230-2647958158-2204241789",
    "MachineAccountName": "WebApp01",
    "Guid": "8665abd4-e947-4dd0-9a51-f8254943c90b",
    "DnsTreeName": "example.com",
    "DnsName": "example.com",
    "NetBiosName": "example"
  },
  "ActiveDirectoryConfig": {
    "GroupManagedServiceAccounts": [
      {
        "Name": "WebApp01",
        "Scope": "example.com"
      }
    ],
    "HostAccountConfig": {
      "PortableCcgVersion": "1",
      "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",
      "PluginInput": {
        "CredentialArn": "arn:aws:secretsmanager:aws-
region:111122223333:secret:MySecret"
      }
    }
  }
}

```

```
}  
  }  
} }
```

## Creating a CredSpec

You create a CredSpec by using the CredSpec PowerShell module on a Windows computer that's joined to the domain. Follow the steps in [Create a credential spec](#) on the Microsoft Learn website.

## Using gMSA for Linux containers on Fargate

Amazon ECS supports Active Directory authentication for Linux containers on Fargate through a special kind of service account called a *group Managed Service Account* (gMSA).

Linux based network applications, such as .NET Core applications, can use Active Directory to facilitate authentication and authorization management between users and services. You can use this feature by designing applications that integrate with Active Directory and run on domain-joined servers. But, because Linux containers can't be domain-joined, you need to configure a Linux container to run with gMSA.

## Considerations

Consider the following before you use gMSA for Linux containers on Fargate:

- You must be running Platform Version 1.4 or later.
- You might need a Windows computer that's joined to the domain to complete the prerequisites. For example, you might need a Windows computer that's joined to the domain to create the gMSA in Active Directory with PowerShell. The RSAT Active Director PowerShell tools are only available for Windows. For more information, see [Installing the Active Directory administration tools](#).
- You must use **domainless gMSA**.

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the container. You generate the CredSpec file, and then store it in an Amazon S3 bucket.

- A task can only support one Active Directory.

## Prerequisites

Before you use the gMSA for Linux containers feature with Amazon ECS, make sure to complete the following:

- You set up an Active Directory domain with the resources that you want your containers to access. Amazon ECS supports the following setups:
  - An Directory Service Active Directory. Directory Service is an AWS managed Active Directory that's hosted on Amazon EC2. For more information, see [Getting Started with AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
  - An on-premises Active Directory. You must ensure that the Amazon ECS Linux container instance can join the domain. For more information, see [AWS Direct Connect](#).
- You have an existing gMSA account in the Active Directory and a user that has permission to access the gMSA service account. For more information, see [Make an Active Directory user for domainless gMSA](#).
- You have an Amazon S3 bucket. For more information, see [Creating a bucket](#) in the *Amazon S3 User Guide*.

## Setting up gMSA-capable Linux Containers on Amazon ECS

### Prepare the infrastructure

The following steps are considerations and setup that are performed once.

- **Make an Active Directory user for domainless gMSA**

When you use domainless gMSA, the container isn't joined to the domain. Other applications that run on the container can't use the credentials to access the domain. Tasks that use a different domain can run on the same container. You provide the name of a secret in AWS Secrets Manager in the CredSpec file. The secret must contain a username, password, and the domain to log in to.

This feature is similar to the *gMSA support for non-domain-joined container hosts* feature. For more information about the Windows feature, see [gMSA architecture and improvements](#) on the Microsoft Learn website.

- a. Configure a user in your Active Directory domain. The user in the Active Directory must have permission to access the gMSA service account that you use in the tasks.

- b. You have a VPC and subnets that can resolve the Active Directory domain name. Configure the VPC with DHCP options with the domain name that points to the Active Directory service name. For information about how to configure DHCP options for a VPC, see [Work with DHCP option sets](#) in the *Amazon Virtual Private Cloud User Guide*.
- c. Create a secret in AWS Secrets Manager.
- d. Create the credential specification file.

## Setting up permissions and secrets

Do the following steps one time for each application and each task definition. We recommend that you use the best practice of granting the least privilege and narrow the permissions used in the policy. This way, each task can only read the secrets that it needs.

1. Make a user in your Active Directory domain. The user in Active Directory must have permission to access the gMSA service accounts that you use in the tasks.
2. After you make the Active Directory user, create a secret in AWS Secrets Manager. For more information, see [Create an AWS Secrets Manager secret](#).
3. Enter the user's username, password, and the domain into JSON key-value pairs called `username`, `password` and `domainName`, respectively.

```
{"username": "username", "password": "password", "domainName": "example.com"}
```

4. You must add the following permissions as an inline policy to the task execution IAM role. Doing so gives the `credentials-fetcher` daemon access to the Secrets Manager secret. Replace the `MySecret` example with the Amazon Resource Name (ARN) of your secret in the Resource list.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue"
      ],
      "Resource": [
```

```

        "arn:aws:secretsmanager:us-east-1:111122223333:secret:MySecret"
      ]
    }
  ]
}

```

### Note

If you use your own KMS key to encrypt your secret, you must add the necessary permissions to this role and add this role to the AWS KMS key policy.

5. Add the credential spec to an Amazon S3 bucket. Then, reference the Amazon Resource Name (ARN) of the Amazon S3 bucket in the `credentialSpecs` field of the task definition.

```

{
  "family": "",
  "executionRoleArn": "",
  "containerDefinitions": [
    {
      "name": "",
      ...
      "credentialSpecs": [
        "credentialSpecDomainless:arn:aws:s3:::${BucketName}/${ObjectName}"
      ],
      ...
    }
  ],
  ...
}

```

To give your tasks access to the S3 bucket, add the following permissions as an inline policy to the Amazon ECS task execution IAM role.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {

```

```

        "Sid": "VisualEditor",
        "Effect": "Allow",
        "Action": [
            "s3:GetObjectVersion",
            "s3:ListBucket"
        ],
        "Resource": [
            "arn:aws:s3:::{bucket_name}",
            "arn:aws:s3:::{bucket_name}/{object}"
        ]
    }
]
}

```

## Credential specification file

Amazon ECS uses an Active Directory credential specification file (*CredSpec*). This file contains the gMSA metadata that's used to propagate the gMSA account context to the Linux container. You generate the CredSpec and reference it in the `credentialSpecs` field in your task definition. The CredSpec file doesn't contain any secrets.

The following is an example CredSpec file.

```

{
  "CmsPlugins": [
    "ActiveDirectory"
  ],
  "DomainJoinConfig": {
    "Sid": "S-1-5-21-2554468230-2647958158-2204241789",
    "MachineAccountName": "WebApp01",
    "Guid": "8665abd4-e947-4dd0-9a51-f8254943c90b",
    "DnsTreeName": "example.com",
    "DnsName": "example.com",
    "NetBiosName": "example"
  },
  "ActiveDirectoryConfig": {
    "GroupManagedServiceAccounts": [
      {
        "Name": "WebApp01",
        "Scope": "example.com"
      }
    ]
  },
}

```

```

    "HostAccountConfig": {
      "PortableCcgVersion": "1",
      "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",
      "PluginInput": {
        "CredentialArn": "arn:aws:secretsmanager:aws-
region:111122223333:secret:MySecret"
      }
    }
  }
}

```

## Creating a CredSpec and uploading it to an Amazon S3

You create a CredSpec by using the CredSpec PowerShell module on a Windows computer that's joined to the domain. Follow the steps in [Create a credential spec](#) on the Microsoft Learn website.

After you create the credential specification file, upload it to an Amazon S3 bucket. Copy the CredSpec file to the computer or environment that you are running AWS CLI commands in.

Run the following AWS CLI command to upload the CredSpec to Amazon S3. Replace *amzn-s3-demo-bucket* with the name of your Amazon S3 bucket. You can store the file as an object in any bucket and location, but you must allow access to that bucket and location in the policy that you attach to the task execution role.

For PowerShell, use the following command:

```

$ Write-S3Object -BucketName "amzn-s3-demo-bucket" -Key "ecs-domainless-gmsa-credspec"
-File "gmsa-cred-spec.json"

```

The following AWS CLI command uses backslash continuation characters that are used by sh and compatible shells.

```

$ aws s3 cp gmsa-cred-spec.json \
s3://amzn-s3-demo-bucket/ecs-domainless-gmsa-credspec

```

## Using Amazon ECS Windows containers with domainless gMSA using the AWS CLI

The following tutorial shows how to create an Amazon ECS task that runs a Windows container that has credentials to access Active Directory with the AWS CLI. By using domainless gMSA,

the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

## Topics

- [Prerequisites](#)
- [Step 1: Create and configure the gMSA account on Active Directory Domain Services \(AD DS\)](#)
- [Step 2: Upload Credentials to Secrets Manager](#)
- [Step 3: Modify your CredSpec JSON to include domainless gMSA information](#)
- [Step 4: Upload CredSpec to Amazon S3](#)
- [Step 5: \(Optional\) Create an Amazon ECS cluster](#)
- [Step 6: Create an IAM role for container instances](#)
- [Step 7: Create a custom task execution role](#)
- [Step 8: Create a task role for Amazon ECS Exec](#)
- [Step 9: Register a task definition that uses domainless gMSA](#)
- [Step 10: Register a Windows container instance to the cluster](#)
- [Step 11: Verify the container instance](#)
- [Step 12: Run a Windows task](#)
- [Step 13: Verify the container has gMSA credentials](#)
- [Step 14: Clean up](#)
- [Debugging Amazon ECS domainless gMSA for Windows containers](#)

## Prerequisites

This tutorial assumes that the following prerequisites have been completed:

- The steps in [Set up to use Amazon ECS](#) have been completed.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.
- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading your AWS CLI, see [Installing the AWS Command Line Interface](#).

**Note**

You can use dual-stack service endpoints to interact with Amazon ECS from the AWS CLI, SDKs, and the Amazon ECS API over both IPv4 and IPv6. For more information, see [Using Amazon ECS dual-stack endpoints](#).

- You set up an Active Directory domain with the resources that you want your containers to access. Amazon ECS supports the following setups:
  - An Directory Service Active Directory. Directory Service is an AWS managed Active Directory that's hosted on Amazon EC2. For more information, see [Getting Started with AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
  - An on-premises Active Directory. You must ensure that the Amazon ECS Linux container instance can join the domain. For more information, see [AWS Direct Connect](#).
- You have a VPC and subnets that can resolve the Active Directory domain name.
- You chose between **domainless gMSA** and **joining each instance to a single domain**. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

Then, choose the data storage for the CredSpec and optionally, for the Active Directory user credentials for domainless gMSA.

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the container. You generate the CredSpec file and then store it in one of the CredSpec storage options in the following table, specific to the Operating System of the container instances. To use the domainless method, an optional section in the CredSpec file can specify credentials in one of the *domainless user credentials* storage options in the following table, specific to the Operating System of the container instances.

| Storage location              | Linux                       | Windows                     |
|-------------------------------|-----------------------------|-----------------------------|
| Amazon Simple Storage Service | CredSpec                    | CredSpec                    |
| AWS Secrets Manager           | domainless user credentials | domainless user credentials |

| Storage location                           | Linux    | Windows                               |
|--------------------------------------------|----------|---------------------------------------|
| Amazon EC2 Systems Manager Parameter Store | CredSpec | CredSpec, domainless user credentials |
| Local file                                 | N/A      | CredSpec                              |

- (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see [What is AWS CloudShell?](#) in the *AWS CloudShell User Guide*.

## Step 1: Create and configure the gMSA account on Active Directory Domain Services (AD DS)

Create and configure a gMSA account on the Active Directory domain.

### Note

This step creates two separate accounts: a Group Managed Service Account (gMSA) that provides the identity for your containers, and a regular user account that is used for domain authentication. These accounts serve different purposes and should have different names.

### 1. Generate a Key Distribution Service root key

#### Note

If you are using Directory Service, then you can skip this step.

The KDS root key and gMSA permissions are configured with your AWS managed Microsoft AD.

If you have not already created a gMSA Service Account in your domain, you'll need to first generate a Key Distribution Service (KDS) root key. The KDS is responsible for creating, rotating, and releasing the gMSA password to authorized hosts. When the `ccg.exe` needs to retrieve gMSA credentials, it contact KDS to retrieve the current password.

To check if the KDS root key has already been created, run the following PowerShell cmdlet with domain admin privileges on a domain controller using the ActiveDirectory PowerShell module. For more information about the module, see [ActiveDirectory Module](#) on the Microsoft Learn website.

```
PS C:\> Get-KdsRootKey
```

If the command returns a key ID, you can skip the rest of this step. Otherwise, create the KDS root key by running the following command:

```
PS C:\> Add-KdsRootKey -EffectiveImmediately
```

Although the argument `EffectiveImmediately` to the command implies the key is effective immediately, you need to wait 10 hours before the KDS root key is replicated and available for use on all domain controllers.

## 2. Create the gMSA account

To create the gMSA account and allow the `ccg.exe` to retrieve the gMSA password, run the following PowerShell commands from a Windows Server or client with access to the domain. Replace `ExampleAccount` with the name that you want for your gMSA account, and replace `example-domain` with your Active Directory domain name (for example, if your domain is `contoso.com`, use `contoso`).

- a. 

```
PS C:\> Install-WindowsFeature RSAT-AD-PowerShell
```
- b. 

```
PS C:\> New-ADGroup -Name "ExampleAccount Authorized Hosts" -SamAccountName "ExampleAccountHosts" -GroupScope DomainLocal
```
- c. 

```
PS C:\> New-ADServiceAccount -Name "ExampleAccount" -DnsHostName "example-domain" -ServicePrincipalNames "host/ExampleAccount", "host/example-domain" -PrincipalsAllowedToRetrieveManagedPassword "ExampleAccountHosts"
```
- d. Create a user with a permanent password that doesn't expire. These credentials are stored in AWS Secrets Manager and used by each task to join the domain. This is a separate user account from the gMSA account created previously. Replace `ExampleServiceUser` with the name you want for this service user account.

```
PS C:\> New-ADUser -Name "ExampleServiceUser" -AccountPassword (ConvertTo-SecureString -AsPlainText "Test123" -Force) -Enabled 1 -PasswordNeverExpires 1
```

e.

```
PS C:\> Add-ADGroupMember -Identity "ExampleAccountHosts" -Members "ExampleServiceUser"
```

- f. Install the PowerShell module for creating CredSpec objects in Active Directory and output the CredSpec JSON.

```
PS C:\> Install-PackageProvider -Name NuGet -Force
```

```
PS C:\> Install-Module CredentialSpec
```

g.

```
PS C:\> New-CredentialSpec -AccountName ExampleAccount
```

3. Copy the JSON output from the previous command into a file called `gmsa-cred-spec.json`. This is the CredSpec file. It is used in Step 3, [Step 3: Modify your CredSpec JSON to include domainless gMSA information](#).

## Step 2: Upload Credentials to Secrets Manager

Copy the Active Directory credentials into a secure credential storage system, so that each task retrieves it. This is the domainless gMSA method. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

- Run the following AWS CLI command and replace the username, password, and domain name to match your environment. Use the service user account name (not the gMSA account name) for the username. Keep the ARN of the secret to use in the next step, [Step 3: Modify your CredSpec JSON to include domainless gMSA information](#)

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws secretsmanager create-secret \
--name gmsa-plugin-input \
--description "Amazon ECS - gMSA Portable Identity." \
--secret-string "{\"username\": \"ExampleServiceUser\", \"password\": \"Test123\",  
\"domainName\": \"contoso.com\"}"
```

## Step 3: Modify your CredSpec JSON to include domainless gMSA information

Before uploading the CredSpec to one of the storage options, add information to the CredSpec with the ARN of the secret in Secrets Manager from the previous step. For more information, see [Additional credential spec configuration for non-domain-joined container host use case](#) on the Microsoft Learn website.

1. Add the following information to the CredSpec file inside the ActiveDirectoryConfig. Replace the ARN with the secret in Secrets Manager from the previous step.

Note that the PluginGUID value must match the GUID in the following example snippet and is required.

```
"HostAccountConfig": {
  "PortableCcgVersion": "1",
  "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",
  "PluginInput": "{\"credentialArn\": \"arn:aws:secretsmanager:aws-region:111122223333:secret:gmsa-plugin-input\"}"
}
```

You can also use a secret in SSM Parameter Store by using the ARN in this format:

```
\"arn:aws:ssm:aws-region:111122223333:parameter/gmsa-plugin-input\".
```

2. After you modify the CredSpec file, it should look like the following example:

```
{
  "CmsPlugins": [
    "ActiveDirectory"
  ],
  "DomainJoinConfig": {
    "Sid": "S-1-5-21-4066351383-705263209-1606769140",
    "MachineAccountName": "ExampleAccount",
```

```

    "Guid": "ac822f13-583e-49f7-aa7b-284f9a8c97b6",
    "DnsTreeName": "example-domain",
    "DnsName": "example-domain",
    "NetBiosName": "example-domain"
  },
  "ActiveDirectoryConfig": {
    "GroupManagedServiceAccounts": [
      {
        "Name": "ExampleAccount",
        "Scope": "example-domain"
      },
      {
        "Name": "ExampleAccount",
        "Scope": "example-domain"
      }
    ],
    "HostAccountConfig": {
      "PortableCcgVersion": "1",
      "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",
      "PluginInput": "{\"credentialArn\": \"arn:aws:secretsmanager:aws-  
region:111122223333:secret:gmsa-plugin-input\"}"
    }
  }
}

```

## Step 4: Upload CredSpec to Amazon S3

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. Copy the CredSpec file to the computer or environment that you are running AWS CLI commands in.
2. Run the following AWS CLI command to upload the CredSpec to Amazon S3. Replace MyBucket with the name of your Amazon S3 bucket. You can store the file as an object in any bucket and location, but you must allow access to that bucket and location in the policy that you attach to the task execution role.

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws s3 cp gmsa-cred-spec.json \  
s3://MyBucket/ecs-domainless-gmsa-credspec
```

## Step 5: (Optional) Create an Amazon ECS cluster

By default, your account has an Amazon ECS cluster named `default`. This cluster is used by default in the AWS CLI, SDKs, and CloudFormation. You can use additional clusters to group and organize tasks and infrastructure, and assign defaults for some configuration.

You can create a cluster from the AWS Management Console, AWS CLI, SDKs, or CloudFormation. The settings and configuration in the cluster don't affect gMSA.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is `bash`.

```
$ aws ecs create-cluster --cluster-name windows-domainless-gmsa-cluster
```

### Important

If you choose to create your own cluster, you must specify `--cluster clusterName` for each command that you intend to use with that cluster.

## Step 6: Create an IAM role for container instances

A *container instance* is a host computer to run containers in ECS tasks, for example Amazon EC2 instances. Each container instance registers to an Amazon ECS cluster. Before you launch Amazon EC2 instances and register them to a cluster, you must create an IAM role for your container instances to use.

To create the container instance role, see [Amazon ECS container instance IAM role](#). The default `ecsInstanceRole` has sufficient permissions to complete this tutorial.

## Step 7: Create a custom task execution role

Amazon ECS can use a different IAM role for the permissions needed to start each task, instead of the container instance role. This role is the *task execution role*. We recommend creating a task

execution role with only the permissions required for ECS to run the task, also known as *least-privilege permissions*. For more information about the principle of least privilege, see [SEC03-BP02 Grant least privilege access](#) in the *AWS Well-Architected Framework*.

1. To create a task execution role, see [Creating the task execution role](#). The default permissions allow the container instance to pull container images from Amazon Elastic Container Registry and stdout and stderr from your applications to be logged to Amazon CloudWatch Logs.

Because the role needs custom permissions for this tutorial, you can give the role a different name than `ecsTaskExecutionRole`. This tutorial uses `ecsTaskExecutionRole` in further steps.

2. Add the following permissions by creating a custom policy, either an inline policy that only exists in for this role, or a policy that you can reuse. Replace the ARN for the Resource in the first statement with the Amazon S3 bucket and location, and the second Resource with the ARN of the secret in Secrets Manager.

If you encrypt the secret in Secrets Manager with a custom key, you must also allow `kms:Decrypt` for the key.

If you use SSM Parameter Store instead of Secrets Manager, you must allow `ssm:GetParameter` for the parameter, instead of `secretsmanager:GetSecretValue`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::MyBucket/ecs-domainless-gmsa-credspec/gmsa-cred-spec.json"
    },
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue"
      ],

```

```
        "Resource": "arn:aws:secretsmanager:us-  
east-1:111122223333:secret:gmsa-plugin-AbCdEf"  
      }  
    ]  
  }  
}
```

## Step 8: Create a task role for Amazon ECS Exec

This tutorial uses Amazon ECS Exec to verify functionality by running a command inside a running task. To use ECS Exec, the service or task must turn on ECS Exec and the task role (but not the task execution role) must have `ssmmessages` permissions. For the required IAM policy, see [ECS Exec permissions](#).

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

To create a task role using the AWS CLI, follow these steps.

1. Create a file called `ecs-tasks-trust-policy.json` with the following contents:

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Principal": {  
        "Service": "ecs-tasks.amazonaws.com"  
      },  
      "Action": "sts:AssumeRole"  
    }  
  ]  
}
```

2. Create an IAM role. You can replace the name `ecs-exec-demo-task-role` but keep the name for following steps.

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws iam create-role --role-name ecs-exec-demo-task-role \  
--assume-role-policy-document file://ecs-tasks-trust-policy.json
```

You can delete the file `ecs-tasks-trust-policy.json`.

3. Create a file called `ecs-exec-demo-task-role-policy.json` with the following contents:

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "ssmmessages:CreateControlChannel",  
        "ssmmessages:CreateDataChannel",  
        "ssmmessages:OpenControlChannel",  
        "ssmmessages:OpenDataChannel"  
      ],  
      "Resource": "*"   
    }  
  ]  
}
```

4. Create an IAM policy and attach it to the role from the previous step.

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws iam put-role-policy \  
--role-name ecs-exec-demo-task-role \  
--policy-name ecs-exec-demo-task-role-policy \  
--policy-document file://ecs-exec-demo-task-role-policy.json
```

You can delete the file `ecs-exec-demo-task-role-policy.json`.

## Step 9: Register a task definition that uses domainless gMSA

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. Create a file called `windows-gmsa-domainless-task-def.json` with the following contents:

```
{
  "family": "windows-gmsa-domainless-task",
  "containerDefinitions": [
    {
      "name": "windows_sample_app",
      "image": "mcr.microsoft.com/windows/servercore/iis",
      "cpu": 1024,
      "memory": 1024,
      "essential": true,
      "credentialSpecs": [
        "credentialSpecdomainless:arn:aws:s3:::ecs-domainless-gmsa-credspec/gmsa-cred-spec.json"
      ],
      "entryPoint": [
        "powershell",
        "-Command"
      ],
      "command": [
        "New-Item -Path C:\\inetpub\\wwwroot\\index.html -ItemType file -Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p>' -Force ; C:\\ServiceMonitor.exe w3svc"
      ],
      "portMappings": [
        {
          "protocol": "tcp",
          "containerPort": 80,
          "hostPort": 8080
        }
      ]
    }
  ]
}
```

```
    ]
  }
],
"taskRoleArn": "arn:aws:iam::111122223333:role/ecs-exec-demo-task-role",
"executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole"
}
```

2. Register the task definition by running the following command:

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws ecs register-task-definition \
--cli-input-json file://windows-gmsa-domainless-task-def.json
```

## Step 10: Register a Windows container instance to the cluster

Launch an Amazon EC2 Windows instance and run the ECS container agent to register it as a container instance in the cluster. ECS runs tasks on the container instances that are registered to the cluster that the tasks are started in.

1. To launch an Amazon EC2 Windows instance that is configured for Amazon ECS in the AWS Management Console, see [Launching an Amazon ECS Windows container instance](#). Stop at the step for *user data*.
2. For gMSA, the user data must set the environment variable ECS\_GMSA\_SUPPORTED before starting the ECS container agent.

For ECS Exec, the agent must start with the argument `-EnableTaskIAMRole`.

To secure the instance IAM role by preventing tasks from reaching the EC2 IMDS web service to retrieve the role credentials, add the argument `-AwsVpcBlockIMDS`. This only applies to tasks that use the `awsVpc` network mode.

```
<powershell>
[Environment]::SetEnvironmentVariable("ECS_GMSA_SUPPORTED", $TRUE, "Machine")
Import-Module ECSTools
Initialize-ECSAgent -Cluster windows-domainless-gmsa-cluster -EnableTaskIAMRole -
AwsVpcBlockIMDS
```

```
</powershell>
```

3. Review a summary of your instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

## Step 11: Verify the container instance

You can verify that there is a container instance in the cluster using the AWS Management Console. However, gMSA needs additional features that are indicated as *attributes*. These attributes aren't visible in the AWS Management Console, so this tutorial uses the AWS CLI.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. List the container instances in the cluster. Container instances have an ID that is different from the ID of the EC2 instance.

```
$ aws ecs list-container-instances
```

Output:

```
{
  "containerInstanceArns": [
    "arn:aws:ecs:aws-region:111122223333:container-
instance/default/MyContainerInstanceID"
  ]
}
```

For example, 526bd5d0ced448a788768334e79010fd is a valid container instance ID.

2. Use the container instance ID from the previous step to get the details for the container instance. Replace `MyContainerInstanceID` with the ID.

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws ecs describe-container-instances \
  ----container-instances MyContainerInstanceID
```

Note that the output is very long.

3. Verify that the `attributes` list has an object with the key called `name` and a value `ecs.capability.gmsa-domainless`. The following is an example of the object.

Output:

```
{
  "name": "ecs.capability.gmsa-domainless"
}
```

## Step 12: Run a Windows task

Run an Amazon ECS task. If there is only 1 container instance in the cluster, you can use `run-task`. If there are many different container instances, it might be easier to use `start-task` and specify the container instance ID to run the task on, than to add placement constraints to the task definition to control what type of container instance to run this task on.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is `bash`.

1. The following command uses backslash continuation characters that are used by `sh` and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
aws ecs run-task --task-definition windows-gmsa-domainless-task \
  --enable-execute-command --cluster windows-domainless-gmsa-cluster
```

Note the task ID that is returned by the command.

2. Run the following command to verify that the task has started. This command waits and doesn't return the shell prompt until the task starts. Replace `MyTaskID` with the task ID from the previous step.

```
$ aws ecs wait tasks-running --task MyTaskID
```

## Step 13: Verify the container has gMSA credentials

Verify that the container in the task has a Kerberos token. gMSA

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws ecs execute-command \  
--task MyTaskID \  
--container windows_sample_app \  
--interactive \  
--command powershell.exe
```

The output will be a PowerShell prompt.

2. Run the following command in the PowerShell terminal inside the container.

```
PS C:\> klist get ExampleAccount$
```

In the output, note the Principal is the one that you created previously.

## Step 14: Clean up

When you are finished with this tutorial, you should clean up the associated resources to avoid incurring charges for unused resources.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. Stop the task. Replace MyTaskID with the task ID from step 12, [Step 12: Run a Windows task](#).

```
$ aws ecs stop-task --task MyTaskID
```

2. Terminate the Amazon EC2 instance. Afterwards, the container instance in the cluster will be deleted automatically after one hour.

You can find and terminate the instance by using the Amazon EC2 console. Or, you can run the following command. To run the command, find the EC2 instance ID in the output of the `aws ecs describe-container-instances` command from step 1, [Step 11: Verify the container instance](#). `i-10a64379` is an example of an EC2 instance ID.

```
$ aws ec2 terminate-instances --instance-ids MyInstanceID
```

3. Delete the CredSpec file in Amazon S3. Replace `MyBucket` with the name of your Amazon S3 bucket.

```
$ aws s3api delete-object --bucket MyBucket --key ecs-domainless-gmsa-credspec/gmsa-cred-spec.json
```

4. Delete the secret from Secrets Manager. If you used SSM Parameter Store instead, delete the parameter.

The following command uses backslash continuation characters that are used by `sh` and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws secretsmanager delete-secret --secret-id gmsa-plugin-input \  
--force-delete-without-recovery
```

5. Deregister and delete the task definition. By deregistering the task definition, you mark it as inactive so it can't be used to start new tasks. Then, you can delete the task definition.
  - a. Deregister the task definition by specifying the version. ECS automatically makes versions of task definitions, that are numbered starting from 1. You refer to the versions in the same format as the labels on container images, such as `:1`.

```
$ aws ecs deregister-task-definition --task-definition windows-gmsa-domainless-task:1
```

- b. Delete the task definition.

```
$ aws ecs delete-task-definitions --task-definition windows-gmsa-domainless-task:1
```

6. (Optional) Delete the ECS cluster, if you created a cluster.

```
$ aws ecs delete-cluster --cluster windows-domainless-gmsa-cluster
```

## Debugging Amazon ECS domainless gMSA for Windows containers

### Amazon ECS task status

ECS tries to start a task exactly once. Any task that has an issue is stopped, and set to the status STOPPED. There are two common types of issues with tasks. First, tasks that couldn't be started. Second, tasks where the application has stopped inside one of the containers. In the AWS Management Console, look at the **Stopped reason** field of the task for the reason why the task was stopped. In the AWS CLI, describe the task and look at the `stoppedReason`. For steps in the AWS Management Console and AWS CLI, see [Viewing Amazon ECS stopped task errors](#).

### Windows Events

Windows Events for gMSA in containers are logged in the Microsoft-Windows-Containers-CCG log file and can be found in the Event Viewer in the section Applications and Services in Logs\Microsoft\Windows\Containers-CCG\Admin. For more debugging tips, see [Troubleshoot gMSAs for Windows containers](#) on the Microsoft Learn website.

### ECS agent gMSA plugin

Logging for gMSA plugin for the ECS agent on the Windows container instance is in the following directory, `C:/ProgramData/Amazon/gmsa-plugin/`. Look in this log to see if the domainless user credentials were downloaded from the storage location, such as Secrets Manager, and that the credential format was read correctly.

## Learn how to use gMSAs for EC2 Windows containers for Amazon ECS

Amazon ECS supports Active Directory authentication for Windows containers through a special kind of service account called a *group Managed Service Account* (gMSA).

Windows based network applications such as .NET applications often use Active Directory to facilitate authentication and authorization management between users and services. Developers commonly design their applications to integrate with Active Directory and run on domain-

joined servers for this purpose. Because Windows containers cannot be domain-joined, you must configure a Windows container to run with gMSA.

A Windows container running with gMSA relies on its host Amazon EC2 instance to retrieve the gMSA credentials from the Active Directory domain controller and provide them to the container instance. For more information, see [Create gMSAs for Windows containers](#).

#### Note

This feature is not supported on Windows containers on Fargate.

## Topics

- [Considerations](#)
- [Prerequisites](#)
- [Setting up gMSA for Windows Containers on Amazon ECS](#)

## Considerations

The following should be considered when using gMSAs for Windows containers:

- When using the Amazon ECS-optimized Windows Server 2016 Full AMI for your container instances, the container hostname must be the same as the gMSA account name defined in the credential spec file. To specify a hostname for a container, use the `hostname` container definition parameter. For more information, see [Network settings](#).
- You chose between **domainless gMSA** and **joining each instance to a single domain**. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

Then, choose the data storage for the CredSpec and optionally, for the Active Directory user credentials for domainless gMSA.

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the container. You generate the CredSpec file and then store it in one of the CredSpec storage options in the following table, specific to the Operating System of the container instances. To use the

domainless method, an optional section in the CredSpec file can specify credentials in one of the *domainless user credentials* storage options in the following table, specific to the Operating System of the container instances.

| Storage location                           | Linux                       | Windows                               |
|--------------------------------------------|-----------------------------|---------------------------------------|
| Amazon Simple Storage Service              | CredSpec                    | CredSpec                              |
| AWS Secrets Manager                        | domainless user credentials | domainless user credentials           |
| Amazon EC2 Systems Manager Parameter Store | CredSpec                    | CredSpec, domainless user credentials |
| Local file                                 | N/A                         | CredSpec                              |

## Prerequisites

Before you use the gMSA for Windows containers feature with Amazon ECS, make sure to complete the following:

- You set up an Active Directory domain with the resources that you want your containers to access. Amazon ECS supports the following setups:
  - An Directory Service Active Directory. Directory Service is an AWS managed Active Directory that's hosted on Amazon EC2. For more information, see [Getting Started with AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
  - An on-premises Active Directory. You must ensure that the Amazon ECS Linux container instance can join the domain. For more information, see [AWS Direct Connect](#).
- You have an existing gMSA account in the Active Directory. For more information, see [Create gMSAs for Windows containers](#).
- **You chose to use *domainless gMSA* or the Amazon ECS Windows container instance hosting the Amazon ECS task must be *domain joined* to the Active Directory and be a member of the Active Directory security group that has access to the gMSA account.**

By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

- You added the required IAM permissions. The permissions that are required depend on the methods that you choose for the initial credentials and for storing the credential specification:
  - If you use *domainless gMSA* for initial credentials, IAM permissions for AWS Secrets Manager are required on the Amazon EC2 instance role.
  - If you store the credential specification in SSM Parameter Store, IAM permissions for Amazon EC2 Systems Manager Parameter Store are required on the task execution role.
  - If you store the credential specification in Amazon S3, IAM permissions for Amazon Simple Storage Service are required on the task execution role.

## Setting up gMSA for Windows Containers on Amazon ECS

To set up gMSA for Windows Containers on Amazon ECS, you can follow the complete tutorial that includes configuring the prerequisites [Using Amazon ECS Windows containers with domainless gMSA using the AWS CLI](#).

The following sections cover the CredSpec configuration in detail.

### Topics

- [Example CredSpec](#)
- [Domainless gMSA setup](#)
- [Referencing a Credential Spec File in a Task Definition](#)

### Example CredSpec

Amazon ECS uses a credential spec file that contains the gMSA metadata used to propagate the gMSA account context to the Windows container. You can generate the credential spec file and reference it in the `credentialSpec` field in your task definition. The credential spec file does not contain any secrets.

The following is an example credential spec file:

```
{
  "CmsPlugins": [
    "ActiveDirectory"
  ],
  "DomainJoinConfig": {
    "Sid": "S-1-5-21-2554468230-2647958158-2204241789",
```

```

    "MachineAccountName": "WebApp01",
    "Guid": "8665abd4-e947-4dd0-9a51-f8254943c90b",
    "DnsTreeName": "contoso.com",
    "DnsName": "contoso.com",
    "NetBiosName": "contoso"
  },
  "ActiveDirectoryConfig": {
    "GroupManagedServiceAccounts": [
      {
        "Name": "WebApp01",
        "Scope": "contoso.com"
      }
    ]
  }
}

```

## Domainless gMSA setup

We recommend domainless gMSA instead of joining the container instances to a single domain. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

1. Before uploading the CredSpec to one of the storage options, add information to the CredSpec with the ARN of the secret in Secrets Manager or SSM Parameter Store. For more information, see [Additional credential spec configuration for non-domain-joined container host use case](#) on the Microsoft Learn website.

### Domainless gMSA credential format

The following is the JSON format for the domainless gMSA credentials for your Active Directory. Store the credentials in Secrets Manager or SSM Parameter Store.

```

{
  "username": "WebApp01",
  "password": "Test123!",
  "domainName": "contoso.com"
}

```

2. Add the following information to the CredSpec file inside the ActiveDirectoryConfig. Replace the ARN with the secret in Secrets Manager or SSM Parameter Store.

Note that the PluginGUID value must match the GUID in the following example snippet and is required.

```
"HostAccountConfig": {
  "PortableCcgVersion": "1",
  "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",
  "PluginInput": "{\"credentialArn\": \"arn:aws:secretsmanager:aws-region:111122223333:secret:gmsa-plugin-input\"}"
}
```

You can also use a secret in SSM Parameter Store by using the ARN in this format:  
 \"arn:aws:ssm:*aws-region*:111122223333:parameter/*gmsa-plugin-input*\".

3. After you modify the CredSpec file, it should look like the following example:

```
{
  "CmsPlugins": [
    "ActiveDirectory"
  ],
  "DomainJoinConfig": {
    "Sid": "S-1-5-21-4066351383-705263209-1606769140",
    "MachineAccountName": "WebApp01",
    "Guid": "ac822f13-583e-49f7-aa7b-284f9a8c97b6",
    "DnsTreeName": "contoso",
    "DnsName": "contoso",
    "NetBiosName": "contoso"
  },
  "ActiveDirectoryConfig": {
    "GroupManagedServiceAccounts": [
      {
        "Name": "WebApp01",
        "Scope": "contoso"
      },
      {
        "Name": "WebApp01",
        "Scope": "contoso"
      }
    ]
  },
  "HostAccountConfig": {
    "PortableCcgVersion": "1",
    "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",
```

```

    "PluginInput": "{\\"credentialArn\\": \\"arn:aws:secretsmanager:aws-region:111122223333:secret:gmsa-plugin-input\\"}"
  }
}

```

## Referencing a Credential Spec File in a Task Definition

Amazon ECS supports the following ways to reference the file path in the `credentialSpecs` field of the task definition. For each of these options, you can provide `credentialSpec:` or `domainlesscredentialSpec:`, depending on whether you are joining the container instances to a single domain, or using domainless gMSA, respectively.

### Amazon S3 Bucket

Add the credential spec to an Amazon S3 bucket and then reference the Amazon Resource Name (ARN) of the Amazon S3 bucket in the `credentialSpecs` field of the task definition.

```

{
  "family": "",
  "executionRoleArn": "",
  "containerDefinitions": [
    {
      "name": "",
      ...
      "credentialSpecs": [
        "credentialSpecdomainless:arn:aws:s3:::${BucketName}/${ObjectName}"
      ],
      ...
    }
  ],
  ...
}

```

You must also add the following permissions as an inline policy to the Amazon ECS task execution IAM role to give your tasks access to the Amazon S3 bucket.

### JSON

```
{
```

```

    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "VisualEditor",
        "Effect": "Allow",
        "Action": [
          "s3:Get*",
          "s3:List*"
        ],
        "Resource": [
          "arn:aws:s3:::{bucket_name}",
          "arn:aws:s3:::{bucket_name}/{object}"
        ]
      }
    ]
  }
}

```

### SSM Parameter Store parameter

Add the credential spec to an SSM Parameter Store parameter and then reference the Amazon Resource Name (ARN) of the SSM Parameter Store parameter in the `credentialSpecs` field of the task definition.

```

{
  "family": "",
  "executionRoleArn": "",
  "containerDefinitions": [
    {
      "name": "",
      ...
      "credentialSpecs": [

        "credentialSpecdomainless:arn:aws:ssm:region:111122223333:parameter/parameter_name"

      ],
      ...
    }
  ],
  ...
}

```

You must also add the following permissions as an inline policy to the Amazon ECS task execution IAM role to give your tasks access to the SSM Parameter Store parameter.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetParameters"
      ],
      "Resource": "arn:aws:ssm:*:111122223333:parameter/example*"
    }
  ]
}
```

### Local File

With the credential spec details in a local file, reference the file path in the `credentialSpecs` field of the task definition. The file path referenced must be relative to the `C:\ProgramData\Docker\CredentialSpecs` directory and use the backslash (`\`) as the file path separator.

```
{
  "family": "",
  "executionRoleArn": "",
  "containerDefinitions": [
    {
      "name": "",
      ...
      "credentialSpecs": [
        "credentialspec:file://CredentialSpecDir\CredentialSpecFile.json"
      ],
      ...
    }
  ],
  ...
}
```

# Using EC2 Image Builder to build customized Amazon ECS-optimized AMIs

AWS recommends that you use the Amazon ECS-optimized AMIs because they are preconfigured with the requirements and recommendations to run your container workloads. There might be times when you need to customize your AMI to add additional software. You can use EC2 Image Builder for the creation, management, and deployment of your server images. You retain ownership of the customized images created in your account. You can use EC2 Image Builder pipelines to automate updates and system patching for your images, or use a stand-alone command to create an image with your defined configuration resources.

You create a recipe for your image. The recipe includes a parent image, and any additional components. You also create a pipeline which distributes your customized AMI.

You create a recipe for your image. An Image Builder image recipe is a document that defines the base image and the components that are applied to the base image to produce the desired configuration for the output AMI image. You also create a pipeline which distributes your customized AMI. For more information, see [How EC2 Image Builder works](#) in the *EC2 Image Builder User Guide*.

We recommend that you use one of the following Amazon ECS-optimized AMIs as your "Parent image" in EC2 Image Builder:

- Linux
  - Amazon ECS-optimized AL2023 x86
  - Amazon ECS-optimized Amazon Linux 2023 (arm64) AMI
  - Amazon ECS-optimized Amazon Linux 2 kernel 5 AMI
  - Amazon ECS-optimized Amazon Linux 2 x86 AMI
- Windows
  - Amazon ECS-optimized Windows 2022 Full x86
  - Amazon ECS-optimized Windows 2022 Core x86
  - Amazon ECS-optimized Windows 2019 Full x86
  - Amazon ECS-optimized Windows 2019 Core x86
  - Amazon ECS-optimized Windows 2016 Full x86

We also recommend that you select "Use latest available OS version". The pipeline will use semantic versioning for the parent image, which helps detect the dependency updates in automatically scheduled jobs. For more information, see [Semantic versioning](#) in the *EC2 Image Builder User Guide*.

AWS regularly updates Amazon ECS-optimized AMI images with security patches and the new container agent version. When you use an AMI ID as your parent image in your image recipe, you need to regularly check for updates to the parent image. If there are updates, you must create a new version of your recipe with the updated AMI. This ensures that your custom images incorporate the latest version of the parent image. For information about how to create a workflow to automatically update your EC2 instances in your Amazon ECS cluster with the newly created AMIs, see [How to create an AMI hardening pipeline and automate updates to your ECS instance fleet](#).

You can also specify the Amazon Resource Name (ARN) of a parent image that's published through a managed EC2 Image Builder pipeline. Amazon routinely publishes Amazon ECS-optimized AMI images through managed pipelines. These images are publicly accessible. You must have the correct permissions to access the image. When you use an image ARN instead of an AMI in your Image Builder recipe, your pipeline automatically uses the most recent version of the parent image each time it runs. This approach eliminates the need to manually create new recipe versions for each update.

## Clean up the Amazon ECS-optimized AMI

When using an Amazon ECS-optimized AMI as a parent image, you must clean up the image to prevent transient issues. The Amazon ECS-optimized AMI is preconfigured for the Amazon ECS agent to auto-start and register as a container instance with Amazon ECS. Using it as a base image without proper cleanup can cause problems in your custom AMI.

To clean up the image for future use, create a component that runs the following commands to stop the ecs-init package and Docker processes:

```
sudo systemctl stop ecs
sudo systemctl stop docker
```

Remove all the log files from the current instance to prevent preserving them when saving the image. Use the example script in [Security best practices for EC2 Image Builder](#) to clean up the various files from the instance.

To clean up the Amazon ECS specific data, run the following commands:

```
sudo rm -rf /var/log/ecs/*
sudo rm /var/lib/ecs/data/agent.db
```

For more information about creating custom Amazon ECS-optimized AMIs, see [How do I create a custom AMI from an Amazon ECS-optimized AMI?](#) in the AWS Knowledge Center.

## Using the image ARN with infrastructure as code (IaC)

You can configure the recipe using the EC2 Image Builder console, or infrastructure as code (for example, CloudFormation), or the AWS SDK. When you specify a parent image in your recipe, you can specify an EC2 AMI ID, Image Builder image ARN, AWS Marketplace product ID, or container image. AWS publishes both AMI IDs and Image Builder image ARNs of Amazon ECS-Optimized AMIs publicly. The following is the ARN format for the image:

```
arn:${Partition}:imagebuilder:${Region}:${Account}:image/${ImageName}/${ImageVersion}
```

The ImageVersion has the following format. Replace *major*, *minor* and *patch* with the latest values.

```
<major>.<minor>.<patch>
```

You can replace *major*, *minor* and *patch* to specific values or you can use Versionless ARN of an image, so your pipeline remains up-to-date with the latest version of the parent image. A versionless ARN uses wildcard format 'x.x.x' to represent the image version. This approach allows the Image Builder service to automatically resolve to the most recent version of the image. Using versionless ARN ensures that your reference always point to the latest image available, streamlining the process of maintaining up to date images in your deployment. When you create a recipe with the console, EC2 Image Builder automatically identifies the ARN for your parent image. When you use IaC to create the recipe, you must identify the ARN and select the desired image version or use versionless arn to indicate latest available image. We recommend that you create an automated script to filter and only display images that align with your criteria. The following Python script shows how to retrieve a list of Amazon ECS-optimized AMIs.

The script accepts two optional arguments: `owner` and `platform`, with default values of "Amazon", and "Windows" respectively. The valid values for the `owner` argument are: `Self`,

Shared, Amazon, and ThirdParty. The valid values for the platform argument are Windows and Linux. For example, if you run the script with the owner argument set to Amazon and the platform set to Linux, the script generates a list of images published by Amazon including Amazon ECS-Optimized images.

```
import boto3
import argparse

def list_images(owner, platform):
    # Create a Boto3 session
    session = boto3.Session()

    # Create an EC2 Image Builder client
    client = session.client('imagebuilder')

    # Define the initial request parameters
    request_params = {
        'owner': owner,
        'filters': [
            {
                'name': 'platform',
                'values': [platform]
            }
        ]
    }

    # Initialize the results list
    all_images = []

    # Get the initial response with the first page of results
    response = client.list_images(**request_params)

    # Extract images from the response
    all_images.extend(response['imageVersionList'])

    # While 'nextToken' is present, continue paginating
    while 'nextToken' in response and response['nextToken']:
        # Update the token for the next request
        request_params['nextToken'] = response['nextToken']

        # Get the next page of results
        response = client.list_images(**request_params)
```

```

        # Extract images from the response
        all_images.extend(response['imageVersionList'])

    return all_images

def main():
    # Initialize the parser
    parser = argparse.ArgumentParser(description="List AWS images based on owner and platform")

    # Add the parameters/arguments
    parser.add_argument("--owner", default="Amazon", help="The owner of the images. Default is 'Amazon'.")
    parser.add_argument("--platform", default="Windows", help="The platform type of the images. Default is 'Windows'.")

    # Parse the arguments
    args = parser.parse_args()

    # Retrieve all images based on the provided owner and platform
    images = list_images(args.owner, args.platform)

    # Print the details of the images
    for image in images:
        print(f"Name: {image['name']}, Version: {image['version']}, ARN: {image['arn']}")

if __name__ == "__main__":
    main()

```

## Using the image ARN with CloudFormation

An Image Builder image recipe is a blueprint that specifies the parent image and components required to achieve the intended configuration of the output image. You use the `AWS::ImageBuilder::ImageRecipe` resource. Set the `ParentImage` value to the image ARN. Use the versionless ARN of your desired image to ensure your pipeline always uses the most recent version of the image. For example, `arn:aws:imagebuilder:us-east-1:aws:image/amazon-linux-2023-ecs-optimized-x86/x.x.x`. The following `AWS::ImageBuilder::ImageRecipe` resource definition uses an Amazon managed image ARN:

```

ECSRecipe:
  Type: AWS::ImageBuilder::ImageRecipe

```

**Properties:**

Name: MyRecipe

Version: '1.0.0'

**Components:**

- ComponentArn: [&lt;The component arns of the image recipe&gt;]

ParentImage: "arn:aws:imagebuilder:us-east-1:aws:image/amazon-linux-2023-ecs-optimized-x86/x.x.x"

For more information about the [AWS::ImageBuilder::ImageRecipe](#) resource see in the *AWS CloudFormation User Guide*.

You can automate the creation of new images in your pipeline by setting the Schedule property of the `AWS::ImageBuilder::ImagePipeline` resource. The schedule includes a start condition and cron expression. For more information, see [AWS::ImageBuilder::ImagePipeline](#) in the *AWS CloudFormation User Guide*.

The following of `AWS::ImageBuilder::ImagePipeline` example has the pipeline run a build at 10:00AM Coordinated Universal Time (UTC) every day. Set the following Schedule values:

- Set `PipelineExecutionStartCondition` to `EXPRESSION_MATCH_AND_DEPENDENCY_UPDATES_AVAILABLE`. The build initiates only if dependent resources like the parent image or components, which use the wildcard 'x' in their semantic versions, are updated. This ensures the build incorporates the latest updates of those resources.
- Set `ScheduleExpression` to the cron expression (`0 10 * * ? *`).

**ECSPipeline:**Type: `AWS::ImageBuilder::ImagePipeline`**Properties:**

Name: my-pipeline

ImageRecipeArn: &lt;arn of the recipe you created in previous step&gt;

InfrastructureConfigurationArn: &lt;ARN of the infrastructure configuration associated with this image pipeline&gt;

**Schedule:**

PipelineExecutionStartCondition:

`EXPRESSION_MATCH_AND_DEPENDENCY_UPDATES_AVAILABLE`ScheduleExpression: '`cron(0 10 * * ? *)`'

## Using the image ARN with Terraform

The approach for specifying your pipeline's parent image and schedule in Terraform aligns with that in AWS CloudFormation. You use the `aws_imagebuilder_image_recipe` resource. Set the `parent_image` value to the image ARN. Use the versionless ARN of your desired image to ensure your pipeline always uses the most recent version of the image. For more information, see [aws\\_imagebuilder\\_image\\_recipe](#) in the Terraform documentation.

In the schedule configuration block of the `aws_imagebuilder_image_pipeline` resource, set the `schedule_expression` argument value to a cron expression of your choice to specify how often the pipeline runs, and set the `pipeline_execution_start_condition` to `EXPRESSION_MATCH_AND_DEPENDENCY_UPDATES_AVAILABLE`. For more information, see [aws\\_imagebuilder\\_image\\_pipeline](#) in the Terraform documentation.

## Using AWS Deep Learning Containers on Amazon ECS

AWS Deep Learning Containers provide a set of Docker images for training and serving models in TensorFlow and Apache MXNet (Incubating) on Amazon ECS. Deep Learning Containers enable optimized environments with TensorFlow, NVIDIA CUDA (for GPU instances), and Intel MKL (for CPU instances) libraries. Container images for Deep Learning Containers are available in Amazon ECR to reference in Amazon ECS task definitions. You can use Deep Learning Containers along with Amazon Elastic Inference to lower your inference costs.

To get started using Deep Learning Containers without Elastic Inference on Amazon ECS, see [Amazon ECS setup](#) in the *AWS Deep Learning AMIs Developer Guide*.

## Tutorial: Creating a Service Using a Blue/Green Deployment

Amazon ECS has integrated blue/green deployments into the Create Service wizard on the Amazon ECS console. For more information, see [Creating an Amazon ECS rolling update deployment](#).

The following tutorial shows how to create an Amazon ECS service containing a Fargate task that uses the blue/green deployment type with the AWS CLI.

**Note**

Support for performing a blue/green deployment has been added for CloudFormation. For more information, see [Perform Amazon ECS blue/green deployments through CodeDeploy using CloudFormation](#) in the *AWS CloudFormation User Guide*.

## Prerequisites

This tutorial assumes that you have completed the following prerequisites:

- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading the AWS CLI, see [Installing the AWS Command Line Interface](#).
- The steps in [Set up to use Amazon ECS](#) have been completed.
- Your IAM user has the required permissions specified in the [AmazonECS\\_FullAccess](#) IAM policy example.
- You have a VPC and security group created to use. For more information, see [the section called "Create a virtual private cloud"](#).
- The Amazon ECS CodeDeploy IAM role is created. For more information, see [Amazon ECS CodeDeploy IAM Role](#).

## Step 1: Create an Application Load Balancer

Amazon ECS services using the blue/green deployment type can use an Application Load Balancer, Network Load Balancer, Service Connect, or be headless. For managed traffic shifting, you need a load balancer or Service Connect. This tutorial uses an Application Load Balancer.

### To create an Application Load Balancer

1. Use the [create-load-balancer](#) command to create an Application Load Balancer. Specify two subnets that aren't from the same Availability Zone as well as a security group.

```
aws elbv2 create-load-balancer \  
  --name bluegreen-alb \  
  --subnets subnet-abcd1234 subnet-abcd5678 \  
  --security-groups sg-abcd1234 \  
  --region us-east-1
```

The output includes the Amazon Resource Name (ARN) of the load balancer, with the following format:

```
arn:aws:elasticloadbalancing:region:aws_account_id:loadbalancer/app/bluegreen-alb/e5ba62739c16e642
```

2. Use the [create-target-group](#) command to create a target group. This target group will route traffic to the original task set in your service.

```
aws elbv2 create-target-group \  
  --name bluegreentarget1 \  
  --protocol HTTP \  
  --port 80 \  
  --target-type ip \  
  --vpc-id vpc-abcd1234 \  
  --region us-east-1
```

The output includes the ARN of the target group, with the following format:

```
arn:aws:elasticloadbalancing:region:aws_account_id:targetgroup/bluegreentarget1/209a844cd01825a4
```

3. Use the [create-listener](#) command to create a load balancer listener with a default rule that forwards requests to the target group.

```
aws elbv2 create-listener \  
  --load-balancer-arn  
  arn:aws:elasticloadbalancing:region:aws_account_id:loadbalancer/app/bluegreen-alb/e5ba62739c16e642 \  
  --protocol HTTP \  
  --port 80 \  
  --default-actions  
  Type=forward,TargetGroupArn=arn:aws:elasticloadbalancing:region:aws_account_id:targetgroup/bluegreentarget1/209a844cd01825a4 \  
  --region us-east-1
```

The output includes the ARN of the listener, with the following format:

```
arn:aws:elasticloadbalancing:region:aws_account_id:listener/app/bluegreen-alb/e5ba62739c16e642/665750bec1b03bd4
```

## Step 2: Create an Amazon ECS Cluster

Use the [create-cluster](#) command to create a cluster named `tutorial-bluegreen-cluster` to use.

```
aws ecs create-cluster \  
  --cluster-name tutorial-bluegreen-cluster \  
  --region us-east-1
```

The output includes the ARN of the cluster, with the following format:

```
arn:aws:ecs:region:aws_account_id:cluster/tutorial-bluegreen-cluster
```

## Step 3: Register a Task Definition

Use the [register-task-definition](#) command to register a task definition that is compatible with Fargate. It requires the use of the `awsvpc` network mode. The following is the example task definition used for this tutorial.

First, create a file named `fargate-task.json` with the following contents. Ensure that you use the ARN for your task execution role. For more information, see [Amazon ECS task execution IAM role](#).

```
{  
  "family": "sample-fargate",  
  "networkMode": "awsvpc",  
  "containerDefinitions": [  
    {  
      "name": "sample-app",  
      "image": "public.ecr.aws/docker/library/httpd:latest",  
      "portMappings": [  
        {  
          "containerPort": 80,  
          "hostPort": 80,  
          "protocol": "tcp"  
        }  
      ],  
      "essential": true,  
      "entryPoint": [  
        "sh",  
        "-c"  
      ]  
    }  
  ]  
}
```

```

    ],
    "command": [
        "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample
App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </
head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1>
<h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon
ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-
foreground\""]
    ]
}
],
"requiresCompatibilities": [
    "FARGATE"
],
"cpu": "256",
"memory": "512"
}

```

Then register the task definition using the `fargate-task.json` file that you created.

```

aws ecs register-task-definition \
  --cli-input-json file://fargate-task.json \
  --region us-east-1

```

## Step 4: Create an Amazon ECS Service

Use the [create-service](#) command to create a service.

First, create a file named `service-bluegreen.json` with the following contents.

```

{
  "cluster": "tutorial-bluegreen-cluster",
  "serviceName": "service-bluegreen",
  "taskDefinition": "tutorial-task-def",
  "loadBalancers": [
    {
      "targetGroupArn":
"arn:aws:elasticloadbalancing:region:aws_account_id:targetgroup/
bluegreentarget1/209a844cd01825a4",
      "containerName": "sample-app",
      "containerPort": 80
    }
  ]
}

```

```

    ],
    "launchType": "FARGATE",
    "schedulingStrategy": "REPLICA",
    "deploymentController": {
        "type": "CODE_DEPLOY"
    },
    "platformVersion": "LATEST",
    "networkConfiguration": {
        "awsvpcConfiguration": {
            "assignPublicIp": "ENABLED",
            "securityGroups": [ "sg-abcd1234" ],
            "subnets": [ "subnet-abcd1234", "subnet-abcd5678" ]
        }
    },
    "desiredCount": 1
}

```

Then create your service using the `service-bluegreen.json` file that you created.

```

aws ecs create-service \
  --cli-input-json file://service-bluegreen.json \
  --region us-east-1

```

The output includes the ARN of the service, with the following format:

```
arn:aws:ecs:region:aws_account_id:service/tutorial-bluegreen-cluster/service-bluegreen
```

## Step 5: Create the AWS CodeDeploy Resources

Use the following steps to create your CodeDeploy application, the Application Load Balancer target group for the CodeDeploy deployment group, and the CodeDeploy deployment group.

### To create CodeDeploy resources

1. Use the [create-application](#) command to create an CodeDeploy application. Specify the ECS compute platform.

```

aws deploy create-application \
  --application-name tutorial-bluegreen-app \
  --compute-platform ECS \
  --region us-east-1

```

The output includes the application ID, with the following format:

```
{
  "applicationId": "b8e9c1ef-3048-424e-9174-885d7dc9dc11"
}
```

2. Use the [create-target-group](#) command to create a second Application Load Balancer target group, which will be used when creating your CodeDeploy deployment group.

```
aws elbv2 create-target-group \
  --name bluegreentarget2 \
  --protocol HTTP \
  --port 80 \
  --target-type ip \
  --vpc-id "vpc-0b6dd82c67d8012a1" \
  --region us-east-1
```

The output includes the ARN for the target group, with the following format:

```
arn:aws:elasticloadbalancing:region:aws_account_id:targetgroup/
bluegreentarget2/708d384187a3cfdc
```

3. Use the [create-deployment-group](#) command to create an CodeDeploy deployment group.

First, create a file named `tutorial-deployment-group.json` with the following contents. This example uses the resource that you created. For the `serviceRoleArn`, specify the ARN of your Amazon ECS CodeDeploy IAM role. For more information, see [Amazon ECS CodeDeploy IAM Role](#).

```
{
  "applicationName": "tutorial-bluegreen-app",
  "autoRollbackConfiguration": {
    "enabled": true,
    "events": [ "DEPLOYMENT_FAILURE" ]
  },
  "blueGreenDeploymentConfiguration": {
    "deploymentReadyOption": {
      "actionOnTimeout": "CONTINUE_DEPLOYMENT",
      "waitTimeInMinutes": 0
    },
    "terminateBlueInstancesOnDeploymentSuccess": {
```

```

        "action": "TERMINATE",
        "terminationWaitTimeInMinutes": 5
    },
    "deploymentGroupName": "tutorial-bluegreen-dg",
    "deploymentStyle": {
        "deploymentOption": "WITH_TRAFFIC_CONTROL",
        "deploymentType": "BLUE_GREEN"
    },
    "loadBalancerInfo": {
        "targetGroupPairInfoList": [
            {
                "targetGroups": [
                    {
                        "name": "bluegreentarget1"
                    },
                    {
                        "name": "bluegreentarget2"
                    }
                ]
            },
            {
                "prodTrafficRoute": {
                    "listenerArns": [
                        "arn:aws:elasticloadbalancing:region:aws_account_id:listener/app/bluegreen-alb/e5ba62739c16e642/665750bec1b03bd4"
                    ]
                }
            }
        ]
    },
    "serviceRoleArn": "arn:aws:iam::aws_account_id:role/ecsCodeDeployRole",
    "ecsServices": [
        {
            "serviceName": "service-bluegreen",
            "clusterName": "tutorial-bluegreen-cluster"
        }
    ]
}

```

Then create the CodeDeploy deployment group.

```

aws deploy create-deployment-group \
  --cli-input-json file://tutorial-deployment-group.json \
  --region us-east-1

```

The output includes the deployment group ID, with the following format:

```
{
  "deploymentGroupId": "6fd9bdc6-dc51-4af5-ba5a-0a4a72431c88"
}
```

## Step 6: Create and Monitor an CodeDeploy Deployment

Use the following steps to create and upload an application specification file (AppSpec file) and an CodeDeploy deployment.

### To create and monitor an CodeDeploy deployment

1. Create and upload an AppSpec file using the following steps.
  - a. Create a file named `appspec.yaml` with the contents of the CodeDeploy deployment group. This example uses the resources that you created earlier in the tutorial.

```
version: 0.0
Resources:
  - TargetService:
      Type: AWS::ECS::Service
      Properties:
        TaskDefinition: "arn:aws:ecs:region:aws_account_id:task-
definition/first-run-task-definition:7"
        LoadBalancerInfo:
          ContainerName: "sample-app"
          ContainerPort: 80
          PlatformVersion: "LATEST"
```

- b. Use the [s3 mb](#) command to create an Amazon S3 bucket for the AppSpec file.

```
aws s3 mb s3://tutorial-bluegreen-bucket
```

- c. Use the [s3 cp](#) command to upload the AppSpec file to the Amazon S3 bucket.

```
aws s3 cp ./appspec.yaml s3://tutorial-bluegreen-bucket/appspec.yaml
```

2. Create the CodeDeploy deployment using the following steps.

- a. Create a file named `create-deployment.json` with the contents of the CodeDeploy deployment. This example uses the resources that you created earlier in the tutorial.

```
{
  "applicationName": "tutorial-bluegreen-app",
  "deploymentGroupName": "tutorial-bluegreen-dg",
  "revision": {
    "revisionType": "S3",
    "s3Location": {
      "bucket": "tutorial-bluegreen-bucket",
      "key": "appspec.yaml",
      "bundleType": "YAML"
    }
  }
}
```

- b. Use the [create-deployment](#) command to create the deployment.

```
aws deploy create-deployment \
  --cli-input-json file://create-deployment.json \
  --region us-east-1
```

The output includes the deployment ID, with the following format:

```
{
  "deploymentId": "d-RPCR1U3TW"
}
```

- c. Use the [get-deployment-target](#) command to get the details of the deployment, specifying the deploymentId from the previous output.

```
aws deploy get-deployment-target \
  --deployment-id "d-IMJU3A8TW" \
  --target-id tutorial-bluegreen-cluster:service-bluegreen \
  --region us-east-1
```

Continue to retrieve the deployment details until the status is Succeeded, as shown in the following output.

```
{
```

```
"deploymentTarget": {
  "deploymentTargetType": "ECSTarget",
  "ecsTarget": {
    "deploymentId": "d-RPCR1U3TW",
    "targetId": "tutorial-bluegreen-cluster:service-bluegreen",
    "targetArn": "arn:aws:ecs:region:aws_account_id:service/tutorial-
bluegreen-cluster/service-bluegreen",
    "lastUpdatedAt": 1543431490.226,
    "lifecycleEvents": [
      {
        "lifecycleEventName": "BeforeInstall",
        "startTime": 1543431361.022,

```

## Step 7: Clean Up

When you have finished this tutorial, clean up the resources associated with it to avoid incurring charges for resources that you aren't using.

### Cleaning up the tutorial resources

1. Use the [delete-deployment-group](#) command to delete the CodeDeploy deployment group.

```
aws deploy delete-deployment-group \
    --application-name tutorial-bluegreen-app \
```

```
--deployment-group-name tutorial-bluegreen-dg \  
--region us-east-1
```

2. Use the [delete-application](#) command to delete the CodeDeploy application.

```
aws deploy delete-application \  
  --application-name tutorial-bluegreen-app \  
  --region us-east-1
```

3. Use the [delete-service](#) command to delete the Amazon ECS service. Using the `--force` flag allows you to delete a service even if it has not been scaled down to zero tasks.

```
aws ecs delete-service \  
  --service arn:aws:ecs:region:aws_account_id:service/tutorial-bluegreen-cluster/service-bluegreen \  
  --force \  
  --region us-east-1
```

4. Use the [delete-cluster](#) command to delete the Amazon ECS cluster.

```
aws ecs delete-cluster \  
  --cluster tutorial-bluegreen-cluster \  
  --region us-east-1
```

5. Use the [s3 rm](#) command to delete the AppSpec file from the Amazon S3 bucket.

```
aws s3 rm s3://tutorial-bluegreen-bucket/appspect.yaml
```

6. Use the [s3 rb](#) command to delete the Amazon S3 bucket.

```
aws s3 rb s3://tutorial-bluegreen-bucket
```

7. Use the [delete-load-balancer](#) command to delete the Application Load Balancer.

```
aws elbv2 delete-load-balancer \  
  --load-balancer-arn  
  arn:aws:elasticloadbalancing:region:aws_account_id:loadbalancer/app/bluegreen-alb/e5ba62739c16e642 \  
  --region us-east-1
```

8. Use the [delete-target-group](#) command to delete the two Application Load Balancer target groups.

```
aws elbv2 delete-target-group \  
  --target-group-arn  
  arn:aws:elasticloadbalancing:region:aws_account_id:targetgroup/  
bluegreentarget1/209a844cd01825a4 \  
  --region us-east-1
```

```
aws elbv2 delete-target-group \  
  --target-group-arn  
  arn:aws:elasticloadbalancing:region:aws_account_id:targetgroup/  
bluegreentarget2/708d384187a3cfdc \  
  --region us-east-1
```

# Amazon ECS service quotas

When you create your AWS account, we set default *quotas* (also referred to as limits) on your AWS resources on a per-Region basis. If you attempt to exceed the quota for a resource, the request fails.

The Service Quotas console is a central location where you can view and manage your quotas for AWS services, and request a quota increase for many of the resources that you use. Use the quota information that we provide to manage your resources. Plan to request any quota increases in advance of the time that you'll need them.

For more information about Amazon ECS and Fargate quotas, see [Amazon ECS endpoints and quotas](#) in the *Amazon Web Services General Reference*. For information about API throttling in the Amazon ECS API, see [Request throttling for the Amazon ECS API](#).

Amazon ECS Managed Instances follow the Amazon EC2 quotas. For more information, see [Amazon EC2 service quotas](#) in the Amazon EC2 User Guide.

## Managing your Amazon ECS and AWS Fargate service quotas in the AWS Management Console

Amazon ECS has integrated with Service Quotas, an AWS service that enables you to view and manage your quotas from a central location. For more information, see [What is Service Quotas?](#) in the *Service Quotas User Guide*.

Service Quotas makes it easy to look up the value of your Amazon ECS service quotas.

### AWS Management Console

#### To view Amazon ECS and Fargate service quotas using the AWS Management Console

1. Open the Service Quotas console at <https://console.aws.amazon.com/servicequotas/>.
2. In the navigation pane, choose **AWS services**.
3. From the **AWS services** list, search for and select **Amazon Elastic Container Service (Amazon ECS)** or **AWS Fargate**.

In the **Service quotas** list, you can see the service quota name, applied value (if it is available), AWS default quota, and whether the quota value is adjustable.

4. To view additional information about a service quota, such as the description, choose the quota name.
5. (Optional) To request a quota increase, select the quota that you want to increase, select **Request quota increase**, enter or select the required information, and select **Request**.

To work more with service quotas using the AWS Management Console see the [Service Quotas User Guide](#). To request a quota increase, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

## AWS CLI

### To view Amazon ECS and Fargate service quotas using the AWS CLI

Run the following command to view the default Amazon ECS quotas.

```
aws service-quotas list-aws-default-service-quotas \
  --query 'Quotas[*]'.
{Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}' \
  --service-code ecs \
  --output table
```

Run the following command to view the default Fargate quotas.

```
aws service-quotas list-aws-default-service-quotas \
  --query 'Quotas[*]'.
{Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}' \
  --service-code fargate \
  --output table
```

Run the following command to view your applied Fargate quotas.

```
aws service-quotas list-service-quotas \
  --service-code fargate
```

#### Note

Amazon ECS doesn't support applied quotas.

For more information about working with service quotas using the AWS CLI, see the [Service Quotas AWS CLI Command Reference](#). To request a quota increase, see the [request-service-quota-increase](#) command in the [AWS CLI Command Reference](#).

## Handle Amazon ECS service quotas and API throttling limits

Amazon ECS is integrated with several AWS services, including Elastic Load Balancing, AWS Cloud Map, and Amazon EC2. With this tight integration, Amazon ECS includes several features such as service load balancing, Service Connect, task networking, and cluster auto scaling. Amazon ECS and the other AWS services that it integrates with all maintain service quotas and API rate limits to ensure consistent performance and utilization. These service quotas also prevent the accidental provisioning of more resources than needed and protect against malicious actions that might increase your bill.

By familiarizing yourself with your service quotas and the AWS API rate limits, you can plan for scaling your workloads without worrying about unexpected performance degradation. For more information, see [Request throttling for the Amazon ECS API](#).

When scaling your workloads on Amazon ECS, we recommend that you consider the following service quota.

- AWS Fargate has quotas that limit the number of concurrent running tasks in each AWS Region. There are quotas for both On-Demand and Fargate Spot tasks on Amazon ECS. Each service quota also includes any Amazon EKS pods that you run on Fargate.
- For tasks that run on Amazon EC2 instances, the maximum number of Amazon EC2 instances that you can register for each cluster is 5,000. If you use Amazon ECS cluster auto scaling with an Auto Scaling group capacity provider, or if you manage Amazon EC2 instances for your cluster on your own, this quota might become a deployment bottleneck. If you require more capacity, you can create more clusters or request a service quota increase.
- If you use Amazon ECS cluster auto scaling with an Auto Scaling group capacity provider, when scaling your services consider the Tasks in the PROVISIONING state per cluster quota. This quota is the maximum number of tasks in the PROVISIONING state for each cluster for which capacity providers can increase capacity. When you launch a large number of tasks all at the same time, you can easily meet this quota. One example is if you simultaneously deploy tens of services, each with hundreds of tasks. When this happens, the capacity provider needs to launch new container instances to place the tasks when the cluster has insufficient capacity. While the capacity provider is launching additional Amazon EC2 instances, the Amazon ECS

service scheduler likely will continue to launch tasks in parallel. However, this activity might be throttled because of insufficient cluster capacity. The Amazon ECS service scheduler implements a back-off and exponential throttling strategy for retrying task placement as new container instances are launched. As a result, you might experience slower deployment or scale-out times. To avoid this situation, you can plan your service deployments in one of the following ones. Either deploy a large number of tasks don't require increasing cluster capacity, or keep spare cluster capacity for new task launches.

In addition to considering Amazon ECS service quota when scaling your workloads, consider also the service quota for the other AWS services that are integrated with Amazon ECS.

## Elastic Load Balancing

You can configure your Amazon ECS services to use Elastic Load Balancing to distribute traffic evenly across the tasks. For more information and recommended best practices for how to choose a load balancer, see [Use load balancing to distribute Amazon ECS service traffic](#).

### Elastic Load Balancing service quotas

When you scale your workloads, consider the following Elastic Load Balancing service quotas. Most Elastic Load Balancing service quotas are adjustable, and you can request an increase in the Service Quotas console.

#### Application Load Balancer

When you use an Application Load Balancer, depending on your use case, you might need to request a quota increase for:

- The `Targets per Application Load Balancer` quota which is the number of targets behind your Application Load Balancer.
- The `Targets per Target Group per Region` quota which is the number of targets behind your Target Groups.

For more information, see [Quotas for your Application Load Balancers](#) in *User Guide for Application Load Balancers*.

#### Network Load Balancer

There are stricter limitations on the number of targets you can register with a Network Load Balancer. When using a Network Load Balancer, you often will want to enable cross-zone support, which comes with additional scaling limitations on Targets per Availability Zone. Per Network Load Balancer the maximum number of targets per Availability Zone for each Network Load Balancer. For more information, see [Quotas for your Network Load Balancers](#) in the *User Guide for Network Load Balancers*.

## Elastic Load Balancing API throttling

When you configure an Amazon ECS service to use a load balancer, the target group health checks must pass before the service is considered healthy. For performing these health checks, Amazon ECS invokes Elastic Load Balancing API operations on your behalf. If you have a large number of services configured with load balancers in your account, you might slower service deployments because of potential throttling specifically for the `RegisterTarget`, `DeregisterTarget`, and `DescribeTargetHealth` Elastic Load Balancing API operations. When throttling occurs, throttling errors occur in your Amazon ECS service event messages.

If you experience AWS Cloud Map API throttling, you can contact Support for guidance on how to increase your AWS Cloud Map API throttling limits. For more information about monitoring and troubleshooting such throttling errors, see [Handle Amazon ECS throttling issues](#).

## Elastic network interfaces

With your tasks use the `awsvpc` network mode, Amazon ECS provisions a unique elastic network interface (ENI) for each task. When your Amazon ECS services use an Elastic Load Balancing load balancer, these network interfaces are also registered as targets to the appropriate target group defined in the service.

## Elastic network interface service quotas

When you run tasks that use the `awsvpc` network mode, a unique elastic network interface is attached to each task. If those tasks must be reached over the internet, assign a public IP address to the elastic network interface for those tasks. When you scale your Amazon ECS workloads, consider these two important quotas:

- The `Network interfaces per Region` quota which is the maximum number of network interfaces in an AWS Region for your account.
- The `Elastic IP addresses per Region` quota which is the maximum number of elastic IP addresses in an AWS Region.

Both of these service quotas are adjustable and you can request an increase from your Service Quotas console for these. For more information, see [Amazon VPC service quotas](#) in the *Amazon Virtual Private Cloud user Guide*.

For Amazon ECS workloads that are hosted on Amazon EC2 instances, when running tasks that use the `awsvpc` network mode consider the `Maximum network interfaces` service quota, the maximum number of network instances for each Amazon EC2 instance. This quota limits the number of tasks that you can place on an instance. You cannot adjust the quota and it's not available in the Service Quotas console. For more information, see [IP addresses per network interface per instance type](#) in the *Amazon EC2 User Guide*.

Although you can't change the number of network interfaces that can be attached to an Amazon EC2 instance, you can use the elastic network interface trunking feature to increase the number of available network interfaces. For example, by default a `c5.large` instance can have up to three network interfaces. The primary network interface for the instance counts as one. So, you can attach an additional two network interfaces to the instance. Because each task that uses the `awsvpc` network mode requires a network interface, you can typically only run two such tasks on this instance type. This can lead to under-utilization of your cluster capacity. If you enable elastic network interface trunking, you can increase the network interface density to place a larger number of tasks on each instance. With trunking turned on, a `c5.large` instance can have up to 12 network interfaces. The instance has the primary network interface and Amazon ECS creates and attaches a "trunk" network interface to the instance. As a result, with this configuration you can run 10 tasks on the instance instead of the default two tasks. For more information, see [Increasing Amazon ECS Linux container instance network interfaces](#).

## Elastic network interface API throttling

When you run tasks that use the `awsvpc` network mode, Amazon ECS relies on the following Amazon EC2 APIs. Each of these APIs have different API throttles. For more information, see [Request throttling for the Amazon EC2 API](#) in the *Amazon EC2 API Reference*.

- `CreateNetworkInterface`
- `AttachNetworkInterface`
- `DetachNetworkInterface`
- `DeleteNetworkInterface`
- `DescribeNetworkInterfaces`
- `DescribeVpcs`

- DescribeSubnets
- DescribeSecurityGroups
- DescribeInstances

If the Amazon EC2 API calls are throttled during the elastic network interface provisioning workflows, the Amazon ECS service scheduler automatically retries with exponential back-offs. These automatic retries might sometimes lead to a delay in launching tasks, which results in slower deployment speeds. When API throttling occurs, you will see the message `Operations are being throttled. Will try again later.` on your service event messages. If you consistently meet Amazon EC2 API throttles, you can contact Support for guidance on how to increase your API throttling limits. For more information about monitoring and troubleshooting throttling errors, see [Handling throttling issues](#).

## AWS Cloud Map

Amazon ECS service discovery and Service Connect use AWS Cloud Map APIs to manage namespaces for your Amazon ECS services. If your services have a large number of tasks, consider the following recommendations.

### AWS Cloud Map service quotas

When Amazon ECS services are configured to use service discovery or Service Connect, the `Tasks per service` quota which is the maximum number of tasks for the service, is affected by the `AWS Cloud Map Instances per service` service quota which is the maximum number of instances for that service. In particular, the AWS Cloud Map service quota decreases the amount of instances that you can run to at most 1,000 instances per service. You cannot change the AWS Cloud Map quota. For more information, see [AWS Cloud Map service quotas](#).

### AWS Cloud Map API throttling

Amazon ECS calls the `ListInstances`, `GetInstancesHealthStatus`, `RegisterInstance`, and `DeregisterInstance` AWS Cloud Map APIs on your behalf. They help with service discovery and perform health checks when you launch a task. When multiple services that use service discovery with a large number of tasks are deployed at the same time, this can result in exceeding the AWS Cloud Map API throttling limits. When this happens, you likely will see the following message: `Operations are being throttled. Will try again later` in your Amazon ECS service event messages and slower deployment and task launch speed. AWS Cloud Map doesn't document

throttling limits for these APIs. If you experience throttling from these, you can contact Support for guidance on increasing your API throttling limits. For more recommendations about monitoring and troubleshooting such throttling errors, see [Handle Amazon ECS throttling issues](#).

# Using the API for Amazon ECS

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon ECS also provides an API. You can use the API to automate tasks for managing Amazon ECS resources.

- For a list of API operations by Amazon ECS resource, see [Actions by Amazon ECS resource](#).
- For an alphabetical list of API operations, see [Actions](#).
- For an alphabetical list of data types, see [Data types](#).
- For a list of common query parameters, see [Common parameters](#).
- For descriptions of the error codes, see [Common errors](#).

For more information about the AWS CLI, see [AWS Command Line Interface reference for Amazon ECS](#).

## Actions by Amazon ECS resource

The following section lists the API actions by resource.

### Topics

- [Account setting actions](#)
- [Cluster actions](#)
- [Cluster capacity provider actions](#)
- [Container actions](#)
- [Container agent actions](#)
- [Container instance actions](#)
- [Namespace actions](#)
- [Service actions](#)
- [Service deployment actions](#)
- [Service revision actions](#)
- [Task definition actions](#)

- [Task actions](#)
- [Task set actions](#)
- [Tag actions](#)

## Account setting actions

The following API actions are available for account settings:

- [DeleteAccountSetting](#)
- [ListAccountSettings](#)
- [PutAccountSetting](#)
- [PutAccountSettingDefault](#)

## Cluster actions

The following API actions are available for clusters:

- [CreateCluster](#)
- [DeleteCluster](#)
- [DescribeClusters](#)
- [ListClusters](#)
- [UpdateCluster](#)
- [UpdateClusterSettings](#)

## Cluster capacity provider actions

The following APIs are available for cluster capacity providers:

- [CreateCapacityProvider](#)
- [DeleteCapacityProvider](#)
- [DescribeCapacityProviders](#)
- [PutClusterCapacityProviders](#)
- [UpdateCapacityProvider](#)

## Container actions

The following APIs are available for containers:

- [ExecuteCommand](#)

## Container agent actions

The following APIs are available for container agents:

- [UpdateContainerAgent](#)

## Container instance actions

The following APIs are available for container instances:

- [DeregisterContainerInstance](#)
- [DescribeContainerInstances](#)
- [DeleteAttributes](#)
- [ListAttributes](#)
- [ListContainerInstances](#)
- [PutAttributes](#)
- [UpdateContainerInstancesState](#)

## Namespace actions

### Note

Namespaces are an AWS Cloud Map resource. Namespaces are necessary in Amazon ECS to use the ECS Service Connect or ECS service discovery features. Amazon ECS requests namespaces from AWS Cloud Map and then displays your namespaces in the AWS Management Console. Use the AWS Cloud Map console or API for additional configuration options.

The following APIs are available for namespaces:

- [CreateCluster](#)

## Service actions

The following APIs are available for services:

- [CreateService](#)
- [DeleteService](#)
- [DescribeServices](#)
- [ListServices](#)
- [UpdateService](#)

## Service deployment actions

The following APIs are available for service deployments:

- [DescribeServiceDeployments](#)
- [ListServiceDeployments](#)
- [StopServiceDeployment](#)

## Service revision actions

The following APIs are available for service revisions:

- [DescribeServiceRevisions](#)

## Task definition actions

The following APIs are available for task-definitions:

- [DeleteTaskDefinitions](#)
- [DeregisterTaskDefinition](#)
- [DescribeTaskDefinition](#)
- [ListTaskDefinitionFamilies](#)

- [ListTaskDefinitions](#)
- [RegisterTaskDefinition](#)

## Task actions

The following APIs are available for tasks:

- [DescribeTasks](#)
- [GetTaskProtection](#)
- [ListTasks](#)
- [RunTask](#)
- [StartTask](#)
- [StopTask](#)
- [UpdateTaskProtection](#)

## Task set actions

The following APIs are available for task sets:

- [CreateTaskSet](#)
- [DeleteTaskSet](#)
- [DescribeTaskSets](#)
- [UpdateServicePrimaryTaskSet](#)
- [UpdateTaskSet](#)

## Tag actions

The following APIs are available for tags:

- [ListTagsForResource](#)
- [TagResource](#)
- [UntagResource](#)

# Request throttling for the Amazon ECS API

Amazon Elastic Container Service throttles all API requests for each AWS account on a per-Region basis. We do this to ensure consistent performance and fair usage of the service for all Amazon ECS customers. Throttling ensures that calls to the Amazon ECS API do not exceed the maximum allowed API request quotas for both Amazon ECS and the other AWS services that it integrates with. API calls are subject to the request quotas whether they originate from:

- A third-party application
- A command line tool
- The Amazon ECS console

If you exceed an API throttling quota, you get the `ThrottlingException` error code.

```
An error occurred (ThrottlingException) when calling the DescribeClusters operation
(reached max retries: 4): Rate exceeded.
com.amazonaws.services.ecs.model.AmazonECSException: Rate exceeded (Service: AmazonECS;
Status Code: 400; Error
Code: ThrottlingException; Request ID: 5ed90669-e454-464d-9b2f-6523bc86f537; Proxy:
null)
```

## How throttling is applied

Amazon ECS uses the [token bucket algorithm](#) to implement API throttling. With this algorithm, your account has a *bucket* that holds a specific number of *tokens*. The number of tokens in the bucket represents your throttling quota at any given second.

Amazon ECS examines the rate of API request submissions for all Amazon ECS APIs in your account, per Region, and applies two types of API throttling quotas: *sustained* and *burst*. The sustained rate is the average number of API requests allowed per second over time for an operation. The burst rate is the maximum number of API requests allowed in any one second. With burst, you can periodically make a higher number of API requests than the sustained rate. Following which, Amazon ECS throttles subsequent API requests until the rate of API requests allowed over time stabilizes to the sustained rate. In the token bucket algorithm, the *bucket maximum capacity* signifies the burst rate and the *bucket refill rate* is the sustained rate. We will use these terms to provide you an illustration of Amazon ECS API request throttling in the following example.

You are throttled on the number of API requests you make and each request removes one token from the token bucket. For example, the bucket size for *Cluster read actions*, such as the `DescribeClusters` API, is 50 tokens, so you can make up to 50 `DescribeClusters` requests in one second. If you exceed 50 requests in a second, you are throttled and the remaining requests within that second fail.

Buckets automatically refill at a set rate. If the bucket is below its maximum capacity, a set number of tokens is added back to it every second until it reaches its maximum capacity. If the bucket is full when refill tokens arrive, they are discarded. The bucket cannot hold more than its maximum number of tokens. For example, the bucket size for *Cluster read actions*, such as the `DescribeClusters` API, is 50 tokens, and the refill rate is 20 tokens per second. If you make 50 `DescribeClusters` API requests in a second, the bucket is immediately reduced to zero tokens. The bucket is then refilled by 20 tokens every second, until it reaches its maximum capacity of 50 tokens. This means that the previously empty bucket reaches its maximum capacity after 2.5 seconds.

You do not need to wait for the bucket to be completely full before you can make API requests. You can use tokens as they are added to the bucket. If you immediately use the refill tokens, the bucket does not reach its maximum capacity. For example, the bucket size for *Cluster read actions*, such as the `DescribeClusters` API, is 50 tokens, and the refill rate is 20 tokens per second. If you deplete the bucket by making 50 API requests in a second, you can continue to make 20 API requests per second. The bucket can refill to the maximum capacity only if you make fewer than 20 API requests per second.

## Request Token Bucket Sizes and Refill Rates

For request rate limiting purposes, API actions are grouped into categories. All API actions in a category share the same token bucket. For instance, `DescribeClusters` and `ListClusters` APIs share the *Cluster read actions* bucket, for which capacity is 50 and refill rate is 20. This means that the cumulative number of API requests for all *Cluster read actions* is throttled by the same burst rate quota of 50 API requests. Thus, you can make 25 `DescribeClusters` and 25 `ListClusters` API requests in one second, or 30 `DescribeClusters` and 20 `ListClusters`, or 50 `DescribeClusters` and 0 `ListClusters`, or 0 `DescribeClusters` and 50 `ListClusters`, but you cannot make 50 `DescribeClusters` and 50 `ListClusters` requests at the same time. Sustained rate is similarly applied cumulatively to all API requests within a bucket.

The following table shows the bucket capacity (or burst) and refill rate (or sustained) for all AWS Regions. All API action categories enforce rate quotas for each AWS account on a per-Region basis.

| API action category              | Actions                                                                                                                                                                                                             | Bucket maximum capacity (or Burst rate) | Bucket refill rate (or Sustained rate) |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|----------------------------------------|
| Cluster modify actions           | <ul style="list-style-type: none"> <li>CreateCluster</li> <li>DeleteCluster</li> <li>PutClusterCapacity Providers</li> <li>UpdateCluster</li> <li>UpdateClusterSettings</li> </ul>                                  | 20                                      | 1                                      |
| Cluster read actions             | <ul style="list-style-type: none"> <li>DescribeClusters</li> <li>ListClusters</li> </ul>                                                                                                                            | 50                                      | 20                                     |
| Task definition modify actions   | <ul style="list-style-type: none"> <li>DeregisterTaskDefinition</li> <li>RegisterDaemonTask Definition</li> <li>RegisterTaskDefinition</li> </ul>                                                                   | 20                                      | 1                                      |
| Task definition read actions     | <ul style="list-style-type: none"> <li>DescribeDaemonTask Definition</li> <li>DescribeTaskDefinition</li> <li>ListDaemonTaskDefinitions</li> <li>ListTaskDefinitions</li> <li>ListTaskDefinitionFamilies</li> </ul> | 50                                      | 20                                     |

<sup>1</sup> AWS Fargate additionally throttles Amazon ECS RunTask API to the rates listed [here](#) in the *Amazon ECS Developer Guide*.

## Adjusting API throttling quotas

You can request an increase for API throttling quotas for your AWS account. To request a quota adjustment, contact the [AWS Support Center](#).

## Handling API throttling

You can implement an error retry and exponential back-off strategy to avoid the impact of throttling errors on your workloads. If you use AWS SDK, the automatic retry logic is already built-in and configurable. You can refer to the following resources for more details:

- [Error retries and exponential backoff in AWS](#) in the AWS General Reference Guide
- [Exponential backoff and jitter](#) blog post
- [Timeouts, retries, and backoff with jitter](#) article in the Amazon Builder's Library

Retries and back-off help your application recover from throttling, but they do not reduce the number of API requests you make. If you are consistently throttled, the most effective remedy is to lower your request rate at the source. Consider the following practices before requesting a quota increase:

- **Spread out scheduled work.** Avoid running batch jobs, deployments, or polling loops for many resources at the same instant (for example, on the same cron minute). Distribute the work across a wider time window and add jitter to start times so that requests do not arrive as a single burst.
- **Poll less frequently and react to events.** Instead of repeatedly calling `Describe` and `List` actions to detect change, lengthen your polling interval or subscribe to Amazon ECS state changes through Amazon EventBridge and react to changes as they happen.
- **Cache and reuse results.** Cache the responses of read actions such as `DescribeTasks` and `ListTasks` and reuse them across your application, rather than calling the API for every task or on every request.
- **Batch your requests.** Where an API accepts multiple resources in a single call (for example, passing multiple task IDs to `DescribeTasks`), use it instead of making one request per resource.
- **Retrieve task metadata locally.** For information about a running task, use the [task metadata endpoint](#) from inside the task instead of calling `DescribeTasks`.

Request-rate quotas protect service performance and fair usage across customers. If you have applied these practices and still require a higher request rate for a legitimate workload, you can request an increase as described in [the section called "Adjusting API throttling quotas"](#).

# Ensuring idempotency

When you perform a mutating operation, you might see an exception because of timeouts or server issues occurring after the resources are mutated. This can make it difficult to determine whether the mutation occurred, and could lead to multiple retries. However, if the original operation and the subsequent retries actually performed the mutations you might have applied stacking changes or created more resources than you intended to. Idempotency ensures that an operation mutates resources no more than one time. With an idempotent request, if the original request mutated successfully, any subsequent retries complete successfully without performing any further mutation.

## Topics

- [Idempotency in Amazon ECS](#)
- [Idempotency for RunTask](#)
- [Examples](#)
- [Retry recommendations for idempotent requests](#)

## Idempotency in Amazon ECS

The following API actions optionally support idempotency using a *client token*. The corresponding AWS CLI commands also support idempotency using a client token. A client token is a unique, case-sensitive string. To make an idempotent API request using one of these actions, specify a client token in the request. You should not reuse the same client token for other API requests. If you retry a request that completed successfully using the same client token and the same parameters, the retry succeeds without performing any further actions.

### Idempotent using a client token

- `CreateService`

The client token can be up to 36 ASCII characters in the range of 33-126 (inclusive).

- `CreateTaskSet`

The client token can be up to 36 ASCII characters in the range of 33-126 (inclusive).

- `RunTask`

The client token can be up to 64 ASCII characters in the range of 33-126 (inclusive).

## Types of idempotency

- **cluster** – Requests with the same token in the same cluster are idempotent. For example, ClientToken A can only be used as a request parameter one time for RunTask requests in Cluster X. RunTask requests to other clusters are considered a separate request. Therefore, you can use ClientToken A for a RunTask request for cluster Y.

## Idempotency for RunTask

The RunTask API supports idempotency using a client token. A client token is a unique string that you specify when you make an API request. If you retry an API request with the same client token and the same request parameters after it has completed successfully, the result of the original request is returned. If you retry a successful request using the same client token, but one or more of the parameters are different, other than the Region or Availability Zone, the retry fails with a `ConflictException`. If you do not specify your own client token, the AWS SDK and AWS Command Line Interface automatically generate a client token for the request to ensure that it is idempotent. A client token can be any string that includes up to 64 ASCII characters in the range of 33-126 (inclusive).

The time to live (TTL) for the RunTask client token is 24 hours. You should not reuse the same client token for different requests. The client token maximum TTL is valid for whichever of the following two values is lower:

- 24 hours
- The lifetime of the resource plus one hour

The lifetime of a resource is the timestamp at which the task was created to the timestamp at which the last status (`LastStatus`) transitioned to `STOPPED`. When you use RunTask to launch more than one task, the lifetime of the resource equals the lifetime of the last task that transitioned to `STOPPED`.

## RunTask retry rules and responses

When you retry a request because you received a 5xx exception, the retried successful response normally includes all of the information that the original request would have returned. Tasks that have been stopped for under an hour only include the task ARN, last status, and desired status.

The following is an example snippet of the response from a retry when there is one running task, one stopped task, and one task that failed to launch.

```
{
  "failures": [
    {
      "arn": "arn:aws:ecs:us-east-1:123456789012:container/4df26bb4-f057-467b-a079-961675296e64",
      "reason": "RESOURCE:MEMORY"
    }
  ],
  "tasks": [
    {
      "desiredStatus": "RUNNING",
      "taskArn": "arn:aws:ecs:us-east-1:123456789012:task/default/fdf2c302-468c-4e55-b884-5331d816e7fb",
      ...
    },
    {
      "taskArn": "arn:aws:ecs:us-east-1:123456789012:task/default/fdf2c302-468c-4e55-b884-5331d819999",
      "lastStatus": "STOPPED",
      ...
    }
  ]
}
```

Failures that are over an hour old only include the number of failed tasks.

## Examples

### AWS CLI command examples

To make an AWS CLI command idempotent, add the `--client-token` option.

#### Example: create-service

The following [create-service](#) command uses idempotency as it includes a client token.

```
aws ecs create-service \
  --cluster MyCluster \
  --service MyService \
```

```
--task-definition MyTaskDefinition:2 \
--desired-count 2 \
--launch-type FARGATE \
--platform-version LATEST \
--network-configuration
"awsvpcConfiguration={subnets=["subnet-12344321"],securityGroups=["sg-12344321"],assignPublicI
\
--client-token 550e8400-e29b-41d4-a716-44665544
```

### Example: create-task-set

The following [create-task-set](#) command uses idempotency as it includes a client token.

```
aws ecs create-task-set \
--cluster MyCluster \
--service MyService \
--task-definition MyTaskDefinition:2 \
--network-configuration
"awsvpcConfiguration={subnets=["subnet-12344321"],securityGroups=["sg-12344321"]}" \
--client-token 550e8400-e29b-41d4-a716-44665544
```

### Example: run-task

The following [run-task](#) command uses idempotency as it includes a client token.

```
aws ecs run-task \
--cluster MyCluster \
--task-definition MyTaskDefinition:2 \
--client-token 550e8400-e29b-41d4-a716-446655440000
```

## API request examples

To make an API request idempotent, add the `clientToken` parameter.

### Example: CreateService

The following [CreateService](#) API request uses idempotency as it includes a client token.

```
POST / HTTP/1.1
Host: ecs.us-east-1.amazonaws.com
Accept-Encoding: identity
```

```
Content-Length: 87
X-Amz-Target: AmazonEC2ContainerServiceV20141113.CreateService
X-Amz-Date: 20150429T170125Z
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
  "serviceName": "MyService",
  "taskDefinition": "MyTaskDefinition:2",
  "desiredCount": 10,
  "capacityProviderStrategy": [
    {
      "base": "number",
      "capacityProvider": "FARGATE",
      "weight": 1
    }
  ],
  "capacityProviderStrategy": [
    {
      "base": "number",
      "capacityProvider": "FARGATE_SPOT",
      "weight": 1
    }
  ],
  "clientToken": "550e8400-e29b-41d4-a716-44665544"
}
```

### Example: CreateTaskSet

The following [CreateTaskSet](#) API request uses idempotency as it includes a client token.

```
POST / HTTP/1.1
Host: ecs.us-east-1.amazonaws.com
Accept-Encoding: identity
Content-Length: 87
X-Amz-Target: AmazonEC2ContainerServiceV20141113.CreateTaskSet
X-Amz-Date: 20150429T170125Z
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
  "serviceName": "MyService",
  "taskDefinition": "mytask:1",
  "desiredCount": 1,
```

```

    "capacityProviderStrategy": [
      {
        "base": "number",

### Example: RunTask

The following [RunTask](#) API request uses idempotency as it includes a client token.

```

POST / HTTP/1.1
Host: ecs.us-east-1.amazonaws.com
Accept-Encoding: identity
Content-Length: 45
X-Amz-Target: AmazonEC2ContainerServiceV20141113.RunTask
X-Amz-Date: 20161121T215740Z
User-Agent: aws-cli/1.11.13 Python/2.7.12 Darwin/16.1.0 botocore/1.4.66
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

```

## Retry recommendations for idempotent requests

The following table shows some common responses that you might get for idempotent API requests, and provides retry recommendations.

| Response                                                    | Recommendation | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 200 (OK)                                                    | Do not retry   | The original request completed successfully. Any subsequent retries return successfully.                                                                                                                                                                                                                                                                                                                                                                                             |
| 400-series response codes ( <a href="#">client errors</a> ) | Do not retry   | <p>There is a problem with the request, from among the following:</p> <ul style="list-style-type: none"><li>• It includes a parameter or parameter combination that is not valid.</li><li>• It uses an action or resource for which you do not have permissions.</li><li>• It uses a resource that is in the process of changing states.</li></ul> <p>If the request involves a resource that is in the process of changing states, retrying the request could possibly succeed.</p> |
| 500-series response codes ( <a href="#">server errors</a> ) | Retry          | The error is caused by an AWS server-side issue and is generally transient. Repeat the request with an appropriate back-off strategy.                                                                                                                                                                                                                                                                                                                                                |

# Document history

The following table describes the major updates and new features for the *Amazon Elastic Container Service Developer Guide*. We also update the documentation frequently to address the feedback that you send us.

| Change                                                                        | Description                                                                                                                                                                                                                                                                                                                            | Date              |
|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Add permissions to <a href="#">AmazonECS_FullAccess</a> managed policy.       | The AmazonECS_FullAccess managed IAM policy was updated to include the <code>cloudformation:TagResource</code> and <code>cloudformation:UntagResource</code> permissions. These permissions allow tags to be added to CloudFormation stacks when a stack is created or updated.                                                        | September 2, 2026 |
| Add permissions to <a href="#">AmazonECSServiceRolePolicy</a> managed policy. | The AmazonECSServiceRolePolicy managed IAM policy was updated to include the <code>autoscaling:TerminateInstanceInAutoScalingGroup</code> permission. This permission allows Amazon ECS to terminate Amazon EC2 instances in customer ASGs that fail to register with the Amazon ECS cluster.                                          | April 24, 2026    |
| Update permissions to AmazonECSInfrastructureRolePolicyForManagedInstances .  | The permissions were updated to maintain consistency of the EC2 service name across partitions. This update does not change the existing permission model or grant additional access.                                                                                                                                                  | February 26, 2026 |
| Update permissions to AmazonECSInfrastructureRolePolicyForManagedInstances .  | The AmazonECSInfrastructureRolePolicyForManagedInstances policy has been updated to support Capacity Reservations on Amazon ECS Managed Instances by adding the following permissions: <ul style="list-style-type: none"> <li><code>resource-groups:ListGroupResources</code> permission has been added to allow Amazon ECS</li> </ul> | February 24, 2026 |

| Change                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Date             |
|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
|                                                                               | <p>to fetch a grouping of capacity reservations. To run this command, the following permissions are also required: <code>cloudformation:DescribeStacks</code> , <code>cloudformation:ListStackResources</code> , <code>tag:GetResources</code></p> <ul style="list-style-type: none"> <li>• <code>ec2:DescribeCapacityReservations</code> permission has been added to allow Amazon ECS to gather details about capacity reservations necessary to integrate with Amazon ECS Managed Instances.</li> <li>• <code>ec2:RunInstances</code> permission has been modified to include Amazon ResourceGroups group resources for Amazon ECS to provision targeted Amazon EC2 capacity reservations.</li> </ul> |                  |
| Add permissions to <a href="#">AmazonECSServiceRolePolicy</a> managed policy. | The <code>AmazonECSServiceRolePolicy</code> managed IAM policy was updated to include the <code>ssmmessages:OpenDataChannel</code> permission. This permission allows Amazon ECS to open data channels for ECS Exec sessions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | January 20, 2026 |

| Change                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Date              |
|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Update permissions to AmazonECSInfrastructureRolePolicyForManagedInstances .  | <p>The AmazonECSInfrastructureRolePolicyForManagedInstances policy has been updated to modify the CreateFleet permissions. The resource-based conditions for subnets, security groups and EC2 images have been removed because:</p> <ul style="list-style-type: none"> <li>Subnets and security groups are not created or managed by Amazon ECS, so they do not contain the required AmazonECSManaged tags.</li> <li>While Amazon ECS owns and manages EC2 images, the tags are not visible to customers, preventing the application of resource-based policies.</li> </ul> <p>This change ensures that the policy functions correctly with resources that lack the expected ECS management tags.</p> | December 15, 2025 |
| Correct <a href="#">managed instances</a> lifetime policy                     | Updated managed instances documentation to clarify instance lifetime terminology and extend maximum instance lifetime from 14 days to 21 days.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | December 11, 2025 |
| Add permissions to <a href="#">AmazonECSServiceRolePolicy</a> managed policy. | The AmazonECSServiceRolePolicy managed IAM policy was updated to include the ec2:DescribeInstanceEventWindows permission. This permission allows Amazon ECS to fetch Amazon EC2 Event Windows for services and clusters associated with Event Windows.                                                                                                                                                                                                                                                                                                                                                                                                                                                | November 20, 2025 |
| Add permissions to AmazonECSServiceRolePolicy .                               | The AmazonECSServiceRolePolicy was updated to include the ec2:AssociateTrunkInterface and ec2:DisassociateTrunkInterface permissions to enable Amazon ECSto provision and de-provision the Task ENI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | November 14, 2025 |

| Change                                                                                                                      | Description                                                                                                                                                                                                                                                                                     | Date              |
|-----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Update <a href="#">the section called “AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity”</a> policy | Updated <a href="#">the section called “AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity”</a> policy to allow Amazon ECS to monitor lifecycle of Amazon ECS created secrets.                                                                                            | November 13, 2025 |
| Amazon ECS canary deployments                                                                                               | Amazon ECS canary deployments enable you to test new application versions by routing a small percentage of traffic to the new version while maintaining the majority on the stable version. For more information, see <a href="#">Amazon ECS canary deployments</a> .                           | October 28, 2025  |
| Amazon ECS linear deployments                                                                                               | Amazon ECS linear deployments enable you to gradually shift traffic from the current service revision to a new revision in equal percentage increments, providing controlled deployment with monitoring at each step. For more information, see <a href="#">Amazon ECS linear deployments</a> . | October 28, 2025  |
| Amazon ECS Managed Instances Regions                                                                                        | Amazon ECS Managed Instances is now available in additional Regions. For more information, see <a href="#">Architect for Amazon ECS Managed Instances</a> .                                                                                                                                     | October 27, 2025  |
| AWS for Fluent Bit version 3.0.0                                                                                            | AWS for Fluent Bit version 3.0.0 is now available , based on Fluent Bit version 4.1.1 and AL2023. For more information, see <a href="#">AWS for Fluent Bit image repositories for Amazon ECS</a> .                                                                                              | October 14, 2025  |
| FireLens container non-root user support                                                                                    | Amazon ECS supports running the FireLens container as a non-root user. For more information, see <a href="#">Send Amazon ECS logs to an AWS service or AWS Partner</a> .                                                                                                                        | October 13, 2025  |

| Change                                                                                            | Description                                                                                                                                                                                                                                                                                                         | Date               |
|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| Amazon ECS event capture in the console                                                           | The Amazon ECS console provides event capture functionality that stores Amazon ECS-generated events, such as service actions and task state changes, to CloudWatch Logs through EventBridge. For more information, see <a href="#">Task lifecycle events</a> .                                                      | October 2, 2025    |
| Amazon ECS supports Amazon ECS Managed Instances for running containerized workloads              | Amazon ECS supports Amazon ECS Managed Instances for running containerized workloads. For more information, see <a href="#">Amazon ECS Amazon ECS Managed Instances</a> .                                                                                                                                           | September 30, 2025 |
| Add new <a href="#">the section called "AmazonECSInstanceRolePolicyForManagedInstances"</a>       | Added new AmazonECSInstanceRolePolicyForManagedInstances policy that provides permissions for Amazon ECS managed instances to register with Amazon ECS clusters.                                                                                                                                                    | September 30, 2025 |
| Add new <a href="#">the section called "AmazonECSInfrastructureRolePolicyForManagedInstances"</a> | Added new AmazonECSInfrastructureRolePolicyForManagedInstances policy that provides Amazon ECS access to create and manage Amazon EC2 managed resources.                                                                                                                                                            | September 30, 2025 |
| Support for running Amazon ECS workloads in an IPv6-only configuration                            | Amazon ECS workloads can now be run in an IPv6-only configuration that allows tasks to communicate exclusively over IPv6. For more information, see <a href="#">Amazon ECS task networking options for the EC2 launch type</a> and <a href="#">Amazon ECS task networking options for the Fargate launch type</a> . | September 29, 2025 |

| Change                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                         | Date               |
|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| Support for Amazon ECS Service Connect using shared AWS Cloud Map namespaces                      | Amazon ECS Service Connect now supports the use of shared AWS Cloud Map namespaces for cross-account service-to-service communication. For more information, see <a href="#">Amazon ECS Service Connect with shared AWS Cloud Map namespaces</a> .                                                                                                                                                                  | September 12, 2025 |
| Amazon ECS enhances task definition editing in the AWS console with Amazon Q                      | For more information, see <a href="#">Using Amazon Q to provide task definition recommendations in the Amazon ECS console</a>                                                                                                                                                                                                                                                                                       | September 10, 2025 |
| Support for running ECS Exec commands from the console                                            | You can now run ECS Exec commands directly from the Amazon ECS console. For more information, see <a href="#">Running ECS Exec commands from the console</a> .                                                                                                                                                                                                                                                      | September 4, 2025  |
| Add new <a href="#">the section called "AmazonECSInfrastructureRolePolicyForManagedInstances"</a> | Added new AmazonECSInfrastructureRolePolicyForManagedInstances policy that provides Amazon ECS access to create and manage Amazon EC2 managed resources.                                                                                                                                                                                                                                                            | August 31, 2025    |
| Add permissions to <a href="#">AmazonEC2ContainerServiceforEC2Role</a> managed policy.            | The AmazonEC2ContainerServiceforEC2Role managed IAM policy was updated to include the <code>ecs:ListTagsForResource</code> permission. This permission allows the Amazon ECS agent to retrieve task and container instance tags through the task metadata endpoint ( <code>\${ECS_CONTAINER_METADATA_URI_V4}/taskWithTags</code> ). For more information, see <a href="#">AmazonEC2ContainerServiceforEC2Role</a> . | August 4, 2025     |

| Change                                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                               | Date          |
|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Add permissions to <a href="#">AmazonECSInfrastructureRolePolicyForLoadBalancers</a> .    | The AmazonECSInfrastructureRolePolicyForLoadBalancers managed IAM policy was updated with new permissions for describing, deregistering and registering target groups.                                                                                                                                                                                                                    | July 25, 2025 |
| Support for updating a service deployment controller                                      | Amazon ECS supports updating a service deployment controller, allowing you to change between different deployment types for an existing service. For more information, see <a href="#">Update Amazon ECS service parameters</a> .                                                                                                                                                         | July 15, 2025 |
| Amazon ECS native blue/green deployments                                                  | Amazon ECS supports native blue/green deployments, allowing you to validate new service revisions before directing production traffic to them. For more information, see <a href="#">Amazon ECS blue/green deployments</a> .                                                                                                                                                              | July 15, 2025 |
| Add new <a href="#">AmazonECSInfrastructureRolePolicyForLoadBalancers</a> managed policy. | This policy provides access to other AWS service resources required to manage load balancers associated with Amazon ECS workloads on your behalf. For more information, see <a href="#">AmazonECSInfrastructureRolePolicyForLoadBalancers</a> .                                                                                                                                           | July 15, 2025 |
| SOCI index manifest v2 support                                                            | Fargate customers looking to use SOCI will only be able to use the SOCI index manifest v2. Existing customers that have previously used SOCI on Fargate can continue to use the SOCI index manifest v1, however we strongly advise those customers migrate to SOCI index manifest v2. For more information, see <a href="#">Lazy loading container images using Seekable OCI (SOCI)</a> . | July 2, 2025  |

| Change                                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                         | Date          |
|--------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Added the task ID in service action events generated due to health failures.                                             | For more information, see <a href="#">Amazon ECS service unhealthy event messages</a> .                                                                                                                                                                                                                                                                                                             | June 30, 2025 |
| Update to default log driver mode.                                                                                       | The default logging mode for Amazon ECS has been updated from blocking to non-blocking . You can override this default mode by specifying a mode in your container definition's logConfiguration or configure your own default by setting the defaultLogDriverMode account setting using the Amazon ECS console or the AWS CLI. For more information, see <a href="#">Default log driver mode</a> . | June 25, 2025 |
| Add permissions to <a href="#">AmazonECSServiceRolePolicy</a> .                                                          | The AmazonECSServiceRolePolicy managed IAM policy was updated with new AWS Cloud Map permissions which Amazon ECS can update AWS Cloud Map service attributes for services that Amazon ECS manages.                                                                                                                                                                                                 | June 24, 2025 |
| Support for the Amazon ECS-optimized Windows Server 2025 Full AMI and Amazon ECS-optimized Windows Server 2025 Core AMI. | For more information, see <a href="#">Amazon ECS-optimized Windows AMIs</a> .                                                                                                                                                                                                                                                                                                                       | June 20, 2025 |
| Support for updating a service capacity provider strategy.                                                               | You can now update a service capacity provider strategy. For more information, see <a href="#">Update service parameters</a> .                                                                                                                                                                                                                                                                      | June 12, 2025 |

| Change                                                                                      | Description                                                                                                                                                                                                                                                                                       | Date              |
|---------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Add permissions to <a href="#">AmazonECSInfrastructureRolePolicyForVolumes</a>              | The AmazonECSInfrastructureRolePolicyForVolumes policy has been updated to add the <code>ec2:DescribeInstances</code> permission. The permission helps prevent device name collision for Amazon EBS volumes that are attached to Amazon ECS tasks that run on the same container instance.        | June 2, 2025      |
| Support for volume initialization rate for Amazon EBS volumes attached to Amazon ECS tasks. | You can now set a <code>volumeIntiializationRate</code> to determine the rate, in MiB/s, at which data is fetched from a snapshot of an existing Amazon EBS volume to create new volumes for attachment to Amazon ECS tasks. For more information, see <a href="#">volumeInitializationRate</a> . | May 13, 2025      |
| Support for stopping a service deployment.                                                  | You can now stop a service deployment. For more information, see <a href="#">Stopping Amazon ECS service deployments</a> .                                                                                                                                                                        | May 2, 2025       |
| Support for Amazon ECS dual-stack endpoints.                                                | You can now use dual-stack endpoints to interact with Amazon ECS. Dual-stack endpoints support requests to Amazon ECS over both Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6). For more information, see <a href="#">Using Amazon ECS dual-stack endpoints</a> .      | April 30, 2025    |
| Support for configuring a default log driver mode at the account level in an AWS Region.    | You can now configure a default delivery mode of log messages from a container to the log driver that you specify in your <code>logConfiguration</code> using the <code>defaultLogDriverMode</code> account setting. For more information, see <a href="#">Default log driver mode</a> .          | April 17, 2025    |
| Support for migrating a service with a short ARN format to the long ARN format.             | You can now migrate a service with a short ARN format to the long ARN format packet. For more information, see <a href="#">Migrate an Amazon ECS short service ARN to a long ARN</a> .                                                                                                            | February 13, 2025 |

| Change                                                                       | Description                                                                                                                                                                                                                                   | Date              |
|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Support for three types of fault injection on Amazon ECS and Fargate.        | You can now use network blackhole port, network latency, and network packet loss fault injection with Amazon ECS and Fargate. For more information, see <a href="#">Use AWS Fault Injection Service to test your Amazon ECS workloads</a> .   | December 19, 2024 |
| Support for CloudWatch Container Insights with enhanced observability.       | You can use CloudWatch Container Insights with enhanced observability. For more information, see <a href="#">Monitor Amazon ECS containers using Container Insights with enhanced observability</a> .                                         | December 2, 2024  |
| Support for predictive scaling.                                              | You can use predictive scaling to anticipate future needs and proactively increase tasks in your service as needed. For more information, see <a href="#">Use historical patterns to scale CloudWatch services with predictive scaling</a> .  | November 21, 2024 |
| Support for service-<br>r<br>ebalancing.                                     | You can now have Amazon ECS automatically balance your service tasks across Availability Zones. For more information, see <a href="#">Balancing an Amazon ECS service across Availability Zones</a> .                                         | November 19, 2024 |
| Support for configuring resolution of container image tags to image digests. | You can now configure the resolution of container image tags to digests for each container in tasks that are part of a service. For more information, see <a href="#">Container image resolution</a> and <a href="#">versionConsistency</a> . | November 19, 2024 |
| Add new AmazonECS InfrastructureRole PolicyFor VpcLattice IAM policy         | The <a href="#">AmazonECSInfrastructureRolePolicyForVpcLattice</a> policy provides access to other AWS service resources required to manage VPC Lattice feature in Amazon ECS workloads on your behalf.                                       | November 18, 2024 |

| Change                                                                                     | Description                                                                                                                                                                                                                                                                                                    | Date              |
|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| VPC Lattice is now available for Amazon ECS services.                                      | You can now use VPC Lattice to standardize your service-to-service connectivity, security, and observability. For more information, see <a href="#">Use Amazon VPC Lattice to connect, observe, and secure your Amazon ECS services</a> .                                                                      | November 18, 2024 |
| Support for service history using service deployments and service revisions.               | You can use service deployments and service revisions to view deployment history. For more information, see <a href="#">View service history using Amazon ECS service deployments</a> and <a href="#">Amazon ECS service revisions</a> .                                                                       | October 30, 2024  |
| Support for Amazon EBS volumes for the EC2 launch type using the Windows operating system. | Amazon ECS support Amazon EBS volumes attached to tasks running on EC2 instances with the Windows operating system. For more information, see <a href="#">Use Amazon EBS volumes with Amazon ECS</a> .                                                                                                         | October 24, 2024  |
| Add permissions to AmazonECSInfrastructureRolePolicyForVolumes.                            | The AmazonECSInfrastructureRolePolicyForVolumes policy has been updated to allow customers to create an Amazon EBS volume from a snapshot. For more information, see <a href="#">AmazonECSInfrastructureRolePolicyForVolumes</a> .                                                                             | October 10, 2024  |
| Fargate Spot is available for Linux ARM.                                                   | Support for Fargate Spot on Linux ARM was added to Amazon ECS.                                                                                                                                                                                                                                                 | September 6, 2024 |
| Container restart policy for individual containers in Amazon ECS tasks.                    | You can enable restart policies for essential and non-essential containers defined in your task definition to overcome transient failures faster and maintain task availability. For more information, see <a href="#">Restart individual containers in Amazon ECS tasks with container restart policies</a> . | August 15, 2024   |

| Change                                                                                            | Description                                                                                                                                                                                                                                                                                                                                | Date             |
|---------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Added permissions to <a href="#">the section called "AmazonECS_FullAccess"</a>                    | The AmazonECS_FullAccess policy was updated to add iam:PassRole permissions for IAM roles for a role named ecsInfrastructureRole . This is the default IAM role created by the AWS Management Console that is intended to be used as an ECS infrastructure role that allows Amazon ECS to manage Amazon EBS volumes attached to ECS tasks. | August 13, 2024  |
| Amazon Linux 2023, CentOS Stream 9, Fedora 40, and Ubuntu 24 support added for ECS Anywhere       | Support for the Amazon Linux 2023, CentOS Stream 9, Fedora 40, and Ubuntu 24 operating systems was added to ECS Anywhere. For more information, see <a href="#">Supported operating systems and system architectures</a> .                                                                                                                 | July 23, 2024    |
| Container image resolution for services that use the <i>rolling update</i> (ECS) deployment type. | To ensure that all tasks in a service that uses the rolling update deployment controller use the same container image, Amazon ECS resolves container image names and any image tags specified in the task definition to container image digests. For more information, see <a href="#">Container image resolution</a> .                    | July 10, 2024    |
| Debian 11 and Debian 12 support added for ECS Anywhere                                            | Support for the Debian 11 and Debian 12 operating systems was added to ECS Anywhere. For more information, see <a href="#">Supported operating systems and system architectures</a> .                                                                                                                                                      | March 28, 2024   |
| gMSA for Linux Containers on Fargate support                                                      | Amazon ECS supports Active Directory authentication for Linux containers on Fargate through a special kind of service account called a group Managed Service Account (gMSA). For more information, see <a href="#">Using gMSA for Linux containers on Fargate</a> .                                                                        | March 5, 2024    |
| CloudWatch metrics added for Amazon EBS volumes attached to tasks                                 | Amazon ECS now publishes CloudWatch metrics for the Amazon EBS storage utilization for tasks that have an Amazon EBS volume attached. For more information, see <a href="#">Amazon ECS CloudWatch metrics</a> .                                                                                                                            | February 8, 2024 |

| Change                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Date             |
|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Service Connect TLS                                        | You can now use <a href="#">TLS with Service Connect</a> .                                                                                                                                                                                                                                                                                                                                                                                                         | January 22, 2024 |
| Service Connect TLS managed policy                         | Added new <a href="#">AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity</a> policy.                                                                                                                                                                                                                                                                                                                                                         | January 22, 2024 |
| Service Connect timeout configuration update               | Service Connect <a href="#">timeout configuration</a> can now be updated and includes two optional parameters - <code>idleTimeout</code> and <code>perRequestTimeout</code> .                                                                                                                                                                                                                                                                                      | January 22, 2024 |
| Amazon ECS managed instance draining                       | You can use Amazon ECS <a href="#">managed instance draining</a> to facilitate graceful termination of Amazon ECS instances.                                                                                                                                                                                                                                                                                                                                       | January 19, 2024 |
| Ubuntu 22 support added for ECS Anywhere                   | Support for the Ubuntu 22 operating system was added to ECS Anywhere. For more information, see <a href="#">Supported operating systems and system architectures</a> .                                                                                                                                                                                                                                                                                             | January 16, 2024 |
| Add AmazonECSInfrastructureRolePolicyForVolumes IAM policy | The <a href="#">AmazonECSInfrastructureRolePolicyForVolumes</a> was added. The policy grants the permissions that are needed by Amazon ECS to make AWS API calls to manage Amazon EBS volumes associated with Amazon ECS workloads.                                                                                                                                                                                                                                | January 11, 2024 |
| Amazon EBS data volume for Amazon ECS task                 | You can configure 1 <a href="#">Amazon EBS data volume</a> per task during deployment for attachment to standalone Amazon ECS tasks or tasks managed by an ECS service. Configuring a volume at deployment allows you to create reusable task definitions not constrained to specific volume types or settings. Amazon EBS volumes provide a highly available, cost-effective, durable, high-performance block storage for data intensive containerized workloads. | January 11, 2024 |

| Change                                               | Description                                                                                                                                                                                      | Date              |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Amazon ECS classic console reached end of life       | The Amazon ECS console has reached the end of life.                                                                                                                                              | December 4, 2023  |
| Updated policy                                       | The <a href="#">AmazonECSServiceRolePolicy</a> managed IAM policy was updated with new events permissions and additional autoscaling and autoscaling-plans permissions.                          | December 4, 2023  |
| Runtime Monitoring support                           | You can use Runtime Monitoring to monitor your Amazon ECS workloads to identify malicious or unauthorized behavior. For more information, see <a href="#">Runtime Monitoring</a> .               | November 26, 2023 |
| Updated policy                                       | The <a href="#">AmazonECSServiceRolePolicy</a> managed IAM policy was updated to allow access to the AWS Cloud Map DiscoverInstancesRevision API.                                                | October 4, 2023   |
| AWS Fargate task retirement configuration            | You can configure the wait period before Fargate tasks are retired. For more information, see <a href="#">AWS Fargate task maintenance</a> .                                                     | September 5, 2023 |
| Additional task definition parameters in AWS Fargate | AWS Fargate adds support for <code>pidMode</code> and <code>systemControls</code> in Linux platform version 1.4.0. For more information, see <a href="#">Task definitions</a> .                  | August 9, 2023    |
| Amazon ECS console task definition page redesign     | The task definition page in the Amazon ECS console has been redesigned and contains additional options. For more information, see <a href="#">Creating a task definition using the console</a> . | July 26, 2023     |

| Change                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                 | Date          |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Fargate supports lazy loading with Seekable OCI indexes | AWS Fargate is introducing Seekable OCI (SOCI) indexes. With SOCI, containers only spend a few seconds on the image pull before they can start, providing time for environment setup and application instantiation while the image is downloaded in the background. For more information, see <a href="#">Lazy loading container images using Seekable OCI (SOCI)</a> .                                     | July 17, 2023 |
| Improved support for gMSA on Linux and Windows          | The task definition has a new <code>credentialSpecs</code> field for gMSA for Linux and Windows. A new complete tutorial for domainless gMSA on Windows has been added, see <a href="#">Tutorial: Using Windows Containers with Domainless gMSA using the AWS CLI</a> . For more information, see <a href="#">Using gMSAs for Linux Containers</a> and <a href="#">Using gMSAs for Windows Containers</a> . | July 14, 2023 |
| Improved ECS Agent versions documentation               | The documentation for the Amazon ECS Agent versions has been updated. We recommend that you use the v20.10.13 version or newer of Docker with the latest version of the Amazon ECS container agent. The released versions and changes to the agent are available on GitHub. For more information, see <a href="#">Amazon ECS Linux container agent versions</a> .                                           | June 20, 2023 |
| Updated Region availability for Fargate ARM64 support   | The Region availability for Fargate ARM64 support has been updated. For more information, see <a href="#">Considerations</a> .                                                                                                                                                                                                                                                                              | June 19, 2023 |
| Improve cluster auto scaling documentation              | The documentation for Amazon ECS scaling of Amazon EC2 Auto Scaling has significant improvements in accuracy and readability. For more information, see <a href="#">Amazon ECS cluster auto scaling</a> .                                                                                                                                                                                                   | May 4, 2023   |

| Change                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                             | Date           |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Tagging authorization for resource creation.                        | Users must have permissions for actions that create the resource, such as <code>ecsCreateCluster</code> . When you create a resource and specify tags for that resource, AWS performs additional authorization to verify that there are permissions to create tags. For more information, see <a href="#">Tagging authorization</a> and <a href="#">Grant permission to tag resources on creation</a> . | April 18, 2023 |
| Support for gMSA for Linux containers on EC2                        | You can use gMSA to authenticate to Active Directory for Linux containers on EC2. For more information, see <a href="#">Using gMSAs for Linux Containers</a> .                                                                                                                                                                                                                                          | April 14, 2023 |
| Support for ephemeral storage for Windows containers on AWS Fargate | You can use ephemeral storage for Windows containers on AWS Fargate. For more information, see <a href="#">Fargate task storage</a> .                                                                                                                                                                                                                                                                   | April 14, 2023 |
| AWS Cost Management support for task-level CUR data                 | You can turn on task-level cost and resource usage in the Cost and Usage Reports. This adds Split Cost Allocation Data for tasks that run on AWS Fargate and EC2. For more information, see <a href="#">Task-level Cost and Usage Reports</a> .                                                                                                                                                         | April 12, 2023 |
| Amazon Linux 2023 Amazon ECS-optimized AMI                          | You can deploy workloads on the Amazon Linux 2023 Amazon ECS-optimized AMI. For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a> .                                                                                                                                                                                                                                                 | April 10, 2023 |
| AWS Fargate Federal Information Processing Standard (FIPS) 140      | You can deploy workloads on Amazon ECS on AWS Fargate in a manner compliant with Federal Information Processing Standard (FIPS) 140. For more information, see <a href="#">AWS Fargate Federal Information Processing Standard (FIPS-140)</a> .                                                                                                                                                         | April 10, 2023 |

| Change                                                                 | Description                                                                                                                                                                                                                                                     | Date              |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Task definition deletion                                               | You can delete a task definition using the Amazon ECS console, SDK, and AWS CLI. For more information, see <a href="#">Deleting a task definition revision using the console</a> and <a href="#">Task definitions</a> .                                         | February 24, 2023 |
| AWS Fargate service recommendations in Compute Optimizer               | AWS Compute Optimizer generates task and container size recommendations based on the utilization of running tasks in Amazon ECS services on AWS Fargate. For more information, see <a href="#">Viewing recommendations for Amazon ECS services on Fargate</a> . | January 27, 2023  |
| Amazon ECS console                                                     | The new Amazon ECS console is now the default console. For more information, see <a href="#">New Amazon ECS console</a> .                                                                                                                                       | January 19, 2023  |
| Updated AmazonECS_FullAccess IAM policy                                | The AmazonECS_FullAccess IAM policy is updated to include permissions to add tags to load balancers during creation. For more information, see <a href="#">AmazonECS_FullAccess</a> .                                                                           | January 4, 2023   |
| Use CloudWatch alarms to detect Amazon ECS service deployment failures | You can configure Amazon ECS to set the deployment to failed when it detects that a specified CloudWatch alarm has gone into the ALARM state. For more information, see <a href="#">the section called "Rolling update deployments"</a> .                       | December 19, 2022 |
| Support for container port mapping                                     | You can set a port number range on the container that's bound to the dynamically mapped host port range. For more information, see <a href="#">the section called "Port mappings"</a> .                                                                         | December 15, 2022 |
| General availability of Amazon ECS Service Connect                     | This feature adds service discovery and service mesh that is controlled by Amazon ECS service deployments. For more information, see <a href="#">the section called "Service Connect"</a> .                                                                     | November 27, 2022 |

| Change                                                                | Description                                                                                                                                                                                                                                                                         | Date               |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| The new Amazon ECS console experience for task definitions is updated | The new Amazon ECS console experience now contains a JSON editor for task definitions. For more information, see <a href="#">the section called “Creating a task definition using the console”</a> .                                                                                | October 27, 2022   |
| The new Amazon ECS console experience for task definitions is updated | The new Amazon ECS console experience now contains a JSON editor for task definitions. For more information, see <a href="#">the section called “Creating a task definition using the console”</a> .                                                                                | October 27, 2022   |
| The new Amazon ECS console experience is updated                      | The new Amazon ECS console experience has been updated with additional service and task parameters. For more information, see <a href="#">the section called “Creating a rolling update deployment”</a> and <a href="#">the section called “Running an application as a task”</a> . | October 7, 2022    |
| New information in task metadata endpoint version 4                   | The task metadata endpoint version 4 now includes the VPC ID and the service name. For more information, see <a href="#">the section called “Task metadata endpoint version 4”</a> .                                                                                                | October 7, 2022    |
| New task definition sizes                                             | Amazon ECS on Fargate now supports the 8 vCPU and 16 vCPU task sizes. For more information, see <a href="#">the section called “Task size”</a> .                                                                                                                                    | September 16, 2022 |
| ECS CLI pages archived                                                | The ECS CLI documentation has been archived. We recommend using AWS Copilot for your command line tool needs. For more information, see <a href="#">Creating Amazon ECS resources using the AWS Copilot command line interface</a> .                                                | September 15, 2022 |
| New Fargate quotas                                                    | Fargate is transitioning from task count-based quotas to vCPU-based quotas. For more information, see <a href="#">Amazon ECS endpoints and quotas</a> .                                                                                                                             | September 8, 2022  |

| Change                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Date              |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Support for Amazon EC2 Auto Scaling warm pools.            | You can now use Amazon EC2 Auto Scaling warm pools to scale out your applications faster and save costs. For more information, see <a href="#">Configuring pre-initialized instances for your Amazon ECS Auto Scaling group</a> .                                                                                                                                                                                                                                          | March 23, 2022    |
| Support for Windows instances in ECS Anywhere.             | ECS Anywhere now supports Windows instances. For more information, see <a href="#">Amazon ECS clusters for external instances</a> .                                                                                                                                                                                                                                                                                                                                        | March 3, 2022     |
| Added ECS Exec support for external instances              | ECS Exec is now supported for external instances . For more information, see <a href="#">Monitor Amazon ECS containers with ECS Exec</a> .                                                                                                                                                                                                                                                                                                                                 | January 24, 2022  |
| The new Amazon ECS console experience updated              | The new Amazon ECS console experience supports creating and deleting a cluster, updating a task definition, and deregistering a task definition. For more information, see <a href="#">Creating an Amazon ECS cluster for Fargate workloads</a> , <a href="#">Deleting an Amazon ECS cluster</a> , <a href="#">Updating an Amazon ECS task definition using the console</a> , and <a href="#">Deregistering an Amazon ECS task definition revision using the console</a> . | December 8, 2021  |
| The new Amazon ECS console experience updated              | The new Amazon ECS console experience supports creating a task definition. For more information, see <a href="#">Creating an Amazon ECS task definition using the console</a> .                                                                                                                                                                                                                                                                                            | November 23, 2021 |
| Amazon ECS supports the 64-bit ARM architecture for Linux. | Amazon ECS supports the 64-bit ARM CPU architecture for the Linux operating system. For more information, see <a href="#">the section called "Task definitions for 64-bit ARM workloads"</a> .                                                                                                                                                                                                                                                                             | November 23, 2021 |

| Change                                                            | Description                                                                                                                                                                                                                                                                         | Date              |
|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Amazon ECS support for the fluentd log-driver-buffer-limit option | Amazon ECS supports the <code>fluentd log-driver-buffer-limit</code> option. For more information, see <a href="#">Send Amazon ECS logs to an AWS service or AWS Partner</a> .                                                                                                      | November 22, 2021 |
| Amazon ECS-optimized Linux AMI build script                       | Amazon ECS has open-sourced the build scripts that are used to build the Linux variants of the Amazon ECS-optimized AMI. For more information, see <a href="#">Amazon ECS-optimized Linux AMI build script</a> .                                                                    | November 19, 2021 |
| Container instance health                                         | Amazon ECS adds support for container instance health monitoring. For more information, see <a href="#">Monitor Amazon ECS container instance health</a> .                                                                                                                          | November 10, 2021 |
| Support for Windows Amazon ECS Exec                               | Amazon ECS Exec supports Windows. For more information, see <a href="#">Monitor Amazon ECS containers with ECS Exec</a> .                                                                                                                                                           | November 1, 2021  |
| Support for Windows containers on Fargate.                        | Amazon ECS supports Windows containers on Fargate. For more information, see <a href="#">Fargate Windows platform version change log</a> .                                                                                                                                          | October 28, 2021  |
| GPU support for external instances on Amazon ECS Anywhere         | Amazon ECS supports specifying GPU requirements in the task definition for tasks run on external instances. For more information, see <a href="#">Amazon ECS task definitions for GPU workloads</a> and <a href="#">Registering an external instance to an Amazon ECS cluster</a> . | October 8, 2021   |
| Support of awsipc network mode on Windows                         | Amazon ECS supports awsipc network mode on Windows. For more information, see <a href="#">Allocate a network interface for an Amazon ECS task</a> .                                                                                                                                 | July 15, 2021     |
| General availability of Bottlerocket                              | Amazon ECS supports an Amazon ECS-optimized AMI variant of the Bottlerocket operating system is available as an AMI. For more information, see <a href="#">Amazon ECS-optimized Bottlerocket AMIs</a> .                                                                             | June 30, 2021     |

| Change                                            | Description                                                                                                                                                                                                                                                                                | Date              |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Amazon ECS scheduled tasks update                 | Amazon EventBridge added support for additional parameters when creating rules that trigger Amazon ECS scheduled tasks.                                                                                                                                                                    | June 25, 2021     |
| AWS managed policies for Amazon ECS               | Amazon ECS added documentation of AWS managed policies for service-linked roles. For more information, see <a href="#">AWS managed policies for Amazon Elastic Container Service</a> .                                                                                                     | June 8, 2021      |
| Getting started with the AWS CDK                  | Added a getting started guide for using the AWS CDK with Amazon ECS. For more information, see <a href="#">Creating Amazon ECS resources using the AWS CDK</a> .                                                                                                                           | May 27, 2021      |
| Amazon ECS Anywhere                               | Amazon ECS has added support for registering an on-premise server or virtual machine (VM) with your cluster. For more information, see <a href="#">Amazon ECS clusters for external instances</a> .                                                                                        | May 25, 2021      |
| Amazon ECS-optimized Windows Server 20H2 Core AMI | Amazon ECS has added support for a new Windows Amazon ECS-optimized AMI variant for Windows Server 20H2 Core. For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a> .                                                                                                  | April 19, 2021    |
| Amazon ECS Exec                                   | Amazon ECS has released a new debugging tool called ECS Exec. For more information, see <a href="#">Monitor Amazon ECS containers with ECS Exec</a> .                                                                                                                                      | March 15, 2021    |
| VPC endpoint policy support                       | Amazon ECS now supports VPC endpoint policies. For more information, see <a href="#">Creating a VPC endpoint policy for Amazon ECS</a> .                                                                                                                                                   | January 11, 2021  |
| New console experience                            | Amazon ECS has released a new console experience which supports creating or updating a service or running a standalone task. For more information, see <a href="#">Creating an Amazon ECS rolling update deployment</a> and <a href="#">Running an application as an Amazon ECS task</a> . | December 28, 2020 |

| Change                                                                  | Description                                                                                                                                                                                                                                                                                                                                                   | Date              |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Capacity provider update                                                | Amazon ECS added support for updating an existing Auto Scaling group capacity provider.                                                                                                                                                                                                                                                                       | November 23, 2020 |
| ECS now supporting Amazon FSx for Windows File Server for Windows tasks | Amazon ECS added support for specifying Amazon FSx for Windows File Server volumes in Windows task definitions. For more information, see <a href="#">Use FSx for Windows File Server volumes with Amazon ECS</a> .                                                                                                                                           | November 11, 2020 |
| VPC dual-stack mode support added                                       | Amazon ECS added support for using a VPC in dual-stack mode with tasks using the awsvpc network mode, which provides support for IPv6 addresses. For more information, see <a href="#">Using a VPC in dual-stack mode</a> .                                                                                                                                   | November 5, 2020  |
| Task metadata endpoint v4 update                                        | Amazon ECS added additional metadata to the task metadata endpoint v4 output. For more information, see <a href="#">Amazon ECS task metadata endpoint version 4</a> .                                                                                                                                                                                         | November 5, 2020  |
| Support for Local Zones and Wavelength Zones                            | Amazon ECS added support for workloads in Local Zones and Wavelength Zones. For more information, see <a href="#">Amazon ECS applications in shared subnets, Local Zones, and Wavelength Zones</a> .                                                                                                                                                          | September 4, 2020 |
| Amazon ECS variant of Bottlerocket AMI                                  | Bottlerocket is a Linux-based open source operating system that is purpose-built by AWS for running containers. An Amazon ECS-optimized AMI variant of the Bottlerocket operating system is available as an AMI you can use when launching Amazon ECS container instances. For more information, see <a href="#">Amazon ECS-optimized Bottlerocket AMIs</a> . | August 31, 2020   |

| Change                                                          | Description                                                                                                                                                                                                                                                                                                                                                                | Date            |
|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Task metadata endpoint version 4 updated for network rate stats | The task metadata endpoint version 4 has been updated to provide network rate stats for Amazon ECS tasks that use the <code>awsvpc</code> or <code>bridge</code> network modes hosted on Amazon EC2 instances running at least version <code>1.43.0</code> of the container agent. For more information, see <a href="#">Amazon ECS task metadata endpoint version 4</a> . | August 10, 2020 |
| Fargate usage metrics                                           | AWS Fargate provides CloudWatch usage metrics which provide visibility into your accounts usage of Fargate On-Demand and Fargate Spot resources. For more information, see <a href="#">Usage metrics</a> .                                                                                                                                                                 | August 3, 2020  |
| AWS Copilot version 0.1.0                                       | The new AWS Copilot CLI launched, providing high-level commands to simplify modeling, creating, releasing, and managing containerized applications on Amazon ECS from a local development environment. For more information, see <a href="#">Creating Amazon ECS resources using the AWS Copilot command line interface</a> .                                              | July 9, 2020    |
| AWS Fargate platform versions deprecation schedule              | The Fargate platform version deprecation schedule has been added. For more information, see <a href="#">AWS Fargate Linux platform version deprecation</a> .                                                                                                                                                                                                               | July 8, 2020    |
| AWS Fargate Region expansion                                    | Amazon ECS on AWS Fargate has expanded to the Europe (Milan) Region.                                                                                                                                                                                                                                                                                                       | June 25, 2020   |
| Amazon ECS optimized Amazon Linux 2 (Neuron) AMI released       | Amazon ECS released an Amazon ECS optimized Amazon Linux 2 (Neuron) AMI for inferential workloads.<br><br>For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a> .                                                                                                                                                                                      | June 24, 2020   |

| Change                                        | Description                                                                                                                                                                                                                                                                                                               | Date           |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Added support for deleting capacity providers | Amazon ECS added support for deleting Auto Scaling group capacity providers.                                                                                                                                                                                                                                              | June 11, 2020  |
| AWS Fargate platform version 1.4.0 update     | Beginning on May 28, 2020, any new Fargate task that is launched using platform version 1.4.0 will have its 20 GB ephemeral storage encrypted with an AES-256 encryption algorithm using an AWS Fargate-managed encryption key. For more information, see <a href="#">Fargate task ephemeral storage for Amazon ECS</a> . | May 28, 2020   |
| Environment variable file support             | Added support for specifying environment variable files in a task definition, which enables you to bulk add environment variables to your containers. For more information, see <a href="#">Pass an individual environment variable to an Amazon ECS container</a> .                                                      | May 18, 2020   |
| AWS Fargate Region expansion                  | AWS Fargate with Amazon ECS has expanded to the Africa (Cape Town) Region.                                                                                                                                                                                                                                                | May 11, 2020   |
| Service quota updated                         | <p>The following service quota was updated:</p> <ul style="list-style-type: none"><li>Clusters per account was raised from 2,000 to 10,000.</li></ul> <p>For more information, see <a href="#">Amazon ECS endpoints and quotas</a>.</p>                                                                                   | April 17, 2020 |

| Change                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Date          |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| AWS Fargate platform version 1.4.0 | <p>AWS Fargate platform version 1.4.0 is released, which contains the following features:</p> <ul style="list-style-type: none"><li>• Added support for using Amazon EFS file system volumes for persistent task storage. For more information, see <a href="#">Use Amazon EFS volumes with Amazon ECS</a>.</li><li>• The ephemeral task storage has been increased to 20 GB. For more information, see <a href="#">Fargate task ephemeral storage for Amazon ECS</a>.</li><li>• The network traffic behavior to and from tasks has been updated. Starting with platform version 1.4, all Fargate tasks receive a single elastic network interface (referred to as the task ENI) and all network traffic flows through that ENI within your VPC and will be visible to you through your VPC flow logs. For more information, see <a href="#">Amazon ECS task networking options for the Fargate launch type</a>.</li><li>• Task ENIs add support for jumbo frames. Network interfaces are configured with a maximum transmission unit (MTU), which is the size of the largest payload that fits within a single frame. The larger the MTU, the more application payload can fit within a single frame, which reduces per-frame overhead and increases efficiency. Supporting jumbo frames will reduce overhead when the network path between your task and the destination supports jumbo frames, such as all traffic that remains within your VPC.</li><li>•</li></ul> | April 8, 2020 |

| Change | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Date |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
|        | <p>CloudWatch Container Insights will include network performance metrics for Fargate tasks. For more information, see <a href="#">Monitor Amazon ECS containers using Container Insights with enhanced observability</a>.</p> <ul style="list-style-type: none"><li>• Added support for the task metadata endpoint v4 which provides additional information for your Fargate tasks, including network stats for the task and which Availability Zone the task is running in. For more information, see <a href="#">Amazon ECS task metadata endpoint version 4</a>.</li><li>• Added support for the SYS_PTRACE Linux parameter in container definitions. For more information, see <a href="#">Linux parameters</a>.</li><li>• The Fargate container agent replaces the use of the Amazon ECS container agent for all Fargate tasks. This change should not have an effect on how your tasks run.</li><li>• The container runtime is now using Containerd instead of Docker. This change should not have an effect on how your tasks run. You will notice that some error messages that originate with the container runtime will change from mentioning Docker to more general errors.</li></ul> <p>For more information, see <a href="#">Fargate platform versions for Amazon ECS</a>.</p> |      |

| Change                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  | Date              |
|--------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Amazon EFS file system support for task volumes                                                  | Amazon EFS file systems can be used as data volumes for both your Amazon ECS and Fargate tasks. For more information, see <a href="#">Use Amazon EFS volumes with Amazon ECS</a> .                                                                                                                                                                                                                                                           | April 8, 2020     |
| Amazon ECS Task Metadata Endpoint version 4                                                      | Beginning with Amazon ECS container agent version 1.39.0 and Fargate platform version 1.4.0, an environment variable named <code>ECS_CONTAINER_METADATA_URI_V4</code> is injected into each container in a task. When you query the task metadata version 4 endpoint, various task metadata and <a href="#">Docker stats</a> are available to tasks. For more information, see <a href="#">Amazon ECS task metadata endpoint version 4</a> . | April 8, 2020     |
| Support for specific versions of Secrets Manager secrets to be injected as environment variables | Added support for specifying sensitive data using specific versions of Secrets Manager secrets. For more information, see <a href="#">Pass sensitive data to an Amazon ECS container</a> .                                                                                                                                                                                                                                                   | February 24, 2020 |
| Added additional CodeDeploy deployment configuration options for blue/green deployments          | The CodeDeploy service added new canary and linear deployment configurations for the Amazon ECS deployment type. The ability to define custom deployment configurations is also available. For more information, see <a href="#">CodeDeploy blue/green deployments for Amazon ECS</a> .                                                                                                                                                      | February 6, 2020  |
| Added the <code>efsVolumeConfiguration</code> task definition parameter                          | The <code>efsVolumeConfiguration</code> task definition parameter is in public preview, which makes it easier to use Amazon EFS file systems with your Amazon ECS tasks. For more information, see <a href="#">Use Amazon EFS volumes with Amazon ECS</a> .                                                                                                                                                                                  | January 17, 2020  |

| Change                                              | Description                                                                                                                                                                                                                | Date              |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Amazon ECS container agent logging behavior updated | The Amazon ECS container agent logging locations and rotation behavior has been updated. For more information, see <a href="#">Amazon ECS container agent log configuration parameters</a> .                               | January 13, 2020  |
| Fargate Spot                                        | Amazon ECS added support for running tasks using Fargate Spot. For more information, see <a href="#">Amazon ECS clusters for Fargate</a> .                                                                                 | December 3, 2019  |
| Cluster Auto Scaling                                | Amazon ECS cluster auto scaling enables you to have more control over how you scale tasks within a cluster. For more information, see <a href="#">Automatically manage Amazon ECS capacity with cluster auto scaling</a> . | December 3, 2019  |
| Cluster Capacity Providers                          | Amazon ECS cluster capacity providers determine the infrastructure to use for your tasks. For more information, see <a href="#">Amazon ECS clusters</a> .                                                                  | December 3, 2019  |
| Creating a cluster on an AWS Outposts               | Amazon ECS now supports creating clusters on an AWS Outposts. For more information, see <a href="#">the section called "Amazon Elastic Container Service on AWS Outposts"</a> .                                            | December 3, 2019  |
| Service Action Events                               | Amazon ECS now sends events to Amazon EventBridge when certain service actions occur. For more information, see <a href="#">Amazon ECS service action events</a> .                                                         | November 25, 2019 |
| Amazon ECS GPU-optimized AMI Supports G4 Instances  | Amazon ECS added support for the g4 instance type family when using the Amazon ECS GPU-optimized AMI. For more information, see <a href="#">Amazon ECS task definitions for GPU workloads</a> .                            | October 8, 2019   |

| Change                                                        | Description                                                                                                                                                                                                                                                                                                           | Date               |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| FireLens for Amazon ECS                                       | FireLens for Amazon ECS is in general availability. FireLens for Amazon ECS enables you to use task definition parameters to route logs to an AWS service or partner destination for log storage and analytics. For more information, see <a href="#">Send Amazon ECS logs to an AWS service or AWS Partner</a> .     | September 30, 2019 |
| AWS Fargate region expansion                                  | AWS Fargate with Amazon ECS has expanded to the Europe (Paris), Europe (Stockholm), and Middle East (Bahrain) regions.                                                                                                                                                                                                | September 30, 2019 |
| Deep Learning Containers with Elastic Inference on Amazon ECS | Amazon ECS supports attaching Amazon Elastic Inference accelerators to your containers to make running deep learning inference workloads more efficient.                                                                                                                                                              | September 3, 2019  |
| FireLens for Amazon ECS                                       | FireLens for Amazon ECS is in public preview. FireLens for Amazon ECS enables you to use task definition parameters to route logs to an AWS service or partner destination for log storage and analytics. For more information, see <a href="#">Send Amazon ECS logs to an AWS service or AWS Partner</a> .           | August 30, 2019    |
| CloudWatch Container Insights                                 | CloudWatch Container Insights is now generally available. It enables you to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. For more information, see <a href="#">Monitor Amazon ECS containers using Container Insights with enhanced observability</a> . | August 30, 2019    |

| Change                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     | Date            |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Container Level Swap Configuration                      | Amazon ECS added support for controlling the usage of swap memory space on your Linux container instances at the container level. Using a per-container swap configuration, each container within a task definition can have swap enabled or disabled, and for those that have it enabled, the maximum amount of swap space used can be limited. For more information, see <a href="#">Managing container swap memory space on Amazon ECS</a> . | August 16, 2019 |
| AWS Fargate region expansion                            | AWS Fargate with Amazon ECS has expanded to the Asia Pacific (Hong Kong) Region.                                                                                                                                                                                                                                                                                                                                                                | August 6, 2019  |
| Elastic Network Interface Trunking                      | Added additional supported Amazon EC2 instance types for ENI trunking feature. For more information, see <a href="#">Supported instances for increased Amazon ECS container network interfaces</a> .                                                                                                                                                                                                                                            | August 1, 2019  |
| Registering Multiple Target Groups with a Service       | Added support for specifying multiple target groups in a service definition. For more information, see <a href="#">Registering multiple target groups with an Amazon ECS service</a> .                                                                                                                                                                                                                                                          | July 30, 2019   |
| Specifying Sensitive Data Using Secrets Manager Secrets | Added tutorial for specifying sensitive data using Secrets Manager secrets. For more information, see <a href="#">Specifying sensitive data using Secrets Manager secrets in Amazon ECS</a> .                                                                                                                                                                                                                                                   | July 20, 2019   |
| CloudWatch Container Insights                           | Amazon ECS has added support for CloudWatch Container Insights. For more information, see <a href="#">Monitor Amazon ECS containers using Container Insights with enhanced observability</a> .                                                                                                                                                                                                                                                  | July 9, 2019    |

| Change                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Date          |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Resource-level permissions for Amazon ECS services and tasksets | Amazon ECS has expanded resource-level permissions support for Amazon ECS services and tasks. For more information, see <a href="#">How Amazon Elastic Container Service works with IAM</a> .                                                                                                                                                                                                                                                                                                                          | June 27, 2019 |
| New Amazon ECS-optimized AMI patched for AWS-2019-005           | Amazon ECS has updated the Amazon ECS-optimized AMI to address the vulnerabilities described in <a href="#">AWS-2019-005</a> .                                                                                                                                                                                                                                                                                                                                                                                         | June 17, 2019 |
| Elastic Network Interface Trunking                              | Amazon ECS introduces support for launching container instances using supported Amazon EC2 instance types that have increased elastic network interface (ENI) density. Using these instance types and opting in to the <code>awsvpcTrunking</code> account setting provides increased ENI density on newly launched container instances which allows you to place more tasks on each container instance. For more information, see <a href="#">Increasing Amazon ECS Linux container instance network interfaces</a> . | June 6, 2019  |
| AWS Fargate platform version 1.3.0 update                       | Beginning on May 1, 2019, any new Fargate task that is launched supports the <code>splunk</code> log driver in addition to the <code>awslogs</code> log driver. For more information, see <a href="#">Storage and logging</a> .                                                                                                                                                                                                                                                                                        | May 1, 2019   |
| AWS Fargate platform version 1.3.0 update                       | Beginning on May 1, 2019, any new Fargate task that is launched supports referencing sensitive data in the log configuration of a container using the <code>secretOptions</code> container definition parameter. For more information, see <a href="#">Pass sensitive data to an Amazon ECS container</a> .                                                                                                                                                                                                            | May 1, 2019   |

| Change                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                 | Date           |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| AWS Fargate platform version 1.3.0 update          | Beginning on April 2, 2019, any new Fargate task that is launched supports injecting sensitive data into your containers by storing your sensitive data in either AWS Secrets Manager secrets or AWS Systems Manager Parameter Store parameters and then referencing them in your container definition. For more information, see <a href="#">Pass sensitive data to an Amazon ECS container</a> .                                          | Apr 2, 2019    |
| AWS Fargate platform version 1.3.0 update          | Beginning on March 27, 2019, any new Fargate task launched can use additional task definition parameters that enable you to define a proxy configuration, dependencies for container startup and shutdown as well as a per-container start and stop timeout value. For more information, see <a href="#">Proxy configuration</a> , <a href="#">Container dependency</a> , and <a href="#">Container timeouts</a> .                          | March 27, 2019 |
| Amazon ECS introduces the external deployment type | The <i>external</i> deployment type enables you to use any third-party deployment controller for full control over the deployment process for an Amazon ECS service. For more information, see <a href="#">Deploy Amazon ECS services using a third-party controller</a> .                                                                                                                                                                  | March 27, 2019 |
| AWS Deep Learning Containers on Amazon ECS         | AWS Deep Learning Containers are a set of Docker images for training and serving models in TensorFlow on Amazon Elastic Container Service (Amazon ECS). Deep Learning Containers provide optimized environments with TensorFlow, Nvidia CUDA (for GPU instances), and Intel MKL (for CPU instances) libraries and are available in Amazon ECR. For more information, see <a href="#">Using AWS Deep Learning Containers on Amazon ECS</a> . | March 27, 2019 |

| Change                                                         | Description                                                                                                                                                                                                                                                                                                                                                       | Date             |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Amazon ECS introduces enhanced container dependency management | Amazon ECS introduces additional task definition parameters that enable you to define dependencies for container startup and shutdown as well as a per-container start and stop timeout value. For more information, see <a href="#">Container dependency</a> .                                                                                                   | March 7, 2019    |
| Amazon ECS introduces the PutAccountSettingDefault API         | <p>Amazon ECS introduces the PutAccountSettingDefault API that allows a user to set the default ARN/ID format opt in status for all the users and roles on the account. Previously, setting the account's default opt in status required the use of the account owner.</p> <p>For more information, see <a href="#">Amazon Resource Names (ARNs) and IDs</a>.</p> | February 8, 2019 |
| Amazon ECS supports GPU workloads                              | <p>Amazon ECS introduces support for GPU workloads by enabling you to create clusters with GPU-enabled container instances. In a task definition you can specify the number of required GPUs and the ECS agent will pin the physical GPUs to the container.</p> <p>For more information, see <a href="#">Amazon ECS task definitions for GPU workloads</a>.</p>   | February 4, 2019 |
| Amazon ECS expanded secrets support                            | <p>Amazon ECS expanded support for using AWS Secrets Manager secrets directly in your task definitions to inject sensitive data into your containers.</p> <p>For more information, see <a href="#">Pass sensitive data to an Amazon ECS container</a>.</p>                                                                                                        | January 21, 2019 |

| Change                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Date              |

| Service limits updated                                   | <p>The following service limits were updated:</p> <ul style="list-style-type: none"><li>• Number of clusters per Region, per account was raised from 1000 to 2000.</li><li>• Number of container instances per cluster was raised from 1000 to 2000.</li><li>• Number of services per cluster was raised from 500 to 1000.</li></ul> <p>For more information, see <a href="#">Amazon ECS service quotas</a>.</p> | December 14, 2018 |
| AWS Fargate region expansion                             | <p>AWS Fargate with Amazon ECS has expanded to the Asia Pacific (Mumbai) and Canada (Central) Regions.</p> <p>For more information, see <a href="#">Supported Regions for Amazon ECS on AWS Fargate</a>.</p>                                                                                                                                                                                                     | December 7, 2018  |
| Amazon ECS blue/green deployments                        | <p>Amazon ECS added support for blue/green deployments using CodeDeploy. This deployment type allows you to verify a new deployment of a service before sending production traffic to it.</p> <p>For more information, see <a href="#">CodeDeploy blue/green deployments for Amazon ECS</a>.</p>                                                                                                                 | November 27, 2018 |
| Amazon ECS-optimized Amazon Linux 2 (arm64) AMI released | <p>Amazon ECS released an Amazon ECS-optimized Amazon Linux 2 AMIs for arm64 architecture.</p> <p>For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a>.</p>                                                                                                                                                                                                                                 | November 26, 2018 |

| Change                                                        | Description                                                                                                                                                                                                                              | Date              |
|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Added support for additional Docker flags in task definitions | <p>Amazon ECS introduced support for the following Docker flags in task definitions:</p> <ul style="list-style-type: none"><li>• <a href="#">IPC mode</a></li><li>• <a href="#">PID mode</a></li></ul>                                   | November 16, 2018 |
| Amazon ECS secrets support                                    | <p>Amazon ECS added support for using AWS Systems Manager Parameter Store parameters to inject sensitive data into your containers.</p> <p>For more information, see <a href="#">Pass sensitive data to an Amazon ECS container</a>.</p> | November 15, 2018 |
| Resource tagging                                              | <p>Amazon ECS added support for adding metadata tags to your services, task definitions, tasks, clusters, and container instances.</p> <p>For more information, see <a href="#">Tagging Amazon ECS resources</a>.</p>                    | November 15, 2018 |
| AWS Fargate Region expansion                                  | <p>AWS Fargate with Amazon ECS has expanded to the US West (N. California) and Asia Pacific (Seoul) Regions.</p> <p>For more information, see <a href="#">Architect for AWS Fargate for Amazon ECS</a>.</p>                              | November 7, 2018  |

| Change                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Date             |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Service limits updated                           | <p>The following service limits were updated:</p> <ul style="list-style-type: none"><li>• Number of tasks using the Fargate launch type, per Region, per account was raised from 20 to 50.</li><li>• Number of public IP addresses for tasks using the Fargate launch type was raised from 20 to 50.</li></ul> <p>For more information, see <a href="#">Amazon ECS service quotas</a>.</p>                                                                                                | October 31, 2018 |
| AWS Fargate Region expansion                     | <p>AWS Fargate with Amazon ECS has expanded to the Europe (London) Region.</p> <p>For more information, see <a href="#">Architect for AWS Fargate for Amazon ECS</a>.</p>                                                                                                                                                                                                                                                                                                                 | October 26, 2018 |
| Amazon ECS-optimized Amazon Linux 2 AMI Released | <p>Amazon ECS vends Linux AMIs that are optimized for the service in two variants. The latest and recommended version is based on x<sub>86_64</sub>. Amazon ECS also vends AMIs that are based on the <a href="#">Amazon Linux 2 AMI</a>, but we recommend that you migrate your workloads to the Amazon Linux 2 variant, as support for the Amazon Linux AMI will end no later than June 30, 2020.</p> <p>For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a>.</p> | October 18, 2018 |

| Change                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Date               |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| Amazon ECS Task Metadata Endpoint version 3                        | Beginning with version 1.21.0 of the Amazon ECS container agent, the agent injects an environment variable called <code>ECS_CONTAINER_METADATA_URI</code> into each container in a task. When you query the task metadata version 3 endpoint, various task metadata and <a href="#">Docker stats</a> are available to tasks that use the <code>awsvpc</code> network mode at an HTTP endpoint that is provided by the Amazon ECS container agent. For more information, see <a href="#">Monitor workloads using Amazon ECS metadata</a> . | October 18, 2018   |
| Amazon ECS service discovery Region expansion                      | Amazon ECS service discovery has expanded support to the Canada (Central), South America (São Paulo), Asia Pacific (Seoul), Asia Pacific (Mumbai), and Europe (Paris) Regions.<br><br>For more information, see <a href="#">Use service discovery to connect Amazon ECS services with DNS names</a> .                                                                                                                                                                                                                                     | September 27, 2018 |
| Added support for additional Docker flags in container definitions | Amazon ECS introduced support for the following Docker flags in container definitions: <ul style="list-style-type: none"><li>• <a href="#">System controls</a></li><li>• <a href="#">Interactive</a></li><li>• <a href="#">Pseudo terminal</a></li></ul>                                                                                                                                                                                                                                                                                  | September 17, 2018 |

| Change                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                             | Date               |

| AWS Fargate Region expansion                  | <p>AWS Fargate with Amazon ECS has expanded to the Europe (Frankfurt), Asia Pacific (Singapore), and Asia Pacific (Sydney) Regions.</p> <p>For more information, see <a href="#">Architect for AWS Fargate for Amazon ECS</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | July 19, 2018 |
| Amazon ECS service scheduler strategies added | <p>Amazon ECS introduced the concept of service scheduler strategies.</p> <p>There are two service scheduler strategies available:</p> <ul style="list-style-type: none"><li>• <b>REPLICA</b>—The replica scheduling strategy places and maintains the desired number of tasks across your cluster. By default, the service scheduler spreads tasks across Availability Zones. You can use task placement strategies and constraints to customize task placement decisions. For more information, see <a href="#">Replica scheduling strategy</a>.</li><li>• <b>DAEMON</b>—The daemon scheduling strategy deploys exactly one task on each active container instance that meets all of the task placement constraints that you specify in your cluster. When using this strategy, there is no need to specify a desired number of tasks, a task placement strategy, or use Service Auto Scaling policies. For more information, see <a href="#">Daemon scheduling strategy</a>.</li></ul> <div><p> <b>Note</b></p><p>Fargate tasks do not support the DAEMON scheduling strategy.</p></div> | June 12, 2018 |

| Change                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             | Date           |
|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Amazon ECS container agent v1.18.0                                                 | <p>New version of the Amazon ECS container agent released, which added the following functionality:</p> <ul style="list-style-type: none"> <li>Added support for customizing the container agent image pull behavior using the <code>ECS_IMAGE_PULL_BEHAVIOR</code> parameter. For more information, see <a href="#">Amazon ECS container agent configuration</a>.</li> </ul> <p>For more information, see <a href="#">amazon-ecs-agent github</a>.</p> | May 24, 2018   |
| Added Support for bridge and host Network Modes When Configuring Service Discovery | <p>Added support for configuring service discovery for Amazon ECS services using task definitions that specify the bridge or host network modes. For more information, see <a href="#">Use service discovery to connect Amazon ECS services with DNS names</a>.</p>                                                                                                                                                                                     | May 22, 2018   |
| Added support for additional Amazon ECS-optimized AMI metadata parameters          | <p>Added subparameters that allow you to programmatically retrieve the Amazon ECS-optimized AMI ID, image name, operating system, container agent version, and runtime version. Query the metadata using the Systems Manager Parameter Store API. For more information, see <a href="#">Retrieving Amazon ECS-optimized Linux AMI metadata</a>.</p>                                                                                                     | May 9, 2018    |
| AWS Fargate Region expansion                                                       | <p>AWS Fargate with Amazon ECS has expanded to the US East (Ohio), US West (Oregon), and EU West (Ireland) Regions.</p> <p>For more information, see <a href="#">Architect for AWS Fargate for Amazon ECS</a>.</p>                                                                                                                                                                                                                                      | April 26, 2018 |

| Change                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Date           |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Amazon ECS-optimized AMI Metadata Retrieval | Added ability to programmatically retrieve Amazon ECS-optimized AMI metadata using the Systems Manager Parameter Store API. For more information, see <a href="#">Retrieving Amazon ECS-optimized Linux AMI metadata</a> .                                                                                                                                                                                                                                                  | April 10, 2018 |
| AWS Fargate platform version                | <p>New AWS Fargate platform version released, which contains:</p> <ul style="list-style-type: none"> <li>• Added support for <a href="#">Monitor workloads using Amazon ECS metadata</a>.</li> <li>• Added support for <a href="#">Health check</a>.</li> <li>• Added support for <a href="#">Use service discovery to connect Amazon ECS services with DNS names</a></li> </ul> <p>For more information, see <a href="#">Fargate platform versions for Amazon ECS</a>.</p> | March 26, 2018 |
| Amazon ECS Service Discovery                | Added integration with Route 53 to support Amazon ECS service discovery. For more information, see <a href="#">Use service discovery to connect Amazon ECS services with DNS names</a> .                                                                                                                                                                                                                                                                                    | March 22, 2018 |
| Docker shm-size and tmpfs support           | <p>Added support for the Docker shm-size and tmpfs parameters in Amazon ECS task definitions.</p> <p>For more information about the updated ECS CLI syntax, see <a href="#">Linux parameters</a>.</p>                                                                                                                                                                                                                                                                       | March 20, 2018 |
| Container Health Checks                     | Added support for Docker health checks in container definitions. For more information, see <a href="#">Health check</a> .                                                                                                                                                                                                                                                                                                                                                   | March 8, 2018  |

| Change                                                         | Description                                                                                                                                                                                                                                                                                                                                                  | Date              |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| AWS Fargate                                                    | Added overview for Amazon ECS with AWS Fargate. For more information, see <a href="#">Architect for AWS Fargate for Amazon ECS</a> .                                                                                                                                                                                                                         | February 22, 2018 |
| Amazon ECS Task Metadata Endpoint                              | Beginning with version 1.17.0 of the Amazon ECS container agent, various task metadata and <a href="#">Docker stats</a> are available to tasks that use the <code>awsvpc</code> network mode at an HTTP endpoint that is provided by the Amazon ECS container agent. For more information, see <a href="#">Monitor workloads using Amazon ECS metadata</a> . | February 8, 2018  |
| Amazon ECS Service Auto Scaling using target tracking policies | <p>Added support for ECS Service Auto Scaling using target tracking policies in the Amazon ECS console. For more information, see <a href="#">Use a target metric to scale Amazon ECS services</a>.</p> <p>Removed the previous tutorial for step scaling in the ECS first run wizard. This was replaced with the new tutorial for target tracking.</p>      | February 8, 2018  |
| Docker 17.09 support                                           | Added support for Docker 17.09. For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a> .                                                                                                                                                                                                                                                  | January 18, 2018  |
| New service scheduler behavior                                 | Updated information about the behavior for service tasks that fail to launch. Documented new service event message that triggers when a service task has consecutive failures. .                                                                                                                                                                             | January 11, 2018  |
| Elastic Load Balancing health check initialization wait period | Added ability to specify a wait period for health checks.                                                                                                                                                                                                                                                                                                    | December 27, 2017 |
| Task-level CPU and memory                                      | Added support for specifying CPU and memory at the task-level in task definitions. For more information, see <a href="#">TaskDefinition</a> .                                                                                                                                                                                                                | December 12, 2017 |

| Change                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Date              |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Task execution role           | <p>The Amazon ECS container agent makes calls to the Amazon ECS API actions on your behalf, so it requires an IAM policy and role for the service to know that the agent belongs to you. The following actions are covered by the task execution role:</p> <ul style="list-style-type: none"><li>• Calls to Amazon ECR to pull the container image</li><li>• Calls to CloudWatch to store container application logs</li></ul> <p>For more information, see <a href="#">Amazon ECS task execution IAM role</a>.</p> | December 7, 2017  |
| Windows containers support GA | <p>Added support for Windows Server 2016 containers. For more information, see <a href="#">Amazon ECS-optimized AMI variants</a>.</p>                                                                                                                                                                                                                                                                                                                                                                               | December 5, 2017  |
| AWS Fargate GA                | <p>Added support for launching Amazon ECS services using the Fargate launch type. For more information, see <a href="#">Architect your solution for Amazon ECS</a>.</p>                                                                                                                                                                                                                                                                                                                                             | November 29, 2017 |
| Amazon ECS name change        | <p>Amazon Elastic Container Service is renamed (previously Amazon EC2 Container Service).</p>                                                                                                                                                                                                                                                                                                                                                                                                                       | November 21, 2017 |

| Change                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Date               |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| Task networking                                | The task networking features provided by the awsvpc network mode give Amazon ECS tasks the same networking properties as Amazon EC2 instances. When you use the awsvpc network mode in your task definitions, every task that is launched from that task definition gets its own elastic network interface, a primary private IP address, and an internal DNS hostname. The task networking feature simplifies container networking and gives you more control over how containerized applications communicate with each other and other services within your VPCs. For more information, see <a href="#">Amazon ECS task networking options for EC2</a> . | November 14, 2017  |
| Amazon ECS container metadata                  | Amazon ECS containers are now able to access metadata such as their Docker container or image ID, networking configuration, or Amazon ARNs. For more information, see <a href="#">Amazon ECS container metadata file</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                 | November 2, 2017   |
| Docker 17.06 support                           | Added support for Docker 17.06. For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | November 2, 2017   |
| Support for Docker flags: device and init      | Added support for Docker's device and init features in task definitions using the <code>LinuxParameters</code> parameter ( <code>devices</code> and <code>initProcessEnabled</code> ). For more information, see <a href="#">LinuxParameters</a> .                                                                                                                                                                                                                                                                                                                                                                                                         | November 2, 2017   |
| Support for Docker flags: cap-add and cap-drop | Added support for Docker's cap-add and cap-drop features in task definitions using the <code>LinuxParameters</code> parameter ( <code>capabilities</code> ). For more information, see <a href="#">LinuxParameters</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                   | September 22, 2017 |
| Network Load Balancer support                  | Amazon ECS added support for Network Load Balancers in the Amazon ECS console.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | September 7, 2017  |

| Change                                                            | Description                                                                                                                                                                                                                                                                         | Date              |
|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| RunTask overrides                                                 | Added support for task definition overrides when running a task. This allows you to run a task while changing a task definition without the need to create a new task definition revision. For more information, see <a href="#">Running an application as an Amazon ECS task</a> . | June 27, 2017     |
| Amazon ECS scheduled tasks                                        | Added support for scheduling tasks using cron.                                                                                                                                                                                                                                      | June 7, 2017      |
| Spot Instances in the Amazon ECS console                          | Added support for creating Spot Fleet container instances within the Amazon ECS console. For more information, see <a href="#">Launching an Amazon ECS Linux container instance</a> .                                                                                               | June 6, 2017      |
| Amazon SNS notification for new Amazon ECS-optimized AMI releases | Added ability to subscribe to SNS notifications about new Amazon ECS-optimized AMI releases.                                                                                                                                                                                        | March 23, 2017    |
| Microservices and batch jobs                                      | Added documentation for two common use cases for Amazon ECS: microservices and batch jobs.                                                                                                                                                                                          | February 2017     |
| Container instance draining                                       | Added support for container instance draining, which provides a method for removing container instances from a cluster. For more information, see <a href="#">Draining Amazon ECS container instances</a> .                                                                         | January 24, 2017  |
| Docker 1.12 support                                               | Added support for Docker 1.12. For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a> .                                                                                                                                                                          | January 24, 2017  |
| New task placement strategies                                     | Added support for task placement strategies: attribute-based placement, bin pack, Availability Zone spread, and one per host. For more information, see <a href="#">Use strategies to define Amazon ECS task placement</a> .                                                        | December 29, 2016 |

| Change                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                      | Date               |
|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| Windows container support in beta                                         | Added support for Windows Server 2016 containers (beta). For more information, see <a href="#">Amazon ECS-optimized AMI variants</a> .                                                                                                                                                                                                                                                           | December 20, 2016  |
| Blox OSS support                                                          | Added support for Blox OSS, which allows for custom task schedulers. For more information, see <a href="#">Schedule your containers on Amazon ECS</a> .                                                                                                                                                                                                                                          | December 1, 2016   |
| Amazon ECS event stream for CloudWatch Events                             | Amazon ECS now sends container instance and task state changes to CloudWatch Events. For more information, see <a href="#">Automate responses to Amazon ECS errors using EventBridge</a> .                                                                                                                                                                                                       | November 21, 2016  |
| Amazon ECS container logging to CloudWatch Logs                           | Added support for the awslogs driver to send container log streams to CloudWatch Logs. For more information, see <a href="#">Send Amazon ECS logs to CloudWatch</a> .                                                                                                                                                                                                                            | September 12, 2016 |
| Amazon ECS services with Elastic Load Balancing support for dynamic ports | Added support for a load balancer to support multiple instance:port combinations per listener, which increases flexibility for containers. Now you can let Docker dynamically define the container's host port and the ECS scheduler registers the instance:port with the load balancer. For more information, see <a href="#">Use load balancing to distribute Amazon ECS service traffic</a> . | August 11, 2016    |
| IAM roles for Amazon ECS tasks                                            | Added support for associating IAM roles with a task. This provides finer-grained permissions to containers as opposed to a single role for an entire container instance. For more information, see <a href="#">Amazon ECS task IAM role</a> .                                                                                                                                                    | July 13, 2016      |
| Docker 1.11 support                                                       | Added support for Docker 1.11. For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a> .                                                                                                                                                                                                                                                                                       | May 31, 2016       |

| Change                                                    | Description                                                                                                                                                                                                                                                                                       | Date              |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Task automatic scaling                                    | Amazon ECS added support for automatically scaling your tasks run by a service. For more information, see <a href="#">Automatically scale your Amazon ECS service</a> .                                                                                                                           | May 18, 2016      |
| Task definition filtering on task family                  | Added support for filtering a list of task definition based on the task definition family. For more information, see <a href="#">ListTaskDefinitions</a> .                                                                                                                                        | May 17, 2016      |
| Docker container and Amazon ECS agent logging             | Amazon ECS added ability to send ECS agent and Docker container logs from container instances to CloudWatch Logs to simplify troubleshooting issues.                                                                                                                                              | May 5, 2016       |
| ECS-optimized AMI now supports Amazon Linux 2016.03.      | The ECS-optimized AMI added support for Amazon Linux 2016.03. For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a> .                                                                                                                                                         | April 5, 2016     |
| Docker 1.9 support                                        | Added support for Docker 1.9. For more information, see <a href="#">Amazon ECS-optimized Linux AMIs</a> .                                                                                                                                                                                         | December 22, 2015 |
| CloudWatch metrics for cluster CPU and memory reservation | Amazon ECS added custom CloudWatch metrics for CPU and memory reservation.                                                                                                                                                                                                                        | December 22, 2015 |
| New Amazon ECS first-run experience                       | The Amazon ECS console first-run experience added zero-click role creation.                                                                                                                                                                                                                       | November 23, 2015 |
| Task placement across Availability Zones                  | The Amazon ECS service scheduler added support for task placement across Availability Zones.                                                                                                                                                                                                      | October 8, 2015   |
| CloudWatch metrics for Amazon ECS clusters and services   | Amazon ECS added custom CloudWatch metrics for CPU and memory utilization for each container instance, service, and task definition family in a cluster. These new metrics can be used to scale container instances in a cluster using Auto Scaling groups or to create custom CloudWatch alarms. | August 17, 2015   |

| Change                                                              | Description                                                                                                                                                              | Date          |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| UDP port support                                                    | Added support for UDP ports in task definitions.                                                                                                                         | July 7, 2015  |
| Environment variable overrides                                      | Added support for deregisterTaskDefinition and environment variable overrides for runTask.                                                                               | June 18, 2015 |
| Automated Amazon ECS agent updates                                  | Added ability to see the ECS agent version that is running on a container instance. Also able to update the ECS agent from the AWS Management Console, AWS CLI, and SDK. | June 11, 2015 |
| Amazon ECS service scheduler and Elastic Load Balancing integration | Added ability to define a service and associate that service with an Elastic Load Balancing load balancer.                                                               | April 9, 2015 |
| Amazon ECS GA                                                       | Amazon ECS general availability in the US East (N. Virginia), US West (Oregon), Asia Pacific (Tokyo), and Europe (Ireland) Regions.                                      | April 9, 2015 |
